# Assouad-like dimensions of random Moran measures 

Kathryn E. Hare and Franklin Mendivil

#### Abstract

In this paper, we determine the almost sure values of the $\Phi$ dimensions of random measures supported on random Moran sets that satisfy a uniform separation condition. The $\Phi$-dimensions are intermediate Assouadlike dimensions, the (quasi-)Assouad dimensions and $\theta$-Assouad spectrum being special cases. Their values depend on the size of $\Phi$, with one size coinciding with the Assouad dimension and the other coinciding with the quasi-Assouad dimension. We give many applications, including to equicontractive self-similar measures and 1-variable random Moran measures such as Cantor-like measures with probabilities that are uniformly distributed. We can also deduce the $\Phi$ dimensions of the underlying random sets.

## 1. Introduction

Many notions of dimension have been developed to quantify the size of sets and measures, in part, to better understand the geometry of the set and the nature of the measure. Perhaps the most well known are Hausdorff and box dimensions, global notions of size. More recently, there has been much interest in understanding the local complexity of sets and measures and for this various dimensions have been introduced including the (upper and lower) Assouad dimensions, which quantify the 'thickest' and 'thinnest' parts of sets and measures (see [1, 6, 20, 21]), the less extreme quasi-Assouad dimensions $([\mathbf{2}, \mathbf{1 6}, \mathbf{1 7}, \mathbf{2 2})$ ), the $\theta$-Assouad spectrum ( $\mathbf{9}$ ), and the most general, intermediate $\Phi$-dimensions ( $\mathbf{9}, \mathbf{1 1}, \mathbf{1 5})$. The $\Phi$ dimensions range between the box and Assouad dimensions. They are localized, like the Assouad dimensions, but vary in the depth of the scales considered, thus they provide very refined information. In this paper, we continue the study of the upper and lower $\Phi$-dimensions of measures, with a focus on random measures supported on random Moran sets.

There is a long history of the study of dimensional properties of random sets, with early important early papers including [3, 14, for example. More recently, Assouad-like dimensions of random sets have been investigated in papers such as [7, 8, 12, 24, 25].

[^0]By a random Moran measure, we will mean a probability measure supported on a random Moran set in $\mathbb{R}^{D}$ that can be thought of as arising from a random homogenous model of uncountably many equicontractive iterated function systems satisfying a suitable uniform strong separation condition. The number of children at each level, the ratios of child to parent diameters and the probability weights assigned to each child that specify the measure, are all to be iid random variables. We refer the reader to Section 2.2 for the technical details.

The values of the $\Phi$-dimensions of these random measures depend on how the dimension function $\Phi$ compares with the function $\Psi(x)=\log |\log x| /|\log x|$ near 0 , as was also seen to be the case in $[12$ where the $\Phi$-dimensions of random rearrangements of Cantor-like sets were considered. Under mild technical assumptions on the probability and ratio distributions, when $\Phi(x) \gg \Psi(x)^{11}$ (such as for the quasiAssouad dimensions), then almost surely the value of all the upper $\Phi$-dimensions of the random measure is $\mathbb{E}(\log m) / \mathbb{E}(\log r)$ where $m$ is the minimum probability and $r$ is the child/parent diameter ratio. For the lower $\Phi$-dimension we simply replace the minimum probability $m$ by the maximum $M$. When $\Phi(x) \ll \Psi(x)$ (such as for the Assouad dimensions) and the essential infimum of either the ratios or the probabilities is bounded away from 0 , then the upper (and lower) $\Phi$-dimensions again coincide, being the almost sure extreme behaviour of $\log m / \log r$ (resp., $\log M / \log r$ ). These results are formally stated and proven in Sections 3 and 4

One special case to which our theorems apply is when the set is deterministic and the probabilities are chosen uniformly distributed. For example, take the classical middle-third Cantor set. If the two probabilities, $p, 1-p$, are equal, all the dimensions (of either the set or the measure) equal $\log 2 / \log 3$. In contrast, if the probabilities are chosen with $p$ uniformly distributed over $(0,1)$, then for $\Phi \gg \Psi$, the upper $\Phi$-dimension of the random measure is almost surely $(1+\log 2) / \log 3$, while the lower dimension is $(1-\log 2) / \log 3$ (which, perhaps surprisingly, do not average to $\log 2 / \log 3$ ). For $\Phi \ll \Psi$ the upper and lower $\Phi$-dimensions are almost surely $\infty$ and 0 respectively. More complicated formulas hold if the Cantor set has $T$ children, with $T>2$, and the probabilities are chosen uniformly over the simplex $\left\{\left(p_{i}\right)_{i=1}^{T}: \sum_{i=1}^{T} p_{i}=1, p_{i} \geq 0\right\}$.

Another special case to which our theorems apply is a random 1 -variable (homogeneous) model with finitely many equicontractive iterated function systems, satisfying the strong separation condition. In $\mathbf{2 4}$ it was shown that the upper quasi-Assouad dimensions for these random sets coincide almost surely with their Hausdorff dimensions. If we take the measure with uniform probabilities, the $\Phi$ dimensions of the measure equal those of the random set, thus the Hausdorff dimension coincides almost surely with the $\Phi$-dimensions for all $\Phi \gg \Psi$ (including both the upper and lower quasi-Assouad dimensions). A different formula applies for $\Phi \ll \Psi$, (including the Assouad dimension).

These examples are discussed in Section [5] along with others. Section 2 contains the definitions of the $\Phi$-dimensions, as well as their basic properties, and details the random setup.

[^1]
## 2. Preliminaries

2.1. Dimensions of sets and measures. Given a bounded metric space $X$, we denote the open ball centred at $x \in X$ and radius $R$ by $B(x, R)$. By a measure, we will always mean a Borel probability measure on the metric space $X$.

DEFINITION 1. By a dimension function, we mean a map $\Phi:(0,1) \rightarrow \mathbb{R}^{+}$ such that $x^{1+\Phi(x)}$ decreases to 0 as $x$ decreases to 0 .

Interesting examples include the constant functions $\Phi(x)=\delta \geq 0, \Phi(x)=$ $1 /|\log x|$ and $\Phi(x)=\log |\log x| /|\log x|$.

DEFINITION 2. Let $\Phi$ be a dimension function and let $\mu$ be a measure on $X$. The upper and lower $\Phi$-dimensions of $\mu$ are given by

$$
\overline{\operatorname{dim}}_{\Phi} \mu=\inf \left\{\begin{array}{c}
d:\left(\exists C_{1}, C_{2}>0\right)\left(\forall 0<r<R^{1+\Phi(R)} \leq R \leq C_{1}\right) \\
\frac{\mu(B(x, R))}{\mu(B(x, r))} \leq C_{2}\left(\frac{R}{r}\right)^{d} \forall x \in \operatorname{supp} \mu
\end{array}\right\}
$$

and

$$
\underline{\operatorname{dim}}_{\Phi} \mu=\sup \left\{\begin{array}{c}
d:\left(\exists C_{1}, C_{2}>0\right)\left(\forall 0<r<R^{1+\Phi(R)} \leq R \leq C_{1}\right) \\
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq C_{2}\left(\frac{R}{r}\right)^{d} \forall x \in \operatorname{supp} \mu
\end{array}\right\}
$$

REMARK 1. (i) The upper and lower Assouad dimensions of $\mu$ (also known as the upper and lower regularity dimensions) studied by Käenmäki et al in [19, 20 and Fraser and Howroyd in [6, and denoted $\operatorname{dim}_{A} \mu$ and $\operatorname{dim}_{L} \mu$ respectively, are the upper and lower $\Phi$-dimensions with $\Phi$ the constant function 0 . It is well known that a measure $\mu$ is doubling if and only if $\operatorname{dim}_{A} \mu<\infty$ and uniformly perfect if and only if $\operatorname{dim}_{L} \mu>0$.
(ii) If we let $\Phi_{\theta}=1 / \theta-1$, then $\overline{\operatorname{dim}}_{\Phi_{\theta}} \mu$ and $\operatorname{dim}_{\Phi_{\theta}} \mu$ are (basically) the upper and lower $\theta$-Assouad spectrum introduced in [9]. The upper and lower quasiAssouad dimensions of $\mu$ developed in [16, 17, are given by

$$
\operatorname{dim}_{q A} \mu=\lim _{\theta \rightarrow 1} \overline{\operatorname{dim}}_{\Phi_{\theta}} \mu, \operatorname{dim}_{q L} \mu=\lim _{\theta \rightarrow 1} \underline{\operatorname{dim}}_{\Phi_{\theta}} \mu
$$

As noted in [15, there are always dimension functions which give rise to the quasi-Assouad dimensions, but these need to be tailored to the particular measure.
(iii) The upper Minkowski dimension, $\overline{\operatorname{dim}}_{M} \mu$, and the Frostman dimension, $\operatorname{dim}_{F} \mu$, coincide with the upper and lower $\Phi$-dimensions respectively for $\Phi \rightarrow \infty$; see 4 and Proposition [1.

The upper and lower $\Phi$-dimensions of a measure were introduced in $\mathbf{1 5}$ to provide more refined information about the local behaviour of a measure than that given by the upper and lower Assouad dimensions. They were motivated, in part, by related definitions for dimensions of sets. To recall these, we use the notation $N_{r}(Y)$ to mean the least number of balls of radius $r$ that cover $Y \subseteq X$.

Definition 3. The upper and lower $\Phi$-dimensions of $E \subseteq X$ are given by

$$
\overline{\operatorname{dim}}_{\Phi} E=\inf \left\{\begin{array}{c}
\alpha:\left(\exists C_{1}, C_{2}>0\right)\left(\forall 0<r \leq R^{1+\Phi(R)} \leq R<C_{1}\right) \\
N_{r}(B(z, R) \bigcap E) \leq C_{2}\left(\frac{R}{r}\right)^{\alpha} \forall z \in E
\end{array}\right\}
$$

and

$$
\underline{\operatorname{dim}}_{\Phi} E=\sup \left\{\begin{array}{c}
\alpha:\left(\exists C_{1}, C_{2}>0\right)\left(\forall 0<r \leq R^{1+\Phi(R)} \leq R<C_{1}\right) \\
N_{r}(B(z, R) \bigcap E) \geq C_{2}\left(\frac{R}{r}\right)^{\alpha} \forall z \in E
\end{array}\right\} .
$$

The $\Phi$-dimensions were first thoroughly studied in [11], expanding upon the earlier work of $\mathbf{9} \mathbf{9}$. The (quasi-) upper and lower Assouad dimensions and the upper and lower $\theta$-Assouad spectrum are again special cases, arising in the same manner as for measures. It is known that

$$
\operatorname{dim}_{L} E \leq \underline{\operatorname{dim}}_{\Phi} E \leq \underline{\operatorname{dim}}_{B} E \leq \overline{\operatorname{dim}}_{B} E \leq \overline{\operatorname{dim}}_{\Phi} E \leq \operatorname{dim}_{A} E
$$

and for closed sets $\operatorname{dim}_{L} E \leq \operatorname{dim}_{H} E$. For further background and proofs, we refer the reader to the references mentioned in the introduction, as well as Fraser's monograph, 5.

Obviously, if $\Phi(x) \leq \Psi(x)$ for all $x>0$, then for any measure $\mu$ we have

$$
\overline{\operatorname{dim}}_{\Psi} \mu \leq \overline{\operatorname{dim}}_{\Phi} \mu \text { and } \underline{\operatorname{dim}}_{\Phi} \mu \leq \underline{\operatorname{dim}}_{\Psi} \mu .
$$

A similar statement holds for the $\Phi$-dimension of sets. The next Proposition summarizes other relationships between these dimensions. For the proofs of these facts and many other properties of the $\Phi$-dimensions of measures, we refer the reader to 15 and the references cited there.

Proposition 1. Let $\Phi$ be a dimension function and $\mu$ be a measure.
(i) Then $\overline{\operatorname{dim}}_{\Phi} \mu \geq \overline{\operatorname{dim}}_{\Phi} \operatorname{supp} \mu \geq \operatorname{dim}_{H} \operatorname{supp} \mu$ and

$$
\begin{equation*}
\operatorname{dim}_{L} \mu \leq \underline{\operatorname{dim}}_{\Phi} \mu \leq \operatorname{dim}_{F} \mu \leq \overline{\operatorname{dim}}_{M} \mu \leq \overline{\operatorname{dim}}_{\Phi} \mu \leq \operatorname{dim}_{A} \mu \tag{2.1}
\end{equation*}
$$

If $\mu$ is doubling, then $\underline{\operatorname{dim}}_{\Phi} \mu \leq \underline{\operatorname{dim}}_{\Phi} \operatorname{supp} \mu$.
(ii) If $\Phi(x) \rightarrow 0$ as $x \rightarrow 0$, then $\underline{\operatorname{dim}}_{\Phi} \mu \leq \operatorname{dim}_{q L} \mu$ and $\operatorname{dim}_{q A} \mu \leq \overline{\operatorname{dim}}_{\Phi} \mu$.
(iii) If there exists $x_{0}>0$ such that $\Phi(x) \leq C /|\log x|$ for $0<x \leq x_{0}$, then $\overline{\operatorname{dim}}_{\Phi} \mu=\operatorname{dim}_{A} \mu$ and $\underline{\operatorname{dim}}_{\Phi} \mu=\operatorname{dim}_{L} \mu$.
(iv) If $\Theta=\limsup \operatorname{sum}_{x \rightarrow 0} \Phi(x)^{-1}$, then

$$
\begin{aligned}
\underline{\operatorname{dim}}_{\Phi} \mu & \geq \operatorname{dim}_{F} \mu-\Theta\left(\overline{\operatorname{dim}}_{M} \mu-\operatorname{dim}_{F} \mu\right) \\
\overline{\operatorname{dim}}_{\Phi} \mu & \leq \overline{\operatorname{dim}}_{M} \mu+\Theta\left(\overline{\operatorname{dim}}_{M} \mu-\operatorname{dim}_{F} \mu\right)
\end{aligned}
$$

2.2. The random set-up. Let $I \subseteq \mathbb{R}^{D}$. We denote by $\operatorname{diam}(I)$ the diameter of $I$. Given $r>0$, we say the subset $J \subseteq I$ is an $r$-similarity of $I$ if there is a similarity $S_{\sigma}$ such that $J=S_{\sigma}(I)$ and $\operatorname{diam}(J)=r \cdot \operatorname{diam}(I)$. (Thus $S_{\sigma}$ has contraction factor $r$.) We say the collection of $r$-similarities, $J_{1}, \ldots, J_{t}$, is $\tau$ separated if $d\left(J_{i}, J_{j}\right) \geq \tau \cdot r \cdot \operatorname{diam}(I)$ for all $i \neq j$. When such a collection of $t$ sets exists, we say $I$ has the $(t, r, \tau)$-separation property.

