# THE MEASURES WITH $L^{2}$-BOUNDED RIESZ TRANSFORM AND THE PAINLEVÉ PROBLEM FOR LIPSCHITZ HARMONIC FUNCTIONS 

XAVIER TOLSA

#### Abstract

This work provides a geometric characterization of the measures $\mu$ in $\mathbb{R}^{n+1}$ with polynomial upper growth of degree $n$ such that the $n$-dimensional Riesz transform $\mathcal{R} \mu(x)=\int \frac{x-y}{|x-y|^{n+1}} d \mu(y)$ belongs to $L^{2}(\mu)$. More precisely, it is shown that $$
\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\|\mu\| \approx \iint_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \frac{\mu(B(x, r))}{r^{n}} \frac{d r}{r} d \mu(x)+\|\mu\|
$$ where $\beta_{\mu, 2}(x, r)^{2}=\inf _{L} \frac{1}{r^{n}} \int_{B(x, r)}\left(\frac{\operatorname{dist}(y, L)}{r}\right)^{2} d \mu(y)$, with the infimum taken over all affine $n$-planes $L \subset \mathbb{R}^{n+1}$. As a corollary, one obtains a characterization of the removable sets for Lipschitz harmonic functions in terms of a metric-geometric potential and one deduces that the class of removable sets for Lipschitz harmonic functions is invariant by bilipschitz mappings.

## 1. Introduction

Given a Radon measure $\mu$ in $\mathbb{R}^{n+1}$, its ( $n$-dimensional) Riesz transform at $x \in \mathbb{R}^{n+1}$ is defined by

$$
\mathcal{R} \mu(x)=\int \frac{x-y}{|x-y|^{n+1}} d \mu(y),
$$

whenever the integral makes sense. For $f \in L_{\text {loc }}^{1}(\mu)$, one writes $\mathcal{R}_{\mu} f(x)=\mathcal{R}(f \mu)(x)$. Given $\varepsilon>0$, the $\varepsilon$-truncated Riesz transform of $\mu$ equals

$$
\mathcal{R}_{\varepsilon} \mu(x)=\int_{|x-y|>\varepsilon} \frac{x-y}{|x-y|^{n+1}} d \mu(y),
$$

and the operator $\mathcal{R}_{\mu, \varepsilon}$ is defined by $\mathcal{R}_{\mu, \varepsilon} f(x)=\mathcal{R}_{\varepsilon}(f \mu)(x)$.
We say that $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$ if the operators $\mathcal{R}_{\mu, \varepsilon}$ are bounded uniformly in $L^{2}(\mu)$ uniformly on $\varepsilon$, and then we denote

$$
\left\|\mathcal{R}_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)}=\sup _{\varepsilon>0}\left\|\mathcal{R}_{\mu, \varepsilon}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)} .
$$

We also write

$$
\mathcal{R}_{*} \mu(x)=\sup _{\varepsilon>0}\left|\mathcal{R}_{\varepsilon} \mu(x)\right|, \quad \text { pv } \mathcal{R} \mu(x)=\lim _{\varepsilon>0} \mathcal{R}_{\varepsilon} \mu(x),
$$

in case that the latter limit exists. Remark that, sometimes, abusing notation we will write $\mathcal{R} \mu$ instead of pv $\mathcal{R} \mu$.

This paper provides a full geometric description of the measures $\mu$ with no point masses such that $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$. In the case $n=1$, such description has already been obtained (see [MV], [Le], To1]), relying on the connection between Menger curvature and the Cauchy kernel found by Melnikov [Me]. In higher dimensions, a similar connection is missing, and thus the obtention of analogous results presents major difficulties. In the case when the measure $\mu$ is AD-regular (i.e., Ahlfors-David regular) that geometric description is equivalent to the codimension 1 David-Semmes problem, solved by Nazarov, the author of the current paper, and Volberg in (NToV1]. Recall that a measure $\mu$ is AD-regular (or $n$-AD-regular) if there exists a constant $C>0$ such that

$$
C^{-1} r^{n} \leq \mu(B(x, r)) \leq C r^{n} \quad \text { for all } x \in \operatorname{supp} \mu \text { and } 0<r \leq \operatorname{diam}(\operatorname{supp} \mu) .
$$

One of the main motivations for the description of the measures $\mu$ such that $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$ is the characterization of the removable singularities for Lipschitz harmonic functions. Also, one may expect other applications regarding the study of harmonic and elliptic measures. Indeed, in some of the recent advances on this topic, the connection between harmonic measure, the Riesz transform, and rectifiability has played an essential role (see AHM+], AMT, and AMTV, for example).

Next we need to introduce additional notation. For a ball $B \subset \mathbb{R}^{n+1}$, we consider its $n$-dimensional density (with respect to $\mu$ ):

$$
\theta_{\mu}(B)=\frac{\mu(B)}{r(B)^{n}}
$$

and its $\beta_{2, \mu}$ coefficient:

$$
\beta_{2, \mu}(B)=\inf _{L}\left(\frac{1}{r(B)^{n}} \int_{B}\left(\frac{\operatorname{dist}(x, L)}{r(B)}\right)^{2} d \mu(x)\right)^{1 / 2}
$$

where the infimum is taken over all $n$-planes $L \subset \mathbb{R}^{n+1}$ and $r(B)$ stands for the radius of $B$. For $B=B(x, r)$ we may also write $\theta_{\mu}(x, r)$ and $\beta_{2, \mu}(x, r)$ instead of $\theta_{\mu}(B)$ and $\beta_{2, \mu}(B)$. The coefficients $\beta_{2, \mu}$ were introduced by David and Semmes in their fundamental works [DS1], DS2] on uniform rectifiability. They can be considered as $L^{2}$ variants of some analogous coefficients considered previously by Peter Jones in his celebrated travelling salesman theorem Jo.

The first main result of this paper is the following.
Theorem 1.1. Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ satisfying the polynomial growth condition

$$
\begin{equation*}
\mu(B(x, r)) \leq \theta_{0} r^{n} \quad \text { for all } x \in \operatorname{supp} \mu \text { and all } r>0 \tag{1.1}
\end{equation*}
$$

and such that $\mathcal{R}_{*} \mu(x)<\infty \mu$-a.e. Then

$$
\begin{equation*}
\iint_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r} d \mu(x) \leq C\left(\|\operatorname{pv} \mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|\right) \tag{1.2}
\end{equation*}
$$

where $C$ is an absolute constant.
Let us remark that the growth condition (1.1) and the assumption that $\mathcal{R}_{*} \mu(x)<$ $\infty \mu$-a.e. imply the existence of principal values $\operatorname{pv} \mathcal{R} \mu(x) \mu$-a.e., by [NToV2], and so $\|\mathrm{pv} \mathcal{R} \mu\|_{L^{2}(\mu)}$ is well defined.

A converse to the estimate (1.2) also holds: if $\mu$ satisfies the growth condition (1.1), then

$$
\begin{equation*}
\|\operatorname{pv} \mathcal{R} \mu\|_{L^{2}(\mu)}^{2} \leq C \iint_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r} d \mu(x)+C \theta_{0}^{2}\|\mu\| \tag{1.3}
\end{equation*}
$$

where $C$ is an absolute constant. This was shown in AT in the case $n=1$, and in Gi] in full generality.

From (1.3), Theorem 1.1, and a direct application of the $T 1$ theorem for non-doubling measures ( $\mathrm{NTrV1}, \mathrm{NTrV2})$ one deduces the following.

Theorem 1.2. Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ with no point masses. Then $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$ if and only if it satisfies the polynomial growth condition

$$
\begin{equation*}
\mu(B(x, r)) \leq C r^{n} \quad \text { for all } x \in \operatorname{supp} \mu \text { and all } r>0 \tag{1.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{B} \int_{0}^{r(B)} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r} d \mu(x) \leq C^{2} \mu(B) \quad \text { for any ball } B \subset \mathbb{R}^{n+1} \tag{1.5}
\end{equation*}
$$

Further, the optimal constant $C$ is comparable to $\left\|\mathcal{R}_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)}$.

In the case $n=1$ the preceding results are already known. They were proven in AT, relying on the corona decomposition involving the curvature of $\mu$ from [To3]. Further, for arbitrary $n>1$, Theorems 1.1 and 1.2 were proven recently by Dąbrowski and the author [DT] for a special class of measures $\mu$ with an appropriate Wolff type energy satisfying some scale invariant estimates. In fact, the proof of Theorems 1.1 and 1.2 in full generality in the current paper relies heavily on the results from [DT].

It is also known that if one assumes that there exists a sufficiently large class of $L^{2}(\mu)$ bounded singular integral operators with an odd Calderon-Zygmund kernel, then the condition (1.5) holds, in any codimension (i.e., assuming that, instead of $\mathbb{R}^{n+1}$, the ambient space is $\mathbb{R}^{d}$, with $d \geq n$ ). This was proved in JNT.

Observe that, when $\mu$ is $n$-AD-regular, $\theta_{\mu}(x, r) \approx 1$ for all $x \in \operatorname{supp} \mu$ and $0<r \leq$ $\operatorname{diam}(\operatorname{supp} \mu)$, and so the condition (1.5) is equivalent to the uniform $n$-rectifiability of $\mu$, by [DS1]. So one deduces that the $L^{2}(\mu)$ boundedness of $\mathcal{R}_{\mu}$ implies the uniform $n$ rectifiability of $\mu$ and then one recovers the solution of the David-Semmes problem from [NToV1. Recall that a measure $\mu$ in $\mathbb{R}^{d}$ is called uniformly $n$-rectifiable (UR) if it is $n$-AD-regular and there exist constants $\kappa, M>0$ such that for all $x \in \operatorname{supp} \mu$ and all $0<r \leq \operatorname{diam}(\operatorname{supp} \mu)$ there is a Lipschitz mapping $g$ from the ball $B_{n}(0, r) \subset \mathbb{R}^{n}$ to $\mathbb{R}^{d}$ with $\operatorname{Lip}(g) \leq M$ such that

$$
\mu\left(B(x, r) \cap g\left(B_{n}(0, r)\right)\right) \geq \kappa r^{n} .
$$

It is worth comparing Theorem 1.2 with a related result obtained in [JNRT] in connection with the fractional Riesz transform $\mathcal{R}^{s}$ associated with the kernel $x /|x|^{s+1}$ for $s \in(n, n+1)$. The precise result, which involves the $s$-dimensional density $\theta_{\mu}^{s}(x, r)=\mu(B(x, r)) r^{-s}$, is the following.

Theorem ( $J$ JNRT]). Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ with no point masses and let $s \in(n, n+1)$. Then $\mathcal{R}_{\mu}^{s}$ is bounded in $L^{2}(\mu)$ if and only if

$$
\begin{equation*}
\int_{B} \int_{0}^{r(B)} \theta_{\mu}^{s}(x, r)^{2} \frac{d r}{r} d \mu(x) \leq C^{2} \mu(B) \quad \text { for any ball } B \subset \mathbb{R}^{n+1} \tag{1.6}
\end{equation*}
$$

Further, the optimal constant $C$ is comparable to $\left\|\mathcal{R}_{\mu}^{s}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)}$.
In the preceding theorem one does not need to ask any growth condition analogous to (1.4) (with $n$ interchanged with $s$ ) because this condition is already implied by (1.6). Observe that in (1.6) the density $\theta_{\mu}^{s}(x, r)$ replaces $\beta_{2, \mu}(x, r)^{2}$ in (1.5), which scales similarly to $\theta^{s}(x, r)$ when $n=s$. On the other hand, the proof of the last theorem in [JNRT] makes an extensive use of blowup techniques, which essentially rely on the fact that any measure $\mu$ satisfying the growth condition $\mu(B(x, r)) \leq r^{s}$ for all $x \in \mathbb{R}^{n+1}, r>0$, and such that $\mathcal{R}^{s} \mu=0$ in a suitable $B M O(\mu)$ sense, must be the zero measure (see [JN1], JN2]). In the codimension 1 case, one might expect that if $\mu$ satisfies (1.4) and $\mathcal{R} \mu=0$ in the $B M O(\mu)$ sense, then $\mu=\left.c \mathcal{H}^{n}\right|_{L}$ for some $n$-plane $L$. However, this is still an open problem. If this were known to be true, probably in the present paper (and in [DT]) we could use blowup arguments analogous to the ones in JNRT.

