NONCOMMUTATIVE POISSON VERTEX ALGEBRAS AND COURANT–DORFMAN ALGEBRAS

DAVID FERNÁNDEZ AND REIMUNDO HELUANI

Abstract. We introduce double Courant–Dorfman algebras, which are noncommutative versions of Roytenberg’s Courant–Dorfman algebras, since we prove that they satisfy the Kontsevich–Rosenberg principle. In addition, we establish a one–to–one correspondence between double Courant–Dorfman algebras and double Poisson vertex algebras, as introduced by De Sole, Kac and Valeri. This at the same time provides a vertex version of Van den Bergh’s construction of double Poisson algebras, as well as a noncommutative version of the correspondence between Poisson vertex algebras and Courant–Dorfman algebras.

1. Introduction

1.1. Let \( \mathbb{k} \) be a field of characteristic zero, and \( A = \oplus_{n \geq 0} A_n \) be an \( \mathbb{N} \)-graded Poisson algebra of degree \(-1\), that is, a graded, commutative, associative, unital \( \mathbb{k} \)-algebra, whose multiplication is of degree 0 (i.e., if \( a \in A_p \), \( b \in A_q \), then \( a \cdot b \in A_{p+q} \)), together with a \( \mathbb{k} \)-linear Lie algebra bracket of degree \(-1\) (that is, if \( a \in A_p \), \( b \in A_q \), we have \( \{a, b\} \in A_{p+q-1} \)). Both operations are subject to the Leibniz identity

\[
\{a, b \cdot c\} = c \cdot \{a, b\} + b \cdot \{a, c\}. \tag{1.1}
\]

Then the pair \( \mathcal{O} = A_0 \), \( \mathcal{E} = A_1 \) is a Lie–Rinehart pair (also known as a Lie algebroid in the geometric context). More precisely,

1. \( \mathcal{O} \) is a commutative associative unital \( \mathbb{k} \)-algebra.
2. \( \mathcal{E} \) is an \( \mathcal{O} \)-module.
3. \( \mathcal{E} \) is a \( \mathbb{k} \)-linear Lie algebra with bracket \( [-, -] = \{ -, - \}|_{\mathcal{E}} \).
(4) \( \mathcal{E} \) acts on \( \mathcal{O} \) by derivations, i.e. there exists a \( \mathbb{k} \)-linear map of Lie algebras \( \pi : \mathcal{E} \to \text{Der}_{\mathbb{k}} \mathcal{O} \), given by \( \pi(a)(f) = \{a, f\} \) for \( a \in \mathcal{E} \) and \( f \in \mathcal{O} \).

These data are compatible in the following way:

\[
[a, f \cdot b] = f \cdot [a, b] + \pi(a)(f) \cdot b, \quad f \in \mathcal{O}, \ a, b \in \mathcal{E}.
\]

Conversely, given a Lie–Rinehart pair one canonically constructs a Poisson algebra of degree \(-1\) on the space \( \text{Sym}^\ast \mathcal{E} \), by extending the Lie bracket from \( A_1 = \mathcal{E} \) using the Leibniz rule [11]. As a commutative algebra, the symmetric algebra is freely generated over \( \mathcal{O} \) by its degree 1 part given by \( \mathcal{E} \). If we start with a graded Poisson algebra of degree 1 as above, and construct the corresponding Lie–Rinehart pair, we obtain a canonical surjection \( \text{Sym}^\ast \mathcal{E} \to A \), which is the identity in degrees 0 and 1.

This provides a one–to–one correspondence between Lie–Rinehart pairs over \( \mathbb{k} \) and graded Poisson algebras of degree \(-1\), freely generated in degrees 0 and 1.

1.2. Recall that a \textit{graded Poisson vertex algebra (PVA)} \( A \) of degree \(-1\) is a graded, commutative, associative, unital algebra \( A = \oplus_{n \geq 0} A_n \), together with a derivation of degree 1, \( \partial : A_\bullet \to A_{\bullet + 1} \), and a \textit{Lie conformal bracket} of degree \(-1\), which is defined as an operation

\[
A \otimes A \longrightarrow A[\lambda], \quad a \otimes b \longmapsto \{a_\lambda b\} = \sum_{j \geq 0} a_{(j)} b_{\frac{\lambda^j}{j!}},
\]

making \( A \) into a \( \mathbb{k} \)-Lie conformal algebra [21] such that

\[
a \in A_p, \ b \in A_q \implies a_{(j)} b \in A_{p+q-j-1}.
\]

These operations are related by the Leibniz rule

\[
\{a_\lambda b \cdot c\} = b \cdot \{a_\lambda c\} + c \cdot \{a_\lambda b\}.
\]

One of the main features of Poisson vertex algebras is that they are the quasi-classical limits of Borcherds’ vertex algebras. Every vertex algebra \( V \) comes equipped with a canonical decreasing filtration known as the \textit{Li filtration} [25]:

\[
V = F_0 V \supset F_1 V \supset \cdots \supset F_p V \supset F_{p+1} V \supset \cdots
\]

The associated graded algebra \( A = \text{gr}_F V = \oplus_{p \geq 0} F_p V / F_{p+1} V \) carries a structure of Poisson vertex algebra. This is a commutative associative graded algebra (the normally ordered product of \( V \) descends to the multiplication of \( A \)), with a unit (given by the image of the vacuum vector \( 1 \in V \)) and a derivation of degree 1 (given by the translation operator of \( V \)). In addition, the \( \lambda \)-bracket of \( V \) descends to a Lie conformal structure on \( A \) satisfying the Leibniz rule with respect to the multiplication.

The canonical example of a Poisson vertex algebra is given by the ring of functions of the \textit{arc space} of a Poisson manifold. If \( P \) is a Poisson algebra, we put \( J_0 = P \), and let \( J \) be the unital associative commutative algebra with a derivation of degree 1, freely generated (as a differential algebra) by \( J_0 \). For example, we will have \( J_1 = \Omega^1 J_0 \), the module of Kähler differentials of \( J_0 \), and \( \partial : J_0 \to J_1 \) will be given by the universal derivation. Then the Poisson bracket of \( J_0 \) can be uniquely extended to a \( \lambda \)-bracket on \( J \) by sesquilinearity and the Leibniz rule [4]. In the particular case where \( P = \mathbb{k}[x_1, \ldots, x_n] \) is a polynomial algebra, we have that \( J = \mathbb{k}[x_1^{(p)}, \ldots, x_n^{(p)}]_{p \geq 0} \) is a differential polynomial algebra. The derivation is defined by \( \partial x^{(p)}_i = x^{(p+1)}_i \) and the degrees of the generators are given by \( \deg x^{(p)}_i = p \).
It was noted in [4] that the quasi-classical limit of any vertex algebra is a quotient of the free algebra $\mathcal{J}$ described in the previous paragraph. Indeed, given a vertex algebra $V$, one considers its associated graded algebra with respect to the Li filtration, $A = \operatorname{gr}_F V$. Then $P := A_0$ is a Poisson algebra (known as Zhu’s $C_2$-quotient) and by the universal property, it follows that $A$ is a quotient of the arc algebra $J$ of $P$ described above.

1.3. A chiral or vertex version of §1 is given as follows. Let $A = \bigoplus_{n \geq 0} A_n$ be a graded Poisson vertex algebra of degree $-1$. It was observed by Ekstrand and Zabzine [16], following works of Bressler [9], Roytenberg [28] and the second author [20], that the pair $\Omega = A_0$, $\mathcal{E} = A_1$ is a Courant–Dorfman algebra [1], which consists of the following data:

1. a commutative $k$-algebra $\Omega$.
2. an $\Omega$-module $\mathcal{E}$.
3. a symmetric bilinear form $\langle -, - \rangle : \mathcal{E} \otimes \mathcal{E} \to \Omega$, given by $\langle a, b \rangle = a_{(1)} b$.
4. an $\mathcal{E}$-valued derivation of $\Omega$: $\partial : \Omega \to \mathcal{E}$.
5. a $k$-bilinear operation called the Dorfman bracket $[-, -] : \mathcal{E} \otimes \mathcal{E} \to \mathcal{E}$, given by $[a, b] = a_{(0)} b$.

These data are required to satisfy the following compatibility conditions:

\[
\begin{align*}
[a, f \cdot b] &= f[a, b] + \langle a, \partial f \rangle b, \\
\langle a, \partial (b, c) \rangle &= \langle [a, b], c \rangle + \langle a, [b, c] \rangle, \\
\partial \langle a, b \rangle &= [a, b] + [b, a], \\
[a, [b, c]] &= [a, [b, c]] + [b, [a, c]], \\
0 &= [\partial f, a], \\
0 &= \langle \partial f, \partial g \rangle,
\end{align*}
\]

for all $a, b, c \in \mathcal{E}$ and $f, g \in \Omega$. If $\langle -, - \rangle$ is non-degenerate, then the last two conditions and the first one are redundant and one obtains the definition of Courant algebroids of [27].

Conversely, given a Courant–Dorfman algebra $(\Omega, \mathcal{E}, \partial)$, one canonically constructs a graded Poisson vertex algebra $A$, freely generated in degrees 0 and 1, such that $A_0 = \Omega$ and $A_1 = \mathcal{E}$. This gives a one–to–one correspondence between graded Poisson vertex algebras of degree $-1$, freely generated in degrees 0 and 1, and Courant–Dorfman algebras.

1.4. There are different ways to produce noncommutative generalizations or deformations of the correspondences unveiled in §1.1–1.3. Given a Lie–Rinehart pair $(\Omega, \mathcal{E})$ one can construct its universal enveloping algebra $U(\mathcal{E})$ [6], which is a filtered associative algebra generalizing the algebra of differential operators in the case $\mathcal{E} = \text{Der}_k \Omega$, and the universal enveloping algebra of a Lie algebra in the case $\Omega = k$. Its associated graded algebra coincides with $\text{Sym}^* \mathcal{E}$ as a Poisson algebra.

The chiral rendition is more complicated. Given a Courant–Dorfman algebra $(\Omega, \mathcal{E}, \partial)$ one aims at constructing a filtered vertex algebra, whose associated graded Poisson vertex algebra recovers the given Courant–Dorfman algebra in degrees 0 and 1. As explained in [18] and [5], there is an obstruction to constructing this algebra.

\textbf{Note that in [16], Ekstrand and Zabzine used the term ‘weak Courant–Dorfman algebra’, rather than ‘Courant–Dorfman algebra’. However, as in the present article we will mainly follow [28], hereafter we will omit the adjective ‘weak’.}
Another noncommutative generalization of the correspondence in §1.1 was given by Van den Bergh [31, 32] by constructing a noncommutative generalization of a Poisson algebra using his notion of double Poisson algebra. It consists of an associative $k$-algebra $A$ and a linear map

$$\{\{−, −\}\} : A \otimes A \rightarrow A \otimes A,$$

satisfying suitable skewsymmetry and Leibniz rules, as well as the (double) Jacobi identity; see (3.3) and (3.5). Remarkably, if $a \in A$, the Leibniz rule (3.3b) can be rephrased by saying that $\{\{a, −\}\} : A \rightarrow A \otimes A$ is a double derivation (cf. §3.1) rather than a plain derivation.

Besides giving a powerful notion of noncommutative Poisson algebras with significant applications in geometric representation theory, Van den Bergh’s double Poisson algebras have been used in [26, 3] to develop an interesting theory of noncommutative Hamiltonian Ordinary Differential Equations (ODEs), which extends the well-known connection in classical mechanics between (classical) Poisson geometry and (commutative) Hamiltonian ODEs. Furthermore, in classical field theory, the study of Hamiltonian Partial Differential Equations (PDEs) is realized by Poisson vertex algebras.

In their groundbreaking article [15], De Sole, Kac and Valeri started the study of integrable PDEs in noncommutative variables by introducing the fundamental notion of double Poisson vertex algebras, which are a cross between Van den Bergh’s double Poisson algebras and familiar Poisson vertex algebras, as discussed in §1.2. They rely on the notion of a double $\lambda$-bracket that consists of a bilinear map

$$\{\{−, −\}\} : V \otimes V \rightarrow (V \otimes V)[\lambda]$$

satisfying appropriate sesquilinearity conditions, Leibniz rules, skewsymmetry and the Jacobi identity (see Definitions 4.1 and 4.2), resembling the corresponding axioms in the definition of double Poisson algebras. Note that in [10], Casati and Wang introduced a multiplicative analogue of double Poisson vertex algebras with applications in differential-difference Hamiltonian equations (see also [11] for a multiplicative perspective on the theory of integrable systems in noncommutative variables).

In the light of the discussion depicted in §1.3, it is natural to ask whether the double Poisson vertex algebras as introduced in [15] can be put in correspondence with suitable noncommutative generalizations of Courant–Dorfman algebras. The main goal of this article is to show that the answer is in the affirmative.