Of course, if $I$ contains a non-empty open set, and $\tau>0$ is given, then $I$ will have the $(t, r, \tau)$-separation property for all $t \in \mathbb{N}$ and $r \leq r_{t}$, for some suitably small $r_{t}>0$. For example, if $I_{0}=[0,1] \subseteq \mathbb{R}$, then $r_{t}=1 /(t+\tau(t-1))$ will work. This condition can be viewed as a uniform strong separation condition.

From here on, $I_{0}$ will denote a (fixed) compact subset of $\mathbb{R}^{D}$ with diameter 1 and non-empty interior. We fix $0<\tau<1$ and for each $t \in \mathbb{N}$ we choose $r_{t} \in(0,1 / 2]$ so that $I_{0}$ has $(t, r, \tau)$-separation property for all $r \leq r_{t}$. For each $t=2,3, \ldots$ we define the probability simplices:

$$
\begin{gathered}
\mathcal{S}_{t}=\left\{\left(x_{1}, \ldots, x_{t}\right) \in \mathbb{R}^{t}: x_{i}>0, \sum_{i=1}^{t} x_{i}=1\right\} \\
\Omega_{t}=\left(0, r_{t}\right] \times \mathcal{S}_{t} \subseteq(0,1) \times \mathcal{S}_{t}
\end{gathered}
$$

and

$$
\Omega_{0}=\bigcup_{t \geq 2} \Omega_{t} .
$$

Let $\pi$ be a Borel probability measure on $\Omega_{0}$ and let $\mathbb{P}$ be the product measure on the infinite product $\Omega=\Omega_{0}^{\mathbb{N}}$ induced by $\pi$.

Continuing, we define random variables $T$ and $r$, and a random vector $p$ on $\Omega_{0}$. To do this, for $\omega \in \Omega_{0}$, we have $\omega \in \Omega_{t}$ for some $t=2,3, \ldots$ with $\omega=$ $\left(r, p^{(1)}, p^{(2)}, \ldots, p^{(t)}\right)$. Using this, we define

$$
T(\omega)=t, r(\omega)=r, p(\omega)=\left(p^{(1)}, p^{(2)}, \ldots, p^{(t)}\right) \in \mathcal{S}_{t} .
$$

A common way to define the measure $\pi$ on $\Omega_{0}$ is as a two-step process where one first chooses the integer $t$ randomly according to some distribution and then independently choose $r$ uniformly from $\left(0, r_{t}\right]$ and $p$ uniformly from $\mathcal{S}_{t}$.

With this framework, $\omega \in \Omega$ drawn according to $\mathbb{P}$ represents an independent and identically distributed random sample ( $T_{n}, r_{n}, p_{n}$ ) from $\pi$ on $\Omega_{0}$.

Using this iid sample, we can now construct a random Moran fractal. Beginning with the compact set $I_{0}$ and $\omega \in \Omega$, we select a collection of $T_{1}(\omega)$ subsets that are $r_{1}(\omega)$-similarities of $I_{0},\left\{I_{0}^{(j)}\right\}_{j=1}^{T_{1}(\omega)}$, that are $\tau$-separated. This is possible as $r_{1}(\omega) \leq r_{T_{1}(\omega)}$, so $I_{0}$ has the $\left(T_{1}(\omega), r_{1}(\omega), \tau\right)$-separation property. We call the sets $I_{0}^{(j)}, j=1, \ldots, T_{1}(\omega)$, the Moran sets of step (or level) 1 . The Moran sets of step 1 have diameter $r_{1}$ and the distance between any two is at least $\tau r_{1}$.

Being similar to $I_{0}$, the sets $I_{0}^{(j)}$ also have the $(t, r, \tau)$-separation property for all $r \leq r_{t}$, so we may repeat this process. Assume inductively that we have chosen the $\prod_{j=1}^{\bar{n}} T_{j}(\omega)$ Moran sets of step $n$. From each such set, $I_{n}$, we select $T_{n+1}(\omega)$ subsets that are $r_{n+1}(\omega)$-similarities of $I_{n}$ and are $\tau$-separated. These sets all have diameter $r_{1} \cdots r_{n+1}$, are separated by a distance of at least $\tau r_{1} \cdots r_{n+1}$ and are known as the Moran sets of step $n+1$. The Moran sets of step $n+1$ that are subsets of a given Moran set $I_{n}$ of step $n$ are known as the children of the parent set $I_{n}$. We will use the notation $I_{N}(x)$ for the unique Moran set of step $N$ containing $x \in E(\omega)$. Of course, $I_{N-1}(x)$ is its parent.

If we let $\mathcal{M}_{n}(\omega)$ be the union of the step $n$ Moran sets, then the random Moran set $E(\omega)$ is the compact set

$$
E(\omega)=\bigcap_{n=1}^{\infty} \mathcal{M}_{n}(\omega) .
$$

We define a random Moran measure $\mu=\mu_{\omega}$ inductively by the rule that if the $T_{n+1}$ children of the step $n$ Moran set $I$ are labelled $I^{(1)}, \ldots ., I^{\left(T_{n+1}\right)}$, then $\mu\left(I^{(j)}\right)=\mu(I) p_{n+1}^{(j)}$ where $\mu\left(I_{0}\right)=1$. The support of $\mu$ is the random Moran set $E(\omega)$.

It is not difficult to see that the $\Phi$-dimensions of these random measures is a tail event and hence our interest is in almost sure results.

Example 1. The classical middle-third Cantor set is a simple example of a Moran set where $I_{0}=[0,1], \tau=1 / 3, T_{n}(\omega)=2$ and $r_{n}(\omega)=1 / 3$ for all $\omega$ and $n$. The uniform Cantor measure is a special case of this construction with probabilities ( $1 / 2,1 / 2$ ). More generally, any self-similar set/measure arising from an iterated function system (IFS) $\left\{S_{j}, p_{j}\right\}_{j=1}^{M}$, of equicontractive similarities $S_{j}$ acting
on $I_{0}$ and satisfying the strong separation condition, (meaning, the sets $S_{j}\left(I_{0}\right)$ are disjoint) and associated probabilities $p_{j}$, is a random Moran set/measure in our sense.

Example 2. Another natural class of examples of random Moran sets are the finite random 1-variable (homogeneous) models which arise from a finite family of iterated function systems, $\left\{\mathcal{F}_{i}\right\}$, where each IFS $\mathcal{F}_{i}$ consists of equicontractive similarities acting on (the common set) $I_{0}$ and satisfying the strong separation condition, where at each step in the construction we randomly choose one IFS to apply at that level. See [24.

More generally, our construction can be thought of as a random 1-variable IFS construction where we have an uncountable family of IFSs with associated probabilities.

Other examples are given in Section 5 .
2.3. Preliminary Results. Throughout the paper, we will assume $L$ is the smallest integer such that

$$
2^{-L} \leq \tau / 2
$$

First, we will verify that we can replace balls by suitable Moran sets for the calculation of the $\Phi$-dimensions. The $\tau$-separation condition is required for this.

Lemma 1. Fix $\omega \in \Omega, R>0$ and $x \in E(\omega)$. Choose $N=N(\omega)$ such that

$$
r_{1}(\omega) \cdots r_{N+1}(\omega) \leq R<r_{1}(\omega) \cdots r_{N}(\omega)
$$

Then

$$
I_{N+1}(x) \cap E(\omega) \subseteq B(x, R) \cap E(\omega) \subseteq I_{N-L}(x)
$$

and hence

$$
\mu\left(I_{N+1}(x)\right) \leq \mu(B(x, R)) \leq \mu\left(I_{N-L}(x)\right)
$$

Proof. Since $R$ is at least the diameter of any Moran set of step $N+1$, $I_{N+1}(x) \subseteq B(x, R)$.

Now consider all the step $N$ Moran sets that intersect $B(x, R)$. If two of these sets, say $I^{(1)}, I^{(2)}$, are subsets of different Moran sets of level $N-k$, then the distance between these two sets, call it $\delta$, is at least the minimum distance between any two level $N-k$ Moran sets and hence is at least $\tau r_{1} \cdots r_{N-k}$. But $\tau \geq 2^{1-L}$ and $r_{j} \leq 1 / 2$, hence

$$
\delta \geq 2 \cdot 2^{-L} r_{1} \cdots r_{N-k} \geq 2 r_{1} \cdots r_{N-k} r_{N-k+1} \cdots r_{N-k+L}
$$

As $I^{(1)}$ and $I^{(2)}$ both intersect $B(x, R)$, we must have $\delta \leq 2 R<2 r_{1} \cdots r_{N}$ and therefore $k<L$. Thus all the step $N$ Moran sets that intersect $B(x, R)$ are subsets of the same Moran set of level $N-L$, namely $I_{N-L}(x)$.

Next, we introduce the positive-valued random variables

$$
\begin{gathered}
M_{n}=\max _{j} p_{n}^{(j)}, m_{n}=\min _{j} p_{n}^{(j)}, \\
X_{n}=-\log M_{n}, Y_{n}=-\log m_{n}, \text { and } Z_{n}=-\log r_{n}
\end{gathered}
$$

Of course, the collections $\left(M_{n}\right)_{n},\left(m_{n}\right)_{n},\left(X_{n}\right)_{n},\left(Y_{n}\right)_{n}$ and $\left(Z_{n}\right)$ are all independent and identically distributed.

Since $\sum_{j=1}^{T_{n}} p_{n}^{(j)}=1$ for each $n, M_{n} \geq 1 / T_{n}$, so if the number of children is bounded, then $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$ for any $\lambda$. More generally, $\mathbb{E}\left(e^{\lambda W_{1}}\right)<\infty$ for $W_{1}$ any of $X_{1}, Y_{1}$ or $Z_{1}$ if there exists $\delta>0$ such that $W_{1}(\omega)>\delta$ a.s.

Basic Assumption: Throughout this paper we will assume that there exists some $A>0$ such that $\mathbb{E}\left(e^{\lambda Z_{1}}\right)<\infty$ for all $|\lambda| \leq A$.

Note that this happens if and only if $\mathbb{E}\left(r_{1}^{-A}\right)<\infty$, as is true, for example, when the ratios $r_{n}$ are uniformly distributed. This is an important assumption because we will make heavy use of the following probabilistic result, sometimes known as the Chernoff technique.

Theorem 1. ([23, Thm. 2.6]) Suppose $\left(F_{n}\right)$ are iid rv's and for some $A>0$, $\mathbb{E}\left(e^{\lambda F_{1}}\right)<\infty$ for all $|\lambda| \leq A$. Then for all $a>0$, there exists $b>0$ such that

$$
\mathbb{P}\left(\left|\sum_{j=1}^{k} F_{j}-k E\left(F_{1}\right)\right| \geq a k\right) \leq \exp (-b k)
$$

for all $k \in \mathbb{N}$.
REMARK 2. (i) If $W$ is a non-negative random variable with $\mathbb{P}(W \leq x) \leq C x^{\theta}$ for small $x$ and $\theta>0$, then $\mathbb{E}\left(e^{-\lambda \log W}\right)=\mathbb{E}\left(W^{-\lambda}\right)<\infty$ for small $|\lambda|$. In particular this holds if $W$ has a probability density function $f(x)$ with $f(x) \leq C x^{q}$ and $q>-1$.
(ii) Since $\left\{p \in \mathcal{S}_{t}: \min _{i} p_{i} \leq z\right\} \subseteq\left(\partial \mathcal{S}_{t}\right)_{2 z}$ (the $2 z$-dilation of the boundary of $\mathcal{S}_{t}$ ), part (i) means it is enough that $\mathbb{P}\left(\left(\partial \mathcal{S}_{t}\right)_{z}\right) \leq C z^{\theta}$ for some $C, \theta>0$ and small $z$ to have $\mathbb{E}\left(e^{\lambda Y}\right)<\infty$ for small $|\lambda|$. Thus if the probability distribution on $\mathcal{S}_{t}$ has bounded density function, this will be true.
(iii) Since $\max _{i} p_{i} \geq 1 / t$ for $p \in \mathcal{S}_{t}$, we know that $M_{n}$ is close to zero only when $T_{n}$, the number of children, is very large. Very roughly, $\mathbb{P}\left(M_{n} \leq \lambda\right) \leq \mathbb{P}\left(T_{n} \geq\right.$ $1 / \lambda)$. If $\mathbb{P}(T=t) \leq C t^{-\theta}$ with $\theta>1$ and the distribution on $\mathcal{S}_{t}$ is uniform, then $\mathbb{E}\left(e^{\lambda X}\right)<\infty$ for small $|\lambda|$. Thus this can happen even if $\mathbb{E}(T)=\infty$ (take any $\theta \in(1,2))$.