As shown in AT, the finiteness of the double integral on the left hand side of (1.2) is equivalent to the existence of a suitable corona decomposition for $\mu$ satisfying an appropriate packing condition. This condition is stable by bilipschitz maps (see also [Gi] for more details). So we get the following corollary.

Corollary 1.3. Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ with no point masses. Let $\varphi: \mathbb{R}^{n+1} \rightarrow$ $\mathbb{R}^{n+1}$ be a bilipschitz map. Let $\sigma=\varphi \# \mu$ be the image measure of $\mu$ by $\varphi$. If $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$, then $\mathcal{R}_{\sigma}$ is bounded in $L^{2}(\sigma)$. Further,

$$
\left\|\mathcal{R}_{\sigma}\right\|_{L^{2}(\sigma) \rightarrow L^{2}(\sigma)} \leq C\left\|\mathcal{R}_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)},
$$

where $C$ depends only on the bilipschitz constant of $\varphi$.
Remark that, up to now, the preceding result was not known even for the case of invertible affine maps such as the one defined by

$$
\varphi\left(x_{1}, \ldots, x_{n+1}\right)=\left(2 x_{1}, x_{2}, \ldots, x_{n+1}\right)
$$

As shown in [Gi], the conditions (1.4) and (1.5) imply the $L^{2}(\mu)$ boundedness of any singular integral operator of the form

$$
T_{\mu} f(x)=\int K(x-y) f(y) d \mu(y)
$$

where $K$ is an odd kernel such that

$$
\begin{equation*}
\left|\nabla^{j} K(x)\right| \lesssim \frac{1}{|x|^{n+j}} \quad \text { for all } x \neq 0 \text { and } 0 \leq j \leq 2 \tag{1.7}
\end{equation*}
$$

(remark that $T_{\mu}$ is said to be bounded in $L^{2}(\mu)$ is the truncated operators $T_{\mu, \varepsilon}$, defined analogously to $\mathcal{R}_{\mu, \varepsilon}$, are bounded in $L^{2}(\mu)$ uniformly on $\varepsilon>0$ ). Then we deduce the following.
Corollary 1.4. Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ with no point masses. Let $T_{\mu}$ be a singular integral operator associated with an odd kernel $K$ satisfying (1.7). If $\mathcal{R}_{\mu}$ is bounded in $L^{2}(\mu)$, then $T_{\mu}$ is also bounded in $L^{2}(\mu)$. Further,

$$
\left\|T_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)} \leq C\left\|\mathcal{R}_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)},
$$

where $C$ depends just on $n$ and the implicit constants in (1.7).
Lipschitz We turn now to the applications of the results above to Lipschitz harmonic functions and Lipschitz harmonic capacity. Given a compact set $E \subset \mathbb{R}^{n+1}$, one says that $E$ is removable for Lipschitz harmonic functions if for any open set $\Omega \supset E$, any function $f: \Omega \rightarrow \mathbb{R}$ which is Lipschitz in $\Omega$ and harmonic in $\Omega \backslash E$ can be extended in a harmonic way to the whole $\Omega$. To study this problem and some related questions on approximation by Lipschitz harmonic functions it is useful to introduce the Lipschitz harmonic capacity $\kappa$ (see $[\mathrm{Pa}$ and $[\mathrm{MP}]$ ). This is defined by

$$
\kappa(E)=\sup |\langle\Delta f, 1\rangle|,
$$

where the supremum is taken over all Lipschitz functions $f: \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ which are harmonic in $\mathbb{R}^{n+1} \backslash E$ and satisfy $\|\nabla f\|_{\infty} \leq 1$, with $\Delta f$ understood in the sense of distributions. It turns out that $E$ is removable for Lipschitz harmonic functions if and only if $\kappa(E)=0$.

Extending previous results for analytic capacity from To2, Volberg showed in [0] that

$$
\kappa(E) \approx \sup \mu(E)
$$

where the supremum is taken over all measures $\mu$ satisfying the polynomial growth condition (1.4) with constant $C=1$ and such that $\left\|\mathcal{R}_{\mu}\right\|_{L^{2}(\mu) \rightarrow L^{2}(\mu)} \leq 1$. Combining this result with Theorem 1.2, we obtain:

Corollary 1.5. Let $E \subset \mathbb{R}^{n+1}$ be compact. Then

$$
\kappa(E) \approx \mu(E)
$$

where the supremum is taken over all Radon measures $\mu$ such that

$$
\mu(B(x, r)) \leq r^{n} \quad \text { for all } x \in \operatorname{supp} \mu \text { and all } r>0
$$

and

$$
\iint_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r} d \mu(x) \leq \mu(E) .
$$

To derive this corollary, remark that if $\mu$ satisfies the conditions above, by Chebyshev one deduces that there is a big piece $F \subset E \cap \operatorname{supp} \mu$, with $\mu(F) \approx \mu(E)$, such that the measure $\widetilde{\mu}=\left.\mu\right|_{F}$ satisfies (1.5), and so $\mathcal{R}_{\widetilde{\mu}}$ is bounded in $L^{2}(\widetilde{\mu})$. Hence $\kappa(E) \gtrsim \mu(F) \approx \mu(E)$. The converse direction of the corollary is a straightforward consequence of the aforementioned theorem of Volberg and Theorem 1.2,

As explained above, the conditions on the measure $\mu$ in Corollary 1.5 are stable by bilipschitz maps. So we deduce that if $\varphi: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ is bilipschitz, then

$$
\kappa(E) \approx \kappa(\varphi(E)) \quad \text { for any compact set } E \subset \mathbb{R}^{n+1}
$$

with the implicit constant just depending on the bilipschitz constant of $\varphi$ and the ambient dimension.

Another suggestive characterization of the capacity $\kappa(E)$ can be given in terms of the following potential, which we call the Jones-Wolff potential of $\mu$ :

$$
U_{\mu}(x)=\sup _{r>0} \theta_{\mu}(x, r)+\left(\int_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r}\right)^{1 / 2}
$$

Corollary 1.6. Let $E \subset \mathbb{R}^{n+1}$ be compact. Then

$$
\kappa(E) \approx \sup \left\{\mu(E): U_{\mu}(x) \leq 1 \forall x \in E\right\} .
$$

An immediate consequence of this result is that $E$ is non-removable for Lipschitz harmonic functions if and only if it supports a non-zero measure such that $U_{\mu}(x) \leq 1$ for all $x \in E$.

The characterization of the capacity $\kappa$ and of removable sets for Lipschitz harmonic functions in terms of a metric-geometric potential such as $U_{\mu}$ should be considered as an analogue of the characterization of analytic capacity and of removable sets for bounded analytic functions in terms of curvature of measures To2]. So one can think of the results stated in Corollaries 1.5 and 1.6 as possible solutions of the Painlevé problem for Lipschitz harmonic functions.

Next we describe the main ideas involved in the proof of Theorem 1.1. As explained above, the proof relies on the results obtained in [DT]. More precisely, for a Radon measure $\sigma$ we consider the Wolff type energy

$$
\mathbb{E}(\sigma)=\iint_{0}^{\infty}\left(\frac{\sigma(B(x, r))}{r^{n-\frac{3}{8}}}\right)^{2} \frac{d r}{r} d \sigma(x)=\iint_{0}^{\infty} r^{\frac{3}{4}} \theta_{\sigma}\left(B(x, r)^{2} \frac{d r}{r} d \sigma(x) .\right.
$$

As in [DT], given the Radon measure $\mu$, we consider a suitably modified version of the David-Mattila lattice $\mathcal{D}_{\mu}$ associated with $\mu$. Then for a given $\mathcal{P}$-doubling cube $Q \in \mathcal{D}_{\mu}$, we
let $\mathcal{E}(4 Q)$ be an appropriate discrete version of $\mathbb{E}\left(\left.\mu\right|_{4 Q}\right) \ell(Q)^{-3 / 4}$. We say that a $\mathcal{P}$-doubling cube $Q$ has high energy, and we write $Q \in \mathrm{HE}$, if

$$
\mathcal{E}(4 Q) \geq M_{0}^{2} \Theta(Q)^{2} \mu(Q)
$$

where $M_{0} \gg 1$ is some fixed constant, $\Theta(Q)$ is another discrete version of $\theta_{\mu}\left(2 B_{Q}\right)$, and $B_{Q}$ is a ball concentric with $Q$, containing $Q$, with radius comparable to $\ell(Q)$ (for the precise definitions of $\mathcal{P}$-doubling cubes, $\Theta(Q)$, and $\mathcal{E}(4 Q)$ see Section (3). In [DT, Main Theorem 3.4] it is shown that

$$
\iint_{0}^{\infty} \beta_{2, \mu}(x, r)^{2} \theta_{\mu}(x, r) \frac{d r}{r} d \mu(x) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|+\sum_{Q \in \mathrm{HE}} \mathcal{E}(4 Q)\right)
$$

So to prove Theorem 1.1 it suffices to show that

$$
\begin{equation*}
\sum_{Q \in \mathrm{HE}} \mathcal{E}(4 Q) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|\right) . \tag{1.8}
\end{equation*}
$$

This is the task we perform in this paper (see Main Proposition (3.7).
To prove (1.8) we introduce in Section 3 a related energy $\mathcal{E}_{\infty}$ which is more appropriate for the stopping time conditions and the bootstrapping argument involved in the proof of (1.8). The objective is then to show that the family DB of $\mathcal{P}$-doubling cubes $Q$ such that

$$
\mathcal{E}_{\infty}(9 Q) \geq M_{0} \Theta(Q)^{2} \mu(Q)
$$

satisfies a Carleson type estimate analogous to (1.8). The first step is the construction of a family (called GDF) of cubes $Q$ which, in a sense, contain many stopping cubes whose density is much larger than the density $\Theta(Q)$. The selection of this family, in Section 4 is one of the key steps for the proof proof of Theorem 1.1. In Section 5 we associate a family of "tractable trees" of cubes with each cube from GDF, by arguments somewhat similar to others appearing in [DT], although here we need to consider different and additional stopping conditions. In the tractable trees the density of $\mu$ oscillates in such a way that one can bound from below the Haar coefficients of $\mathcal{R} \mu$ for the cubes which belong to that tree or are close to that tree. For each tractable tree $\mathcal{T}$, this is shown by a variational argument applied to a measure $\eta$ that approximates the measure $\mu$ at the level of some regularized stopping cubes of $\mathcal{T}$. This argument provides a lower estimate for $\|\mathcal{R} \eta\|_{L^{p}(\eta)}$, essentially in the same way as in [DT], and so we refer to the appropriate lemma from [DT] when this is required in Section 7.