Firstly, in [2] (see also [17]), Álvarez-Cónsul and the first author were able to unveil noncommutative analogues of the prominent Courant algebroids, called double Courant algebroids. They were obtained by developing a differential-graded symplectic (Batalin–Vilkovisky) version of the noncommutative geometry based on double derivations as in [13] 31 32 modeled around the notion of bisymplectic $\mathbb{N}Q$-algebras: noncommutative versions of symplectic $\mathbb{N}Q$-manifolds originally introduced in [1]. Hence, following ideas of [27, 29], from a bisymplectic $\mathbb{N}Q$-algebra of weight 2 the axioms characterizing double Courant algebroids were established. Based on them, in this article we succeed in introducing the notion of double Courant–Dorfman algebras as a 5-tuple $(A, E, \{\{−, −\}\}, \partial, [−, −])$, where $E$ is a bimodule over an associative $k$-algebra $A$, a derivation $\partial : A \rightarrow E$ and a pairing $\{\{−, −\}\} : E \otimes E \rightarrow A \otimes A$ in the sense of [32] — see §5.3. The main ingredient is the double Courant–Dorfman bracket on the tensor algebra $T_A E$: a bilinear map

$$[−, −] : T_A E \otimes T_A E \rightarrow T_A E \otimes T_A E,$$
of degree -1. It is required that these data satisfy natural compatibility conditions reminiscent of (1.2); see Definitions 5.2 and 5.3.

We could write that double Poisson algebras and double Poisson vertex algebras were noncommutative generalizations of familiar Poisson algebras and Poisson vertex algebras, respectively, since, as shown in (7.2) and Proposition 7.1, they satisfy the paradigm in noncommutative geometry: the Kontsevich–Rosenberg principle. As explained in §7.1 it states that a noncommutative algebro-geometric structure on an associative algebra should naturally induce the corresponding standard algebro-geometric structure on its representation varieties. One of the main results of this article is Theorem 7.4 where we prove that our double Courant–Dorfman algebras, as introduced in Definition 5.3, do satisfy the Kontsevich–Rosenberg principle, inducing the familiar Courant–Dorfman algebras on representation varieties. As in [31, §7] and [15, §3.7], to prove this theorem, we take advantage of the explicit description based on indices of the coordinate ring of the representation variety and bimodules over it — see (7.1) and (7.5).

Once we ascertain that double Courant–Dorfman algebras are the objects that we were looking for, we are in position to prove Theorem 6.1, which is the main result of this article. It states that there exists a one–to–one correspondence between double Courant–Dorfman algebras and graded double Poisson vertex algebras of degree −1, freely generated in degrees 0 and 1, providing a noncommutative version of the correspondence between Poisson vertex algebras and Courant–Dorfman algebras presented in §1.3. The key point of the proof is the following identity that relates double Poisson λ-brackets and the data characterizing double Courant–Dorfman algebras:

\[
\{\{e, f\}\} = [e, f] + \langle e, f \rangle \lambda,
\]

for all \(e, f \in E\).

1.6. As shown in [30], there exists yet another geometric interpretation for the notion of a Lie algebroid \((\mathcal{E}, \mathcal{E})\) in terms of supermanifolds: the exterior algebra \(\wedge_{\mathcal{E}}\mathcal{E}\) is the algebra of functions of a symplectic supermanifold of weight 1. Similarly, associated to a Courant algebroid, Roytenberg [27] constructs a symplectic \(\mathbb{N}\mathcal{Q}\)-manifold of weight 2. Furthermore, as pointed out in [1, §3.1] Álvarez-Cónsul and the first author [2] defined double Courant algebroids using bisymplectic \(\mathbb{N}\mathbb{Q}\)-algebras of weight 2, which are noncommutative counterparts of the symplectic \(\mathbb{N}\mathcal{Q}\)-manifolds of weight 2 of Roytenberg. Hence, this article completes the chart below, by showing the relation between double Courant–Dorfman algebras and double Courant algebroids, noncommutative symplectic \(\mathbb{N}\mathbb{Q}\)-geometries and double Poisson vertex algebras:

1.7. The organization of this article is as follows. After establishing basic notational conventions in Section 2, we collect in Section 3 the basic notions of noncommutative geometry needed in the rest of the article. In Section 4 we recall the notion of double Poisson vertex
algebras following [15]. In Section 5 we recall the definitions of Courant–Dorfman algebras following [28] and we define their noncommutative counterparts: double Courant–Dorfman algebras, which are one of the key objects of our work. In Section 6 we prove our main result, Theorem 6.1 establishing an equivalence between double Courant–Dorfman algebras and double Poisson vertex algebras, freely generated in degrees 0 and 1. Finally, Section 7 is devoted to establish the Kontsevich–Rosenberg principle for double Courant–Dorfman algebras. In Appendix A we collect two some technical results that we need to prove our main results, which may be of independent interest.

Acknowledgments. The first author is supported by the Alexander von Humboldt Stiftung in the framework of an Alexander von Humboldt professorship endowed by the German Federal Ministry of Education and Research. During the initial stage of this work, he was supported by IMPA and CAPES through their postdoctorate of excellence fellowships at UFRJ. He deeply acknowledges their support and excellent working conditions. The second author is partially supported by CNPq grant number 305688/2019-7.

The authors wish to thank Henrique Bursztyn, Alejandro Cabrera and Mario García-Fernández for useful conversations. Special thanks are due to Daniele Valeri for his kind encouragement, as well as for drawing our attention to the crucial article [15].

2. Notation and Conventions

Throughout this article, all associative and commutative algebras will be unital and finitely generated over a base field $k$ of characteristic 0. In fact, a $k$-algebra $A$ will mean a unital and finitely generated associative (not necessarily commutative) $k$-algebra. Unless otherwise stated, all unadorned notation will mean over the base field $k$; in particular, $\otimes := \otimes_k$ and $\Hom(-,-) := \Hom_k(-,-)$. The opposite algebra and the enveloping algebra of an associative algebra $A$ will be denoted $A^{\text{op}}$ and $A^{e} := A \otimes A^{\text{op}}$, respectively. We will identify the category of $A$-bimodules and the category of (left) $A^e$-modules.

Given two $A$-bimodules $E$ and $F$, their tensor product $E \otimes F$ has two commuting $A$-bimodule structures, called the outer and the inner $A$-bimodule structures, denoted $(E \otimes F)_{\text{out}}$ and $(E \otimes F)_{\text{inn}}$, respectively, given by

\[
\begin{align*}
  a'(e \otimes f)a'' &= (a'e) \otimes (fa'') \quad \text{on } (E \otimes F)_{\text{out}}, \\
  a' * (e \otimes f) * a'' &= (ea'') \otimes (af) \quad \text{on } (E \otimes F)_{\text{inn}},
\end{align*}
\]

for all $a', a'' \in A$, and $e \otimes f \in E \otimes F$. In particular, the underlying $A$-bimodule of $A$ determines two $A$-bimodules with the same underlying vector space $A \otimes A$: $(A \otimes A)_{\text{out}}$ and $(A \otimes A)_{\text{inn}}$. Unless explicitly stated, we endow the tensor product $E \otimes F$ (and in particular $A \otimes A_{\text{out}}$) with the outer $A$-bimodule structure. We will systematically use Sweedler’s notation, consisting of dropping the summation sign: if $v \in E \otimes F$, we write $v = v' \otimes v'' \in E \otimes F$, where $v' \in E$ and $v'' \in F$.

Furthermore, following [15] §1.3], given $n \in \mathbb{N}_{\geq 2}$, for every $i = 0, \ldots, n - 1$, we define the $i$-th left and right $A$-module structures of $A^{\otimes n}$ by

\[
\begin{align*}
  a' \ast_i (a_1 \otimes \cdots \otimes a_n) &= a_1 \otimes \cdots \otimes a_i \otimes a_{i+1} \otimes \cdots \otimes a_n, \\
  (a_1 \otimes \cdots \otimes a_n) \ast_i a'' &= a_1 \otimes \cdots \otimes a_{n-i} a'' \otimes \cdots \otimes a_n,
\end{align*}
\] (2.1)
for all $a', a'', a_1, \ldots, a_n \in A$. The index denotes the number of “jumps”. In particular, the outer bimodule structure can be written as $a' \ast_0 (a_1 \otimes a_2) \ast_0 a''$, whilst the inner bimodule structure as $a' \ast_1 (a_1 \otimes a_2) \ast_1 a''$. Moreover, following [15] §1.3, let $E_i$ be an $A$-bimodule for $1 \leq i \leq 3$, and given $e_i \in E_i$, we define

$$
eq_1 \otimes_1 (e_2 \otimes e_3) := e_2 \otimes e_1 \otimes e_3 \in E_2 \otimes E_1 \otimes E_3,$$

$$(e_1 \otimes e_2) \otimes_1 e_3 := e_1 \otimes e_3 \otimes e_2 \in E_1 \otimes E_3 \otimes E_2. \quad (2.2)$$

We define the bidual of the $A$-bimodule $E$ as the $A$-bimodule

$$M^\vee := \text{Hom}_A(E, (A \otimes A)_{\text{out}}), \quad (2.3)$$

where the $A$-bimodule structure is induced by the one in $(A \otimes A)_{\text{inn}}$ (i.e. $(a \phi b)e = a \ast (\phi e) \ast b = (\phi' e)b \otimes a(\phi'' e)$, for all $\phi \in E^\vee$, $e \in E$, $a, b \in A$).

Let $n \in \mathbb{N}$ and $V_1, \ldots, V_n$ be vector spaces. We will denote by $S_n$ the group of permutations of $n$ elements $\{1, \ldots, n\}$, which acts on $V_1 \otimes \cdots \otimes V_n$ in the usual way. If $s \in S_n$, we have a linear map

$$\sigma_s : V_1 \otimes \cdots \otimes V_n \longrightarrow V_{s^{-1}(1)} \otimes \cdots \otimes V_{s^{-1}(n)},$$

given by the formula

$$\sigma_s(v) = v_{s^{-1}(1)} \otimes \cdots \otimes v_{s^{-1}(n)},$$

for all $v = v_1 \otimes \cdots \otimes v_n$, with $v_i \in V_i$. If $s = (1 \ldots n)$ is the cyclic permutation (which sends 1 to 2), we use the notation

$$(v_1 \otimes \cdots \otimes v_{n-1} \otimes v_n)^{\sigma} = v_n \otimes v_1 \otimes \cdots \otimes v_{n-1}.$$

3. Basics on noncommutative geometry

In this section, following [13, 31, 32], we will introduce the basics on noncommutative geometry that we shall need below. One of the main features of our approach to noncommutative geometry is that the role of vector fields is played by double derivations that we will define in §3.1. Since double Poisson vertex algebras in §4 will be based on them, in §3.2 we introduce double Poisson algebras [31]; furthermore, they are noncommutative analogues of Poisson algebras — see §7. Finally, we define (symmetric) pairings in §3.3 which will be extensively used in §5.

3.1. Noncommutative differential forms and double derivations. Let $A$ be a unital associative $k$-algebra (the unit is denoted by 1), and $E$ be an $A$-bimodule. A derivation of $A$ into $E$ is an additive map $\theta : A \rightarrow E$ satisfying $\theta(1) = 0$, and the Leibniz rule $\theta(ab) = (\theta a)b + a(\theta b)$, for all $a, b \in A$. The vector space of derivations $\theta : A \rightarrow E$ is denoted $\text{Der}(A, E)$. If $E = A$ (regarded as an $A$-bimodule over itself), we simply write $\text{Der} A$.

We define the $A$-bimodule of noncommutative differential 1-forms $\Omega^1_{nc} A$ as the kernel of the multiplication of $A$ (regarded as an $A$-subbimodule of $A \otimes A$). It carries the universal derivation $d$, defined as the derivation $d : A \rightarrow \Omega^1_{nc} A$, $a \mapsto da := 1 \otimes a - a \otimes 1$. Cuntz–Quillen [13] proved that the pair $(\Omega^1_{nc} A, d)$ satisfies the following universal property: for any derivation $\theta : A \rightarrow E$, there exists a unique $A$-bimodule morphism $i_\theta : \Omega^1_{nc} A \rightarrow E$ such that $\theta = i_\theta \circ d$. It is convenient to rephrase this universal property by saying that there exists a canonical isomorphism of $A$-bimodules

$$\text{Der}(A, E) \overset{\simeq}{\longrightarrow} \text{Hom}_A(\Omega^1_{nc} A, E), \quad \theta \mapsto i_\theta, \quad (3.1)$$
whose inverse map is given by \( i_\theta \mapsto \theta = i_\theta \circ d \). Taking the bidual \( (\Omega_{nc}^1 A)\) of the \( A \)-bimodule \( \Omega_{nc}^1 A \), we obtain
\[
(\Omega_{nc}^1 A)^\vee := \text{Hom}_{A^e}(\Omega_{nc}^1 A, (A \otimes A)_{out}) \simeq \text{Der}(A, (A \otimes A)_{out}),
\]
where the last isomorphism comes from (3.1) with \( E = (A \otimes A)_{out} \). Hence, we define the \( A \)-bimodule \( \text{Der} A := \text{Der}(A, (A \otimes A)_{out}) \), whose \( A \)-bimodule structure is induced by the inner \( A \)-bimodule structure (that is, \( (a\Delta b)(c) = a \ast \Delta(c) \ast b = \Delta'(c)b \otimes a\Delta''(c) \), for all \( a, b, c \in A \), \( \Delta \in \text{Der} A \)). The elements \( \Delta : A \to A \otimes A \) of \( \text{Der} A \) are called double derivations.