Notation 1. Given a dimension function $\Phi$ and random Moran set $E(\omega)$, we define the associated depth function $\phi=\phi_{\omega}: \mathbb{N} \rightarrow \mathbb{N}$ by the rule that $\phi_{\omega}(n)$ is the minimal positive integer $k$ such that

$$
r_{1}(\omega) \cdots r_{n+k}(\omega) \leq\left(r_{1} \cdots r_{n}\right)^{1+\Phi\left(r_{1} \cdots r_{n}\right)}
$$

Consequently,

$$
\begin{align*}
r_{1} \cdots r_{n+\phi(n)} & \leq\left(r_{1} \cdots r_{n}\right)^{1+\Phi\left(r_{1} \cdots r_{n}\right)} \text { and }  \tag{2.2}\\
r_{1} \cdots r_{n+\phi(n)-1} & >\left(r_{1} \cdots r_{n}\right)^{1+\Phi\left(r_{1} \cdots r_{n}\right)} . \tag{2.3}
\end{align*}
$$

This notion was introduced in $[11$ to study the formulas for the $\Phi$-dimensions of (deterministic) Cantor sets. There it was shown that if $C$ is the central Cantor set with intervals of length $r_{1} \cdots r_{n}$ at step $n$ and $\inf _{n} r_{n}>0$, then

$$
\begin{aligned}
& \overline{\operatorname{dim}}_{\Phi} C=\limsup _{n}\left(\sup _{k \geq \phi(n)} \frac{n \log 2}{\log r_{n+1} \cdots r_{n+k}}\right) \\
& \underline{\operatorname{dim}}_{\Phi} C=\liminf _{n}\left(\inf _{k \geq \phi(n)} \frac{n \log 2}{\log r_{n+1} \cdots r_{n+k}}\right)
\end{aligned}
$$

In this situation, there is a simple relationship between $\phi$ and $\Phi$ : with $C=$ $\inf r_{n} / \sup r_{n}$ we have $\phi(n)-1 \leq C n \Phi\left(r_{1} \cdots r_{n}\right) \leq \phi(n)$.

For the random problem, it will be helpful to have information about the size of $\phi_{\omega}(n)$ that is independent of $\omega$ (in an almost sure sense). As we will see in the next result, the answer depends on how $\Phi(x)$ compares with the function $\log |\log x| /|\log x|$.

Notation 2. Given functions $G, H:(0,1) \rightarrow \mathbb{R}^{+}$, we define

$$
\begin{equation*}
\zeta_{N}^{(G)}=\frac{G\left(2^{-N}\right) \log (N \log 2)}{2 \mathbb{E}\left(Z_{1}\right)} \tag{2.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\chi_{N}^{(H)}=\frac{H\left(2^{-N}\right) \log \left(2 N \mathbb{E}\left(Z_{1}\right)\right)}{\log 2} . \tag{2.5}
\end{equation*}
$$

Apply Theorem 1 to choose a constant $B$ so that for all $k \in \mathbb{N}$,

$$
\begin{equation*}
\mathbb{P}\left(\left|\sum_{j=1}^{k} Z_{j}-k \mathbb{E}\left(Z_{1}\right)\right| \geq k \mathbb{E}\left(Z_{1}\right)\right) \leq \exp (-B k) \tag{2.6}
\end{equation*}
$$

Lemma 2. (i) Suppose $\Phi(x) \geq G(x) \log |\log x| /|\log x|$ where $G$ is non-decreasing as $x$ decreases to 0 and $G(x) \geq 4 \mathbb{E}\left(Z_{1}\right) / B$ for all $x \in(0,1)$. Then

$$
\mathbb{P}\left(\omega: \phi_{\omega}(N)<\zeta_{N}^{(G)} \text { i.o. }\right)=0
$$

(ii) If $\Phi(x) \leq H(x) \log |\log x| /|\log x|$ where $H(x)$ is non-increasing as $x$ decreases to 0 , then $\mathbb{P}\left(\omega: \phi_{\omega}(N)>\chi_{N}^{(H)}\right.$ i.o. $)=0$.

Proof. (i) If $\phi_{\omega}(N)<\zeta_{N}^{(G)}=\zeta_{N}$, then

$$
r_{1} r_{2} \cdots r_{N+\zeta_{N}} \leq r_{1} r_{2} \cdots r_{N+\phi_{\omega}(N)} \leq\left(r_{1} \cdots r_{N}\right)^{1+\Phi\left(r_{1} \cdots r_{N}\right)}
$$

so

$$
r_{N+1} r_{N+2} \cdots r_{N+\zeta_{N}} \leq\left(r_{1} \cdots r_{N}\right)^{\Phi\left(r_{1} \cdots r_{N}\right)}
$$

and therefore

$$
\sum_{j=N+1}^{N+\zeta_{N}}-\log r_{j} \geq \Phi\left(r_{1} \cdots r_{N}\right)\left|\log r_{1} \cdots r_{N}\right| \geq G\left(r_{1} \cdots r_{N}\right) \log \left|\log r_{1} \cdots r_{N}\right|
$$

But $r_{1} \cdots r_{N} \leq 2^{-N}$, so by monotonicity, $G\left(r_{1} \cdots r_{N}\right) \geq G\left(2^{-N}\right)$ and $\left|\log r_{1} \cdots r_{N}\right| \geq$ $N \log 2$. Hence if $\phi_{\omega}(N)<\zeta_{N}$, then

$$
\sum_{j=N+1}^{N+\zeta_{N}} Z_{j}=\sum_{j=N+1}^{N+\zeta_{N}}-\log r_{j} \geq G\left(2^{-N}\right) \log (N \log 2)=2 \zeta_{N} \mathbb{E}\left(Z_{1}\right)
$$

so the choice of $B$ gives

$$
\begin{aligned}
\mathbb{P}\left(\omega: \phi_{\omega}(N)<\zeta_{N}\right) & =\mathbb{P}\left(\sum_{j=1}^{\zeta_{N}} Z_{j} \geq 2 \zeta_{N} \mathbb{E}\left(Z_{1}\right)\right) \\
& \leq \mathbb{P}\left(\left|\sum_{j=1}^{\zeta_{N}} Z_{j}-\zeta_{N} \mathbb{E}\left(Z_{1}\right)\right| \geq \zeta_{N} \mathbb{E}\left(Z_{1}\right)\right) \leq \exp \left(-B \zeta_{N}\right) .
\end{aligned}
$$

Since $G\left(2^{-N}\right) \geq 4 \mathbb{E}\left(Z_{1}\right) / B$, there is a constant $c$ such that

$$
\begin{equation*}
\exp \left(-B \zeta_{N}\right)=(N \log 2)^{-B G\left(2^{-N}\right) / 2 \mathbb{E}\left(Z_{1}\right)} \leq c N^{-2} \tag{2.7}
\end{equation*}
$$

Thus

$$
\sum_{N} \mathbb{P}\left(\omega: \phi_{\omega}(N)<\zeta_{N}\right) \leq c \sum_{N} N^{-2}<\infty
$$

and the Borel Cantelli lemma implies that $\mathbb{P}\left(\omega: \phi_{\omega}(N)<\zeta_{N}^{(G)}\right)$ i.o. $)=0$.
(ii) The arguments are similar, but easier, for (ii). If $\phi_{\omega}(N)>\chi_{N}^{(H)}$, then

$$
r_{1} \cdots r_{N+\chi_{N}} \geq r_{1} \cdots r_{N+\phi(N)-1} \geq\left(r_{1} \cdots r_{N}\right)^{1+\Phi\left(r_{1} \cdots r_{N}\right)}
$$

Hence

$$
\begin{aligned}
\chi_{N}^{(H)} \log 2 & \leq-\log r_{N+1} \cdots r_{N+\chi_{N}} \leq-\Phi\left(r_{1} \cdots r_{N}\right) \log \left(r_{1} \cdots r_{N}\right) \\
& =H\left(r_{1} \cdots r_{N}\right) \log \left|\log r_{1} \cdots r_{N}\right| \leq H\left(2^{-N}\right) \log \left|\log r_{1} \cdots r_{N}\right|
\end{aligned}
$$

Putting in the formula for $\chi_{N}^{(H)}$ and taking exponentials gives

$$
2 N \mathbb{E}\left(Z_{1}\right) \leq\left|\log r_{1} \cdots r_{N}\right|=\sum_{i=1}^{N}-\log r_{i}
$$

Applying Theorem 1 again, we obtain

$$
\mathbb{P}\left(\phi_{\omega}(N)>\chi_{N}^{(H)}\right) \leq \mathbb{P}\left(\sum_{i=1}^{N} Z_{i} \geq 2 N \mathbb{E}\left(Z_{1}\right)\right) \leq \exp (-B N)
$$

and the Borel Cantelli lemma gives the result.

## 3. Dimension Results for Large $\Phi$

Terminology: We call a dimension function $\Phi$ large if it satisfies $\Phi(x) \gg$ $\log |\log x| /|\log x|$.

The constant functions $\Phi=\delta>0$ or any dimension function $\Phi \rightarrow \infty$ are examples of large dimension functions.

THEOREM 2. There is a set $\Gamma$, of full measure in $\Omega$, with the following properties:
(i) If there exists $A>0$ such that $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$ for all $|\lambda| \leq A$, then $\operatorname{dim}_{\Phi} \mu_{\omega}=$ $\mathbb{E}\left(X_{1}\right) / \mathbb{E}\left(Z_{1}\right)$ for all large dimension functions $\Phi$ and for all $\omega \in \Gamma$.
(ii) If there exists $A>0$ such that $\mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for all $|\lambda| \leq A$, then $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega}=$ $\mathbb{E}\left(Y_{1}\right) / \mathbb{E}\left(Z_{1}\right)$ for all large dimension functions $\Phi$ and for all $\omega \in \Gamma$.

Since positive constant functions are large dimension functions, the following corollary is immediate.

Corollary 1. If there exists $A>0$ such that $\mathbb{E}\left(e^{\lambda X_{1}}\right), \mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for all $|\lambda| \leq A$, then $\operatorname{dim}_{q L} \mu_{\omega}=\operatorname{dim}_{F} \mu_{\omega}=\mathbb{E}\left(X_{1}\right) / \mathbb{E}\left(Z_{1}\right)$ and $\operatorname{dim}_{q A} \mu_{\omega}=\overline{\operatorname{dim}}_{M} \mu_{\omega}=$ $\mathbb{E}\left(Y_{1}\right) / \mathbb{E}\left(Z_{1}\right)$ almost surely.

We will abbreviate the statement 'there exists $A>0$ such that $\mathbb{E}\left(e^{\lambda W}\right)<\infty$ for all $|\lambda| \leq A$ ' by ' $\mathbb{E}\left(e^{\lambda W}\right)<\infty$ for small $|\lambda|$ ' and set

$$
\underline{d}=\mathbb{E}\left(X_{1}\right) / \mathbb{E}\left(Z_{1}\right), \quad \bar{d}=\mathbb{E}\left(Y_{1}\right) / \mathbb{E}\left(Z_{1}\right)
$$

We begin with two lemmas. We recall that $\zeta_{N}^{(\cdot)}$ was defined in (2.4).

Lemma 3. (i) Assume $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$ for small $|\lambda|$. For each $\varepsilon>0$, there is a constant $K_{\varepsilon} \geq 1$ such that if

$$
F_{N}(\varepsilon)=\left\{\omega: \exists k \geq \zeta_{N}^{\left(K_{\varepsilon}\right)}-1 \text { with } \prod_{i=N+2}^{N+k-L-1} M_{i}^{-1}<\prod_{i=N+1}^{N+k} r_{i}^{-\underline{d}(1-\varepsilon)}\right\}
$$

then $\mathbb{P}\left(F_{N}(\varepsilon)\right.$ i.o. $)=0$.
(ii) Assume $\mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for small $|\lambda|$. For each $\varepsilon>0$, there is a constant $K_{\varepsilon} \geq 1$ such that if

$$
G_{N}(\varepsilon)=\left\{\omega: \exists k \geq \zeta_{N}^{\left(K_{\varepsilon}\right)}-1 \text { with } \prod_{i=N-L+1}^{N+k} m_{i}^{-1}>\prod_{i=N+2}^{N+k-1} r_{i}^{-\bar{d}(1+\varepsilon)}\right\}
$$

then $\mathbb{P}\left(G_{N}(\varepsilon)\right.$ i.o. $)=0$.
REMARK 3. We remark we can take the same constant $K_{\varepsilon}$ in both parts; the choice of constant will be clear from the proof. We also note that once $N$ is suitably large, we will have $\zeta_{N}^{\left(K_{\varepsilon}\right)}>\max (3, L+3)$, whence the products above are well defined.