To complete the estimates from below for the Haar coefficients of $\mathcal{R} \mu$ near the tree $\mathcal{T}$, in Section 8 we transfer the lower estimates obtained for $\|\mathcal{R} \eta\|_{L^{p}(\eta)}$ to $\mathcal{R} \mu$. This is another of the delicate key points of the proof of Theorem [1.2. It requires much more precise estimates than other related arguments appearing in [DT] or [JNRT], mainly because the presence of cubes from DB ( or HE ) in the tree $\mathcal{T}$ originates "error terms" in the transference of those estimates which are difficult to control. Most important, we can only quantify the presence of cubes from DB in most of the trees $\mathcal{T}$ by a bootstrapping argument which gives rather weak bounds.

In the whole paper we denote by $C$ or $c$ some constants that may depend on the dimension and perhaps other fixed parameters. Their values may change at different occurrences. On the contrary, constants with subscripts, like $C_{0}$, retain their values. For $a, b \geq 0$, we write $a \lesssim b$ if there is $C>0$ such that $a \leq C b$. We write $a \approx b$ to mean $a \lesssim b \lesssim a$.

## 2. The modified dyadic lattice of David and Mattila and the dyadic MARTINGALE DECOMPOSITION

2.1. The David-Mattila lattice. We recall now the properties of the dyadic lattice of cubes with small boundaries of David-Mattila associated with a Radon measure $\mu$. This lattice has been constructed in [DM, Theorem 3.2]. Later on we will state some additional useful properties of $\mathcal{D}_{\mu}$ that are obtained by modifying its construction as in [DT].

Lemma 2.1 (David, Mattila). Let $\mu$ be a compactly supported Radon measure in $\mathbb{R}^{d}$. Consider two constants $C_{0}>1$ and $A_{0}>5000 C_{0}$ and denote $E=\operatorname{supp} \mu$. Then there exists a sequence of partitions of $E$ into Borel subsets $Q, Q \in \mathcal{D}_{\mu, k}$, with the following properties:

- For each integer $k \geq 0, E$ is the disjoint union of the "cubes" $Q, Q \in \mathcal{D}_{\mu, k}$, and if $k<l, Q \in \mathcal{D}_{\mu, l}$, and $R \in \mathcal{D}_{\mu, k}$, then either $Q \cap R=\varnothing$ or else $Q \subset R$.
- The general position of the cubes $Q$ can be described as follows. For each $k \geq 0$ and each cube $Q \in \mathcal{D}_{\mu, k}$, there is a ball $B(Q)=B\left(x_{Q}, r(Q)\right)$ such that

$$
\begin{gathered}
x_{Q} \in E, \quad A_{0}^{-k} \leq r(Q) \leq C_{0} A_{0}^{-k} \\
E \cap B(Q) \subset Q \subset E \cap 28 B(Q)=E \cap B\left(x_{Q}, 28 r(Q)\right),
\end{gathered}
$$

and

$$
\text { the balls } 5 B(Q), Q \in \mathcal{D}_{\mu, k}, \text { are disjoint. }
$$

- The cubes $Q \in \mathcal{D}_{\mu, k}$ have small boundaries. That is, for each $Q \in \mathcal{D}_{\mu, k}$ and each integer $l \geq 0$, set

$$
\begin{aligned}
& N_{l}^{e x t}(Q)=\left\{x \in E \backslash Q: \operatorname{dist}(x, Q)<A_{0}^{-k-l}\right\} \\
& N_{l}^{i n t}(Q)=\left\{x \in Q: \operatorname{dist}(x, E \backslash Q)<A_{0}^{-k-l}\right\}
\end{aligned}
$$

and

$$
N_{l}(Q)=N_{l}^{e x t}(Q) \cup N_{l}^{i n t}(Q)
$$

Then

$$
\begin{equation*}
\mu\left(N_{l}(Q)\right) \leq\left(C^{-1} C_{0}^{-3 d-1} A_{0}\right)^{-l} \mu(90 B(Q)) \tag{2.1}
\end{equation*}
$$

- Denote by $\mathcal{D}_{\mu, k}^{d b}$ the family of cubes $Q \in \mathcal{D}_{\mu, k}$ for which

$$
\begin{equation*}
\mu(100 B(Q)) \leq C_{0} \mu(B(Q)) \tag{2.2}
\end{equation*}
$$

We have that $r(Q)=A_{0}^{-k}$ when $Q \in \mathcal{D}_{\mu, k} \backslash \mathcal{D}_{\mu, k}^{d b}$ and

$$
\begin{equation*}
\mu(100 B(Q)) \leq C_{0}^{-l} \mu\left(100^{l+1} B(Q)\right) \quad \text { for all } l \geq 1 \text { with } 100^{l} \leq C_{0} \text { and } Q \in \mathcal{D}_{\mu, k} \backslash \mathcal{D}_{\mu, k}^{d b} \tag{2.3}
\end{equation*}
$$

Remark 2.2. The constants $C_{0}$ and $A_{0}$ are chosen so that

$$
A_{0}=C_{0}^{C(d)}
$$

where $C(d)$ depends just on $d$ and $C_{0}$ is big enough.

We use the notation $\mathcal{D}_{\mu}=\bigcup_{k \geq 0} \mathcal{D}_{\mu, k}$. Observe that the families $\mathcal{D}_{\mu, k}$ are only defined for $k \geq 0$. So the diameter of the cubes from $\mathcal{D}_{\mu}$ are uniformly bounded from above. For $Q \in \mathcal{D}_{\mu, k}$, we set $\ell(Q)=56 C_{0} A_{0}^{-k}$ and we call it the side length of $Q$. Notice that

$$
C_{0}^{-1} \ell(Q) \leq \operatorname{diam}(28 B(Q)) \leq \ell(Q)
$$

Observe that $r(Q) \approx \operatorname{diam}(Q) \approx \ell(Q)$. Also we call $x_{Q}$ the center of $Q$, and the cube $Q^{\prime} \in \mathcal{D}_{\mu, k-1}$ such that $Q^{\prime} \supset Q$ the parent of $Q$. We denote the family of cubes from $\mathcal{D}_{\mu, k+1}$ which are contained in $Q$ by $\mathcal{C h}(Q)$, and we call their elements children or sons of $Q$. We set $B_{Q}=28 B(Q)=B\left(x_{Q}, 28 r(Q)\right)$, so that

$$
E \cap \frac{1}{28} B_{Q} \subset Q \subset B_{Q} \subset B\left(x_{Q}, \ell(Q) / 2\right)
$$

For a given $\gamma \in(0,1)$, let $A_{0}$ be big enough so that the constant $C^{-1} C_{0}^{-3 d-1} A_{0}$ in (2.1) satisfies

$$
C^{-1} C_{0}^{-3 d-1} A_{0}>A_{0}^{\gamma}>10 .
$$

Then we deduce that, for all $0<\lambda \leq 1$,

$$
\begin{array}{r}
\mu(\{x \in Q: \operatorname{dist}(x, E \backslash Q) \leq \lambda \ell(Q)\})+\mu\left(\left\{x \in 3.5 B_{Q} \backslash Q: \operatorname{dist}(x, Q) \leq \lambda \ell(Q)\right\}\right)  \tag{2.4}\\
\leq_{\gamma} c \lambda^{\gamma} \mu\left(3.5 B_{Q}\right) .
\end{array}
$$

We denote $\mathcal{D}_{\mu}^{d b}=\bigcup_{k \geq 0} \mathcal{D}_{\mu, k}^{d b}$. Note that, in particular, from (2.2) it follows that

$$
\begin{equation*}
\mu\left(3 B_{Q}\right) \leq \mu(100 B(Q)) \leq C_{0} \mu(Q) \quad \text { if } Q \in \mathcal{D}_{\mu}^{d b} \tag{2.5}
\end{equation*}
$$

For this reason we will call the cubes from $\mathcal{D}_{\mu}^{d b}$ doubling. Given $Q \in \mathcal{D}_{\mu}$, we denote by $\mathcal{D}_{\mu}(Q)$ the family of cubes from $\mathcal{D}_{\mu}$ which are contained in $Q$. Analogously, we write $\mathcal{D}_{\mu}^{d b}(Q)=\mathcal{D}_{\mu}^{d b} \cap \mathcal{D}(Q)$.

As shown in [DM, Lemma 5.28], every cube $R \in \mathcal{D}_{\mu}$ can be covered $\mu$-a.e. by a family of doubling cubes:

Lemma 2.3. Let $R \in \mathcal{D}_{\mu}$. Suppose that the constants $A_{0}$ and $C_{0}$ in Lemma 2.1 are chosen suitably. Then there exists a family of doubling cubes $\left\{Q_{i}\right\}_{i \in I} \subset \mathcal{D}_{\mu}^{d b}$, with $Q_{i} \subset R$ for all $i$, such that their union covers $\mu$-almost all $R$.

The following result is proved in [DM, Lemma 5.31].
Lemma 2.4. Let $R \in \mathcal{D}_{\mu}$ and let $Q \subset R$ be a cube such that all the intermediate cubes $S$, $Q \subsetneq S \subsetneq R$ are non-doubling (i.e. belong to $\mathcal{D}_{\mu} \backslash \mathcal{D}_{\mu}^{d b}$ ). Suppose that the constants $A_{0}$ and $C_{0}$ in Lemma 2.1 are chosen suitably. Then

$$
\begin{equation*}
\mu(100 B(Q)) \leq A_{0}^{-10 d(J(Q)-J(R)-1)} \mu(100 B(R)) \tag{2.6}
\end{equation*}
$$

Given a ball $B \subset \mathbb{R}^{n+1}$, we consider its $n$-dimensional density:

$$
\theta_{\mu}(B)=\frac{\mu(B)}{r(B)^{n}}
$$

We will also write $\theta_{\mu}(x, r)$ instead of $\theta_{\mu}(B(x, r))$.
From the preceding lemma we deduce:

Lemma 2.5. Let $Q, R \in \mathcal{D}_{\mu}$ be as in Lemma 2.4. Then

$$
\theta_{\mu}(100 B(Q)) \leq\left(C_{0} A_{0}\right)^{n+1} A_{0}^{-9 d(J(Q)-J(R)-1)} \theta_{\mu}(100 B(R))
$$

and

$$
\sum_{S \in \mathcal{D}_{\mu}: Q \subset S \subset R} \theta_{\mu}(100 B(S)) \leq c \theta_{\mu}(100 B(R)),
$$

with $c$ depending on $C_{0}$ and $A_{0}$.
For the easy proof, see [To4, Lemma 4.4], for example.
2.2. The dyadic martingale decomposition and the additional properties from [DT]. For $f \in L^{2}(\mu)$ and $Q \in \mathcal{D}_{\mu}$ we denote

$$
\begin{equation*}
\Delta_{Q} f=\sum_{S \in \mathcal{C h}(Q)} m_{\mu, S}(f) \chi_{S}-m_{\mu, Q}(f) \chi_{Q} \tag{2.7}
\end{equation*}
$$

where $m_{\mu, S}(f)$ stands for the average of $f$ on $S$ with respect to $\mu$. Then we have the orthogonal expansion, for any cube $R \in \mathcal{D}_{\mu}$,

$$
\chi_{R}\left(f-m_{\mu, R}(f)\right)=\sum_{Q \in \mathcal{D}_{\mu}(R)} \Delta_{Q} f,
$$

in the $L^{2}(\mu)$-sense, so that

$$
\| \chi_{R}\left(f-m_{\mu, R}(f)\left\|_{L^{2}(\mu)}^{2}=\sum_{Q \in \mathcal{D}_{\mu}(R)}\right\| \Delta_{Q} f \|_{L^{2}(\mu)}^{2} .\right.
$$

In several places in this paper we will have to estimate terms such as $\left\|\mathcal{R}\left(\chi_{2 B_{Q} \backslash Q} \mu\right)\right\|_{L^{2}\left(\left.\mu\right|_{Q}\right)}$, and so we will need to deal with integrals such as

$$
\int_{2 B_{Q} \backslash Q}\left(\int_{Q} \frac{1}{|x-y|^{n}} d \mu(y)\right)^{2} d \mu(x) .
$$

We will describe now how this integral can be estimated in terms of the energy $\mathcal{E}(9 Q)$ when using the enhanced David-Mattila lattice from DT].