### 3.2. Double Poisson algebras

A double bracket \( \{ \cdot, \cdot \} \) on \( A \) is a linear map
\[
\{ -, - \} : A \otimes A \to A \otimes A, \quad a \otimes b \mapsto \{a, b\}' \otimes \{a, b\}'',
\]
satisfying
\[
\begin{align*}
\{ a, b \}' &= \{ b, a \}', \\
\{ a, b \} &= b \{ a, c \} + \{ a, b \} c,
\end{align*}
\]
for all \( a, b, c \in A \). Note that (3.3a) means that \( \{ a, - \} \) is a double derivation in its second entry (with respect to the outer structure on \( A \otimes A \)). Also, (3.3a) and (3.3b) imply that \( \{ ab, c \} = a \ast \{ b, c \} + \{ a, c \} \ast b \); in other words, a double bracket is a double derivation in its first entry for the inner bimodule structure on \( A \otimes A \).

To define an analogue of the Jacobi identity in this setting, we require a suitable extension of the double bracket \( \{ -, - \} \). Let \( a \in A \), \( b = b_1 \otimes \cdots \otimes b_n \in A^{\otimes n} \), then we define
\[
\begin{align*}
\{ a, b \}_L := & \{ a, b_1 \} \otimes b_2 \otimes \cdots \otimes b_n \in A^{\otimes(n+1)}, \\
\{ a, b \}_R := & b_1 \otimes \cdots \otimes b_{n-1} \otimes \{ a, b_n \} \in A^{\otimes(n+1)}.
\end{align*}
\]

**Definition 3.1** \( [31], \text{Definition 2.3.2} \). A double bracket \( \{ -, - \} \) on a unital associative \( \mathbb{k} \)-algebra \( A \) is a double Poisson bracket if
\[
0 = \{ a, \{ b, c \} \}_L + \sigma_{(123)} \{ b, \{ c, a \} \}_L + \sigma_{(132)} \{ c, \{ a, b \} \}_L.
\]

The equation (3.5) is called the double Jacobi identity. In \([15, \text{Remark 2.2}]\), De Sole–Kac–Valeri rewrote (3.5) in a more convenient way by extending the double brackets in the first argument as well. If \( a \in A \) and \( b = b' \otimes b'' \in A \otimes A \); by (2.2),
\[
\begin{align*}
\{ b' \otimes b'', a \}_L := & \{ b', a \} \otimes b'' = \{ b', a \}' \otimes b'' \otimes \{ b', a \}'', \\
\{ b' \otimes b'', a \}_R := & b' \otimes \{ b'', a \} = b' \otimes a' \otimes b'' \otimes \{ b'', a \}'.
\end{align*}
\]
Then by (3.6) and (3.3a), the double Jacobi identity (3.5) can be equivalently written as
\[
\{ a, \{ b, c \} \}_L = \{ a, b \}_L + \{ b, \{ a, c \} \}_R.
\]

### 3.3. Pairings

Let \( A \) be an associative \( \mathbb{k} \)-algebra, and let \( E \) be an \( A \)-bimodule. Following \([32, \text{§3.1}] \) (see also \([22, \text{§A.3}] \)), a map
\[
\langle -, - \rangle : E \otimes E \to A \otimes A
\]
is called a pairing on \( E \) if for all \( e \in E \), the maps
\[
\langle e, - \rangle : E \to (A \otimes A)_{out}
\]
\[
\langle -, e \rangle : E \to (A \otimes A)_{inn}
\]
are $A$-bimodule morphisms. The pairing is called non-degenerate if $E$ is a finitely generated projective $A$-bimodule and $\langle -, - \rangle$ induces an isomorphism $E \simeq E^\vee$ — recall (2.3). Using Sweedler’s notation to omit the summation symbol, we will write

$$\langle e_1, e_2 \rangle = \langle e_1, e_2 \rangle' \otimes \langle e_1, e_2 \rangle'' \quad \text{with} \quad \langle e_1, e_2 \rangle', \langle e_1, e_2 \rangle'' \in A.$$  

A pairing is called symmetric if $\langle e_1, e_2 \rangle = \langle e_2, e_1 \rangle$, for all $e_1, e_2 \in E$ or, equivalently,

$$\langle e_1, e_2 \rangle' \otimes \langle e_1, e_2 \rangle'' = \langle e_2, e_1 \rangle'' \otimes \langle e_1, e_2 \rangle'.$$  

Finally, similarly to (3.4) and (3.6), we extend the pairing $\langle -, - \rangle$ to $E \otimes A \otimes A \otimes E$ using the inner and the outer tensor products for the first and the second entry, respectively. To do that, using (2.2) we define the maps

$$\langle e_1, - \rangle_L : E \otimes A \rightarrow A^{\otimes 3}, \quad e_2 \otimes a \mapsto \langle e_1, e_2 \rangle \otimes a,$$

$$\langle e_1, - \rangle_R : A \otimes E \rightarrow A^{\otimes 3}, \quad a \otimes e_2 \mapsto a \otimes \langle e_1, e_2 \rangle,$$

$$\langle -, e_2 \rangle_L : E \otimes A \rightarrow A^{\otimes 3}, \quad e_1 \otimes a \mapsto \langle e_1, e_2 \rangle \otimes_1 a = \langle e_1, e_2 \rangle' \otimes a \otimes \langle e_1, e_2 \rangle'',$$

$$\langle -, e_2 \rangle_R : A \otimes E \rightarrow A^{\otimes 3}, \quad a \otimes e_1 \mapsto a \otimes_1 \langle e_1, e_2 \rangle = \langle e_1, e_2 \rangle' \otimes a \otimes \langle e_1, e_2 \rangle''.$$  

Furthermore, we require that

$$\langle e_1, a \otimes e_2 \rangle_L = \langle e_1, e_2 \otimes a \rangle_R = \langle a \otimes e_1, e_2 \rangle_L = \langle e_1 \otimes a, e_2 \rangle_R = 0,$$  

for all $a \in A$ and $e_1, e_2 \in E$.

### 4. Double Poisson vertex algebras

In [15], De Sole, Kac and Valeri developed a theory of integrable systems on noncommutative associative algebras and, remarkably, they introduced double Poisson vertex algebras, which we present in this section.

A differential algebra [15] §3.1] $(\mathcal{V}, \partial)$ is a pair consisting of an associative algebra $\mathcal{V}$, and a derivation $\partial \in \text{Der} \mathcal{V}$. Given a polynomial $P(\lambda) = \sum a_i \otimes \cdots \otimes a_n \lambda_i^{k_1} \cdots \lambda_{n-1}^{k_{n-1}} \in \mathcal{V}^{\otimes n}[\lambda_1, \ldots, \lambda_{n-1}]$, we define

$$(e^{\partial \lambda_i} f) \ast_i P(\lambda_1, \ldots, \lambda_i, \ldots, \lambda_{n-1})$$

$$= \sum_{j=0}^{k_i} \binom{k_i}{j} (a_1 \otimes \cdots \otimes a_i \otimes (\partial^j f)a_{i+1} \otimes \cdots \otimes a_n \lambda_i^{k_1} \cdots \lambda_{i-j}^{k_{n-1}} \cdots \lambda_{n-1}^{k_{n-1}}.$$  

That is, $e^{\partial \lambda_i}$ replaces $\lambda$ by $\lambda + \partial$, and the parentheses point out that $\partial$ is applied to $f$. Moreover, we have

$$P(\lambda_1, \ldots, \lambda_i + \partial, \ldots, \lambda_{n-1}) \rightarrow \ast_{n-i} f$$

$$= \sum_{j=0}^{k_i} \binom{k_i}{j} a_1 \otimes \cdots \otimes a_i (\partial^j f) \otimes \cdots \otimes a_n \lambda_i^{k_1} \cdots \lambda_{i-k}^{k_{n-1}} \cdots \lambda_{n-1}^{k_{n-1}}.$$  

In other words, the arrow means that $\partial$ is applied to $f$.

**Definition 4.1** ([15], p. 1058). A double $\lambda$-bracket on a differential algebra $(\mathcal{V}, \partial)$ is a linear map

$$\{-\lambda - \} : \mathcal{V} \otimes \mathcal{V} \rightarrow (\mathcal{V} \otimes \mathcal{V})[\lambda]$$  

(4.1)
Then, we can rewrite the Jacobi identity (4.6) more explicitly in the following way:

\[
\{ \{ \partial a_\lambda b \} \} = -\lambda \{ a_\lambda b \},
\]
\[
\{ a_\lambda \partial b \} = (\lambda + \partial) \{ a_\lambda b \},
\tag{4.2a, 4.2b}
\]

and the Leibniz rules:

\[
\{ a_\lambda bc \} = b \{ a_\lambda c \} + \{ a_\lambda b \} c,
\tag{4.3a}
\]
\[
\{ ab_\lambda c \} = \{ a_{\lambda+\partial} c \} \to \ast_1 b + (e^{\partial_\lambda a}) \ast_1 \{ b_\lambda c \}.
\tag{4.3b}
\]

Recall that in (3.7) we introduced suitable extensions of the double bracket \(\{-,-\}\) to define the double Jacobi identity (3.7). Similarly, to define a suitable Jacobi identity for double \(\lambda\)-brackets, we need to extend (4.1) as follows (see [15, eq. (4.3)]). For all \(a, b, c \in \mathcal{V}\),

\[
\{ a_\lambda (b \otimes c) \}_L := \{ a_\lambda b \} \otimes c,
\]
\[
\{ a_\lambda (b \otimes c) \}_R := b \otimes \{ a_\lambda c \},
\]
\[
\{ (a \otimes b)_\lambda c \}_L := \{ a_{\lambda+\partial} c \} \to \ast_1 b,
\tag{4.4}
\]

where the notation \(\otimes_1\) was introduced in (2.2).

**Definition 4.2** ([15], Definition 2.2). A **double Poisson vertex algebra** \((\mathcal{V}, \{-,-\})\) is a differential algebra \(\mathcal{V}\), with derivation \(\partial \colon \mathcal{V} \to \mathcal{V}\), endowed with a double \(\lambda\)-bracket \(\{-,-\} : \mathcal{V} \otimes \mathcal{V} \to (\mathcal{V} \otimes \mathcal{V})[\lambda]\), satisfying the following axioms:

(i) Skewsymmetry:

\[
\{ a_\lambda b \} = -\{ b_{-\lambda-\partial a} \}^\sigma,
\tag{4.5}
\]

where \(-\lambda - \partial\) in the right-hand side is moved to the left, acting on the coefficients.

(ii) Jacobi identity:

\[
\{ a_\lambda \{ b_\mu c \} \}_L = \{ b_\mu \{ a_\lambda c \} \}_R + \{ \{ a_\lambda b \} \lambda_\mu c \}_L.
\tag{4.6}
\]

It is easy to check that if \(\partial = 0\), and \(\lambda = \mu = 0\), the axioms of double Poisson vertex algebras become the axioms of double Poisson algebras. So, as emphasized in [15], a double Poisson vertex algebra is a cross between a double Poisson algebra and a Poisson vertex algebra. Furthermore, it is straightforward to check that given a double Poisson vertex algebra, the skewsymmetry (4.5) and the left Leibniz rule (4.3a) imply the right Leibniz rule (4.3b) (the authors acknowledge the help of Daniele Valeri on this point); as a consequence, (4.3b) is redundant in Definition 4.2 and thus we shall omit below.

Finally, following [15, p. 1074], given \(a, b, c \in \mathcal{V}\), we can write the double \(\lambda\)-bracket as

\[
\{ a_\lambda b \} = \sum_{p \in Z_+} (\{ a_p b \}' \otimes (a_p b)_n^\alpha) \lambda^p.
\tag{4.7}
\]

Then, we can rewrite the Jacobi identity (4.6) more explicitly in the following way:

\[
0 = \sum_{p, q \in Z_+} (\{ a_p (b_q c) \}' \otimes (a_p (b_q c)_n^\alpha) \otimes (b_q c)_m^\beta - (a_p c)' \otimes (b_q (a_p c)_n^\alpha) \otimes (b_q (a_p c)_m^\beta)) \lambda^p \mu^q,
\]
\[
- \sum_{p, q \in Z_+} ((a_p b)'_q^\alpha \otimes (\lambda + \partial)^q (a_p b)_n^\alpha \otimes (a_p b)'_q^\beta)) \lambda^p.
\tag{4.8}
\]
5. **Double Courant–Dorfman algebras**

Roytenberg [28] introduced an algebraic analogue of Courant algebroids called *Courant–Dorfman algebras*. Their relationship to Courant algebroids is analogous to that of Lie–Rinehart algebras to Lie algebroids: Courant–Dorfman algebras are algebraic generalizations of Courant algebroids. In this section, based on [2] (see also [17]), we define a noncommutative version of Courant–Dorfman algebras called *double Courant–Dorfman algebras* by adapting Roytenberg’s definition to the noncommutative setting introduced in §3. We start by recalling the familiar definition of Courant–Dorfman algebras [28, Definition 2.1]:

**Definition 5.1.** A *Courant–Dorfman algebra* consists of the following data:

1. a commutative $k$-algebra $C$,
2. a $C$-module $N$,
3. a symmetric bilinear form $\langle -, - \rangle : N \otimes N \to C$,
4. a derivation $\partial : C \to N$,
5. a Dorfman bracket $[-,-] : N \otimes N \to N$.