Proof. To simplify notation, we will let $\zeta_{N}^{\left(K_{\varepsilon}\right)}=\zeta_{N}^{\varepsilon}$.
(i) Upon taking logarithms, we have

$$
F_{N}(\varepsilon)=\left\{\omega: \exists k \geq \zeta_{N}^{\varepsilon}-1 \text { with } \sum_{j=N+2}^{N+k-L-1} X_{j}<\underline{d}(1-\varepsilon) \sum_{j=N+1}^{N+k} Z_{j}\right\}
$$

The definition of $\underline{d}$ ensures that

$$
\underline{d}(1-\varepsilon) \sum_{j=N+1}^{N+k} Z_{j}=\underline{d}(1-\varepsilon)\left[\sum_{j=N+1}^{N+k} Z_{j}-k \mathbb{E}\left(Z_{1}\right)\right]+(1-\varepsilon) k \mathbb{E}\left(X_{1}\right) .
$$

Pick $N_{0}$ such that if $k \geq \zeta_{N_{0}}^{\varepsilon}-1$, then $(1-\varepsilon) k \leq(1-\varepsilon / 2)(k-L-2)$ and $(k-L-2) \varepsilon / 4$ $\geq k \varepsilon / 8$. For all $N \geq N_{0}$, the set $F_{N}(\varepsilon)$ is contained in

$$
\left.\begin{array}{l}
\bigcup_{k \geq \zeta_{N}^{\varepsilon}-1}\left\{\sum_{j=N+2}^{N+k-L-1} X_{j}<\underline{d}(1-\varepsilon)\left[\sum_{j=N+1}^{N+k} Z_{j}-k \mathbb{E}\left(Z_{1}\right)\right]+\left(1-\frac{\varepsilon}{2}\right)(k-L-2) \mathbb{E}\left(X_{1}\right)\right\} \\
=\bigcup_{k \geq \zeta_{N}^{\varepsilon}-1}\left\{\left[\sum_{j=N+2}^{N+k-L-1} X_{j}-(k-L-2) \mathbb{E}\left(X_{1}\right)\right]+\underline{d}(1-\varepsilon)\left[k \mathbb{E}\left(Z_{1}\right)-\sum_{j=N+1}^{N+k} Z_{j}\right]\right\} \\
<-\frac{(k-L-2) \varepsilon}{2} \mathbb{E}\left(X_{1}\right)
\end{array}\right\} . \begin{gathered}
\left.\left[\sum_{j \geq \zeta_{N}^{\varepsilon}-1}^{N+k-L-1} X_{j}-(k-L-2) \mathbb{E}\left(X_{1}\right)\right]+\underline{d}(1-\varepsilon)\left[k \mathbb{E}\left(Z_{1}\right)-\sum_{j=N+1}^{N+k} Z_{j}\right]\right\} \\
\quad<-\frac{(k-L-2) \varepsilon}{4} \mathbb{E}\left(X_{1}\right)-\frac{k \varepsilon}{8} \mathbb{E}\left(X_{1}\right)
\end{gathered}
$$

Hence $F_{N}(\varepsilon) \subseteq \bigcup_{k \geq \zeta_{N}^{\varepsilon}-1}\left(A_{k} \bigcup B_{k}\right)$ where

$$
A_{k}=\left\{\omega:\left|\sum_{i=2}^{k-L-1} X_{i}-(k-L-2) \mathbb{E}\left(X_{1}\right)\right|>\frac{(k-L-2) \varepsilon \mathbb{E}\left(X_{1}\right)}{4}\right\}
$$

and

$$
B_{k}=\left\{\omega:\left|k \mathbb{E}\left(Z_{1}\right)-\sum_{i=1}^{k} Z_{i}\right|>\frac{k \varepsilon \mathbb{E}\left(X_{1}\right)}{8 \underline{d}(1-\varepsilon)}\right\}=\left\{\omega:\left|k \mathbb{E}\left(Z_{1}\right)-\sum_{i=1}^{k} Z_{i}\right|>\frac{k \varepsilon \mathbb{E}\left(Z_{1}\right)}{8(1-\varepsilon)}\right\}
$$

From Theorem 1 there are constants $a_{\varepsilon}, b_{\varepsilon}>0$ such that $\mathbb{P}\left(A_{k}\right) \leq e^{-a_{\varepsilon}(k-L-2)}$ and $\mathbb{P}\left(B_{k}\right) \leq e^{-b_{\varepsilon} k}$ for all $k$. Thus there are constants $C_{\varepsilon}, c_{\varepsilon}>0$ such that for large enough $N$,

$$
\mathbb{P}\left(F_{N}(\varepsilon)\right) \leq \sum_{k \geq \zeta_{N}-1} \mathbb{P}\left(A_{k}\right)+\mathbb{P}\left(B_{k}\right) \leq C_{\varepsilon} e^{-c_{\varepsilon} \zeta_{N}^{\varepsilon}}
$$

Choose $K_{\varepsilon}$ sufficiently large to ensure that $\exp \left(-c_{\varepsilon} \zeta_{N}^{\varepsilon}\right) \leq N^{-2}$ for all $N$. With this choice, $\sum_{N=1}^{\infty} \mathbb{P}\left(F_{N}(\varepsilon)\right)<\infty$ and hence the Borel Cantelli lemma gives the desired result.
(ii) This follows in a very similar fashion. The details are left for the reader.

Lemma 4. (i) Assume $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$ for small $|\lambda|$. For each $\varepsilon>0$, there is a constant $K_{\varepsilon}^{\prime} \geq 1$ such that $\mathbb{P}\left(F_{N}^{\prime}(\varepsilon)\right.$ i.o. $)=0$ where

$$
F_{N}^{\prime}(\varepsilon)=\left\{\omega: \exists k \geq \zeta_{N}^{\left(K_{\varepsilon}^{\prime}\right)} \text { with } \prod_{i=N+1}^{N+k} M_{i}^{-1}>\prod_{i=N+1}^{N+k} r_{i}^{-\underline{d}(1+\varepsilon)}\right\}
$$

(ii) Assume $\mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for small $|\lambda|$. For each $\varepsilon>0$, there is a constant $K_{\varepsilon}^{\prime} \geq 1$ such that $\mathbb{P}\left(G_{N}^{\prime}(\varepsilon)\right.$ i.o. $)=0$ where

$$
G_{N}^{\prime}(\varepsilon)=\left\{\omega: \exists k \geq \zeta_{N}^{\left(K_{\varepsilon}^{\prime}\right)} \text { with } \prod_{i=N+1}^{N+k} m_{i}^{-1}<\prod_{i=N+1}^{N+k} r_{i}^{-\bar{d}(1+\varepsilon)}\right\}
$$

Proof. Again we will only prove (i) as (ii) is similar and to simplify notation we will write $\zeta_{N}^{\left(K_{\varepsilon}^{\prime}\right)}=\zeta_{N}^{\varepsilon}$.

It is straightforward to see that

$$
\begin{gathered}
F_{N}^{\prime}(\varepsilon)=\bigcup_{k \geq \zeta_{N}^{\varepsilon}}\left\{\sum_{j=N+1}^{N+k} X_{j}>\underline{d}(1+\varepsilon) \sum_{j=N+1}^{N+k} Z_{j}\right\} \\
\subseteq \bigcup_{k \geq \zeta_{N}^{\varepsilon}}\left\{\left[\sum_{j=N+1}^{N+k} X_{j}-\mathbb{E}\left(X_{1}\right) k\right]+\underline{d}(1+\varepsilon)\left[k \mathbb{E}\left(Z_{1}\right)-\sum_{j=N+1}^{N+k} Z_{j}\right]>\varepsilon k \mathbb{E}\left(X_{1}\right)\right\} \\
\subseteq \bigcup_{k \geq \zeta_{N}^{\varepsilon}}\left\{\left|\sum_{j=1}^{k} X_{j}-\mathbb{E}\left(X_{1}\right) k\right| \geq \frac{\varepsilon k \mathbb{E}\left(X_{1}\right)}{2}\right\} \bigcup\left\{\left|k \mathbb{E}\left(Z_{1}\right)-\sum_{j=1}^{k} Z_{j}\right| \geq \frac{\varepsilon k \mathbb{E}\left(Z_{1}\right)}{2(\varepsilon+1)}\right\} .
\end{gathered}
$$

From Petrov's theorem, $\mathbb{P}\left(F_{N}^{\prime}(\varepsilon)\right) \leq C_{\varepsilon} e^{-c_{\varepsilon} \zeta_{N}^{\varepsilon}}$ for suitable constants $C_{\varepsilon}, c_{\varepsilon}>0$. Again, make the choice of $K_{\varepsilon}^{\prime}$ to ensure $\sum_{N} \mathbb{P}\left(F_{N}^{\prime}(\varepsilon)\right)<\infty$.

Proof. [of Theorem 2 We begin with some initial observations and notation that will be relevant to both the lower and upper $\Phi$-dimensions.

Let $\varepsilon>0$ and take $\mathcal{K}_{\varepsilon}=\max \left(K_{\varepsilon}, 4 \mathbb{E}\left(Z_{1}\right) / B\right)$ where $K_{\varepsilon}$ is the constant from Lemma 3 and $B$ arises from the probability theorem as outlined in (2.6). Let

$$
\Phi^{\left(\mathcal{K}_{\varepsilon}\right)}(x)=\mathcal{K}_{\varepsilon} \log |\log x| /|\log x|
$$

and take $\zeta_{N}^{\left(\mathcal{K}_{\varepsilon}\right)}$ as defined in (2.4). To simplify notation, we will write $\Phi^{\varepsilon}, \phi^{\varepsilon}$ and $\zeta_{N}^{\varepsilon}$.

According to Lemma 2 there is a set, $\Gamma_{\varepsilon}$, of full measure, with the property that for every $\omega \in \Gamma_{\varepsilon}$ there is some integer $\mathcal{N}_{\omega}$ such that for all $N \geq \mathcal{N}_{\omega}$ we have $\phi_{\omega}^{(\varepsilon)}(N) \geq \zeta_{N}^{(\varepsilon)}$. Let $\Gamma_{\varepsilon}(j)$ be the subset of $\Gamma_{\varepsilon}$ with $\mathcal{N}_{\omega}=j \in \mathbb{N}$.

Since $\zeta_{N}^{\varepsilon} \rightarrow \infty$, we can choose $J_{0}$ such that if $N \geq J_{0}$, then $\zeta_{N}^{\varepsilon} \geq L+4$. Take $\omega \in \Gamma_{\varepsilon}(j)$ and put $J_{j}=\max \left(j, J_{0}\right)$.

Given $0<r<R<r_{1} \cdots r_{J_{j}}$, choose $N=N(\omega)$ and $n=n(\omega)>N$ such that

$$
\begin{align*}
r_{1} \cdots r_{N+1} & \leq R<r_{1} \cdots r_{N} \text { and }  \tag{3.1}\\
r_{1} \cdots r_{n} & \leq r<r_{1} \cdots r_{n-1}
\end{align*}
$$

Note that $N \geq J_{j}$. Furthermore, we have the bounds

$$
\begin{equation*}
\left(r_{N+2} \cdots r_{n-1}\right)^{-1} \leq \frac{R}{r} \leq\left(r_{N+1} \cdots r_{n}\right)^{-1} \tag{3.2}
\end{equation*}
$$

If $r \leq r_{1} \cdots r_{N+1+\phi^{\varepsilon}(N+1)}$, then since the function $x^{1+\Phi(x)}$ is increasing, (2.2) tells us that

$$
r \leq\left(r_{1} \cdots r_{N+1}\right)^{1+\Phi^{\varepsilon}\left(r_{1} \cdots r_{N+1}\right)} \leq R^{1+\Phi^{\varepsilon}(R)}
$$

On the other hand, if $r \leq R^{1+\Phi^{\varepsilon}(R)}$, then by (2.3),

$$
r \leq\left(r_{1} \cdots r_{N}\right)^{1+\Phi^{\varepsilon}\left(r_{1} \cdots r_{N}\right)} \leq r_{1} \cdots r_{N+\phi^{\varepsilon}(N)-1}
$$

and hence $n \geq N+\phi_{\omega}^{\varepsilon}(N)-1 \geq N+\zeta_{N}^{\varepsilon}-1$, so that $n-L-1 \geq N+2$.
From Lemma 1 we know

$$
\frac{\mu\left(I_{N+1}(x)\right)}{\mu\left(I_{n-L-1}(x)\right)} \leq \frac{\mu(B(x, R))}{\mu(B(x, r))} \leq \frac{\mu\left(I_{N-L}(x)\right)}{\mu\left(I_{n}(x)\right)}
$$

Since

$$
\begin{equation*}
\frac{\mu\left(I_{j}(x)\right)}{\mu\left(I_{j+s}(x)\right)}=\frac{\mu\left(I_{j}(x)\right)}{\mu\left(I_{j}(x)\right) p_{j+1}^{\left(i_{j+1}\right)} \cdots p_{j+s}^{\left(i_{j+s}\right)}} \tag{3.3}
\end{equation*}
$$

for a suitable choice of probabilities $p_{\ell}^{\left(i_{\ell}\right)}, \ell=j+1, \ldots, j+s$, we have

$$
\begin{equation*}
\left(M_{N+2} \cdots M_{n-L-1}\right)^{-1} \leq \frac{\mu(B(x, R))}{\mu(B(x, r))} \leq\left(m_{N-L+1} \cdots m_{n}\right)^{-1} \tag{3.4}
\end{equation*}
$$

Computation of the almost sure lower $\Phi$-dimension: Assume $\mathbb{E}\left(e^{\lambda X_{1}}\right)<$ $\infty$ for small $|\lambda|$.