We need some additional notation. Given $Q \in \mathcal{D}_{\mu}$ and $\lambda>1$, we let $\lambda Q$ be the union of cubes $P$ from the same generation as $Q$ such that $\operatorname{dist}\left(x_{Q}, P\right) \leq \lambda \ell(Q)$. Notice that

$$
\begin{equation*}
\lambda Q \subset B\left(x_{Q},\left(\lambda+\frac{1}{2}\right) \ell(Q)\right) . \tag{2.8}
\end{equation*}
$$

Also, we let

$$
\mathcal{D}_{\mu}(\lambda Q)=\left\{P \in \mathcal{D}_{\mu}: P \subset \lambda Q, \ell(P) \leq \ell(Q)\right\}
$$

and

$$
\mathcal{D}_{\mu, k}(\lambda Q)=\left\{P \in \mathcal{D}_{\mu}: P \subset \lambda Q, \ell(P)=A_{0}^{-k} \ell(Q)\right\}, \quad \mathcal{D}_{\mu}^{k}(\lambda Q)=\bigcup_{j \geq k} \mathcal{D}_{\mu, j}(\lambda Q)
$$

Next we set

$$
\begin{equation*}
\widetilde{\mathcal{D}}_{\mu}^{\text {int }}(Q)=\left\{P \in \mathcal{D}_{\mu}(Q): 2 B_{P} \cap(\operatorname{supp} \mu \backslash Q) \neq \varnothing\right\} \tag{2.9}
\end{equation*}
$$

and

$$
\begin{equation*}
\widetilde{\mathcal{D}}_{\mu}^{e x t}(Q)=\left\{P \in \mathcal{D}_{\mu}: \ell(P) \leq \ell(Q), P \subset \mathbb{R}^{n+1} \backslash Q, 2 B_{P} \cap Q \neq \varnothing\right\} \tag{2.10}
\end{equation*}
$$

Also,

$$
\begin{equation*}
\widetilde{\mathcal{D}}_{\mu}(Q)=\widetilde{\mathcal{D}}_{\mu}^{i n t}(Q) \cup \widetilde{\mathcal{D}}_{\mu}^{\text {ext }}(Q), \tag{2.11}
\end{equation*}
$$

and

$$
\widetilde{\mathcal{D}}_{\mu, k}(Q)=\left\{P \in \widetilde{\mathcal{D}}_{\mu}: P \subset \lambda Q, \ell(P)=A_{0}^{-k} \ell(Q)\right\}
$$

We need the following auxiliary result, whose proof follows from a straightforward calculation (see [DT, Lemma 2.7]).

Lemma 2.6. Let $\mu$ be a compactly supported Radon measure in $\mathbb{R}^{d}$ and $Q \in \mathcal{D}_{\mu}$. For any $\alpha \in(0,1)$, we have

$$
\begin{align*}
\int_{2 B_{Q} \backslash Q}\left(\int_{Q} \frac{1}{|x-y|^{n}} d \mu(y)\right)^{2} d \mu(x)+ & \int_{Q}\left(\int_{2 B_{Q} \backslash Q} \frac{1}{|x-y|^{n}} d \mu(y)\right)^{2} d \mu(x)  \tag{2.12}\\
& \lesssim_{\alpha, A_{0}} \sum_{P \in \widetilde{\mathcal{D}}_{\mu}(Q)}\left(\frac{\ell(Q)}{\ell(P)}\right)^{\alpha} \theta_{\mu}\left(2 B_{P}\right)^{2} \mu(P)
\end{align*}
$$

The following result is proven in [DT, Lemma 2.9].
Lemma 2.7. Let $\mu$ be a compactly supported Radon measure in $\mathbb{R}^{d}$. Assume that $\mu$ has polynomial growth of degree $n$ and let $\gamma \in(0,1)$. The lattice $\mathcal{D}_{\mu}$ from Lemma 2.1] can be constructed so that the following holds for all all $Q \in \mathcal{D}_{\mu}$ :

$$
\begin{equation*}
\sum_{P \in \widetilde{\mathcal{D}}_{\mu}(Q)}\left(\frac{\ell(Q)}{\ell(P)}\right)^{\frac{1-\gamma}{2}} \theta_{\mu}\left(2 B_{P}\right)^{2} \mu(P) \leq C(\gamma) \sum_{P \in \mathcal{D}_{\mu}: P \subset 9 Q}\left(\frac{\ell(P)}{\ell(Q)}\right)^{\gamma} \theta_{\mu}\left(2 B_{P}\right)^{2} \mu(P) . \tag{2.13}
\end{equation*}
$$

Remark that saying that $\mu$ has polynomial growth of degree $n$ means that (1.1) holds for some arbitrary constant $\theta_{0}$. In the lemma this assumption is just used to ensure that the sums above are finite. Further, the constant $C(\gamma)$ does not depend on the polynomial growth constant $\theta_{0}$.

By combining Lemmas 2.6 and 2.7 we obtain
Lemma 2.8. Let $\mu$ be a compactly supported Radon measure in $\mathbb{R}^{d}$. Assume that $\mu$ has $n$-polynomial growth and let $\gamma \in(0,1)$. The lattice $\mathcal{D}_{\mu}$ from Lemma 2.1 can be constructed so that the following holds for all $Q \in \mathcal{D}_{\mu}$ :

$$
\begin{aligned}
\int_{2 B_{Q} \backslash Q}\left(\int_{Q} \frac{1}{|x-y|^{n}} d \mu(y)\right)^{2} d \mu(x)+ & \int_{Q}\left(\int_{2 B_{Q} \backslash Q} \frac{1}{|x-y|^{n}} d \mu(y)\right)^{2} d \mu(x) \\
& \leq C(\gamma) \sum_{P \in \mathcal{D}_{\mu}: P \subset 2 Q}\left(\frac{\ell(P)}{\ell(Q)}\right)^{\gamma} \theta_{\mu}\left(2 B_{P}\right)^{2} \mu(P)
\end{aligned}
$$

## 3. The family $h^{k}(Q)$ and the Main Proposition

3.1. $\mathcal{P}$-doubling cubes and the family $\mathrm{hd}^{k}(Q)$. In the rest of the paper we assume that $\mu$ is a compactly supported Radon measure with polynomial growth of degree $n$ such that $\mathcal{R}_{*} \mu(x)<\infty \mu$-a.e. We assume that $\mathcal{D}_{\mu}$ is a David-Mattila dyadic lattice satisfying the properties described in the preceding section, in particular, the ones in Lemmas 2.1 and 2.8, with $\gamma=9 / 10$. By rescaling, we assume that $\mathcal{D}_{\mu, k}$ is defined for all $k \geq k_{0}$, with $A_{0}^{-k_{0}} \approx \operatorname{diam}(\operatorname{supp} \mu)$, and we also suppose that there is a unique cube in $\mathcal{D}_{\mu, k_{0}}$ which coincides with the whole supp $\mu$. Further, from now on, we allow all the constants $C$ and all implicit constants in the relationship " $\lesssim$ " to depend on the parameters $C_{0}, A_{0}$ of the dyadic lattice of David-Mattila.

We denote

$$
\mathcal{P}(Q)=\sum_{R \in \mathcal{D}_{\mu}: R \supset Q} \frac{\ell(Q)}{\ell(R)^{n+1}} \mu\left(2 B_{R}\right)
$$

We say that a cube $Q$ is $\mathcal{P}$-doubling, and we write $Q \in \mathcal{D}_{\mu}^{\mathcal{P}}$, if

$$
\mathcal{P}(Q) \leq C_{d} \frac{\mu\left(2 B_{Q}\right)}{\ell(Q)^{n}}
$$

for $C_{d}=4 A_{0}^{n}$. Notice that

$$
\mathcal{P}(Q) \approx_{C_{0}} \sum_{R \in \mathcal{D}_{\mu}: R \supset Q} \frac{\ell(Q)}{\ell(R)} \theta_{\mu}\left(2 B_{R}\right)
$$

and thus $Q$ being $\mathcal{P}$-doubling implies that

$$
\sum_{R \in \mathcal{D}_{\mu}: R \supset Q} \frac{\ell(Q)}{\ell(R)} \theta_{\mu}\left(2 B_{R}\right) \leq C_{d}^{\prime} \theta_{\mu}\left(2 B_{Q}\right)
$$

for some constant $C_{d}^{\prime}$ depending on $C_{d}$. Conversely, the latter condition implies that $Q$ is $\mathcal{P}$-doubling with another constant $C_{d}$ depending on $C_{d}^{\prime}$.

As shown in [DT, Lemma 3.1], from the properties of the David-Mattila lattice, it follows:
Lemma 3.1. Suppose that $C_{0}$ and $A_{0}$ to be chosen suitably. If $Q$ is $\mathcal{P}$-doubling, then $Q \in \mathcal{D}_{\mu, d b}$.

Notice that, by the preceding lemma, if $Q$ is $\mathcal{P}$-doubling, then

$$
\sum_{R \in \mathcal{D}_{\mu}: R \supset Q} \frac{\ell(Q)^{n+1}}{\ell(R)^{n+1}} \mu\left(2 B_{R}\right) \lesssim_{C_{d}} \mu(Q)
$$

For technical reasons that will be more evident below, it is appropriate to consider a discrete version of the density $\theta_{\mu}$. Given $\lambda \geq 1$ and $Q \in \mathcal{D}_{\mu}$, we let

$$
\Theta(Q)=A_{0}^{k n} \quad \text { if } \frac{\mu\left(2 B_{Q}\right)}{\ell(Q)^{n}} \in\left[A_{0}^{k n}, A_{0}^{(k+1) n}\right)
$$

Clearly, $\Theta(Q) \approx \theta_{\mu}\left(2 B_{Q}\right)$. Notice also that if $\Theta(Q)=A_{0}^{k}$ and $P$ is a son of $Q$, then

$$
\frac{\mu\left(2 B_{P}\right)}{\ell(P)^{n}} \leq \frac{\mu\left(2 B_{Q}\right)}{\ell(P)^{n}}=A_{0}^{n} \frac{\mu\left(2 B_{Q}\right)}{\ell(Q)^{n}}
$$

Thus,

$$
\begin{equation*}
\Theta(P) \leq A_{0}^{n} \Theta(Q) \quad \text { for any son } P \text { of } Q . \tag{3.1}
\end{equation*}
$$

Given $Q \in \mathcal{D}_{\mu}$ and $k \geq 1$, we denote by hd $^{k}(Q)$ the family of maximal cubes $P \in \mathcal{D}_{\mu}$ satisfying

$$
\begin{equation*}
\ell(P)<\ell(Q), \quad \Theta(P) \geq A_{0}^{k n} \Theta(Q) \tag{3.2}
\end{equation*}
$$

The following result is proved in [DT, Lemma 3.3] (see also [RT, Lemma 2.1]).
Lemma 3.2. Let $Q_{0}, Q_{1}, \ldots, Q_{m}$ be a family of cubes from $\mathcal{D}_{\mu}$ such that $Q_{j}$ is son of $Q_{j-1}$ for $1 \leq j \leq m$. Suppose that $Q_{j}$ is not $\mathcal{P}$-doubling for $1 \leq j \leq m$. Then

$$
\begin{equation*}
\frac{\mu\left(B_{Q_{m}}\right)}{\ell\left(Q_{m}\right)^{n}} \leq A_{0}^{-m / 2} \mathcal{P}\left(Q_{0}\right) \tag{3.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathcal{P}\left(Q_{m}\right) \leq 2 A_{0}^{-m / 2} \mathcal{P}\left(Q_{0}\right) \tag{3.4}
\end{equation*}
$$

We also have:
Lemma 3.3. Let $Q \in \mathcal{D}_{\mu}$ be $\mathcal{P}$-doubling. Then, for $k \geq 4$, every $P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)$ is also $\mathcal{P}$-doubling and moreover $\Theta(P)=A_{0}^{n k} \Theta(Q)$.