This data is required to satisfy the following conditions:

\[
\begin{align}
[n_1, cn_2] &= c[n_1, n_2] + \langle n_1, \partial c \rangle n_2, \\
\langle n_1, \partial(n_2, n_3) \rangle &= \langle [n_1, n_2], n_3 \rangle + \langle n_2, [n_1, n_3] \rangle, \\
\partial\langle n_1, n_2 \rangle &= [n_1, n_2] + [n_2, n_1], \\
[n_1, [n_2, n_3]] &= [[n_1, n_2], n_3] + [n_2, [n_1, n_3]], \\
0 &= \langle \partial c, n \rangle, \\
0 &= \langle \partial c, \partial d \rangle,
\end{align}
\]

for all $n, n_1, n_2, n_3 \in N$ and $c, d \in C$.

As Roytenberg pointed out, a $k$-module $N$ equipped with a bracket $[-,-]$ satisfying condition (5.1d) above is called a (k-)Leibniz algebra. Moreover, if the pairing $\langle -, - \rangle$ is nondegenerate, the action of $N$ on $C$ completely determines the derivation $\partial$, so (5.1e) and (5.1f) are redundant. In this case, the notion of a Courant–Dorfman algebra coincides with that of a Courant algebroid (see [28] and references therein).

**Definition 5.2.** Let $A$ be an associative $k$-algebra and $E$ be an $A$-bimodule. Let $T_A E$ be the tensor algebra of $E$ over $A$, with $E$ placed in degree 1. We consider a derivation $\partial : A \to E$ and a pairing $\langle -, - \rangle : E \otimes E \to A \otimes A$ (cf. §3.3). A *double Courant–Dorfman bracket* on $E$ is a linear map $[-,-] : T_A E \otimes T_A E \to T_A E \otimes T_A E$, of degree -1 with respect to the natural grading of the tensor algebra $T_A E$, such that

\[
\begin{align}
[e, a] &= \langle e, \partial a \rangle, & [a, e] &= -\langle \partial a, e \rangle, & [a, b] &= 0,
\end{align}
\]

for all $e \in E$ and $a, b \in A$.

For later purposes, we need to decompose the double Courant–Dorfman bracket $[-,-]$ when restricted to $E \otimes E$. Given $e, f \in E$,

\[
\begin{align}
[e, f] &= [e, f]_l + [e, f]_r \in E \otimes A \oplus A \otimes E. 
\end{align}
\]
Using Sweedler’s notation, we can write
\[ [e, f]_l = [e, f]' \otimes [e, f]'' = [e, f]'_r \otimes [e, f]''_r, \]
with \([e, f]_r', [e, f]''_r \in E\) and \([e, f]'_r, [e, f]''_r \in A\).

In view of Definitions 5.1 and 5.2, to state the definition of Courant–Dorfman algebras in the noncommutative context, we need a suitable Jacobi identity that will require an extension of the double Courant–Dorfman bracket. Inspired by (3.4), (3.6) and (4.4), for all \(a \in A\) and \(e, f \in E\), we define
\[ [e, -]_L : E \otimes A \rightarrow E \otimes A \otimes A \otimes E \otimes A, \quad f \otimes a \mapsto [e, f] \otimes a, \]
\[ [e, -]_L : A \otimes E \rightarrow A \otimes A \otimes E, \quad a \otimes f \mapsto \langle e, \partial a \rangle \otimes f, \]
\[ [e, -]_R : E \otimes A \rightarrow E \otimes A \otimes A, \quad f \otimes a \mapsto f \otimes \langle e, \partial a \rangle \]
\[ [e, -]_R : A \otimes E \rightarrow A \otimes E \otimes A \otimes A \otimes E, \quad a \otimes f \mapsto a \otimes [e, f], \]
\[ [-, f]_L : E \otimes A \rightarrow E \otimes A \otimes A + c.p, \quad e \otimes a \mapsto [e, f] \otimes_1 a + \langle e, f \rangle \otimes_1 e, \]
\[ [-, f]_L : A \otimes E \rightarrow A \otimes E \otimes A, \quad a \otimes e \mapsto -\langle \partial a, f \rangle \otimes_1 e, \]
\[ (5.4) \]

where, \(E \otimes A \otimes A + c.p\) is a shorthand for \(E \otimes A \otimes A \otimes E \otimes A \otimes A \otimes A \otimes E\), and the notation \(\otimes_1\) was introduced in (2.2).

**Definition 5.3.** Let \(A\) be an associative \(k\)-algebra and \(E\) be an \(A\)-bimodule. A **double Courant–Dorfman algebra** is a 5-tuple \((A, E, \langle -,- \rangle, \partial, [-,-])\), where
\[ \langle -,- \rangle : E \otimes E \rightarrow A \otimes A, \]
is a symmetric pairing,
\[ \partial : A \rightarrow E, \]
is a derivation, and
\[ [-,-] : T_A E \otimes T_A E \rightarrow T_A E \otimes T_A E. \]
\[ (5.5) \]
is a double Courant–Dorfman bracket. This data must satisfy the following axioms:
\[ \partial \langle e, f \rangle = [e, f] + [f, e]'^\sigma; \]
\[ (5.6a) \]
\[ 0 = \langle \partial a, e \rangle; \]
\[ (5.6b) \]
\[ 0 = \langle \partial a, \partial b \rangle; \]
\[ (5.6c) \]
\[ [e, fa] = [e, f]a + f \langle e, \partial a \rangle; \]
\[ (5.6d) \]
\[ [e, af] = a[e, f] + \langle e, \partial a \rangle f; \]
\[ (5.6e) \]
\[ [e, [f, g]]_L = [f, [e, g]]_R + [[e, f], g]_L; \]
\[ (5.6f) \]
\[ \langle e, \partial [f, g] \rangle_L = \langle f, [e, g] \rangle_R + [\langle e, f \rangle, g]_L. \]
\[ (5.6g) \]
for all \(a, b \in A\) and \(e, f, g \in E\).

We observe that, in (5.6a) and (5.6g), the derivation \(\partial\) acts on \(\langle -,- \rangle\) by the Leibniz rule; for all \(e_1, e_2 \in E\),
\[ \partial \langle e_1, e_2 \rangle = \partial \langle e_1, e_2 \rangle' \otimes \langle e_1, e_2 \rangle'' + \langle e_1, e_2 \rangle' \otimes \partial \langle e_1, e_2 \rangle''. \]
\[ (5.7) \]

In (5.6g) we use the extensions of \(\langle -,- \rangle\) introduced in (3.10); thus this identity is in \(A^{\otimes 3}\). Moreover, in (5.6d) and (5.6e) the products use the outer bimodule structure.
Remark 5.4. In several places of the article, we will need to write (5.6f) as explicit as possible. Since (5.6f) takes place in \( E \otimes A \otimes A + \text{c.p.} \), we can project onto each summand. Hence, using (5.3), (5.7), (5.4) and (3.11), we have that (5.6f) is equivalent to the following three identities:

\[
\begin{align*}
&[[e, [f, g]]]_l \otimes [f, g]'' = [e, g]' \otimes \langle f, \partial[e, g]'' \rangle + [[e, f]'], g]_l \otimes [e, f]'', \\
&[e, [f, g]]_l \otimes [f, g]' = [e, g]' \otimes [f, [e, g]']_l + \langle [e, f], g \rangle \otimes [e, f]'', \\
&- \langle \partial[e, f]'', g \rangle \otimes [e, f]'',
\end{align*}
\]

where (5.8a) is in \( E \), (5.8b) in \( A \otimes E \otimes A \), and (5.8c) takes place in \( A \otimes A \otimes E \).

6. The equivalence theorem

In this section we prove the main theorem of this article, which is a non-commutative version of [20] Prop. 4.3 in the case of Courant algebroids:

Theorem 6.1. There exists a one-to-one correspondence between double Poisson vertex algebras \( (V, \partial, \{ -, - \}) \) freely generated in weights 0 and 1, and double Courant–Dorfman algebras \( (E, \{ -, - \}, \partial, \{ -, - \}) \).

The rest of this section is devoted to prove Theorem 6.1. In Section 6.1 we construct a double Courant–Dorfman algebra associated with a double Poisson vertex algebra. In Section 6.2 we provide the inverse construction.

6.1. From double Poisson vertex algebras to double Courant–Dorfman algebras.

In this subsection, we shall show that the structure of a double Poisson vertex algebra — see Definition 5.3, which is freely generated in weights 0 and 1, induces a structure of a double Courant–Dorfman algebra, as in Definition 5.3 in its degree 0 and 1 parts.

Let \( (V, \partial, \{ -, - \}) \) be a double Poisson vertex algebra such that \( V = \bigoplus_{k \geq 0} V_k \) whose product has weight 0, the derivation \( \partial \) has weight 1, and the double \( \lambda \)-bracket has weight -1. More precisely, given \( v \in V_i \), \( w \in V_j \), and \( \{ v, w \} = \sum_{q \in \mathbb{Z}^+} \left( ( (v_q w)' \otimes (v_q w)'' ) \lambda^q \right) \), we have \( (v_q w)' \otimes (v_q w)'' \in (V \otimes V)_{i+j-q-1} \), for all \( q \). Since the product in \( V \) has weight 0, note that if \( a, b \in V_0 \) the product \( ab \in V_0 \). Consequently, \( A := V_0 \) has the structure of an associative (not necessarily commutative) \( k \)-algebra. Next, the multiplication of an element of \( V_0 \), both on the right and on the left, by an element \( V_1 \) gives an element of \( V_1 \). Thus, \( E := V_1 \) carries an \( A \)-bimodule structure.

From now on, we fix \( e, f, g \in E \) and \( a, b \in A \). Observe that since the double \( \lambda \)-bracket has weight -1, if \( e, f \in E \), the bracket restricted to \( E \otimes E \) has the following expression:

\[
\{ e, f \lambda \} = \{ e, f \} + \lambda \{ e, f \} \in ((V \otimes V)[\lambda])_1 = E \otimes A \oplus A \otimes E \oplus (A \otimes A) \lambda,
\]

where

(i) The operations

\[
\{ -, - \} : E \otimes E \rightarrow E \otimes A \oplus A \otimes E, \\
\{ -, - \} : E \otimes E \rightarrow A \otimes A
\]

are \( k \)-linear maps.
(ii) We have the derivation
\[ \partial : A \rightarrow E \]
of weight 1 that, by convention, acts on tensor products by the Leibniz rule; see (5.4).

(iii) Since \(|\{-\lambda - \}\}| = -1, |e| = 1\) and \(|a| = 0\), we have an action
\[ \star : E \otimes A \rightarrow A \otimes A, \quad e \otimes a \mapsto e \star a = \{ e_{\lambda}a \} = \langle e, \partial a \rangle; \] (6.2)

(iv) By (iii) and (4.5), we get
\[ \{ a_{\lambda}e \} = -\langle \partial a, e \rangle. \] (6.3)

(v) Finally, since \(a, b \in A, |a| = |b| = 0\), we have an action
\[ \{ a_{\lambda}b \} = 0. \] (6.4)

Now, we will use the axioms of double Poisson vertex algebras expressed in Definition 4.2 to deduce the axioms (5.6a)–(5.6g) that characterize double Courant–Dorfman algebras.

To prove (5.6a), by (4.5) we have the identity
\[ \{ e_{\lambda}f \} = \{-f_{-\lambda - a}e\}^{\sigma}, \] (6.5)
whose left-hand side, by (6.1), can be rewritten as
\[ \{ e_{\lambda}f \} = [e, f] + \lambda \langle e, f \rangle, \] (6.6)
and at the right-hand side of (6.5), we obtain
\[ -\{ f_{-\lambda - a}e \}^{\sigma} = -[f, e]^{\sigma} + \lambda \langle f, e \rangle^{\sigma} + (\partial \langle f, e \rangle)^{\sigma}. \] (6.7)
The terms with different coefficients of \(\lambda\) do not interact each other; thus comparing the coefficients of \(\lambda\) appearing in (6.6) and (6.7), we obtain
\[ \langle e, f \rangle = \langle f, e \rangle^{\sigma}. \] (6.8)
Moreover, since the derivation \(\partial\) acts on tensor products by the Leibniz rule (see (7ii) above), (6.8) implies
\[ \partial \langle e, f \rangle = (\partial \langle f, e \rangle)^{\sigma}. \] (6.9)
Hence, comparing the terms without \(\lambda\) in (6.6) and (6.7), we have
\[ [e, f] = -[f, e]^{\sigma} + \partial \langle e, f \rangle, \]
which is tantamount to (5.6a).