Since $\phi_{\omega}^{(\varepsilon)}(N) \geq \zeta_{N}^{\varepsilon}$ for $N \geq J_{j}$, with the notation $F_{N}(\varepsilon)$ from Lemma 3(i) we have

$$
\left\{\omega \in \Gamma_{\varepsilon}(j): \exists k \geq \phi_{\omega}^{\varepsilon}(N)-1 \text { with } \prod_{i=N+2}^{N+k-L-1} M_{i}^{-1}<\prod_{i=N+1}^{N+k} r_{i}^{-\underline{d}(1-\varepsilon)}\right\} \subseteq F_{N}(\varepsilon)
$$

By Lemma 3, $\mathbb{P}\left(F_{N}(\varepsilon)\right.$ i.o $)=0$, so $\left\{\left(F_{N}(\varepsilon) \text { i.o }\right\}^{c}=\Lambda_{\varepsilon}\right.$ where $\Lambda_{\varepsilon}$ has full measure. Thus the set $\Delta_{\varepsilon}(j)=\Lambda_{\varepsilon} \bigcap \Gamma_{\varepsilon}(j)$ has full measure in $\Gamma_{\varepsilon}(j)$. Moreover, it has the property that for each $\omega \in \Delta_{\varepsilon}(j)$, there is an integer $N_{\varepsilon, j}(\omega) \geq J_{j}$ so that if $N \geq N_{\varepsilon, j}(\omega)$, then for every $k \geq \phi_{\omega}^{\varepsilon}(N)-1$ we have

$$
\left(M_{N+2} \cdots M_{N+k-L-1}\right)^{-1} \geq\left(r_{N+1} \cdots r_{N+k}\right)^{-\underline{d}(1-\varepsilon)} .
$$

For $\omega \in \Delta_{\varepsilon}(j)$, set $\rho(\varepsilon, \omega)=r_{1} \cdots r_{N_{\varepsilon, j}(\omega)}$. If $R \leq \rho(\varepsilon, \omega)$ satisfies (3.1), then $N \geq N_{\varepsilon, j}(\omega)$, hence there can be no choice of $k \geq \phi_{\omega}^{\varepsilon}(N)-1$ with

$$
\left(M_{N+2} \cdots M_{N+k-L-1}\right)^{-1}<\left(r_{N+1} \cdots r_{N+k}\right)^{-\underline{d}(1-\varepsilon)} .
$$

We deduce that for all $r \leq R^{1+\Phi(R)} \leq \rho(\varepsilon, \omega)$ and for all $x \in E(\omega)$,

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq\left(M_{N+2} \cdots M_{n-L-1}\right)^{-1} \geq\left(r_{N+1} \cdots r_{n}\right)^{-\underline{d}(1-\varepsilon)} \geq\left(\frac{R}{r}\right)^{\underline{d}(1-\varepsilon)}
$$

Let $\Delta_{\varepsilon}=\bigcup_{j=1}^{\infty} \Delta_{\varepsilon}(j)$. This is a set of measure one and we have just shown that $\underline{\operatorname{dim}}_{\Phi^{\varepsilon}} \mu_{\omega} \geq \underline{d}(1-\varepsilon)$ for all $\omega \in \Delta_{\varepsilon}$. Take a sequence $\varepsilon_{i} \rightarrow 0$ and let $\Delta=\bigcap_{i=1}^{\infty} \Delta_{\varepsilon_{i}}$. Of course, $\mathbb{P}(\Delta)=1$ and $\underline{\operatorname{dim}}_{\Phi^{\left(\varepsilon_{i}\right)}} \mu_{\omega} \geq \underline{d}\left(1-\varepsilon_{i}\right)$ for all $\omega \in \Delta$.

Now suppose $\Phi$ is any large dimension function. Given any $\varepsilon_{i}$, we have $\Phi(x) \geq$ $\Phi^{\left(\varepsilon_{i}\right)}(x)$ for small enough $x$ and therefore $\operatorname{dim}_{\Phi} \mu_{\omega} \geq \underline{\operatorname{dim}}_{\Phi\left(\varepsilon_{i}\right)} \mu_{\omega}$ for all $\omega$. We conclude that $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega} \geq \underline{d}\left(1-\varepsilon_{i}\right)$ for all $\omega \in \Delta$ and for all $i$, and consequently, $\operatorname{dim}_{\Phi} \mu_{\omega} \geq \underline{d}$ on $\Delta$.

For the opposite inequality, fix $\varepsilon>0$ and choose $K_{\varepsilon}^{\prime}$ and $F_{N}^{\prime}(\varepsilon)$ as in Lemma 4(i) so that $\left\{F_{N}^{\prime}(\varepsilon) \text { i.o. }\right\}^{c}=\Delta_{\varepsilon}^{\prime}$ is a set of measure one. That means, for all $\omega \in$ $\Delta_{\varepsilon}^{\prime}$ there are arbitrarily large $N$ with the property that for all large enough $k$,

$$
\left(M_{N+1} \cdots M_{N+k}\right)^{-1} \leq\left(r_{N+1} \cdots r_{N+k)}\right)^{-\underline{d}(1+\varepsilon)} .
$$

Let $\Phi$ be any large dimension function. For $\omega \in \Delta_{\varepsilon}^{\prime}$, take

$$
R_{N}=\tau r_{1}(\omega) \cdots r_{N}(\omega) / 2
$$

As $\tau / 2 \geq 2^{-L} \geq r_{N+1} \cdots r_{N+L}$, we have $R_{N} \geq r_{1} \cdots r_{N+L}$ and thus if $k \geq \phi_{\omega}(N+L)$, then

$$
\varrho_{N, k}:=r_{1} \cdots r_{N+L+k} \leq R_{N}^{1+\Phi\left(R_{N}\right)}
$$

Fix some Moran set of level $N$ and for each $k \geq L+\phi(N+L)$ consider a descendent Moran set of step $N+k$ where at each step from $N+1$ to $N+k$ we select the child that is assigned the maximum probability. Choose $x=x_{N, k} \in E(\omega)$ in that descendent, so $B\left(x, \varrho_{N, k}\right) \supseteq I_{N+k}(x)$. Since the distance from $x$ to any Moran set of level $N$, other than $I_{N}(x)$, is at least $2 R_{N}$, we have $B\left(x, R_{N}\right) \cap E(\omega) \subseteq I_{N}(x)$, and therefore

$$
\frac{\mu\left(B\left(x, R_{N}\right)\right)}{\mu\left(B\left(x, \varrho_{N, k}\right)\right)} \leq \frac{\mu\left(I_{N}(x)\right)}{\mu\left(I_{N+k}(x)\right)}=\left(M_{N+1} \cdots M_{N+k}\right)^{-1} .
$$

Hence there are choices of $k \geq \phi_{\omega}(N+L)$ such that

$$
\frac{\mu\left(B\left(x, R_{N}\right)\right)}{\mu\left(B\left(x, \varrho_{N, k}\right)\right)} \leq\left(r_{N+1} \cdots r_{N+k}\right)^{-\underline{d}(1+\varepsilon)}=C_{\varepsilon}\left(\frac{R_{N}}{\varrho_{N, k}}\right)^{\underline{d}(1+\varepsilon)}
$$

(with constant $\left.C_{\varepsilon}=(2 / \tau)^{\underline{d}(1+\varepsilon)}\right)$. It follows that $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega} \leq(1+\varepsilon) \underline{d}$ for every $\omega \in \Delta_{\varepsilon}^{\prime}$. Again, take a sequence $\varepsilon_{i} \rightarrow 0$ and let $\Delta^{\prime}=\bigcap_{i=1}^{\infty} \Delta_{\varepsilon_{i}}^{\prime}$, a set of full measure. Obviously, $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega} \leq \underline{d}$ for all $\omega \in \Delta^{\prime}$.

Combining these facts, we see that $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega}=\underline{d}$ for all large dimension functions $\Phi$ and for every $\omega \in \Delta \bigcap \Delta^{\prime}$, a set of measure one.

Computation of the almost sure upper $\Phi$-dimension: This computation is very similar to that of the lower $\Phi$-dimension. First, use the upper bound in (3.4),

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \leq\left(m_{N-L+1} \cdots m_{n}\right)^{-1}
$$

together with Lemma 3(ii) to prove that for each $\varepsilon>0$ there is a set of full measure, $\Delta_{\varepsilon}$, such that $\overline{\operatorname{dim}}_{\Phi^{\left(\mathcal{K}_{\varepsilon}\right)}} \mu_{\omega} \leq \bar{d}(1+\varepsilon)$ for a suitable choice of constant $\mathcal{K}_{\varepsilon}$. But any large dimension function $\Phi$ dominates the function $\Phi^{\left(\mathcal{K}_{\varepsilon}\right)}$ for small enough $x$, hence $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega} \leq \bar{d}(1+\varepsilon)$ on $\Delta_{\varepsilon}$, as well. Then use Lemma4(ii), along with $R_{N}=r_{1} \cdots r_{N}$, $\varrho_{N, k}=\tau r_{1} \cdots r_{N+k} / 2$ and $x_{N, k} \in E(\omega) \bigcap I_{N}$ belonging to a Moran descendent of level $N+k$, where at each step $N+1$ to $N+k$ we choose a Moran set where the minimal probability is assigned, to deduce that $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega} \geq \bar{d}(1-\varepsilon)$ on some set $\Delta_{\varepsilon}^{\prime}$ of full measure (independent of the choice of $\Phi$ ). To complete the proof, take a sequence $\varepsilon_{i} \rightarrow 0$ as before.

Of course, we can take as $\Gamma$ the intersection of the two sets of full measure where the upper and lower $\Phi$ dimensions are the appropriate values.

REMARK 4. Note that the proof actually shows that if $\varepsilon>0$, then (in the notation of the proof) $\operatorname{dim}_{\Phi\left(\mathcal{K}_{\varepsilon}\right)} \mu_{\omega} \geq \underline{d}(1-\varepsilon)$ and $\overline{\operatorname{dim}}_{\Phi\left(\mathcal{K}_{\varepsilon}\right)} \mu_{\omega} \leq \bar{d}(1+\varepsilon)$ a.s.

## 4. Dimension Results for Small $\Phi$

Terminology: We call a dimension function $\Phi$ small if it satisfies $\Phi(x) \ll$ $\log |\log x| /|\log x|$.

The constant function $\Phi=0$ (giving the Assouad dimension) is an example of a small $\Phi$.

Notation 3. Put

$$
\alpha=\inf \left\{s: \log m_{1} / \log r_{1} \leq s \text { a.s. }\right\}=\text { ess sup } \log m_{1} / \log r_{1},
$$

and

$$
\beta=\sup \left\{t: \log M_{1} / \log r_{1} \geq t \text { a.s. }\right\}=\text { ess inf } \log M_{1} / \log r_{1}
$$

Obviously $\alpha \geq \beta$. Here are some other easy facts.
Lemma 5. (i) If ess $\sup M_{1}=1$, or ess $\inf r_{1}=0$ but ess $\inf M_{1} \neq 0$, then $\beta=0$. If ess $\inf m_{1}=0$, but ess inf $r_{1} \neq 0$, then $\alpha=\infty$.
(ii) If $\left\{r_{1}, m_{1}\right\}$ are independent random variables and ess $\inf m_{1}=0$, then $\alpha=\infty$.

Proof. Part (i) is obvious.
(ii) Since $r_{1}(\omega)>0$ for all $\omega$, there must be some $\varepsilon>0$ such that $\mathbb{P}\left(r_{1} \geq \varepsilon\right)>0$. The independence of $r_{1}$ and $m_{1}$ ensures that for any $q \in \mathbb{R}^{+}$,

$$
\begin{aligned}
\mathbb{P}\left(-\log m_{1} \geq-q \log r_{1}\right) & \geq \mathbb{P}\left(-\log m_{1} \geq-q \log \varepsilon \text { and }-\log r_{1} \leq-\log \varepsilon\right) \\
& =\mathbb{P}\left(-\log m_{1} \geq-q \log \varepsilon\right) \mathbb{P}\left(-\log r_{1} \leq-\log \varepsilon\right) \\
& =\mathbb{P}\left(m_{1} \leq \varepsilon^{q}\right) \mathbb{P}\left(r_{1} \geq \varepsilon\right)
\end{aligned}
$$

But $\mathbb{P}\left(m_{1} \leq \varepsilon^{q}\right)>0$ as ess inf $m_{1}=0$ and therefore $\alpha=\infty$.
Theorem 3. There is a set $\Gamma$, of full measure in $\Omega$, with the following properties:
(i) $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega} \leq \beta$ and $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega} \geq \alpha$ for all small dimension functions $\Phi$ and all $\omega \in \Gamma$.
(ii) If either ess $\inf M_{j}>0$ or ess $\inf r_{j}>0$, then $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega} \geq \beta$ for all dimension functions $\Phi$ and all $\omega \in \Gamma$.
(iii) If either ess $\inf m_{j}>0$ or ess $\inf r_{j}>0$, then $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega} \leq \alpha$ for all dimension functions $\Phi$ and all $\omega \in \Gamma$.

Here are some immediate consequences.
Corollary 2. If ess inf $r_{j}>0$, then $\underline{\operatorname{dim}}_{\Phi} \mu_{\omega}=\operatorname{dim}_{L} \mu_{\omega}=\beta$ and $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega}=$ $\operatorname{dim}_{A} \mu_{\omega}=\alpha$ for all small $\Phi$ and almost every $\omega$. If the number of children is bounded, then $\underline{\operatorname{dim}} \Phi \mu_{\omega}=\operatorname{dim}_{L} \mu_{\omega}=\beta$ for all small $\Phi$ and a.e. $\omega$.

Proof. [of Theorem 3 (i) We will assume $\alpha<\infty$; the proof for $\alpha=\infty$ is similar and left for the reader. The definition of $\alpha$ ensures that given $\varepsilon>0$, we can choose $q(\varepsilon) \leq \exp (-3)$ with

$$
0<q(\varepsilon) \leq \mathbb{P}\left(-\log m_{1} \geq(\alpha-\varepsilon)\left(-\log r_{1}\right)\right)
$$

Let

$$
\Phi^{\varepsilon}(x)=\frac{\log 2}{2|\log q(\varepsilon)|} \frac{\log |\log x|}{|\log x|} \text { and } \chi_{N}^{\varepsilon}=\frac{\log \left(2 N \mathbb{E}\left(Z_{1}\right)\right)}{2|\log q(\varepsilon)|}
$$

and obtain the set, $\Gamma_{\varepsilon}$, of full measure from Lemma 2 with the property that $\phi_{\omega}^{\varepsilon}(N) \leq \chi_{N}^{\varepsilon}$ eventually for all $\omega \in \Gamma_{\varepsilon}$. Set $J_{N}(\varepsilon)=\left\lceil\chi_{N}^{\varepsilon}\right\rceil$ (meaning, the next integer) and let

$$
G_{N}^{\varepsilon}=\left\{\left(m_{N+1} \cdots m_{N+J_{N}(\varepsilon)}\right)^{-1} \geq\left(r_{N+1} \cdots r_{N+J_{N}(\varepsilon)}\right)^{-(\alpha-\varepsilon)}\right\}
$$

As the random variables $\left\{m_{i}\right\}$ are independent and identically distributed, as are the random variables $\left\{r_{i}\right\}$,

$$
\begin{aligned}
\mathbb{P}\left(G_{N}^{\varepsilon}\right) & =\mathbb{P}\left(\sum_{i=1}^{J_{N}(\varepsilon)}-\log m_{i} \geq(\alpha-\varepsilon) \sum_{i=1}^{J_{N}(\varepsilon)}-\log r_{i}\right) \\
& \geq \mathbb{P}\left(-\log m_{i} \geq(\alpha-\varepsilon)\left(-\log r_{i}\right) \text { for each } i=1, \ldots, J_{N}(\varepsilon)\right) \\
& =\prod_{i=1}^{J_{N}(\varepsilon)} \mathbb{P}\left(-\log m_{i} \geq(\alpha-\varepsilon)\left(-\log r_{i}\right)\right) \geq q(\varepsilon)^{J_{N}(\varepsilon)}
\end{aligned}
$$

It is easy to check that $q(\varepsilon)^{J_{N}(\varepsilon)} \geq 1 / N$ for large $N$, thus if we set $N_{k}=k \log k$, then

$$
\sum_{k} \mathbb{P}\left(G_{N_{k}}^{\varepsilon}\right) \geq \sum_{k} q(\varepsilon)^{J_{N_{k}}(\varepsilon)} \geq \sum_{k} \frac{1}{k \log k}=\infty
$$

The fact that $|\log q(\varepsilon)| \geq 3$ ensures that $N_{k+1}-N_{k} \geq \log (k+1)>J_{N_{k}}(\varepsilon)$ (for large $k$ ), hence the events $G_{N_{k}}^{\varepsilon}$ are independent and the Borel Cantelli lemma implies $G_{N_{k}}^{\varepsilon}$ occurs infinitely often with probability one, say on $\Gamma_{\varepsilon}^{\prime}$.