This is proven in [DT, Lemma 3.2]. From this result it follows immediately that

$$
\begin{equation*}
\Theta(P) \approx A_{0}^{n k} \Theta(Q) \quad \text { for all } P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q) \text { and all } k \geq 1 \tag{3.5}
\end{equation*}
$$

3.2. The energies $\mathcal{E}, \mathcal{E}^{H}, \mathcal{E}_{\infty}$, and the Main Proposition. For given $\lambda \geq 1$ and $Q \in \mathcal{D}_{\mu}$, we consider the energy

$$
\mathcal{E}(\lambda Q)=\sum_{P \in \mathcal{D}_{\mu}(\lambda Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{3 / 4} \Theta(P)^{2} \mu(P)
$$

We also denote

$$
\mathcal{E}^{H}(\lambda Q)=\sum_{k \geq 0} \sum_{P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(\lambda Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{3 / 4} \Theta(P)^{2} \mu(P)
$$

and

$$
\mathcal{E}_{\infty}(\lambda Q)=\sup _{k \geq 1} \sum_{P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(\lambda Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) .
$$

Lemma 3.4. For every $Q \in \mathcal{D}_{\mu}$ we have

$$
\mathcal{E}(9 Q) \lesssim \mathcal{E}^{H}(9 Q) \lesssim \mathcal{E}_{\infty}(9 Q)
$$

Proof. For a given $R \in \operatorname{hd}^{k}(Q)$, we denote by $\operatorname{Tree}_{H}(R)$ the family of cubes from $\mathcal{D}_{\mu}$ that are contained in $R$ and are not contained in any cube from $\mathrm{hd}^{k+1}(Q)$. Using that $\Theta(P) \lesssim \Theta(R)$ for all $P \in \operatorname{Tree}_{H}(R)$ (remember that we do not keep track of the implicit constants depending on $A_{0}$ ), we get

$$
\begin{aligned}
\mathcal{E}(9 Q) & =\sum_{k \geq 0} \sum_{R \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)} \sum_{P \in \operatorname{Tree}_{H}(R)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{3 / 4} \Theta(P)^{2} \mu(P) \\
& \lesssim \sum_{k \geq 0} \sum_{R \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)} \Theta(R)^{2} \sum_{P \in \operatorname{Tree}_{H}(R)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{3 / 4} \mu(P) \\
& \lesssim \sum_{k \geq 0} \sum_{R \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(R)}{\ell(Q)}\right)^{3 / 4} \Theta(R)^{2} \mu(R)=\mathcal{E}^{H}(9 Q) .
\end{aligned}
$$

To show $\mathcal{E}^{H}(9 Q) \lesssim \mathcal{E}_{\infty}(9 Q)$, denote

$$
m_{k}(Q)=\frac{1}{\ell(Q)} \max \left\{\ell(P): P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)\right\}
$$

Then we have

$$
\begin{aligned}
\mathcal{E}^{H}(9 Q) & =\sum_{k \geq 0} \sum_{P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{3 / 4} \Theta(P)^{2} \mu(P) \\
& \leq \sum_{k \geq 0} m_{k}(Q)^{1 / 4} \sum_{P \in h^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)
\end{aligned}
$$

To estimate $m_{k}(Q)$, observe that if $P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)$ and $k \geq 4$, then

$$
A_{0}^{k n} \theta_{\mu}\left(2 B_{Q}\right) \approx \theta_{\mu}\left(2 B_{P}\right) \lesssim \frac{\ell(Q)^{n}}{\ell(P)^{n}} \theta_{\mu}\left(2 B_{Q}\right)
$$

Hence, $\ell(P) \lesssim A_{0}^{-k} \ell(Q)$, and thus, since this also holds in the case $1 \leq k \leq 3$,

$$
\begin{equation*}
m_{k}(Q) \lesssim A_{0}^{-k} \quad \text { for all } k \geq 1 \tag{3.6}
\end{equation*}
$$

Consequently,

$$
\begin{aligned}
\mathcal{E}^{H}(9 Q) & \lesssim \sum_{k \geq 0} A_{0}^{-k / 4} \sum_{P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \theta_{\mu}\left(2 B_{P}\right)^{2} \mu(P) \\
& \lesssim \sum_{k \geq 0} A_{0}^{-k / 4} \mathcal{E}_{\infty}(9 Q) \approx \mathcal{E}_{\infty}(9 Q) .
\end{aligned}
$$

Remark 3.5. For the record, notice that, given $Q \in \mathcal{D}_{\mu}^{\mathcal{P}}$ and

$$
\begin{equation*}
m_{k}(Q)=\frac{1}{\ell(Q)} \max \left\{\ell(P): P \in \operatorname{hd}^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)\right\} \tag{3.7}
\end{equation*}
$$

as shown in (3.6), it turns out that

$$
\begin{equation*}
m_{k}(Q) \leq C_{1} A_{0}^{-k} \tag{3.8}
\end{equation*}
$$

Given $M \gg 1$ (we will choose $M>A_{0}^{2 n} \gg 1$ ), we say that $Q \in \mathcal{D}_{\mu}$ is $M$-dominated from below if there exists some $k \geq 1$ such that

$$
\begin{equation*}
\sum_{P \in h d^{k}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)>M^{2} \Theta(Q)^{2} \mu(9 Q) \tag{3.9}
\end{equation*}
$$

or in other words,

$$
\begin{equation*}
\mathcal{E}_{\infty}(9 Q)>M^{2} \Theta(Q)^{2} \mu(9 Q) \tag{3.10}
\end{equation*}
$$

We denote by $\operatorname{DB}(M)$ the family of cubes from $\mathcal{D}_{\mu}^{\mathcal{P}}$ that are $M$-dominated from below. Notice that the cubes from $\operatorname{DB}(M)$ are assumed to be $\mathcal{P}$-doubling.

Recall that in [DT, Theorem 3.4], the following result has been obtained:
Theorem 3.6. Let $\mu$ be a Radon measure in $\mathbb{R}^{n+1}$ with polynomial growth of degree $n$ with constant $\theta_{0}$. For any choice of $M>1$, let

$$
\operatorname{HE}(M)=\left\{Q \in \mathcal{D}_{\mu}^{\mathcal{P}}: \mathcal{E}(4 Q) \geq M^{2} \Theta(Q)^{2} \mu(Q)\right\} .
$$

Then we have

$$
\begin{equation*}
\sum_{Q \in \mathcal{D}_{\mu}} \beta_{2, \mu}\left(2 B_{Q}\right)^{2} \Theta(Q) \mu(Q) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|+\sum_{Q \in \operatorname{HE}(M)} \mathcal{E}(4 Q)\right) \tag{3.11}
\end{equation*}
$$

with $C$ depending on $M$.
In the theorem above we wrote $\mathcal{R} \mu$ instead of pv $\mathcal{R} \mu$. From now on we will follow this notation. In the present paper we will obtain the next result.

Main Proposition 3.7. Suppose that $\mu$ has polynomial growth of degree $n$ with constant $\theta_{0}$ and $\mathcal{R}_{*} \mu(x)<\infty \mu$-a.e. Let $M_{0}=A_{0}^{k_{0} n}$, where $k_{0}$ is some big enough absolute constant depending just on $n$. Then

$$
\sum_{Q \in \operatorname{DB}\left(M_{0}\right)} \mathcal{E}_{\infty}(9 Q) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|\right),
$$

where $C$ depends just on $n$ and the parameters of the dyadic lattice $\mathcal{D}_{\mu}$.
Notice that if $Q \in \mathrm{HE}(M)$, by Lemma 3.4, then

$$
M^{2} \Theta(Q)^{2} \mu(Q) \leq \mathcal{E}(4 Q) \lesssim \mathcal{E}^{H}(4 Q) \lesssim \leq \mathcal{E}_{\infty}(9 Q)
$$

Hence, $Q \in \mathrm{DB}\left(M^{\prime}\right)$ for some $M^{\prime}$ depending on $M$. So, by combining Propositions 3.6 and 3.7 and choosing $M$ and $M_{0}$ appropriately, we deduce that

$$
\sum_{Q \in \mathcal{D}_{\mu}} \beta_{2, \mu}\left(2 B_{Q}\right)^{2} \Theta(Q) \mu(Q) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|\right)
$$

which implies Theorem 1.1.
The rest of the paper is devoted to the proof of Main Proposition 3.7.

## 4. The good dominating family GDF

Let

$$
\begin{equation*}
M \geq A_{0}^{k_{0} n}=: M_{0} \quad \text { for some } k_{0} \geq 4 \tag{4.1}
\end{equation*}
$$

For each $Q \in \mathrm{DB}(M)$ we choose the minimal $k(Q, M) \in \mathbb{N}$ such that (3.9) holds with $k=k(Q, M)$.

Lemma 4.1. Assume $k_{0}$ big enough in 4.1). For each $Q \in \mathrm{DB}(M)$, we have

$$
k(Q, M)>\frac{8 n-1}{8 n-2} k_{0}+4
$$

Proof. This follows from the fact that for $j \geq 0$,

$$
\begin{aligned}
\sum_{P \in \operatorname{hd}^{j}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) & \leq C A_{0}^{2 n j} \Theta(Q)^{2} m_{j}(Q)^{1 / 2} \sum_{P \in \operatorname{hd}^{j}(Q) \cap \mathcal{D}_{\mu}(9 Q)} \mu(P) \\
& \leq C_{1} A_{0}^{2 n j-\frac{j}{2}} \Theta(Q)^{2} \mu(9 Q),
\end{aligned}
$$

where we used (3.5) and we applied (3.8) to estimate $m_{j}(Q)$. Then, for $0 \leq j \leq \frac{8 n-1}{8 n-2} k_{0}+4$, we have

$$
\begin{aligned}
\sum_{P \in \text { hd }^{j}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) & \leq C_{1} A_{0}^{\left(2 n-\frac{1}{2}\right)\left(\frac{8 n-1}{8 n-2} k_{0}+4\right)} \Theta(Q)^{2} \mu(9 Q) \\
& =C_{1} M_{0}^{2} A_{0}^{-\frac{k_{0}}{4}+8 n-2} \Theta(Q)^{2} \mu(9 Q) .
\end{aligned}
$$

So, for $k_{0}$ big enough, the right hand side above is smaller than $M^{2} \Theta(Q)^{2} \mu(9 Q)$, which ensures that $k(Q, M)>\frac{8 n-1}{8 n-2} k_{0}+4$.