Next, the sesquilinearity of the double \(\lambda\)-bracket (see (4.2a) and (4iv) above, give the identity
\[ \{ \partial a_{\lambda}e \} = -\lambda \{ a_{\lambda}e \} = \lambda \langle \partial a, e \rangle. \] (6.10)
On the other hand, using (6.1), we have
\[ \{ \partial a_{\lambda}e \} = \{ [\partial a, e] + \lambda \langle \partial a, e \rangle \}. \] (6.11)
If we compare the terms without \(\lambda\) in (6.10) and (6.11), we finally obtain the identity
\[ [\partial a, e] = 0, \] (6.12)
which is (5.6b).

To prove (5.6c), by (4.2a) and (4.2b)
\[ \{ \partial a_{\lambda}b \} = -\lambda \{ a_{\lambda}b \} = -\lambda (\lambda + \partial) \{ a_{\lambda}b \} = 0, \] (6.13)
where the last identity is a consequence of (v) above. On the other hand, by (6.1),
\[\{\partial a, \partial b\} = [\partial a, \partial b] + \lambda \{\partial a, \partial b\}.\]  
(6.14)

Again, comparing the obtained expressions in (6.13) and (6.14), we obtain
\[\{\partial a, \partial b\} = 0,\]  
(6.15)

which corresponds to (5.6c).

To establish the Leibniz identity (5.6d), by (4.3a) and (6.1), we set
\[\{e_\lambda f a\} = \{e_\lambda f\} a + f \{e_\lambda a\} = [e, f] a + \lambda (\{e, f\} a) + f (\{e, \partial a\}).\]  
(6.16)

Now, by (6.1), we get
\[\{e_\lambda f a\} = [e, f a] + \lambda \{e, f a\}.\]  
(6.17)

Identifying the terms without \(\lambda\) in (6.16) and (6.17), we finally obtain:
\[\{e, f a\} = [e, f] a + f \{e, \partial a\},\]  
(6.18)

which is (5.6d). Using similar arguments, the reader can prove (5.6e).

Interestingly, note that comparing the coefficients of \(\lambda\) in (6.16) and (6.17), we get
\[\{e, f a\} = \{e, f\} a.\]  
Similarly, after proving (5.6f), we obtain \(\{e, a f\} = a \{e, f\}\), meaning that \(\{\cdot, \cdot\}\) is \(A\)-bilinear in its second argument with respect to the outer bimodule structure. Moreover, applying (4.3a), (6.1) and (6.8),
\[\{ae_\lambda f\} = -\{f_{-\partial a e}\} = -(a \{f_{-\partial a e}\} + \{f_{-\partial a e}\} e)\]  

\[= -a * [f, e] + \lambda(a * \{e, f\}) + a * (\partial \{e, f\}) - \{\partial a, f\} * e\]  

\[= a * [e, f] + \lambda(a * \{e, f\}) - \{\partial a, f\} * e.\]  

By (6.1), \(\{ae_\lambda f\} = [ae, f] + \lambda \{ae, f\}\). Thus, comparing the obtained expressions, we have
\[\{ae, f\} = a * \{e, f\};\]
in other words, \(\{\cdot, \cdot\}\) is \(A\)-linear in its first argument with respect to the inner bimodule structure. By similar considerations on \(\{e_\lambda f\}\), the identity \(\{e_\lambda f\} = \{e, f\} * a\) holds. These identities together (6.8) imply that \(\{\cdot, \cdot\}\) is a symmetric pairing on \(E\), as defined in §3.3.

Finally, we want to obtain (5.6g) and (5.6h). Firstly, by (4.0), we have
\[0 = \{e_\lambda \{f, g\}\}_L - \{f, g\} \{e_\lambda \}_R - \{e_\lambda f\} _L \]  
(6.19)

and using (5.1), (iii), (v), (3.3) and (4.4), we will rewrite each term. To start with, we focus on the first summand of (6.19):

\[\{e_\lambda \{f, g\}\}_L = \{e_\lambda \} \{f, g\} + \{e_\}\{f, g\} \mu\]  

\[= \{e_\lambda \{f, g\}\} \otimes [f, g] + \{e_\lambda [f, g]\} \otimes [f, g] + \{e_\{f, g\}\} \otimes [f, g] + \{e_\{f, g\}\} \otimes [f, g] \mu\]  

\[= \{e, [f, g]\} \otimes [f, g] + \{e, [f, g]\} \otimes [f, g] + \{e, [f, g]\} \otimes [f, g] + \{e, [f, g]\} \otimes [f, g] \mu\]  

\[+ \{e, [f, g]\} \lambda + \{e, [f, g]\} \mu\]  

(6.20)
Finally, in the third summand of (6.19), we obtain
\[
\{ \{ e, f \} + \langle e, f \rangle \lambda \}_{L}^\lambda = \{ \{ e, f \} \}_{L}^\lambda + \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g + \{ \{ e, f \} \}_{\lambda+\mu+\rho}^\lambda g + \{ \{ e, f \} \}_{\mu+\rho}^\lambda g + \{ \{ e, f \} \}_{\mu+\rho+\sigma}^\lambda g + \{ \{ e, f \} \}_{\mu+\rho+\sigma+\tau}^\lambda g
\]
\[
\text{from Definition 5.3, as in Definition 5.3,}
\]
(6.22)

Then, collecting the terms obtained in (6.20)–(6.22), from (6.19) we finally obtain:
\[
0 = \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g
\]
\[
\begin{align*}
&\{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g \\
&= \{ \{ e, f \} \}_{L}^\lambda - \{ \{ e, f \} \}_{R}^\lambda - \{ \{ e, f \} \}_{\lambda+\mu}^\lambda g
\end{align*}
\]
\[
(6.23a)
\]
\[
(6.23b)
\]
\[
(6.23c)
\]
\[
(6.23d)
\]
\[
(6.23e)
\]
Hence, (6.23a) agrees with (5.8a), (6.23b) with (5.8b), and (6.23c) is tantamount to (5.8c). Thus, by Remark 5.3, (6.8f) follows. Finally, using \( \partial \) acts on tensor products by the Leibniz rule, as well as (3.10) and (3.11), it is clear that (6.23c) gives (5.6g).

So, to sum up, in this subsection we proved that a double Poisson vertex algebra freely generated in weights 0 and 1 gives rise to a double Courant–Dorfman, as stated in Definition 5.3

6.2. From double Courant–Dorfman algebras to double Poisson vertex algebras.

Given a double Courant–Dorfman algebra \((A, E, \langle -,- \rangle, \partial, [-,-])\), as in Definition 5.3 in this subsection we prove that it induces a double Poisson vertex algebra \((\mathcal{V}, \partial, \{ -,- \})\) freely generated in weights 0 and 1. We let \( \mathcal{V} \) be the free graded associative associative \( A \)
algebra with a derivation $T$ of degree 1 generated by $E$ in degree 1. Let $\mathcal{V}$ be its quotient by the differential ideal generated by $(T - \partial)a$ for all $a \in A$. This is a graded differential associative algebra, generated by $A$ in degree 0 and $E$ in degree 1. We denote by $\partial$ the derivation of degree 1 obtained by reduction from $T$ on $\mathcal{V}'$. We define an operation

$$\{ - \lambda - \} : \mathcal{V} \otimes \mathcal{V} \rightarrow (\mathcal{V} \otimes \mathcal{V})[\lambda]$$

of weight -1, given by

$$\{ e_\lambda f \} = [e, f] + \langle e, f \rangle \lambda, \quad (6.24a)$$
$$\{ e_\lambda a \} = \langle e, \partial a \rangle, \quad (6.24b)$$
$$\{ a_\lambda e \} = -\langle \partial a, e \rangle, \quad (6.24c)$$
$$\{ a_\lambda b \} = 0, \quad (6.24d)$$

for all $a, b \in A$ and $e, f \in E$ and extend this to all of $\mathcal{V}$ by the Leibniz property (4.3a). We need to prove that the bracket (6.24) is well defined and is a double $\lambda$-bracket (i.e., $\{ - \lambda - \}$ satisfies the properties of sesquilinearity (1.2a) and (1.2b), as well as the left Leibniz property (4.3a)), further satisfying (4.5) and (4.6). From now on, we fix $a, b \in A$ and $e, f, g \in E$.

By (6.24), it is clear that (4.2a) holds on $A \otimes A$, $E \otimes A$ and $A \otimes E$. Next, by (6.24a), (5.6b) and (6.24c), we have

$$\{ \partial a_\lambda e \} = [\partial a, e] + \lambda \langle \partial a, e \rangle = \lambda \langle [\partial a, e] \rangle = \partial \{ a_\lambda e \},$$

and (4.2a) follows.

Again, by (6.24), it is clear that (4.2b) holds on $A \otimes A$, $E \otimes A$ and $A \otimes E$. To prove that this identity holds on $E \otimes E$, we have

$$\{ e_\lambda \partial a \} = [e, \partial a] + \lambda \langle e, \partial a \rangle = \partial \{ e, \partial a \} - [\partial f, A]^{\sigma} + \lambda \langle e, \partial a \rangle = (\lambda + \partial) \{ e_\lambda a \},$$

where we used (6.24a), (5.6a), (5.6b) and (6.24b).

Next, by (6.24d), the skewsymmetry (4.5) on $A \otimes A$ is trivial. By (6.24c), the symmetry of $\langle - , - \rangle$ and (6.24c), we have

$$- \{ a_\lambda e \}^{\sigma} = \{ \partial a, e \}^{\sigma} = \langle e, \partial a \rangle = \{ e_\lambda a \}.$$

The proof of the identity $- \{ e_\lambda \partial a \}^{\sigma} = \{ a_\lambda e \}$ is completely similar and we leave it to the reader. Next, by (6.9), (6.24d) and (5.6a), we have:

$$- \{ f_\lambda e \}^{\sigma} = -[f, e] - (\lambda + \partial) \langle f, e \rangle^{\sigma}$$
$$= -[f, e]^{\sigma} + \lambda \langle f, e \rangle + \partial \{ f, e \}$$
$$= [f, e] + \lambda \langle f, e \rangle = \{ e_\lambda f \},$$

where we used (3.9).

The left Leibniz property (1.3a) trivially holds when the three elements are in $A$. If $a, b \in A$, $e \in E$, by (6.24c) and (6.24d), we get

$$\{ a_\lambda eb \} - e \{ a_\lambda b \} - \{ a_\lambda e \} b = -\langle \partial a, eb \rangle + \langle \partial a, e \rangle b = 0.$$

Similarly, we can prove that $\{ a_\lambda be \} - b \{ a_\lambda e \} - \{ a_\lambda b \} e = 0$. However, if the element of $E$ is in the first argument, the computation is slightly different:

$$\{ e_\lambda ab \} - a \{ e_\lambda b \} - \{ e_\lambda a \} b = \{ e, \partial(ab) \} - a \{ e, \partial b \} - \{ e, \partial a \} b = 0,$$
where we used (6.24c), (5.7) and the $A$-linearity of the pairing. The most interesting case occurs when only one element belongs to $A$. By (6.24a), (6.24b) and (5.6a) we can write

$$\left\langle e_\lambda f, a \right\rangle - f \left\langle e_\lambda a \right\rangle = \left\langle e_\lambda f, e \right\rangle a$$

Similarly, based on the same arguments, it is straightforward to see that $\left\langle e_\lambda a f \right\rangle - a \left\langle e_\lambda f \right\rangle = 0$. Consequently, $\left\langle -\lambda - \right\rangle$ as defined in (6.24) satisfies the left Leibniz property (4.3a).