For $\omega \in \Gamma_{\varepsilon} \bigcap \Gamma_{\varepsilon}^{\prime}=\Delta_{\varepsilon}$, choose $\mathcal{N}_{\omega}$ such that for $N \geq \mathcal{N}_{\omega}, \phi_{\omega}^{\varepsilon}(N) \leq \chi_{N}^{\varepsilon}$. Put $R_{N}=r_{1}(\omega) \cdots r_{N}(\omega)$ and $\varrho_{N}=\tau r_{1} \cdots r_{N+J_{N}(\varepsilon)} / 2$. As $J_{N}(\varepsilon) \geq \phi_{\omega}^{\varepsilon}(N)$, $\varrho_{N} \leq R_{N}^{1+\Phi^{\varepsilon}\left(R_{N}\right)}$. Take any Moran set $I_{N}$ of step $N$ and consider the descendent at step $N+J_{N}(\varepsilon)$ where the minimal probability was chosen each time. Let $x_{N} \in E(\omega)$ belong to that descendent. The separation property and size of $\varrho_{N}$ ensures that $B\left(x_{N}, \varrho_{N}\right) \cap E(\omega) \subseteq I_{N+J_{N}(\varepsilon)}(x)$, while $B\left(x_{N}, R_{N}\right) \supseteq I_{N}(x)$. Hence

$$
\frac{\mu\left(B\left(x_{N}, R_{N}\right)\right)}{\mu\left(B\left(x_{N}, \varrho_{N}\right)\right)} \geq \frac{\mu\left(I_{N}(x)\right)}{\mu\left(I_{N+J_{N}(\varepsilon)}(x)\right)}=\left(m_{N+1} \cdots m_{N+J_{N}(\varepsilon)}\right)^{-1}
$$

For infinitely many $N \in\left\{N_{k}\right\}$,

$$
\left(m_{N+1} \cdots m_{N+J_{N}(\varepsilon)}\right)^{-1} \geq\left(r_{N+1} \cdots r_{N+J_{N}(\varepsilon)}\right)^{-(\alpha-\varepsilon)}=\left(\frac{\tau}{2}\right)^{\alpha-\varepsilon}\left(\frac{R}{r}\right)^{\alpha-\varepsilon}
$$

thus for suitable arbitrarily small $R, r \leq R^{1+\Phi(R)}$ and $x \in E(\omega)$, we have

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq C_{\varepsilon}\left(\frac{R}{r}\right)^{\alpha-\varepsilon}
$$

for a constant $C_{\varepsilon}>0$. That implies $\overline{\operatorname{dim}}_{\Phi^{\varepsilon}} \mu_{\omega} \geq \alpha-\varepsilon$ for all $\omega \in \Delta_{\varepsilon}$.
If $\Phi$ is any small dimension function, then $\Phi(x) \leq \Phi^{\varepsilon}(x)$ for small $x$ and consequently $\overline{\operatorname{dim}}_{\Phi} \mu_{\omega} \geq \overline{\operatorname{dim}}_{\Phi \varepsilon} \mu_{\omega} \geq \alpha-\varepsilon$ for all $\omega \in \Delta_{\varepsilon}$. Taking a sequence $\varepsilon_{i} \rightarrow 0$, we conclude that $\operatorname{dim}_{\Phi} \mu_{\omega} \geq \alpha$ for all $\omega \in \Delta=\bigcap \Delta_{\varepsilon_{i}}$, a set of full measure.

The arguments are similar for the lower dimension, but in this case we begin with

$$
0<q(\varepsilon) \leq \mathbb{P}\left(-\log M_{1} \geq(\beta+\varepsilon)\left(-\log r_{1}\right)\right)
$$

and define $\Phi^{\varepsilon}$ and $\chi_{N}^{\varepsilon}$ accordingly. Put

$$
G_{N}^{\varepsilon}=\left\{\omega:\left(M_{N+1} \cdots M_{N+L+J_{N+L}(\varepsilon)}\right)^{-1} \leq\left(r_{N+1} \cdots r_{N+L+J_{N+L}(\varepsilon)}\right)^{-(\beta+\varepsilon)}\right\}
$$

For large $k, N_{k+1} \geq N_{k}+L+J_{N_{k}+L}(\varepsilon)$, so analogous reasoning to the above with the Borel Cantelli lemma implies $G_{N_{k}}^{\varepsilon}$ occurs infinitely often with probability one.

Put $R_{N}=\tau r_{1} \cdots r_{N} / 2, \varrho_{N}=r_{1} \cdots r_{N+L+J_{N+L}(\varepsilon)}$, take a Moran set of step $N$ and consider the descendent at step $N+L+J_{N+L}(\varepsilon)$ where we choose the maximum probability each time. For $x_{N} \in E(\omega)$ belonging to this descendent and for suitable arbitrarily large $N \in\left\{N_{k}\right\}$, we have

$$
\begin{aligned}
\frac{\mu\left(B\left(x_{N}, R_{N}\right)\right)}{\mu\left(B\left(x_{N}, \varrho_{N}\right)\right)} & \leq \frac{\mu\left(I_{N}\left(x_{N}\right)\right)}{\mu\left(I_{N+L+J_{N+L}(\varepsilon)}(x)\right)}=\left(M_{N+1} \cdots M_{N+L+J_{N+L}(\varepsilon)}\right)^{-1} \\
& \leq\left(r_{N+1} \cdots r_{N+L+J_{N+L}(\varepsilon)}\right)^{-(\beta+\varepsilon)} \leq C_{\varepsilon}\left(\frac{R}{r}\right)^{\beta+\varepsilon}
\end{aligned}
$$

Thus $\underline{\operatorname{dim}}_{\Phi^{\varepsilon}} \mu \leq \beta+\varepsilon$ on a set of full measure, $\Delta_{\varepsilon}^{\prime}$. As above, we deduce that for any small dimension function $\Phi, \underline{\operatorname{dim}}_{\Phi} \mu \leq \beta$ on the set of full measure $\Delta^{\prime}=\bigcap \Delta_{\varepsilon_{i}}^{\prime}$.
(ii) Fix $\omega$ and assume $r \leq R^{1+\Phi(R)} \leq R$ as in (3.1), so $R / r \leq\left(r_{N+1} \cdots r_{n}\right)^{-1}$. For any $x \in E(\omega)$, Lemma 1 implies

$$
\begin{equation*}
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq\left(M_{N+2} \cdots M_{n-L-1}\right)^{-1} \text { if } n>N+L+2 \tag{4.1}
\end{equation*}
$$

Regardless of $n, \mu(B(x, R)) / \mu(B(x, r)) \geq 1$.
If ess $\inf M_{j}=\delta>0$, then in either case

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq C_{\delta}\left(M_{N} \cdots M_{n}\right)^{-1}
$$

for some constant $C_{\delta}>0$. If, instead, ess $\inf r_{j}=\delta>0$ and $n \leq N+L+2$, then $R / r \leq \delta^{-(L+2)}$, while if $n>N+L+2$, then $R / r \leq C_{\delta}\left(r_{N+2} \cdots r_{n-L-1}\right)^{-1}$.

It follows that for any $\omega$ in the set of full measure, $\Omega_{\varepsilon}$, where $-\log M_{i} /-\log r_{i} \geq$ $\beta-\varepsilon$ for all $i$, there is a constant $c>0$ such that

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \geq c\left(\frac{R}{r}\right)^{\beta-\varepsilon}
$$

We conclude that for any $\Phi, \underline{\operatorname{dim}_{\Phi} \mu \geq \beta}$ on $\bigcap \Omega_{\varepsilon_{j}}$ where $\varepsilon_{j} \rightarrow 0$.
(iii) This is similar to (ii) (but easier) since if $R$ and $r \leq R^{1+\Phi(R)}$ satisfy (3.1), then for all $n>N$,

$$
\frac{\mu(B(x, R))}{\mu(B(x, r))} \leq \frac{\mu\left(I_{N-L}(x)\right)}{\mu\left(I_{n}(x)\right)} \leq\left(m_{N-L+1} \cdots m_{n}\right)^{-1}
$$

Remark 5. In Subsection 5.4, we see that it is possible to have $\overline{\operatorname{dim}}_{\Phi} \mu>\alpha$ and $\operatorname{dim}_{\Phi} \mu<\beta$ on sets of positive measure.

Remark 6. It would be interesting to know formulas for the $\Phi$-dimensions when $\Phi(x) \sim \log |\log x| /|\log x|$.

## 5. Applications

In this section we will consider some classes of examples of random Moran sets and measures to which our results apply.

### 5.1. Fixed probabilities.

Example 3. One obvious special case of this set up is the deterministic model where $T_{j}(\omega)=T, r_{j}(\omega)=r \leq r_{T}$ and $\left(p_{j}^{(1)}(\omega), \ldots, p_{j}^{\left(T_{j}\right)}(\omega)\right)=\left(p^{(1)}, \ldots, p^{(T)}\right)$ for all $j$ and all $\omega$. Formally, this arises by choosing the probability measure to be a single point mass measure. We clearly have $\mathbb{E}\left(e^{\lambda X_{1}}\right), \mathbb{E}\left(e^{\lambda Y_{1}}\right), \mathbb{E}\left(e^{\lambda Z_{1}}\right)<\infty$ for all $\lambda$ and $\mathbb{E}\left(X_{1}\right)=-\log \left(\max p_{1}^{(j)}\right), \mathbb{E}\left(Y_{1}\right)=-\log \left(\min p_{1}^{(j)}\right)$, and $\mathbb{E}\left(Z_{1}\right)=-\log r_{1}$.

An example of this situation is to take an iterated function system on $\mathbb{R}^{D}$, satisfying the strong separation condition, with $T$ similarities all having contraction factor $r>0$, and probabilities $p^{(j)}$. The strong separation condition ensures the $(T, r, \tau)$-separation condition is automatically satisfied for a suitable choice of $\tau>0$. Thus the self-similar measure has

$$
\overline{\operatorname{dim}}_{\Phi} \mu=\frac{\log \left(\min p^{(j)}\right)}{\log r} \text { and } \underline{\operatorname{dim}}_{\Phi} \mu=\frac{\log \left(\max p^{(j)}\right)}{\log r}
$$

for all dimension functions $\Phi$. This class of examples was also worked out in [15].
But we do not require the rigid structure of a self-similar set. For instance, we need not apply the same similarities to different parents and we need not have the same distances between children of different parents.

Example 4. Another special case is when we have a fixed set of probabilities, so $\mathbb{E}\left(e^{\lambda X_{1}}\right), \mathbb{E}\left(e^{\lambda Y_{1}}\right)$ are finite for all $\lambda$, but the ratios are chosen independently and identically distributed from some (non-trivial) set. Provided $\mathbb{E}\left(e^{\lambda Z_{1}}\right)<\infty$ for small $|\lambda|$, then the $\Phi$-dimensions follow from the theorems.

If we choose the probabilities to be equal ( $1 / T$ if there are $T$ children), then there are constants $c, C>0$ such that for any $r \leq R, x \in E(\omega)$ we have

$$
c N_{r}(B(x, R)) \leq \frac{\mu_{\omega}(B(x, R))}{\mu_{\omega}(B(x, r))} \leq C N_{r}(B(x, R))
$$

It follows that the $\Phi$-dimensions of the random measure $\mu_{\omega}$ and the random set $E(\omega)$ coincide.

For example, if we begin with $I_{0}=[0,1] \subseteq \mathbb{R}$, take $T=2$ and assume $r_{j}$ is chosen uniformly over $(0,1 / 2)$, then $\mathbb{E}\left(e^{\lambda Z_{1}}\right)<\infty$ for $|\lambda|<1$ and $\mathbb{E}\left(Z_{1}\right)=1+\log 2$. Thus for large $\Phi$,

$$
\underline{\operatorname{dim}}_{\Phi} E(\omega)=\overline{\operatorname{dim}}_{\Phi} E(\omega)=\frac{\log 2}{1+\log 2} \text { a.s. }
$$

Since ess $\inf r_{j}=0$ and ess $\sup r_{j}=1 / 2$, we have $\beta=0$ and $\alpha=1$, thus for small $\Phi$

$$
\overline{\operatorname{dim}}_{\Phi} E(\omega)=1 \text { and } \underline{\operatorname{dim}}_{\Phi} E(\omega)=0 \text { a.s. }
$$

5.2. Variable probabilities. Another interesting class is when the ratios are constant, $r_{j}=r$ for all $j$, but the probabilities, $\left(p_{j}^{(1)}, \ldots, p_{j}^{\left(T_{j}\right)}\right)$, are iid random variables chosen from a non-trivial probability space. In this case, we obviously have $\mathbb{E}\left(e^{\lambda Z_{1}}\right)<\infty$ for all $\lambda$. Further, the separation condition forces $T_{j} \leq T$ for some $T<\infty$, so $M_{j} \geq 1 / T$ and $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$. Thus we deduce the following results from the two theorems.