Let

$$
k_{\Lambda}=\frac{8 n-1}{8 n-2} k_{0},
$$

so that $k(Q, M)>k_{\Lambda}$ for each $Q \in \mathrm{DB}(M)$, by the preceding lemma. Assuming $k_{0}$ to be a multiple of $8 n-2$, it follows that $k_{\Lambda}$ is natural number. Notice also that $k_{\Lambda}$ is the mean of $k_{0}$ and $4 n k_{0} /(4 n-1)$, so that, if we let

$$
\Lambda=A_{0}^{k_{\Lambda} n}
$$

we have that $\Lambda$ is the geometric mean of $M_{0}$ and $M_{0}^{\frac{4 n}{4 n-1}}$, that is

$$
\begin{equation*}
\Lambda=M_{0}^{1 / 2} M_{0}^{\frac{2 n}{4 n-1}}=M_{0}^{\frac{8 n-1}{8 n-2}}>M_{0} . \tag{4.2}
\end{equation*}
$$

Observe that, for $Q \in \mathrm{DB}(M)$, taking into account that $k(Q, M)-k_{\Lambda}>4$,

$$
\begin{align*}
& M^{2} \Theta(Q)^{2} \mu(9 Q) \leq \sum_{P \in \operatorname{hd}^{k(Q, M)}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)  \tag{4.3}\\
&=\sum_{S \in \operatorname{hd}^{k(Q, M)-k_{\Lambda}(Q) \cap \mathcal{D}_{\mu}(9 Q)}} \sum_{P \in \operatorname{hd}^{k(Q, M)}(Q): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \\
& \leq \Lambda^{2} \sum_{S \in \operatorname{hd}^{k(Q, M)-k_{\Lambda}(Q) \cap \mathcal{D}_{\mu}(9 Q)}} \Theta(S)^{2} \sum_{P \in \operatorname{hd}^{k}(Q, M)}(Q): P \subset S \\
&\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \mu(P) .
\end{align*}
$$

Given $Q \in \mathrm{DB}(M)$ and $S \in \operatorname{hd}^{k(Q, M)-k_{\Lambda}}(Q) \cap \mathcal{D}_{\mu}(9 Q)$, we write $S \in G(Q, M)$ if

$$
\begin{equation*}
\mu(S) \leq 2 \Lambda^{2} \sum_{P \in \operatorname{hd}^{k}(Q, M)(Q): P \subset S}\left(\frac{\ell(P)}{\ell(S)}\right)^{1 / 2} \mu(P) \tag{4.4}
\end{equation*}
$$

We also denote $B(Q, M)=\mathrm{hd}^{k(Q, M)-k_{\Lambda}}(Q) \cap \mathcal{D}_{\mu}(9 Q) \backslash G(Q, M)$.
Given $\lambda>0$, for $Q \in \mathrm{DB}(M)$ and $S \in G(Q, M)$, we denote

$$
\operatorname{big}_{\lambda}(S)=\left\{P \in \operatorname{hd}^{k(Q, M)}: P \subset S, \ell(P) \geq \lambda \ell(S)\right\}
$$

Lemma 4.2. If $\lambda>0$ satisfies

$$
\begin{equation*}
\lambda \leq \frac{c_{0}}{\Lambda^{4}}=: \lambda_{0}(\Lambda) \tag{4.5}
\end{equation*}
$$

for some small absolute constant $c_{0} \in(0,1)$, then, for each $Q \in \mathrm{DB}(M)$ we have

$$
M^{2} \Theta(Q)^{2} \mu(Q) \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{S \in G(Q, M)}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \sum_{P \in \operatorname{big}_{\lambda}(S)} \Theta(P)^{2} \mu(P)
$$

Also, each $S \in G(Q, M)$ satisfies

$$
\Theta(S)^{2} \mu(S) \leq 4 \Lambda^{-\frac{1}{2 n}} \sum_{P \in \operatorname{big}_{\lambda}(S)} \Theta_{\mu}(P)^{2} \mu(P)
$$

Proof. Arguing as in (4.3), by the definition of $B(Q, M)$ we get

$$
\begin{aligned}
M^{2} \Theta_{\mu}(2 Q)^{2} \mu(9 Q) \leq & \sum_{S \in G(Q, M)} \sum_{P \in h^{k}(Q, M)}(Q): P \subset S \\
& \left.+\Lambda^{2} \sum_{S \in B(Q, M)} \Theta(S)^{2} \sum_{P \in h^{k}(Q, M)}^{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \\
\leq & \sum_{S \in G(Q, M)} \sum_{P \in \operatorname{hd}^{k}(Q, M)} \sum_{(Q): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \mu(P) \\
& +\frac{1}{2} \sum_{S \in B(Q, M)} \Theta(S)^{2}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \mu(S) .
\end{aligned}
$$

Using that $B(Q, M) \subset \operatorname{hd}^{k(Q, M)-k_{\Lambda}}(Q) \cap \mathcal{D}_{\mu}(9 Q)$ and that, by the definition of $k(Q, M)$,

$$
\sum_{S \in h^{k}(Q, M)-k_{\Lambda}(Q) \cap \mathcal{D}_{\mu}(9 Q)}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \Theta(S)^{2} \mu(S) \leq M^{2} \Theta(Q)^{2} \mu(9 Q),
$$

we get

$$
M^{2} \Theta(Q)^{2} \mu(9 Q) \leq 2 \sum_{S \in G(Q, M)} \sum_{P \in \text { hd }^{k}(Q, M)}(Q): P \subset S .
$$

Next, for $S \in G(Q, M)$, we split

$$
\sum_{P \in \operatorname{hd}^{k(Q, M)}(Q): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)=\sum_{P \in \operatorname{big}_{\lambda}(S)} \cdots+\sum_{P \in \operatorname{hd}^{k(Q, M)}(Q) \backslash \operatorname{big}_{\lambda}(S): P \subset S} \cdots .
$$

We estimate the last sum:
$\sum_{P \in \operatorname{hd}^{k(Q, M)}(Q) \backslash \operatorname{big}_{\lambda}(S): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \leq \lambda^{1 / 2}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \sum_{P \in h d^{k}(Q, M)} \sum_{(Q): P \subset S} \Theta(P)^{2} \mu(P)$

$$
\begin{aligned}
& \leq \lambda^{1 / 2}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \Lambda^{2} \Theta(S)^{2} \mu(S) \\
& \leq c_{0}^{1 / 2}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \Theta(S)^{2} \mu(S)
\end{aligned}
$$

taking into account the choice of $\lambda$ for the last estimate. By (4.4), since $S \in G(Q, M)$, we have

$$
\begin{align*}
\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \Theta(S)^{2} \mu(S) & \leq 2 \Lambda^{2}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \Theta(S)^{2} \sum_{P \in \mathrm{hd}^{k}(Q, M)} \sum_{(Q): P \subset S}\left(\frac{\ell(P)}{\ell(S)}\right)^{1 / 2} \mu(P)  \tag{4.6}\\
& \leq 2 \sum_{P \in \operatorname{hd}^{k}(Q, M)} \sum_{Q): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)
\end{align*}
$$

Hence, for $c_{0}$ small enough,
$\sum_{P \in \operatorname{hd}^{k(Q, M)}(Q) \backslash \operatorname{big}_{\lambda}(S): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \leq \frac{1}{2} \sum_{P \in \mathrm{hd}^{k}(Q, M)} \sum_{(Q): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P)$.
Consequently, for every $S \in G(Q, M)$,

$$
\begin{equation*}
\sum_{P \in \mathrm{hd}^{k}(Q, M)}(Q): P \subset S \mathrm{l}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \leq 2 \sum_{P \in \operatorname{big}_{\lambda}(S): P \subset S}\left(\frac{\ell(P)}{\ell(Q)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \tag{4.7}
\end{equation*}
$$

From the conditions $P \subset S$ and $\Theta(P)=\Lambda \Theta(S)$ we also get

$$
\Theta(P) \leq \Theta(S) \frac{\ell(S)^{n}}{\ell(P)^{n}}=\Lambda^{-1} \Theta(P) \frac{\ell(S)^{n}}{\ell(P)^{n}}
$$

Thus,

$$
\begin{equation*}
\ell(P) \leq \Lambda^{-1 / n} \ell(S) \tag{4.8}
\end{equation*}
$$

Then we derive

$$
M^{2} \Theta(Q)^{2} \mu(Q) \leq 4 \Lambda^{-\frac{1}{2 n}} \sum_{S \in G(Q, M)}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \sum_{P \in \operatorname{big}_{\lambda}(S)} \Theta(P)^{2} \mu(P),
$$

which proves the first statement of the lemma.
Concerning the second statement, notice that by (4.6), (4.7), and (4.8), we have

$$
\begin{aligned}
\Theta(S)^{2} \mu(S) & \leq 2 \sum_{P \in \operatorname{hd}^{k(Q, M)}(Q): P \subset S}\left(\frac{\ell(P)}{\ell(S)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \\
& \leq 4 \sum_{P \in \operatorname{big}_{\lambda}(S)}\left(\frac{\ell(P)}{\ell(S)}\right)^{1 / 2} \Theta(P)^{2} \mu(P) \\
& \leq 4 \Lambda^{-\frac{1}{2 n}} \sum_{P \in \operatorname{big}_{\lambda}(S)} \Theta(P)^{2} \mu(P) .
\end{aligned}
$$

We denote

$$
\mathrm{DB}:=\mathrm{DB}\left(M_{0}\right)=\bigcup_{M \geq M_{0}}(\mathrm{DB}(M) \backslash \mathrm{DB}(2 M)) .
$$

Remark that the last identity holds because of the polynomial growth of $\mu$. For each $Q \in \mathrm{DB}$, choose $M(Q)$ such that $Q \in \mathrm{DB}(M(Q)) \backslash \mathrm{DB}(2 M(Q))$ We denote by GDF (which stands for "good dominating family") the family of the cubes $S \in \mathcal{D}_{\mu}^{\mathcal{P}}$ belonging to $G(Q, M(Q))$ for some $Q \in \mathrm{DB}$. In particular, by the preceding lemma, the cubes $S \in \mathrm{GDF}$ satisfy the property that there exists a family $\mathcal{I}_{S} \subset \mathcal{D}_{\mu}^{\mathcal{P}}(S)$ such that

$$
\begin{equation*}
\Theta(P)=\Lambda \Theta(S) \quad \text { and } \quad \ell(P) \geq \lambda_{0} \ell(S) \quad \text { for all } P \in \mathcal{I}_{S} \tag{4.9}
\end{equation*}
$$

(with $\lambda_{0}=\lambda_{0}(\Lambda)$ as in (4.5)), and

$$
\begin{equation*}
\mu(S) \leq 4 \Lambda^{2-\frac{1}{2 n}} \sum_{P \in \mathcal{I}_{S}} \mu(P) . \tag{4.10}
\end{equation*}
$$