To prove the Jacobi identity (4.6), we shall distinguish different cases, depending on the number of elements in $A$ and $E$. By (6.24c), (4.6) trivially holds if there are two or three elements belonging to $A$. If $e, f \in E$ and $a \in A$, by (6.24a), (6.24b) and (6.24c), we have

$$\left\langle e_\lambda \left\langle f, \partial a \right\rangle \right\rangle_L - \left\langle f, e_\lambda \left\langle \partial a \right\rangle \right\rangle_R - \left\langle e_\lambda f, \lambda + \mu a \right\rangle_L$$

By (4.4) and (6.24), we have

$$\left\langle e_\lambda \left\langle f, \partial a \right\rangle \right\rangle_L - \left\langle f, e_\lambda \left\langle \partial a \right\rangle \right\rangle_R - \left\langle e_\lambda f, \lambda + \mu a \right\rangle_L$$

which, using (5.7), (3.10) and (3.11), can be equivalently written as

$$\left\langle [e, \partial] \left\langle f, \partial a \right\rangle \right\rangle_L - \left\langle f, [e, \partial] \left\langle \partial a \right\rangle \right\rangle_R - \left\langle [e, f] \lambda \right\rangle_L = 0.$$
Finally, the most delicate case occurs when \( e, f, g \in E \). The idea is to use (6.24) and (4.8) to rewrite each term in (4.6). Its first summand of (4.6) can be written as

\[
\left\{ e, \left\{ f, \mu g \right\} \right\}_L = \left\{ e, \left( \left\{ f, g \right\} \right) \right\}_L + \left\{ e, \left\{ f, g \right\}_\mu \right\} \otimes \left\{ f, g \right\}_\mu.
\]

Using (6.24) and (4.4), the second summand in (4.6) reads as

\[
\left\{ f, \left\{ e, \mu g \right\} \right\}_R = \left\{ e, \left\{ f, \mu g \right\} \right\}_R + \left\{ e, \left\{ f, \mu g \right\} \right\} \otimes \left\{ f, \mu g \right\}.
\]

Finally, we can rewrite the third summand of (6.24):

\[
\left\{ f, \mu \left\{ e, g \right\} \right\}_L = \left\{ e, \left\{ f, \mu g \right\} \right\}_L + \left\{ e, \left\{ f, \mu g \right\} \right\} \otimes \left\{ e, \left\{ f, \mu g \right\} \right\} + \left\{ e, \left\{ f, \mu g \right\} \right\} \otimes \left\{ e, \left\{ f, \mu g \right\} \right\}.
\]

So, at this point, collecting the terms obtained in (6.26)–(6.28), we finally obtained:

\[
\left\{ e, \left\{ f, \mu g \right\} \right\}_L - \left\{ f, \mu \left\{ e, g \right\} \right\}_L - \left\{ e, \mu \left\{ f, g \right\} \right\}_L = \boxed{A} + \boxed{B} + \boxed{C} + \boxed{D} \lambda + \boxed{E} \mu,
\]

where

\[
\boxed{A} := \left[ e, [f, g]_{\lambda \mu} \right] \otimes [f, g]_{\mu} - \left[ e, g \right]_{\lambda \mu} - \left[ e, f \right]_{\lambda \mu} - \left[ e, g \right]_{\lambda \mu} - \left[ e, f \right]_{\lambda \mu},
\]

\[
\boxed{B} := \left[ e, [f, g]_{\lambda \mu} \right] \otimes [f, g]_{\mu} - \left[ e, f \right]_{\lambda \mu} - \left[ e, g \right]_{\lambda \mu} - \left[ e, f \right]_{\lambda \mu},
\]

\[
\boxed{C} := \left[ e, [f, g]_{\lambda \mu} \right] \otimes [f, g]_{\mu} - \left[ e, f \right]_{\lambda \mu} - \left[ e, g \right]_{\lambda \mu} - \left[ e, f \right]_{\lambda \mu},
\]

\[
\boxed{D} := \left[ e, [f, g]_{\lambda \mu} \right] \otimes [f, g]_{\mu} - \left[ e, f \right]_{\lambda \mu} - \left[ e, g \right]_{\lambda \mu} - \left[ e, f \right]_{\lambda \mu}.
\]
we define the functor \( \text{vector} \), we set \( \text{rep} \), since we have the adjunction \( \text{adj} \). By classical results of Bergman [8] and Cohn [12], it is well-known that this functor is endowed with a double structure on \( \text{A} \). The Kontsevich–Rosenberg principle [23, 24] states that a noncommutative algebro-geometric Proposition 7.1 (Proposition 3.20 and Theorem 3.22) that states that double Poisson vertex algebras satisfy the Kontsevich–Rosenberg principle:

7. The Kontsevich–Rosenberg principle for double Courant–Dorfman algebras

7.1. The Kontsevich–Rosenberg principle for double Poisson (vertex) algebras. The Kontsevich–Rosenberg principle [23, 24] states that a noncommutative algebro-geometric structure on \( \text{A} \) should naturally induce the corresponding algebro-geometric structure on the representation scheme \( \text{Rep}(\text{A}, \text{N}) \). Here, if \( d = (d_1, \ldots, d_n) \in \mathbb{N}^n \) denotes a dimension vector, we set \( \text{N} := \sum_{i=1}^{n} d_i \). Then, if \( \text{M}_{\text{N}}(\text{k}) \) stands for the algebra of \( \text{N} \times \text{N} \)-matrices, we define the functor

\[
\text{Rep}_{\text{N}}(\text{A}) \colon \text{CommAlg}_{\text{k}} \rightarrow \text{Sets}, \quad \text{B} \mapsto \text{Hom}(\text{A}, \text{M}_{\text{N}}(\text{B})).
\]

By classical results of Bergman [8] and Cohn [12], it is well-known that this functor is representable, since we have the adjunction

\[
\text{Hom}(\text{A}_{\text{N}}, \text{B}) = \text{Hom}(\text{A}, \text{M}_{\text{N}}(\text{B})),
\]

and consequently the representation scheme \( \text{Rep}(\text{A}, \text{N}) \) is \( \text{Spec}(\text{A}_{\text{N}}) \); equivalently, \( \text{A}_{\text{N}} := \mathbb{k}[\text{Rep}(\text{A}, \text{N})] \). As Van den Bergh [31] pointed out, the algebra \( \text{A}_{\text{N}} \) is isomorphic to the commutative algebra on symbols \( \{a_{ij} \mid a \in \text{A}, 1 \leq i, j \leq \text{N} \} \) subject to the relations

\[
(aa)_{ij} = \alpha a_{ij}, \quad (a + b)_{ij} = a_{ij} + b_{ij}, \quad (ab)_{ij} = a_{ij}b_{ij}, \quad 1_{ij}a_{uv} = \delta_{ja}a_{uv},
\]

for all \( a, b \in \text{A}, \alpha \in \mathbb{k}, i, j, t, u, v \in \{1, \ldots, \text{N} \} \), where from now on we sum over repeated indices. In fact, he proved [31 Proposition 7.5.2] that if \( (\text{A}, \{\cdot, \cdot\}) \) is a double Poisson algebra (see Definition 3.1), then \( (\text{A}_{\text{N}}, \{\cdot, \cdot\}) \) is a Poisson algebra, with bracket given by

\[
\{a_{ij}, b_{uv}\} = \{a, b\}'_{ij} \{a, b\}''_{uv}.
\]

This arrangement of indices in \( (7.2) \) is called the standard index convention. It will repeatedly appear below.

Given a differential algebra \( (\mathcal{V}, \partial) \) (cf. [31], we consider the pair \( (\mathcal{V}_{\text{N}}, \partial_{\text{N}}) \), where \( \mathcal{V}_{\text{N}} \) is as above, and the derivation \( \partial_{\text{N}} \) is defined by

\[
\partial_{\text{N}}(a_{ij}) := (\partial a)_{ij},
\]

where \( a \in \text{A} \) and \( i, j \in \{1, \ldots, \text{N} \} \). One of the main results in [15] is the following result that states that double Poisson vertex algebras satisfy the Kontsevich–Rosenberg principle:

**Proposition 7.1** ([15], Proposition 3.20 and Theorem 3.22). Let \( \mathcal{V} \) be a differential algebra endowed with a double \( \lambda \)-bracket \( \{\cdot, \cdot\} \), written as \( \{a_{\lambda}b\} = \sum_{p \in \mathbb{Z}^+} ((a_{p}b)' \otimes (a_{p}b)'')\lambda^{p} \),

Now, by Remark 5.4, it is clear that \( \langle \langle A \rangle, \langle B \rangle \rangle = 0 \) by (5.6f). Also, since (5.6g) holds, \( \langle \langle E \rangle \rangle = 0. \) Finally, Lemma A.1 gives the vanishing of \( \langle \langle D \rangle \rangle \).

To sum up, in this subsection, given a double Courant–Dorman algebra we proved that it gives rise to a double Poisson vertex algebra freely generated in weights 0 and 1 via (6.24). Consequently, Theorem 6.1 follows.
for all \(a, b \in \mathcal{V}\). Then, for every \(N \geq 1\), there exists a well-defined \(\lambda\)-bracket on \(\mathcal{V}_N\), given by

\[
\{a_{ij} \lambda b_{hl}\} = \sum_{p \in \mathbb{Z}_+} (a_{p}b')_{ij} (a_{p}b'')_{hl} \lambda^p,
\]  
(7.4)

where \(a_{ij}, b_{hk} \in \mathcal{V}_N\). In addition, if \(\mathcal{V}\) is a double Poisson vertex algebra, then \(\mathcal{V}_N\) is a Poisson vertex algebra with \(\lambda\)-bracket defined by (7.4).

7.2. The Kontsevich–Rosenberg principle for double Courant–Dorfman algebras. Van den Bergh [32] also studied how bimodules and their noncommutative structures are reflected into representation spaces. If \(E\) is an \(A\)-bimodule, we define \(E_N\) as the (left) \(A_N\)-module generated by symbols \(\{e_{ij} | 1 \leq i, j \leq N\}\) that are linear in \(e \in E\) and satisfy

\[
(ae)_{ij} = a_{it} e_{tj},
\]  
(7.5a)

\[
(ea)_{ij} = a_{tj} e_{it},
\]  
(7.5b)

for \(i, j, t \in \{1, \ldots, N\}\).

Remark 7.2. Van den Bergh [32, §3.3] formalized the Kontsevich–Rosenberg principle by introducing the additive functor (now called the Van den Bergh functor)

\[
(-)_N : \text{Bimod}(A) \longrightarrow \text{mod}(A_N),
\]  
(7.6)

which is right exact and sends finitely generated projective \(A\)-bimodules to finitely generated projective \(A_N\)-modules — see also [33] §4.3. By [32] Lemma 3.3.1], we consider \(M_N(A_N)\) as an \(A\)-bimodule via the \(\mathbb{k}\)-algebra morphism \(A \rightarrow M_N(A_N), a \mapsto a_{ij}\). Also, we consider \(M_N(A_N)\) as an \(A_N\)-module via the diagonal embedding \(A_N \rightarrow M_N(A_N)\). Then there exists a natural isomorphism

\[
P_N \simeq P \otimes_{A^e} M_N(A_N).
\]

This functor allows us to prove the key isomorphisms (see [32, Proposition 3.3.4])

\[
(\Omega_{nc}^1 A)_N \simeq \Omega_{A_N}^1, \quad (\text{Der} A)_N \simeq \text{Der} A_N,
\]

providing \(A\) is smooth (i.e. \(A\) is finitely generated as a \(\mathbb{k}\)-algebra and \(\Omega_{nc}^1 A\) is a projective \(A^e\)-module). In this article, it will be more convenient to follow the more explicit approach given by (7.5). Nevertheless, the study of the Van den Bergh functor (7.6) has given rise to insightful developments; for instance, [7] and [33] (see also references therein).

The following result states how pairings (in the sense of [33]) induce usual bilinear forms on the representation schemes:

Lemma 7.3 ([32], Lemma 3.3.3). If \(\langle -, - \rangle : E \otimes E \rightarrow A \otimes A\) is a non-degenerate pairing then the corresponding pairing between \(E_N\) (obtained by applying the standard index convention)

\[
\langle -, - \rangle : E_N \otimes E_N \rightarrow A_N, \quad (e_{ij}, f_{uv}) \mapsto \langle \langle e, f \rangle'_{u_j} \langle e, f \rangle''_{i_j} \rangle
\]

is non-degenerate as well.

At this point, we can prove that the Kontsevich–Rosenberg principle holds for double Courant–Dorfman algebras:
Theorem 7.4. Let \((A, E, \langle -,-\rangle, \partial, [-,-])\) be a double Courant–Dorfman algebra. For all \(N \geq 1\), we define
\[
\partial_N a_{ij} := (\partial a)_{ij},
\]
(7.7a)
\[
\langle e_{ij}, f_{uv} \rangle := \langle \langle e, f \rangle_{ij} \rangle_{uv} \langle e, f \rangle^\prime_{uv},
\]
(7.7b)
\[
[e_{ij}, f_{uv}] := [e, f]_{ij}^{\prime} [e, f]_{iv}^{\prime} + [e, f]_{ai}^{\prime} [e, f]_{rj}^{\prime},
\]
(7.7c)
for all \(a \in A\) and \(e, f \in E\). Then the 5-tuple \((A_N, E_N, \langle -,-\rangle, \partial_N, [-,-])\) is a Courant–Dorfman algebra in the definition of Section 5.1.