Corollary 3. (i) There is a set, $\Gamma$, of measure one, such that if $\Phi(x)$ is any large dimension function, then

$$
\operatorname{dim}_{\Phi} \mu_{\omega}=\frac{\mathbb{E}\left(X_{1}\right)}{|\log r|}=\frac{\mathbb{E}\left(\left|\log \max _{k} p_{1}^{(k)}\right|\right)}{|\log r|} \text { for all } \omega \in \Gamma
$$

Further, if there exists $A>0$ such that $\mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for all $|\lambda| \leq A$, then

$$
\overline{\operatorname{dim}}_{\Phi} \mu_{\omega}=\frac{\mathbb{E}\left(Y_{1}\right)}{|\log r|}=\frac{\mathbb{E}\left(\left|\log \min ^{k} p_{1}^{(k)}\right|\right)}{|\log r|} \text { for all } \omega \in \Gamma
$$

(ii) There is a set, $\Gamma$, of measure one, such that if $\Phi(x)$ is any small dimension function, then

$$
\underline{\operatorname{dim}}_{\Phi} \mu_{\omega}=\frac{\operatorname{ess} \inf \left|\log \max _{k} p_{1}^{(k)}\right|}{|\log r|} \text { and } \overline{\operatorname{dim}}_{\Phi} \mu_{\omega}=\frac{\text { ess sup }\left|\log \min _{k} p_{1}^{(k)}\right|}{|\log r|} \forall \omega \in \Gamma
$$

Example 5. When $T_{j}=T$ and the probabilities $\left(p_{j}^{(1)}, \ldots, p_{j}^{(T)}\right)$ are uniformly distributed over the simplex $\mathcal{S}_{T}$ it follows that for small $\Phi$, almost surely $\operatorname{dim}_{\Phi} \mu=0$ and $\overline{\operatorname{dim}}_{\Phi} \mu=\infty$.

When $T=2$ and the probabilities are uniformly distributed, it is easy to compute $\mathbb{E}\left(\left|\log \max p_{1}^{(k)}\right|\right)$ and $\mathbb{E}\left(\left|\log \min p_{1}^{(k)}\right|\right) \operatorname{since} \min (p, 1-p)$ and $\max (p, 1-p)$ are uniformly distributed over $(0,1 / 2]$ and $[1 / 2,1)$ respectively. However, for $T>2$ this is a more challenging combinatorial problem answered in the next Proposition. The proof is given in the Appendix.

Proposition 2. Suppose the probabilities $\left(p_{j}^{(1)}, \ldots, p_{j}^{(T)}\right)$ are uniformly distributed over the simplex $\mathcal{S}_{T}$. Then $\mathbb{E}\left(e^{\lambda X_{1}}\right), \mathbb{E}\left(e^{\lambda Y_{1}}\right)<\infty$ for $|\lambda|<1$ and

$$
\mathbb{E}\left(X_{1}\right)=\sum_{j=1}^{T}(-1)^{j+1}\binom{T}{j} \log j+\sum_{j=1}^{T-1} \frac{1}{j}, \quad \mathbb{E}\left(Y_{1}\right)=\log T+\sum_{j=1}^{T-1} \frac{1}{j} .
$$

Coupled with Corollary 3 this gives many further examples. Here are two.

Example 6. (1) Suppose $E(\omega)$ is the classical middle-third Cantor set. Let $\mu$ be the random measure where the probabilities $\left(p_{j}, 1-p_{j}\right)$ are independent and uniformly distributed random variables. If $\Phi(x)$ is large, then almost surely

$$
\overline{\operatorname{dim}}_{\Phi} \mu=\frac{1+\log 2}{\log 3}, \underline{\operatorname{dim}}_{\Phi} \mu=\frac{1-\log 2}{\log 3} .
$$

(2) Suppose $E(\omega)$ is a Cantor-like set, but with three children and all $r_{j}=$ $r<1 / 3$. Let $\mu$ be the random measure where the probabilities $\left(p_{j}^{(1)}, p_{j}^{(2)}, p_{j}^{(3)}\right)$ are independent and uniformly distributed rv's. If $\Phi(x)$ is large, then almost surely

$$
\overline{\operatorname{dim}}_{\Phi} \mu=\frac{3 / 2+\log 3}{|\log r|}, \underline{\operatorname{dim}}_{\Phi} \mu=\frac{3 / 2-3 \log 2+\log 3}{|\log r|} .
$$

5.3. Random 1-variable model. Another important class of examples are the random 1-variable Moran sets and measures described in Example 2, hence our theorems give formulas for the almost sure upper and lower $\Phi$-dimensions for these measures.

If we choose the probabilities associated with each of the IFS to be equal, then the dimension of the random measure and set $E(\omega)$ coincide. In [24], Troscheit showed that $\operatorname{dim}_{q A} E=\operatorname{dim}_{H} E$ almost surely. In fact, our results show that the upper and lower $\Phi$-dimensions for all large $\Phi$ coincide almost surely, so even $\operatorname{dim}_{q A} E=\operatorname{dim}_{q L} E$ a.s.

If, for example, the finitely many IFS are chosen with equal likelihood, then the dimension formulas are very simple. Assume there are a total of $N$ families of iterated function systems, where the $j$ 'th family consists of $K_{j}$ similarities, having (common) contraction factor $r_{j}$ and probabilities $1 / K_{j}$. Then there is a set, $\Gamma$, of full measure, such that for all all $\omega \in \Gamma$,

$$
\overline{\operatorname{dim}}_{\Phi} E(\omega)=\underline{\operatorname{dim}}_{\Phi} E(\omega)=\frac{\sum_{i=1}^{N} \log K_{i}}{\left|\sum_{i=1}^{N} \log r_{i}\right|} \text { for all large } \Phi
$$

and

$$
\overline{\operatorname{dim}}_{\Phi} E(\omega)=\max \frac{\log K_{i}}{\left|\log r_{i}\right|}, \underline{\operatorname{dim}}_{\Phi} E(\omega)=\min \frac{\log K_{i}}{\left|\log r_{i}\right|} \text { for all small } \Phi .
$$

5.4. Examples of strict inequality in Theorem 3. We conclude with examples that show we need not have $\overline{\operatorname{dim}}_{\Phi} \mu=\alpha$ or $\underline{\operatorname{dim}}_{\Phi} \mu=\beta$ a.s. (in the notation of Theorem (3).

For these examples, we will work in $\mathbb{R}$ with the initial compact set $I_{0}=[0,1]$. Thus all the Moran sets of each step will be intervals. We will also assume a stronger separation condition, namely that the gaps adjacent to the Moran intervals of step $n$ which are assigned measure equal to that of the parent interval times $m_{n}$ (resp., $M_{n}$ ) have length at least $\tau r_{1} \cdots r_{n-1}$.

Proposition 3. In addition to assuming $I_{0}=[0,1] \subseteq \mathbb{R}$ and the stronger separation condition described above, we will assume that for each $n,\left\{m_{n+1}, r_{n+1}\right\}$ is independent of $\left\{m_{l}, r_{l}: l=1, \ldots, n\right\}$. Suppose $\Phi$ is a small dimension function.

If there are constants $\theta, c>0$ such that for all small $z>0, \mathbb{P}\left(m_{1} \leq z\right) \geq c z^{\theta}$, (resp., $\mathbb{P}\left(r_{1} \leq z\right) \geq c z^{\theta}$ ), then $\overline{\operatorname{dim}}_{\Phi} \mu=\infty$ (resp., $\underline{\operatorname{dim}_{\Phi} \mu=0 \text { ) almost surely. }}$

Proof. Being small, we can assume $\Phi \leq H(x) \log |\log x| / \log x \mid$ where $H$ decreases as $x \downarrow 0$. Let $J_{N}=\left\lceil\chi_{N}^{(H)}\right\rceil$. For any $\omega$ in the set of full measure where
$\phi_{\omega}(N) \leq \chi_{N}^{(H)}$ eventually, put $R_{N}=r_{1} \cdots r_{N}$ and $\varrho_{N}=\tau r_{1} \cdots r_{N+J_{N}}$. For large enough $N, \varrho_{N} \leq R_{N}^{1+\Phi\left(R_{N}\right)}$. Take any Moran interval $I_{N}$ of step $N$ and consider the descendent at step $N+J_{N}+1$ where the minimal probability was chosen each time. Let $x_{N} \in E(\omega)$ belong to that descendent. The stronger separation condition ensures that $B\left(x_{N}, \varrho_{N}\right) \bigcap E(\omega) \subseteq I_{N+1+J_{N}}(x) \bigcap E(\omega)$, so

$$
\frac{\mu\left(B\left(x_{N}, R_{N}\right)\right)}{\mu\left(B\left(x_{N}, \varrho_{N}\right)\right)} \geq \frac{\mu\left(I_{N}\left(x_{N}\right)\right)}{\mu\left(I_{N+1+J_{N}}\left(x_{N}\right)\right)}=\left(m_{N+1} \cdots m_{N+J_{N}+1}\right)^{-1}
$$

For $\gamma \in \mathbb{R}^{+}$, let

$$
\begin{aligned}
F_{N} & =\left\{\omega:\left(m_{N+1} \cdots m_{N+J_{N}+1}\right)^{-1} \geq\left(r_{N+1} \cdots r_{N+J_{N}}\right)^{-\gamma}\right\} \\
& =\left\{m_{N+J_{N}+1}^{-1} \geq \prod_{i=1}^{J_{N}}\left(m_{N+i} r_{N+i}^{-\gamma}\right)\right\}
\end{aligned}
$$

Since $m_{1} r_{1}^{-\gamma}$ is real valued, there must be some $K$ such that

$$
0<\mathbb{P}\left(m_{1} r_{1}^{-\gamma} \leq K\right):=\delta
$$

Now,

$$
\begin{aligned}
\mathbb{P}\left(F_{N}\right) & \geq \mathbb{P}\left(m_{N+J_{N}+1}^{-1} \geq K^{J_{N}} \text { and } \prod_{i=1}^{J_{N}}\left(m_{N+i} r_{N+i}^{-\gamma}\right) \leq K^{J_{N}}\right) \\
& \geq \mathbb{P}\left(m_{N+J_{N}+1}^{-1} \geq K^{J_{N}} \text { and }\left(m_{N+i} r_{N+i}^{-\gamma}\right) \leq K \text { each } i=1, \ldots, J_{N}\right)
\end{aligned}
$$

so by independence and the hypothesis on the distribution of $m_{1}$, we have

$$
\mathbb{P}\left(F_{N}\right) \geq \mathbb{P}\left(m_{N+J_{N}+1}^{-1} \geq K^{J_{N}}\right) \prod_{i=1}^{J_{N}} \mathbb{P}\left(m_{N+i} r_{N+i}^{-\gamma} \leq K\right) \geq c\left(K^{-\theta} \delta\right)^{J_{N}}
$$

Arguing with the Borel Cantelli lemma, as in the proof of Theorem 3, we deduce that for each $\gamma$ and a.a. $\omega, \overline{\operatorname{dim}}_{\Phi} \mu \geq \gamma$ and hence $\operatorname{dim}_{\Phi} \mu=\infty$ a.s.

The arguments to see $\underline{\operatorname{dim}}_{\Phi} \mu=0$ are similar, but this time begin with $R_{N}=$ $\tau r_{1} \cdots r_{N-1}$ and $\varrho_{N}=r_{1} \cdots r_{N+L+J_{N+L}}$, which is dominated by $R_{N}^{1+\Phi\left(R_{N}\right)}$ eventually. Take any interval $I_{N}$ of level $N$, consider the descendent at level $N+J_{N}$ where the maximal probability was chosen each time and let $x_{N} \in E(\omega)$ belong to that interval. The stronger separation condition ensures that in this case,

$$
\frac{\mu\left(B\left(x_{N}, R_{N}\right)\right)}{\mu\left(B\left(x_{N}, \varrho_{N}\right)\right)} \leq \frac{\mu\left(I_{N}\left(x_{N}\right)\right)}{\mu\left(I_{N+L+J_{N+L}}\left(x_{N}\right)\right)}=\left(M_{N+1} \cdots M_{N+L+J_{N+L}}\right)^{-1}
$$

For $\varepsilon>0$, choose $K>0$ such that $0<\mathbb{P}\left(M_{1} r_{1}^{-\varepsilon}>1 / K\right):=\delta$ and set

$$
\begin{aligned}
G_{N} & =\left\{\omega:\left(M_{N+1} \cdots M_{N+L+J_{N+L}}\right)^{-1} \leq\left(r_{N} \cdots r_{N+L+J_{N+L}}\right)^{-\varepsilon}\right\} \\
& =\left\{r_{N}^{\varepsilon} \leq \prod_{i=1}^{L+J_{N+L}}\left(M_{N+i} r_{N+i}^{-\varepsilon}\right)\right\}
\end{aligned}
$$

Then

$$
\mathbb{P}\left(G_{N}\right) \geq \mathbb{P}\left(r_{1}^{\varepsilon} \leq K^{-\left(L+J_{N+L}\right)}\right) \delta^{L+J_{N+L}} \geq c\left(K^{-\theta / \varepsilon} \delta\right)^{L+J_{N+L}}
$$

Again, we apply the Borel Cantelli lemma and deduce that for any $\varepsilon>0$ and a.a. $\omega, \underline{\operatorname{dim}}_{\Phi} \mu \leq \varepsilon$.