For a family $\mathcal{I} \subset \mathcal{D}_{\mu}$, we denote

$$
\sigma(\mathcal{I})=\sum_{P \in \mathcal{I}} \Theta(P)^{2} \mu(P)
$$

and for $p \geq 1$,

$$
\sigma_{p}(\mathcal{I})=\sum_{P \in \mathcal{I}} \Theta(P)^{p} \mu(P)
$$

so that $\sigma(\mathcal{I})=\sigma_{2}(\mathcal{I})$. Observe that, for $S \in \operatorname{GDF}$,

$$
\begin{equation*}
\sigma\left(\mathcal{I}_{S}\right)=\Lambda^{2} \Theta(S)^{2} \sum_{P \in \mathcal{I}_{S}} \mu(P) \geq \frac{1}{4} \Lambda^{\frac{1}{2 n}} \sigma(S), \tag{4.11}
\end{equation*}
$$

by (4.10).
Lemma 4.3. We have

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{S \in \mathrm{GDF}} \sigma\left(\mathcal{I}_{S}\right)
$$

Proof. For each $Q \in \mathrm{DB}$, choose $M=M(Q)$ such that $Q \in \mathrm{DB}(M) \backslash \mathrm{DB}(2 M)$. By the definition of $\mathcal{E}_{\infty}(9 Q)$, we have

$$
\mathcal{E}_{\infty}(9 Q) \lesssim M(Q)^{2} \Theta(Q)^{2} \mu(Q) .
$$

Then, by Lemma 4.2 we get

$$
\begin{aligned}
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) & \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{Q \in \mathrm{DB}} \sum_{S \in G(Q, M(Q))}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \sum_{P \in \operatorname{big}_{\lambda}(S)} \Theta(P)^{2} \mu(P) \\
& \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{Q \in \mathcal{D}_{\mu \mathcal{P}}} \sum_{S \in \mathrm{GDF}: S \subset 9 Q}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \sigma\left(\mathcal{I}_{S}\right) \\
& =\Lambda^{-\frac{1}{2 n}} \sum_{S \in \mathrm{GDF}} \sigma\left(\mathcal{I}_{S}\right) \sum_{Q \in \mathcal{D}_{\mu \mathrm{P}: 9 Q \supset S}}\left(\frac{\ell(S)}{\ell(Q)}\right)^{1 / 2} \\
& \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{S \in \mathrm{GDF}} \sigma\left(\mathcal{I}_{S}\right) .
\end{aligned}
$$

Lemma 4.4. Let $\delta_{0} \in(0,1)$. Let $S, P, P^{\prime} \in \mathcal{D}_{\mu}$ be such that $P \subset P^{\prime} \subset S$. Suppose that

$$
\Theta(P) \geq \Lambda \Theta(S) \quad \text { and } \quad \Theta\left(P^{\prime}\right) \leq \delta_{0} \Theta_{\mu}(S)
$$

Then we have

$$
c_{1} \ell(P) \leq\left(\delta_{0} \Lambda^{-1}\right)^{1 / n} \ell\left(P^{\prime}\right) \leq\left(\delta_{0} \Lambda^{-1}\right)^{1 / n} \ell(S) .
$$

Proof. This is an immediate consequence of the following:

$$
\Theta\left(P^{\prime}\right) \frac{\ell\left(P^{\prime}\right)^{n}}{\ell(P)^{n}} \geq \Theta(P) \geq c \Lambda \Theta(S) \geq c \Lambda \delta_{0}^{-1} \Theta\left(P^{\prime}\right)
$$

Remark 4.5. Let

$$
\begin{equation*}
\lambda=\lambda_{0}(\Lambda)=\frac{c_{0}}{\Lambda^{4}} . \tag{4.12}
\end{equation*}
$$

By the preceding lemma, if $\left(\delta_{0} \Lambda^{-1}\right)^{1 / n}<c_{1} \lambda$, or equivalently,

$$
\begin{equation*}
\delta_{0}<c^{\prime} \Lambda^{1-4 n} \tag{4.13}
\end{equation*}
$$

then, for any $S \in \mathrm{GDF}$ and $P \in \mathcal{I}_{S}$, there does not exist any cube $P^{\prime} \in \mathcal{D}_{\mu}$ satisfying

$$
P \subset P^{\prime} \subset S \quad \text { and } \quad \Theta(P) \leq \delta_{0} \Theta(S)
$$

Another easy (but important) property of the family GDF is stated in the next lemma.
Lemma 4.6. Let $S_{1}, S_{2} \in \mathrm{GDF}$ be such that $S_{2} \subsetneq S_{1}$ and $\Theta\left(S_{1}\right)=\Theta\left(S_{2}\right)$. Then there exist $Q \in \mathrm{DB}$ and $Q^{\prime} \in \mathcal{D}_{\mu}$ such that $Q^{\prime} \subset 9 Q, \ell(Q)=\ell\left(Q^{\prime}\right)$ and $S_{1} \supset Q^{\prime} \supset S_{2}$, with $S_{2} \in G(Q, M(Q))$ for some $M(Q) \geq M_{0}$.

Proof. This is due to the fact that, by definition, there exists $Q \in \mathrm{DB}$ such that $S_{2} \in$ $G(Q, M)$ for some $M=M(Q) \geq M_{0}$. So $S_{2} \in \operatorname{hd}^{k(Q, M)-k_{\Lambda}}(Q)$ and $S_{2} \subset 9 Q$. Then $\ell(Q) \leq \ell\left(S_{1}\right)$, because otherwise $S_{2} \notin \mathrm{hd}^{k(Q, M)-k_{\Lambda}}(Q)$ since $S_{2}$ would not be maximal among the cubes $S$ contained in $9 Q$ such that $\Theta(S) \geq A_{0}^{\left(k(Q, M)-k_{\Lambda}\right) n} \Theta(Q)$ (as $S_{1}$ is also contained in $9 Q$ and $\left.\Theta\left(S_{1}\right)=A_{0}^{\left(k(Q, M)-k_{\Lambda}\right) n} \Theta(Q)\right)$. The fact that $\ell\left(S_{1}\right) \geq \ell(Q) \geq \ell\left(S_{2}\right)$ implies the existence of a cube $Q^{\prime}$ such as the one in the lemma.

## 5. The cubes with moderate decrement of Wolff energy and the associated tractable trees

Given $R \in \mathcal{D}_{\mu}^{\mathcal{P}}$, we denote

$$
\mathrm{HD}(R)=\mathrm{hd}^{k_{\Lambda}}(R)
$$

Also, we take $\delta_{0} \leq c^{\prime} \Lambda^{1-4 n}$, so that (4.13) holds. We let $\operatorname{LD}(R)$ be the family of cubes $Q \in \mathcal{D}_{\mu}$ which are maximal and satisfy

$$
\ell(Q)<\ell(R) \quad \text { and } \quad \Theta(Q) \leq \delta_{0} \Theta(R)
$$

We denote by $\operatorname{NDB}(R)$ (which stands for "near DB") the family of cubes $Q$ which do not belong to $\mathrm{LD}(R) \cup \mathrm{HD}(R)$ and satisfy the following:

- $\ell(Q)<\lambda \ell(R)$, with $\lambda=c_{0} \Lambda^{-4}$ as in (4.12), and
- there exists another cube $Q^{\prime} \in \mathrm{DB}$ of the same generation as $Q$ such that $Q^{\prime} \subset 20 Q$. We let $\operatorname{Bad}(R)$ be the family of maximal cubes from $\mathrm{LD}(R) \cup \mathrm{HD}(R) \cup \operatorname{NDB}(R)$ (not necessarily contained in $R$ ) and we denote

$$
\operatorname{Stop}(R)=\operatorname{Bad}(R) \cap \mathcal{D}_{\mu}(R)
$$

Lemma 5.1. For any cube $R \in \mathrm{GDF}$, we have $\mathcal{I}_{R} \subset(\mathrm{HD}(R) \backslash \operatorname{NDB}(R)) \cap \operatorname{Stop}(R)$, and thus

$$
\sigma(\mathrm{HD}(R) \cap \operatorname{Stop}(R) \backslash \mathrm{NDB}(R)) \geq \frac{1}{4} \Lambda^{\frac{1}{2 n}} \sigma(R) .
$$

Remark that $\mathcal{I}_{R}$ is the family of cubes defined in (4.9).
Proof. Recall that, by (4.11),

$$
\sigma\left(\mathcal{I}_{R}\right) \geq \frac{1}{4} \Lambda^{\frac{1}{2 n}} \sigma(R) .
$$

By the choice of $\delta_{0}$ and Remark 4.5, there does not exist any $Q \in \operatorname{LD}(R)$ which contains any cube from $\mathcal{I}_{R}$. Also, the cubes from $Q \in \mathcal{I}_{R}$ satisfy $\ell(Q) \geq \lambda \ell(R)$ and so there does exist any cube $Q^{\prime} \in \operatorname{NDB}(R)$ such that $Q \subset Q^{\prime} \subset R$. So $\mathcal{I}_{R} \subset \mathrm{HD}(R) \cap \operatorname{Stop}(R) \backslash \operatorname{NDB}(R)$. The last statement in the lemma follows from (4.10).

We say that a cube $R \in \mathcal{D}_{\mu}^{\mathcal{P}}$ has moderate decrement of Wolff energy, and we write $R \in \mathrm{MDW}$, if

$$
\sigma(\mathrm{HD}(R) \cap \operatorname{Stop}(R) \backslash \mathrm{NDB}(R)) \geq B^{-1} \sigma(R),
$$

where

$$
B=\Lambda^{\frac{1}{100 n}} .
$$

In particular, by Lemma 5.1, GDF $\subset$ MDW. In this section we will show how to associate to each $R \in$ MDW a suitable family of tractable trees (to be defined later).

Now we introduce the enlarged cubes $e_{j}(R)$. Given $j \geq 0$ and $R \in \mathcal{D}_{\mu, k}$, we let

$$
e_{j}(R)=R \cup \bigcup Q,
$$

where the last union runs over the cubes $Q \in \mathcal{D}_{\mu, k+1}$ such that

$$
\begin{equation*}
\operatorname{dist}\left(x_{R}, Q\right)<\frac{\ell(R)}{2}+2 j \ell(Q) . \tag{5.1}
\end{equation*}
$$

Notice that, since $\operatorname{diam}(Q) \leq \ell(Q)$,

$$
\begin{equation*}
\operatorname{supp} \mu \cap B\left(x_{R}, \frac{1}{2} \ell(R)+2 j \ell(Q)\right) \subset e_{j}(R) \subset B\left(x_{R}, \frac{1}{2} \ell(R)+(2 j+1) \ell(Q)\right) \tag{5.2}
\end{equation*}
$$

Also, we have

$$
\begin{equation*}
e_{j}(R) \subset 2 R \quad \text { for } 0 \leq j \leq \frac{3}{4} A_{0} \tag{5.3}
\end{equation*}
$$

since, for any $Q \in \mathcal{D}_{\mu, k+1}$ satisfying (5.1), its parent satisfies $\widehat{Q}$

$$
\operatorname{dist}\left(x_{R}, \widehat{Q}\right)<\frac{\ell(R)}{2}+2 j A_{0}^{-1} \ell(\widehat{Q}) \leq 2 \ell(R)
$$

For $R \in \mathrm{MDW}$, we let

$$
\operatorname{Stop}\left(e_{j}(R)\right)=\operatorname{Bad}(R) \cap \mathcal{D}_{\mu}\left(e_{j}(R)\right)
$$

where $\mathcal{D}_{\mu}\left(e_{j}(R)\right)$ stands for the subfamily of the cubes from $\mathcal{D}_{\mu}$ which are contained in $e_{j}(R)$ and have side length ta most $\ell(R)$.