Proof. It is clear that \(\partial_N\), as defined in (7.7a), is a derivation of \(A_N\), as well as \(\langle -,-\rangle\) in (7.7b) is a bilinear form on \(E_N\) by Lemma 7.3. Now, we extend (7.7c) to a bilinear form \([-,-]\): \(E_N \times E_N \rightarrow E_N\) that satisfies (5.1a). To see that this form is well-defined, we shall verify the compatibility with the defining relations of \(E_N\) written in (7.5). The linearity of \([-,-]\) follows from the linearity of \([\ [\ -\ ]\ ]\). To verify the compatibility with (7.5a), using (5.3), we can decompose (5.6e) can be written as follows:
\[
[e, af]^\prime \otimes [e, af]^\prime = a\langle e, f \rangle^\prime \otimes [e, f]^\prime \in E \otimes A,
\]
(7.8)
\[
[e, af]^\prime \otimes [e, af]^\prime = a\langle e, f \rangle^\prime \otimes [e, f]^\prime + \langle e, \partial a \rangle^\prime \otimes \langle e, \partial a \rangle^\prime f \in A \otimes E,
\]
Then, by (7.7c) and (7.8) we have
\[
[e_{ij}, (af)_{uv}] = [e, af]_{ij}^{\prime} [e, af]_{iv}^{\prime} + [e, af]_{rj}^{\prime} [e, af]_{rj}^{\prime} + (a\langle e, f \rangle^\prime)_{ij}^{\prime} [e, f]_{iv}^{\prime} + \langle e, \partial a \rangle^\prime \otimes \langle e, \partial a \rangle^\prime f_{iv},
\]
Now, by (7.5a), (7.5b), (7.5c) and (7.5d),
\[
a_{ut} ([e, f]_{it}^{\prime} [e, f]_{iv}^{\prime} + [e, f]_{rj}^{\prime} [e, f]_{rj}^{\prime} + \langle e, \partial a \rangle^\prime \otimes \langle e, \partial a \rangle^\prime f_{iv}),
\]
for all \(i, j, u, v, t \in \{1, \ldots, N\}\). Similarly, we can check the compatibility with (7.5b) as follows. By (5.6d), we can write
\[
[e, fa]^\prime \otimes [e, fa]^\prime = [e, f]_{ij}^{\prime} [e, f]_{iv}^{\prime} + [e, f]_{ij}^{\prime} [e, f]_{iv}^{\prime} + \langle e, \partial a \rangle^\prime \otimes \langle e, \partial a \rangle^\prime f \in E \otimes A,
\]
(7.9)
Hence,
\[
[e_{ij}, (fa)_{uv}] = [e, fa]_{ij}^{\prime} [e, fa]_{iv}^{\prime} + [e, fa]_{rj}^{\prime} [e, fa]_{rj}^{\prime} + (a\langle e, f \rangle^\prime)_{ij}^{\prime} [e, f]_{iv}^{\prime} + \langle e, \partial a \rangle^\prime \otimes \langle e, \partial a \rangle^\prime f_{iv},
\]
as we wished. Moreover, from these computations, (5.1a) follows.

To prove (5.1e), by (7.3), (7.7a) and (7.7c), we have
\[
[\partial_N a_{ij}, e_{uv}] = \langle [\partial a]_{ij}, e_{uv} \rangle = [\partial a, e]_{ij}^{\prime} [\partial a, e]_{iv}^{\prime} + [\partial a, e]_{rj}^{\prime} [\partial a, e]_{rj}^{\prime} = 0,
\]
where the last identity is due to (5.6f).
Similarly, by (7.7a) and (7.7b), we can write
\[
\langle \partial_N a_{ij}, \partial_N b_{uv} \rangle = \langle (\partial a)_{ij}, (\partial b)_{uv} \rangle = \langle \partial a, \partial b \rangle_{uv}^{ij} \langle \partial a, \partial b \rangle_{iv}^{\prime} = 0,
\]
where we used (5.6c) in the last identity.

Now, since \( \partial \) acts on tensor products by the Leibniz identity — see (5.7), we can decompose (5.6a) as follows
\[
\begin{align*}
\partial \langle e, f \rangle' \otimes \langle e, f \rangle'' &= [e, f]'_i [e, f]''_r + [f, e]'_r [f, e]''_i \\
\langle e, f \rangle' \otimes \partial \langle e, f \rangle'' &= [e, f]'_i [e, f]''_r + [f, e]'_r [f, e]''_i \\
\end{align*}
\]
(7.10a)
\[
\begin{align*}
\langle e, f \rangle' \otimes \partial \langle e, f \rangle'' &= [e, f]'_i [e, f]''_r + [f, e]'_r [f, e]''_i \\
\partial \langle e, f \rangle' \otimes \langle e, f \rangle'' &= [e, f]'_i [e, f]''_r + [f, e]'_r [f, e]''_i \\
\end{align*}
\]
(7.10b)

So, using (7.7c) and (7.10), we have:
\[
\begin{align*}
[e_{ij}, f_{uv}] + [f_{uv}, e_{ij}] &= [e, f]'_{iv}_{uv} [e, f]''_{rv} + [e, f]'_{rv}_{iv} [e, f]''_{iv} [f, e]'_{iv}_{rv} + [f, e]'_{rv}_{iv} [f, e]''_{iv} \\
 &= \partial (\langle e, f \rangle)'_{uv} (\langle e, f \rangle)'_{iv} + \langle e, f \rangle'_{iv} \partial (\langle e, f \rangle)'_{uv} \\
 &= \partial_N (\langle e, f \rangle)'_{uv} \langle e, f \rangle''_{iv} + \langle e, f \rangle''_{iv} \partial_N (\langle e, f \rangle)'_{uv} \\
 &= \partial_N (\langle e, f \rangle)'_{uv} \langle e, f \rangle''_{iv} = \partial_N \langle e_{ij}, f_{uv} \rangle,
\end{align*}
\]
where we used (7.7a) and (7.7b), and thus (5.1a) follows.

To prove (5.1b), we will need the following result:

**Claim 7.5.** Let \((A, E, \langle - , - \rangle, \partial, [-, -])\) be a double Courant–Dorfman algebra. Then, for all \(e, f, g \in E\), the following identity holds:
\[
\langle f, g \rangle' \otimes \langle e, \partial \langle f, g \rangle'' \rangle = \langle \partial \langle e, f \rangle', g \rangle'' \otimes [e, [e, g]]' + [\partial \langle e, f \rangle', g \rangle'' \otimes [e, [e, g]]' + \langle [\partial \langle e, f \rangle', g \rangle'', [e, g]]' + \langle e, [e, g]]' \otimes [e, [e, g]]' \rangle_1.
\]
(7.11)

**Proof.** By (5.6c) and (3.9), we have
\[
\begin{align*}
\langle e, \partial \langle f, g \rangle'' \rangle' \otimes \langle e, \partial \langle f, g \rangle'' \rangle' &\otimes \langle f, g \rangle'' \\
&= \langle [e, f]'_i \otimes \langle [e, f]''_r, g \rangle'' \otimes [\partial \langle e, f \rangle', g \rangle'' \otimes [e, [e, g]]' + \langle [\partial \langle e, f \rangle', g \rangle'', [e, g]]' + \langle e, [e, g]]' \otimes [e, [e, g]]' \rangle' \rangle.
\end{align*}
\]
Applying the permutation \(\sigma_{(123)}\), (7.11) follows. \(\square\)

Now, using (7.7f) and the \(A_N\)-bilinearity of \(\langle - , - \rangle\), the left-hand side of (5.1b) can be written as
\[
\begin{align*}
\langle e_{ij}, \partial_N \langle f_{uv}, g_{pq} \rangle \rangle \\
&= \langle e_{ij}, \partial_N \langle \langle f, g \rangle'_{pv} \langle f, g \rangle''_{uv} \rangle \rangle \\
&= \langle e_{ij}, \partial_N \langle \langle f, g \rangle'_{pv} \rangle \langle f, g \rangle''_{uv} \rangle + \langle f, g \rangle'_{pv} \langle e_{ij}, (\partial_N \langle f, g \rangle')'_{uv} \rangle \\
&= \langle \langle e, \partial_N \langle f, g \rangle' \rangle_{uv} \langle e, \partial_N \langle f, g \rangle'' \rangle_{uv} + \langle f, g \rangle''_{uv} \langle e, \partial_N \langle f, g \rangle'' \rangle_{uv} \rangle \\
&= \langle \langle e, [e, g]'_i \rangle_{pv} \langle f, [e, g]''_r \rangle_{iv} + \langle [e, f]'_i \rangle_{pv} \langle e, [e, g]''_r \rangle_{iv} + \langle [e, f]'_i \rangle_{pv} \langle e, [e, g]''_r \rangle_{iv} \rangle \\
&= \langle \langle e, g]'_i \rangle_{pv} \langle f, [e, g]''_r \rangle_{iv} + \langle [e, f]'_i \rangle_{pv} \langle e, [e, g]''_r \rangle_{iv} + \langle [e, f]'_i \rangle_{pv} \langle e, [e, g]''_r \rangle_{iv} \rangle.
\end{align*}
\]
where the last identity is due to (5.6a) and Claim 7.5. On the other hand, by (7.7), we can rewrite the right-hand side of (5.1b) in the following way:

\[
\langle \langle e_{ij}, f_{uv} \rangle, g_{pq} \rangle + \langle f_{uv}, [e_{ij}, g_{pq}] \rangle = \langle [e, f]_{l_{i,j}} [e, f]_{l_{i,v}} g_{pq} \rangle + \langle [e, f]_{r_{i,j}} [e, f]_{r_{i,v}} g_{pq} \rangle + \langle f_{uv}, [e, g]_{r_{i,j}} g_{pq} \rangle + \langle f_{uv}, [e, g]_{r_{i,q}} g_{pq} \rangle
\]

\[
= \langle [e, f]_{l_{i,j}} g_{pq} \rangle [e, f]_{l_{i,v}} + \langle [e, f]_{r_{i,j}} g_{pq} \rangle [e, f]_{r_{i,v}} + \langle [e, f]_{l_{i,j}} g_{pq} \rangle [e, f]_{r_{i,q}} + \langle [e, f]_{r_{i,j}} g_{pq} \rangle [e, f]_{r_{i,q}}
\]

(7.13)

Since we are working in the commutative setting, (7.12) and (7.13) agree, and (5.1b) is satisfied.

Finally, we need to prove that the Jacobi identity (5.1d) holds:

\[
[e_{ij}, [f_{uv}, g_{pq}]] = [[e_{ij}, f_{uv}], g_{pq}] + [f_{uv}, [e_{ij}, g_{pq}]].
\]

(7.14)

Firstly, applying (7.10a) (resp. (7.10b)) in the last summand of (5.8a) (resp. (5.8b)), we obtain the identities

\[
[e, [f, g]]_l \otimes [e, [f, g]]_r \otimes [f, g]'' = [e, g] \otimes \langle f, \partial [e, g]'' \rangle \otimes \langle f, \partial [e, g]'' \rangle
\]

\[
+ \partial \langle [e, f]_l, g \rangle \otimes [e, f]_r \otimes \langle [e, f]_l, g \rangle'' - [g, [e, f]]_l \otimes [e, f]_r \otimes [g, [e, f]]_r,
\]

(7.15a)

\[
\langle e, \partial [f, g]_l \rangle \otimes \langle e, \partial [f, g]_r \rangle \otimes [f, g]'' = [e, g] \otimes [f, [e, g]]_l \otimes [f, [e, g]]_r
\]

\[
+ \langle [e, f]_l, g \rangle \otimes [e, f]_r \otimes \partial \langle [e, f]_l, g \rangle'' - [g, [e, f]]_l \otimes [e, f]_r \otimes [g, [e, f]]_r.
\]

(7.15b)

Next, by (7.7) and (5.1a), we rewrite the term in the left-hand side of (7.14) in the following way:

\[
[e_{ij}, [f_{uv}, g_{pq}]]
\]

\[
= [e_{ij}, [f, g]]_{l_{i,pv}} [f, g]_{r_{i,pu}} + [e_{ij}, [f, g]]_{r_{i,pu}} [f, g]_{r_{i,qv}}
\]

\[
= [f, g]_{l_{i,pv}} [e_{ij}, [f, g]]_{r_{i,qv}} + [e_{ij}, [f, g]]_{r_{i,pu}} [f, g]_{r_{i,qv}}
\]

\[
+ [f, g]_{r_{i,pu}} [e_{ij}, [f, g]]_{r_{i,qv}} + [e_{ij}, [f, g]]_{r_{i,pu}} [f, g]_{r_{i,qv}}
\]

(7.16)
By using (7.15a), (5.8b), (A.5c), (A.5a), (A.5b) and (7.15b), we can rewrite the six terms obtained in (7.16) as

\[
[e, g]_{r,pj} \langle f, \partial[e, g]_{l,iv} \rangle_{pq} + \partial(\partial(\langle e, f, l, g \rangle_{l,iv})_{pq})_{l,iv} \langle e, f, l, g \rangle_{l,iv}
\]

\[
- [g, [e, f]]_{r,pj} \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,ur} + \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} - \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} + \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,iv}.
\]

(7.17)

Note that in the sixth summand we used (3.9). Next, to deal with the first summand at the right-hand side of (7.14), we use (7.7) to obtain:

\[
[g_{pq}, [e, f]]_{l,uv}
\]

\[
= [g_{pq}, \langle e, f \rangle_{l,ur} \langle e, f \rangle_{l,iv}] + \langle g_{pq}, [e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle g_{pq}, \partial_N(\langle e, f \rangle_{l,iv}) \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle g_{pq}, \partial_N(\langle e, f \rangle_{l,ur}) \rangle_{pq}
\]

\[
- [g, [e, f]]_{r,pj} \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,ur} + \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} - \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} + \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,iv}.
\]

(7.18)