Remark 7. Notice that the proof shows that if multiple children of a given parent are assigned the minimum (or maximum) probability, it is enough that the gaps adjacent to one of these children has the suitable size.

EXAMPLE 7. An example with $\overline{\operatorname{dim}}_{\Phi} \mu>\alpha$ : Take $T=2$ and choose $p_{j}$ independently and uniformly distributed over $(0,1)$. Set $r_{j}=m_{j} / 2$ and construct the associated random Cantor set so that the $2^{n}$ Moran intervals at step $n$ have length $r_{1} \cdots r_{n}$. As $m_{j} \leq 1 / 2$, all the gaps at step $n$ have length at least $r_{1} \cdots r_{n-1}$. Since $\mathbb{P}\left(m_{1} \geq z\right)=1-2 z$, an appeal to Proposition 3 shows that $\overline{\operatorname{dim}}_{\Phi} \mu=\infty$ a.s. But, $\log m_{1} / \log r_{1}=\log m_{1} /\left(\log m_{1}-\log 2\right)$ and $\inf \log m_{1}=-\infty$ a.s., thus $\alpha=1$.

More generally, it can be seen in the proof of Proposition 2, that if there are $T$ children at each step and the probabilities are chosen uniformly distributed over $\mathcal{S}_{T}$, then $\mathbb{P}\left(m_{1} \geq z\right)=(1-T z)^{T-1}$. Thus $\mathbb{P}\left(m_{1} \leq z\right)=1-(1-T z)^{T-1} \geq c z$ for suitable $c>0$.

Example 8. An example with $\operatorname{dim}_{\Phi} \mu>\alpha$ and $\operatorname{dim}_{\Phi} \mu<\beta$ : Consider the special case where we take $r_{n}(\omega)=1 /(4 t)$ and $p_{n}(\omega)=(1 / t, \ldots, 1 / t)$ for all $n$, whenever $\omega \in \Omega_{t}$. Formally, we can do this by (for example) defining the discrete probability measure $\pi$ on $\Omega_{0}$ by $\pi=c \sum_{t=2}^{\infty} t^{-2} \delta_{x_{t}}$ where $x_{t}=(1 / 4 t,(1 / t, \ldots, 1 / t)) \in$ $\Omega_{t}$ and $c=\left(\sum_{t \geq 2} t^{-2}\right)^{-1}$. Thus $\mathbb{P}\left(\Omega_{t}\right)=c / t^{2}$ and $\mathbb{E}\left(e^{-\log r_{1} / 2}\right)<\infty$.

Define the Moran set by beginning with $I_{0}=[0,1]$ and applying the rule that at step $n$, the $T_{n}$ children of each parent interval are placed starting at the left endpoint of the parent, with gaps between them of length $r_{1} \cdots r_{n}$, except for the final child of each parent, which will be placed at the right end of the parent. This construction ensures that the stronger separation condition of Proposition 3, as noted in Remark 7. is satisfied with the right-most child. Obviously,

$$
\mathbb{P}\left(m_{1} \leq 1 / t\right)=\mathbb{P}\left(r_{1} \leq 1 / 4 t\right)=\mathbb{P}\left(M_{1} \leq 1 / t\right)=\mathbb{P}(\omega: T(\omega) \geq t) \geq c t^{-2}
$$

so Proposition 3 gives $\overline{\operatorname{dim}}_{\Phi} \mu=\infty$ and $\operatorname{dim}_{\Phi} \mu=0$ almost surely. But $\alpha=\beta=1$. Of course, $M_{n}=m_{n}=4 r_{n}=1 / t$ on $\Omega_{t}$ and $\mathbb{P}\left(\Omega_{t}\right)>0$ for all $t=2,3, \ldots$, so the essential infimum of each of $m_{1}, M_{1}$ and $r_{1}$ equals 0 .

For the special cases of the Assouad dimensions more can be said.
Corollary 4. Assume we begin with $I_{0}=[0,1]$ and the stronger separation condition as in Proposition 3.
(i) If either ess inf $m_{1}=0$ or ess $\inf r_{1}=0$, then $\operatorname{dim}_{A} \mu_{\omega}=\infty$ a.s.
(ii) If either ess $\inf M_{1}=0$ or ess $\inf r_{1}=0$, then $\operatorname{dim}_{L} \mu_{\omega}=0$ a.s.

Proof. (i) Take $R_{N}=r_{1} \cdots r_{N}$ and $\varrho_{N}=\tau r_{1} \cdots r_{N}$. As $\tau<1, \varrho_{N}<R_{N}$ and with a suitable choice of $x_{N}$ as in Proposition 3,

$$
\frac{\mu_{\omega}\left(B\left(x_{N}, R_{N}\right)\right)}{\mu_{\omega}\left(B\left(x_{N}, \varrho_{N}\right)\right)} \geq m_{N+1}^{-1}(\omega)
$$

while $R_{N} / \varrho_{N}=\tau^{-1}$. If ess inf $m_{1}=0$, then it follows from the Borel Cantelli lemma that for any $\varepsilon>0, \mathbb{P}\left(m_{n} \leq \varepsilon\right.$ i.o $)=1$. Thus for a.e. $\omega$ and any $\gamma \in \mathbb{R}^{+}$, we have $m_{N+1}^{-1} \geq\left(R_{N} / \varrho_{N}\right)^{\gamma}$ for large $N$. That implies $\operatorname{dim}_{A} \mu_{\omega}=\infty$ a.s.

If ess inf $r_{1}=0$, but ess $\inf m_{1} \neq 0$, then $\alpha=\infty$ and hence Theorem 3 (with $\Phi=0)$ implies $\operatorname{dim}_{A} \mu_{\omega}=\infty$ a.s.
(ii) Since $M_{n} \geq 1 / T_{n} \geq r_{n}$, if ess inf $M_{1}=0$, then also ess inf $r_{1}=0$, thus we may assume the latter. The argument is similar to (i). Take $\omega$ from
$\left\{\inf r_{1}=0\right\}$. For infinitely many $N, r_{N}(\omega)<\tau$ and for such $N$, put $R_{N}=$ $\tau r_{1} \cdots r_{N-1}$ and $\varrho_{N}=r_{1} \cdots r_{N}<R_{N}$. For suitable $x_{N}$, the gap assumption gives $B\left(x_{N}, R_{N}\right) \bigcap E(\omega)=B\left(x_{N}, \varrho_{N}\right) \bigcap E(\omega)$. Thus $\mu\left(B\left(x_{N}, R_{N}\right)\right) / \mu\left(B\left(x_{N}, \varrho_{N}\right)\right)=1$, while $R_{N} / \varrho_{N}=\tau r_{N}^{-1} \rightarrow \infty$. It follows that $\operatorname{dim}_{L} \mu_{\omega}=0$ a.s.

## 6. Appendix: Proof of Proposition 2

Proof. [of Proposition 2] As $\sum_{j=1}^{T} p_{1}^{(j)}=1$, we have $\min p_{1}^{(k)} \leq 1 / T$, so for every $z \in(0,1 / T)$,

$$
\left\{\left(p_{1}^{(1)}, \ldots, p_{1}^{(T)}\right): \min p_{1}^{(k)} \geq z\right\}=(z, \ldots, z)+(1-T z) \mathcal{S}_{T}
$$

Thus $\mathbb{P}\left(\min p_{1}^{(k)} \geq z\right)=(1-T z)^{T-1}$ and the probability density function for $m_{1}=\min p_{1}^{(k)}$ is the function $f(x)=T(T-1)(1-T x)^{T-2}$ for $0 \leq x \leq 1 / T$.

Using the binomial theorem, it follows that

$$
\begin{aligned}
\mathbb{E}\left(Y_{1}\right) & =\mathbb{E}\left(-\log m_{1}\right)=\int_{0}^{1 / T} T(T-1)(1-T x)^{T-2}(-\log x) d x \\
& =-T(T-1) \sum_{k=0}^{T-2}(-1)^{k} T^{k}\binom{T-2}{k} \int_{0}^{1 / T} x^{k} \log x \\
& =-T(T-1) \sum_{k=0}^{T-2}(-1)^{k} T^{k}\binom{T-2}{k} \frac{T^{-k-1}}{k+1}\left(-\log T-\frac{1}{k+1}\right)
\end{aligned}
$$

Now we apply special cases of Melzak's formula (c.f. [13, vol. 5: 1.3, 1.56]):

$$
\sum_{k=0}^{n}(-1)^{k}\binom{n}{k} \frac{1}{k+1}=\frac{1}{n+1}
$$

and

$$
\sum_{k=0}^{n}(-1)^{k}\binom{n}{k} \frac{1}{(k+1)^{2}}=\frac{1}{n+1} \sum_{k=0}^{n} \frac{1}{k+1}
$$

This gives

$$
\mathbb{E}\left(Y_{1}\right)=\log T+(T-1) \sum_{k=0}^{T-2}\binom{T-2}{k} \frac{(-1)^{k}}{(k+1)^{2}}=\log T+\sum_{k=1}^{T-1} \frac{1}{k}
$$

Similarly, for $|\lambda|<1$,

$$
\begin{aligned}
\mathbb{E}\left(e^{\lambda Y_{1}}\right) & =T(T-1) \int_{0}^{1 / T} x^{-\lambda}(1-T x)^{T-2} d x \\
& =T(T-1) \sum_{k=0}^{T-2}(-1)^{k} T^{k}\binom{T-2}{k} \int_{0}^{1 / T} x^{k-\lambda} d x \\
& =(T-1) T^{\lambda} \sum_{k=0}^{T-2} \frac{(-1)^{k}}{k-\lambda+1}=T^{\lambda} \prod_{k=1}^{T-1} \frac{k}{k-\lambda}
\end{aligned}
$$

Here the last equality is another consequence of Melzak's formula ([13, vol. 5: 1.3]):

$$
\sum_{k=0}^{n}(-1)^{k}\binom{n}{k} \frac{1}{k+1-\lambda}=\frac{n!}{(1-\lambda)(n+\lambda-1) \cdots(2-\lambda)} \text { for } \lambda \neq 1,2, \ldots, n+1
$$

Thus, $\mathbb{E}\left(e^{\lambda Y_{1}}\right)$ is finite if $|\lambda|<1$.
We have $\mathbb{E}\left(e^{\lambda X_{1}}\right)<\infty$ since $\max p_{1}^{(k)} \geq 1 / T$. Lastly, we compute $\mathbb{E}\left(X_{1}\right)$. It was proven in $\mathbf{1 8}$ that

$$
\mathbb{P}\left(M_{1} \leq z\right)=\mathbb{P}\left(\max _{k=1, \ldots, T} p_{1}^{(k)} \leq z\right)=1+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k}(1-k z)_{+}^{T-1}:=F(z)
$$

where $x_{+}=\max \{x, 0\}$. Note that $(1-k z)_{+}=0$ if $z \geq 1 / k$.
Since $M_{1} \geq 1 / T$ with equality only on a set of measure zero, integration by parts and the binomial theorem give

$$
\begin{aligned}
\mathbb{E}\left(X_{1}\right) & =\mathbb{E}\left(-\log M_{1}\right)=\int_{1 / T}^{1}-F^{\prime}(x) \log (x) d x=\int_{1 / T}^{1} \frac{F(x)}{x} d x \\
& =\int_{1 / T}^{1} \frac{d x}{x}+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} \int_{1 / T}^{1 / k} \frac{(1-k x)^{T-1}}{x} d x \\
& =\log T+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} \sum_{j=0}^{T-1}(-k)^{j}\binom{T-1}{j} \int_{1 / T}^{1 / k} x^{j-1} d x
\end{aligned}
$$

Evaluating the integrals gives

$$
\begin{aligned}
\mathbb{E}\left(X_{1}\right)= & \log T+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k}(\log T-\log k) \\
& +\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} \sum_{j=1}^{T-1}\binom{T-1}{j}(-k)^{j}\left(\frac{k^{-j}-T^{-j}}{j}\right) \\
= & \log T+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k}(\log T-\log k)+A+B
\end{aligned}
$$

where

$$
A=\left(\sum_{k=1}^{T}(-1)^{k}\binom{T}{k}\right)\left(\sum_{j=1}^{T-1}\binom{T-1}{j} \frac{(-1)^{j}}{j}\right)
$$

and

$$
B=-\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} \sum_{j=1}^{T-1}\binom{T-1}{j}(-1)^{j} \frac{k^{j} T^{-j}}{j}
$$

Another application of the binomial theorem shows that

$$
\begin{equation*}
1+\sum_{k=1}^{T}(-1)^{k}\binom{T}{k}=0 \tag{6.1}
\end{equation*}
$$

Together with the combinatorial identity (c.f. [13, vol. 5: 1.4])

$$
\sum_{j=1}^{T-1}\binom{T-1}{j} \frac{(-1)^{j}}{j}=-\sum_{n=1}^{T-1} \frac{1}{n}
$$

this proves $A=\sum_{n=1}^{T-1} 1 / n$. Euler's finite difference formula (c.f. [13, vol. 4: 10.1]) implies

$$
\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} k^{j}=0 \text { for } T \geq 2,1 \leq j \leq T-1
$$

Changing the order of the summation and applying this formula shows that

$$
B=\left(\sum_{j=1}^{T-1}\binom{T-1}{j} \frac{(-1)^{j+1}}{T^{j} j}\right)\left(\sum_{k=1}^{T}(-1)^{k}\binom{T}{k} k^{j}\right)=0
$$

Using (6.1), we conclude that

$$
\mathbb{E}\left(X_{1}\right)=\sum_{k=1}^{T}(-1)^{k+1}\binom{T}{k} \log k+\sum_{k=1}^{T-1} \frac{1}{k} .
$$