Similarly, using (7.7), the fact that \(\partial_N\) is a derivation of \(A_N\), and (7.3), we have

\[
\partial_N([e, f]_{l,uv}, g_{pq})
\]

\[
= \partial_N(\langle [e, f]_{l,ur}, [e, f]_{l,iv} \rangle_{pq} + \langle [e, f]_{l,iv}, g_{pq} \rangle + \langle [e, f]_{l,ur}, g_{pq} \rangle + \langle [e, f]_{l,iv}, g_{pq} \rangle + \langle [e, f]_{l,ur}, g_{pq} \rangle + \langle [e, f]_{l,iv}, g_{pq} \rangle)
\]

\[
- [g, \partial[e, f]_{l,ur} \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,ur} + \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} - \langle e, f \rangle_{l,iv} \langle g, \partial[e, f]_{l,ur} \rangle_{pq} + \langle e, f \rangle_{l,iv} \langle e, g \rangle_{l,iv} + \langle e, f \rangle_{l,iv} \langle e, f \rangle_{l,iv}.
\]

(7.19)

where in the first three summands in the last line, we applied the symmetry of \(\langle -,- \rangle\). Therefore, by (5.1a), (7.18) and (7.19), we can rewrite the first summand at the right-hand
side of (7.14) as
\[
[e_{ij}, f_{uw}], g_{pq}] - [g_{pq}, e_{ij}, f_{uw}]
\]
\[
= \partial_N \langle [e_{ij}, f_{uw}], g_{pq} \rangle + \langle \partial_N e_{ij}, f_{uw} \rangle_{ij} + \langle e_{ij}, \partial_N f_{uw} \rangle_{ij} + \langle e_{ij}, f_{uw} \rangle \partial_N g_{pq} + \langle [e_{ij}, f_{uw}], g_{pq} \rangle \partial_N e_{ij} + \langle e_{ij}, f_{uw} \rangle \partial_N g_{pq} + \langle e_{ij}, f_{uw} \rangle \partial_N g_{pq} + \langle e_{ij}, f_{uw} \rangle \partial_N g_{pq}.
\]
(7.20)

Finally, interchanging \( f \) and \( g \) in (7.19) (and consequently the indices \( u \leftrightarrow p \) and \( v \leftrightarrow q \)), it is straightforward to check that the second summand at the right-hand side of (7.14) is:
\[
[f_{uw}, e_{ij}, g_{pq}] = \langle e_{ij}, f_{uw} \rangle \langle g_{pq}, e_{ij} \rangle + \langle e_{ij}, f_{uw} \rangle \langle g_{pq}, e_{ij} \rangle + \langle e_{ij}, f_{uw} \rangle \langle g_{pq}, e_{ij} \rangle + \langle e_{ij}, f_{uw} \rangle \langle g_{pq}, e_{ij} \rangle.
\]
(7.21)

Then, by the commutativity of \( A_N \), the sum of (7.20) and (7.21) is (7.17). Consequently, the Jacobi identity (5.14) holds, and Theorem 7.4 follows.

**APPENDIX A. SOME USEFUL IDENTITIES ON DOUBLE COURANT–DORFMAN ALGEBRAS**

In this appendix we present two some technical results that are needed to prove the main results of this article: Lemma A.1 is used in §6.2 in the proof of Theorem 6.1 and Lemma A.3 is important in the proof of Theorem 7.4.

**Lemma A.1.** Let \((A, E, [\cdot, \cdot, \cdot], \partial, [\cdot, \cdot, \cdot])\) be a double Courant–Dorfman algebra. Then the following identity holds:
\[
\langle e, [f, g] \rangle_L - \langle f, \partial [e, g] \rangle_R - \langle [e, f], g \rangle_R + \langle \partial [e, f], g \rangle_L = 0,
\]
for all \( e, f, g \in E \).

**Proof.** The key point of the proof is the following

**Claim A.2.** Let \( e, f, g \in E \). Then,
\[
\langle e, [f, g] \rangle_{s} \langle f, [g, e] \rangle_{s} = \langle f, [e, g] \rangle_{s} + \langle e, [f, g] \rangle_{s}.
\] (A.1)

**Proof.** By applying the permutation \( \sigma_{(132)} \) to (5.62), we obtain
\[
\langle g, \partial [e, f] \rangle_{s} \langle e, f \rangle + \langle g, \partial [e, f] \rangle_{s} \langle e, f \rangle = \langle e, [f, g] \rangle_{s} \langle f, [g, e] \rangle_{s} + \langle g, \partial [e, f] \rangle_{s} \langle [f, g] \rangle_{s}.
\] (A.2)
where we used (3.10) and (3.11). On the other hand, by (5.7) and (3.9), we can rewrite the right-hand side of (A.1):

\[ 
\langle \partial \langle e, f \rangle, g \rangle_L = \langle \partial \langle e, f \rangle', g \rangle \otimes \langle e, f \rangle'' \\
= \langle g, \partial \langle e, f \rangle' \rangle'' \otimes \langle e, f \rangle'' \otimes \langle g, \partial \langle e, f \rangle' \rangle'. 
\]  
(A.3)

Similarly, the left-hand side of (A.1) reads as:

\[ 
\langle e, [g, f]'' \rangle_L + \langle f, [g, e]'' \rangle_R \\
= \langle e, [g, f]'' \rangle \otimes [g, f]' + [g, e]'' \otimes \langle f, [g, e]'' \rangle \\
= \langle e, [g, f]'' \rangle' \otimes \langle e, [g, f]'' \rangle'' \otimes [g, f]' + [g, e]'' \otimes \langle [g, e]'' \rangle' \otimes \langle [g, e]'' \rangle' 
\]  
(A.4)

where we used the symmetry of \( \langle -, - \rangle \) in the last line. Since (A.3) coincides with the left-hand side of (A.2), and (A.4) coincides with the right-hand side of (A.2), (A.1) holds as desired.

Now, by (5.6g) and (5.6a), we have

\[ 
0 = \langle e, \partial \langle f, g \rangle \rangle_L - \langle f, [e, g] \rangle_R - \langle [e, f], g \rangle_L \\
= \langle e, [f, g] \rangle_L - \langle f, \partial \langle e, g \rangle \rangle_R - \langle [e, f], g \rangle_L + \langle e, [g, f]'' \rangle_L + \langle [g, e]'' \rangle_R \\
= \langle e, [f, g] \rangle_L - \langle f, \partial \langle e, g \rangle \rangle_R - \langle [e, f], g \rangle_L + \partial \langle \langle e, f, g \rangle \rangle_L, 
\]

where in the last line we used Claim A.2.

**Lemma A.3.** Let \((A, E, \langle -, -, \rangle, \partial, [-, -])\) be a double Courant–Dorfman algebra. For all \(e, f, g \in E\), the following identities hold:

\[ 
[e, [f, g]]' = [e, [f, g]]' \otimes [f, g]' = \partial[e, f]'' \otimes \langle g, [e, f]'' \rangle' \otimes \langle g, [e, f]'' \rangle'' \\
+ [f, e, g]' \otimes [e, g]' \otimes [f, [e, g]']' - [e, f]' \otimes \langle g, \partial[e, f]'' \rangle' \otimes \langle g, \partial[e, f]'' \rangle'', 
\]  
(A.5a)

\[ 
[e, [f, g]]' \otimes [e, [f, g]]'' \otimes [f, g]' = [e, f]' \otimes \partial \langle g, [e, f]'' \rangle' \otimes \langle g, [e, f]'' \rangle'' \\
+ \langle f, \partial[e, g]'' \rangle' \otimes [e, g]' \otimes \langle f, \partial[e, g]'' \rangle' - [e, f]' \otimes \langle g, [e, f]'' \rangle' \otimes [g, [e, f]'' \rangle'' 
\]  
(A.5b)

\[ 
\langle e, \partial[f, g]'' \rangle' \otimes \langle e, \partial[f, g]'' \rangle'' \otimes [f, g]' = [e, f]' \otimes \langle g, [e, f]'' \rangle' \otimes \partial \langle g, [e, f]'' \rangle'' \\
+ [f, e, g]' \otimes [e, g]' \otimes [f, [e, g]']' - [e, f]' \otimes [g, [e, f]'' \rangle' \otimes [g, [e, f]'' \rangle''. 
\]  
(A.5c)

**Proof.** By (5.6f) reads as

\[ 
[e, [g, f]]_L = [[e, g], f]_L + [g, [e, f]]_R. 
\]  
(A.6)
for all \(e, f, g \in E\). Firstly, using (5.3) and (5.4), we need to rewrite each term appearing in (A.6). By (3.6a) and (3.6b), the term at the left-hand side of (A.6) can be written as

\[
[e, [g, f]]_L
= [e, \partial\langle g, f \rangle]_L - [e, [f, g]]_L
= [e, \partial\langle g, f \rangle]_L - [e, [f, g]]_L
\]

By (5.6a) and (5.6b), the term at the left-hand side of (A.6) can be written as

\[
\partial\langle e, \partial\langle g, f \rangle \rangle + \langle e, \partial\langle g, f \rangle \rangle - \langle e, \partial\langle f, g \rangle \rangle
\]

Next, applying (5.6a) into the first summand at the right-hand side of (A.6), we have

\[
[[e, g], f]_L
= [[e, g], f]_L + \langle [e, g], f \rangle \partial [e, g]_L + \langle [e, g], f \rangle \partial [e, g]_L
\]

Finally, in the last term of (A.6), by (5.3) and (5.4), we obtain

\[
[g, [e, f]]_R
= [e, f]_R \otimes [g, [e, f]]_R + [e, f]_R \otimes [g, [e, f]]_R
\]
Hence, collecting the terms obtained in (A.7), (A.8), and (A.9) that belong to \(E \otimes A \otimes A\), \(A \otimes E \otimes A\), and \(A \otimes A \otimes E\), we obtain from (A.6) the following three identities:

\[
\begin{align*}
[e, [f, g]]''_r & \otimes [e, [f, g]]''_l \otimes [f, g], \\
= & \partial \langle e, \partial \langle g, f \rangle \rangle' \otimes \langle e, \partial \langle g, f \rangle \rangle'' \otimes \langle g, f \rangle'' - \partial \langle [e, g], f \rangle' \otimes [e, g]' \otimes \langle [e, g], f \rangle'' \\
& + \langle [f, e, g]''_r \otimes [e, g]' \otimes [f, e, g]' \otimes \langle [e, g], f \rangle'' \\
& \langle e, [f, g]]''_r \otimes [e, [f, g]]''_l \otimes [f, g], \\
= & \langle e, \partial \langle g, f \rangle \rangle' \otimes \partial \langle e, \partial \langle g, f \rangle \rangle'' \otimes \langle g, f \rangle'' - \langle [e, g], f \rangle' \otimes \partial [e, g]' \otimes \langle [e, g], f \rangle'' \\
& + \langle [f, e, g]''_r \otimes [e, g]' \otimes \langle [e, g], f \rangle'' \\
& \langle e, [f, g]]''_r \otimes [e, [f, g]]''_l \otimes [f, g], \\
= & \langle e, \partial \langle g, f \rangle \rangle' \otimes \partial \langle e, \partial \langle g, f \rangle \rangle'' \otimes \langle g, f \rangle'' - \langle [e, g], f \rangle' \otimes \partial [e, g]' \otimes \langle [e, g], f \rangle'' \\
& + \langle [f, e, g]''_r \otimes [e, g]' \otimes \langle [e, g], f \rangle''.
\end{align*}
\]

(A.10)

On the other hand, if we apply the derivation \(\partial\) on (5.6b) and project onto the corresponding spaces, we obtain the following identities:

\[
\begin{align*}
\partial \langle e, \partial \langle g, f \rangle \rangle' & \otimes \langle e, \partial \langle g, f \rangle \rangle'' \otimes \langle g, f \rangle'' = \partial \langle [e, g], f \rangle' \otimes \langle g, [e, f]''_r \otimes \langle g, f \rangle'' \\
& + \partial \langle [e, g], f \rangle' \otimes [e, g]' \otimes \langle [e, g], f \rangle'', \\
\langle e, \partial \langle g, f \rangle \rangle' & \otimes \partial \langle e, \partial \langle g, f \rangle \rangle'' \otimes \langle g, f \rangle'' = \langle e, f \rangle' \otimes \partial \langle g, [e, f]''_r \otimes \langle g, f \rangle'' \\
& + \langle [e, g], f \rangle' \otimes \partial [e, g]' \otimes \langle [e, g], f \rangle'', \\
\langle e, \partial \langle g, f \rangle \rangle' & \otimes \partial \langle e, \partial \langle g, f \rangle \rangle'' \otimes \partial \langle g, f \rangle'' = \langle [e, g], f \rangle' \otimes \partial \langle g, [e, f]''_r \otimes \langle g, f \rangle'' \\
& + \langle [e, g], f \rangle' \otimes \partial [e, g]' \otimes \langle [e, g], f \rangle''.
\end{align*}
\]

(A.11)

Finally, plugging (A.11) into (A.10) gives (A.5), as we wished.

\[\square\]