Lemma 5.2. For any $R \in$ MDW there exists some $j$, with $10 \leq j \leq A_{0} / 4$ such that

$$
\begin{equation*}
\sigma\left(\mathrm{HD}(R) \cap \operatorname{Stop}\left(e_{j}(R)\right) \backslash \mathrm{NDB}(R)\right) \leq B^{1 / 4} \sigma\left(\mathrm{HD}(R) \cap \operatorname{Stop}\left(e_{j-10}(R)\right) \backslash \mathrm{NDB}(R)\right) \tag{5.4}
\end{equation*}
$$ assuming $A_{0}$ big enough (possibly depending on $n$ ).

Proof. To shorten notation, here we write $\widetilde{\mathrm{HD}}(R)=\mathrm{HD}(R) \backslash \mathrm{NDB}(R)$. Given $R \in$ MDW, suppose that such $j$ does not exist. Let $j_{0}$ be the largest integer which is multiple of 10 and smaller that $A_{0} / 4$. Then we get

$$
\begin{aligned}
\sigma\left(\widetilde{\mathrm{HD}}(R) \cap \operatorname{Stop}\left(e_{j_{0}}(R)\right)\right) & \geq B^{1 / 4} \sigma\left(\widetilde{\mathrm{HD}}(R) \cap \operatorname{Stop}\left(e_{j_{0}-10}(R)\right)\right) \\
& \geq \ldots \geq\left(B^{\frac{1}{4}}\right)^{\frac{j_{0}}{10}-1} \sigma(\widetilde{\mathrm{HD}}(R) \cap \operatorname{Stop}(R)) \geq B^{\frac{j_{0}}{40}-\frac{5}{4}} \sigma(R) .
\end{aligned}
$$

By (5.3), we have $e_{j_{0}}(R) \subset 2 R$ and thus

$$
\sigma\left(\widetilde{\mathrm{HD}}(R) \cap \operatorname{Stop}\left(e_{j_{0}}(R)\right)\right) \leq \sum_{Q \in \widetilde{\operatorname{HD}}(R) \cap \operatorname{Stop}\left(e_{j_{0}}(R)\right)} \Lambda^{2} \Theta(R)^{2} \mu(Q) \leq \Lambda^{2} \Theta(R)^{2} \mu(2 R) .
$$

Since $R$ is $\mathcal{P}$-doubling so from $\mathcal{D}_{\mu}^{d b}$, denoting by $\widehat{R}$ the parent of $R$, we derive

$$
\begin{equation*}
\mu(2 R) \leq \mu\left(2 B_{\widehat{R}}\right) \leq \frac{\ell(\widehat{R})^{n+1}}{\ell(R)} \mathcal{P}(R) \leq C_{d} A_{0}^{n+1} \mu\left(2 B_{R}\right) \leq C_{0} C_{d} A_{0}^{n+1} \mu(R) \tag{5.5}
\end{equation*}
$$

So we deduce that

$$
B^{\frac{j_{0}}{40}-\frac{5}{4}} \sigma(R) \leq C_{0} C_{d} A_{0}^{n+1} \Lambda^{2} \sigma(R)
$$

or equivalently, recalling the choice of $B$ and $C_{d}$,

$$
\Lambda^{\frac{1}{100 n}\left(\frac{j_{0}}{40}-\frac{5}{4}\right)-2} \leq 4 C_{0} A_{0}^{2 n+1}
$$

Since $\Lambda \geq A_{0}^{n}$ and $j_{0} \approx A_{0}$, it is clear that this inequality is violated if $A_{0}$ is big enough.
Given $R \in$ MDW, let $j \geq 10$ be minimal such that (5.4) holds. We denote $h(R)=j-10$. We write

$$
e(R)=e_{h(R)}, \quad e^{\prime}(R)=e_{h(R)+1}, \quad e^{\prime \prime}(R)=e_{h(R)+2}, \quad e^{(k)}(R)=e_{h(R)+k}(R)
$$

for $k \geq 1$. We let

$$
\begin{aligned}
B(e(R)) & =B\left(x_{R},\left(\frac{1}{2}+2 A_{0}^{-1} h(R)\right) \ell(R)\right) \\
B\left(e^{\prime}(R)\right) & =B\left(x_{R},\left(\frac{1}{2}+2 A_{0}^{-1}(h(R)+1)\right) \ell(R)\right), \\
B\left(e^{\prime \prime}(R)\right) & =B\left(x_{R},\left(\frac{1}{2}+2 A_{0}^{-1}(h(R)+2)\right) \ell(R)\right) \\
B\left(e^{(k)}(R)\right) & =B\left(x_{R},\left(\frac{1}{2}+2 A_{0}^{-1}(h(R)+k)\right) \ell(R)\right)
\end{aligned}
$$

By construction we have

$$
B\left(e^{\prime}(R)\right) \cap \operatorname{supp} \mu \subset e^{\prime}(R),
$$

and analogously replacing $e^{\prime}(R)$ by $e(R)$ or $e^{\prime \prime}(R)$. Remark also that

$$
e(R) \subset B\left(e^{\prime}(R)\right) \quad \text { and } \quad \operatorname{dist}\left(e(R), \partial B\left(e^{\prime}(R)\right)\right) \geq A_{0}^{-1} \ell(R)
$$

and, analogously,

$$
e^{\prime}(R) \subset B\left(e^{\prime \prime}(R)\right) \quad \text { and } \quad \operatorname{dist}\left(e^{\prime}(R), \partial B\left(e^{\prime \prime}(R)\right)\right) \geq A_{0}^{-1} \ell(R) .
$$

Lemma 5.3. For each $R \in \mathrm{MDW}$ we have

$$
B\left(e^{\prime \prime}(R)\right) \subset\left(1+8 A_{0}^{-1}\right) B(e(R)) \subset B\left(e^{(6)}(R)\right),
$$

and more generally, for $k \geq 2$ such that $h(R)+k-2 \leq A_{0} / 2$,

$$
B\left(e^{(k)}(R)\right) \subset\left(1+8 A_{0}^{-1}\right) B\left(e^{(k-2)}(R)\right) \subset B\left(e^{(k+4)}(R)\right)
$$

Also,

$$
B\left(e^{(10)}(R)\right) \subset B\left(x_{R}, \frac{3}{2} \ell(R)\right)
$$

This lemma is proven exactly in the same way as [DT, Lemma 4.4] and so we omit the proof.

Next we need to define some families of cubes that can be considered as "generalized trees". First we introduce some additional notation regarding the stopping cubes. For $R \in \operatorname{MDW}$ we write $\operatorname{Stop}\left(e^{\prime}(R)\right)=\operatorname{Stop}\left(e_{h(R)+1}(R)\right)$. Also, we denote

$$
\begin{aligned}
\mathrm{HD}_{1}(R) & =\operatorname{Stop}(R) \cap \mathrm{HD}(R) \backslash \mathrm{NDB}(R), \\
\mathrm{HD}_{1}(e(R)) & =\operatorname{Stop}(e(R)) \cap \mathrm{HD}(R) \backslash \operatorname{NDB}(R),
\end{aligned}
$$

and

$$
\mathrm{HD}_{1}\left(e^{\prime}(R)\right)=\operatorname{Stop}\left(e^{\prime}(R)\right) \cap \mathrm{HD}(R) \backslash \mathrm{NDB}(R)
$$

Also, we set

$$
\mathrm{HD}_{2}\left(e^{\prime}(R)\right)=\bigcup_{Q \in \mathrm{HD}_{1}\left(e^{\prime}(R)\right)}(\operatorname{Stop}(Q) \cap \mathrm{HD}(Q) \backslash \operatorname{NDB}(Q))
$$

and

$$
\begin{equation*}
\operatorname{Stop}_{2}\left(e^{\prime}(R)\right)=\left(\operatorname{Stop}\left(e^{\prime}(R)\right) \backslash \operatorname{HD}_{1}\left(e^{\prime}(R)\right)\right) \cup \bigcup_{Q \in \operatorname{HD}_{1}\left(e^{\prime}(R)\right)} \operatorname{Stop}(Q) \tag{5.6}
\end{equation*}
$$

Given $R \in \mathrm{MDW}$, we let $\mathcal{T}_{\text {stop }}\left(e^{\prime}(R)\right)$ be the family of cubes made up of $R$ and all the cubes of the next generations which are contained in $e^{\prime}(R)$ but are not strictly contained in any cube from $\operatorname{Stop}_{2}\left(e^{\prime}(R)\right)$.

We define now the family of negligible cubes. We say that a cube $Q \in \mathcal{T}_{\text {stop }}\left(e^{\prime}(R)\right)$ is negligible for $\mathcal{T}_{\text {Stop }}\left(e^{\prime}(R)\right)$, and we write $Q \in \operatorname{Neg}\left(e^{\prime}(R)\right)$ if if there does not exist any cube from $\mathcal{T}_{\text {stop }}\left(e^{\prime}(R)\right)$ that contains $Q$ and is $\mathcal{P}$-doubling.

Lemma 5.4. Let $R \in \operatorname{MDW}$. If $Q \in \operatorname{Neg}\left(e^{\prime}(R)\right)$, then $Q \subset e^{\prime}(R) \backslash R, Q$ is not contained in any cube from $\mathrm{HD}_{1}\left(e^{\prime}(R)\right)$, and

$$
\begin{equation*}
\ell(Q) \gtrsim \delta_{0}^{2} \ell(R) \tag{5.7}
\end{equation*}
$$

This lemma is proven in the same way as [DT, Lemma 4.5] and so we omit the proof.
The cubes from $\mathrm{Stop}_{2}\left(e^{\prime}(R)\right)$ need not be $\mathcal{P}$-doubling. This may cause some problems for some of the estimates involving the Riesz transform localized around the trees $\mathcal{T}_{\text {stop }}\left(e^{\prime}(R)\right)$ that will be required later. For this reason, we need to consider enlarged versions of them. For $R \in \mathrm{MDW}$, we let $\operatorname{End}\left(e^{\prime}(R)\right)$ be family made up of the following cubes:

- the cubes from $\operatorname{Stop}_{2}\left(e^{\prime}(R)\right) \cap \operatorname{Neg}\left(e^{\prime}(R)\right)$,
- the cubes that are contained in any cube from $\operatorname{Stop}_{2}\left(e^{\prime}(R)\right) \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)$, which are $\mathcal{P}$-doubling, and moreover are maximal.

Notice that all the cubes from $\operatorname{End}\left(e^{\prime}(R)\right)$ are $\mathcal{P}$-doubling, with the possible exception of the ones from $\operatorname{Neg}\left(e^{\prime}(R)\right)$. We let $\mathcal{T}\left(e^{\prime}(R)\right)$ be the family of cubes that are contained in $e^{\prime}(R)$ and are not strictly contained in any cube from $\operatorname{End}\left(e^{\prime}(R)\right)$.

Given $R \in$ MDW, we say that $\mathcal{T}\left(e^{\prime}(R)\right)$ is tractable (or that $R$ is tractable) if

$$
\sigma\left(\mathrm{HD}_{2}\left(e^{\prime}(R)\right)\right) \leq B \sigma\left(\mathrm{HD}_{1}(e(R))\right)
$$

In this case we write $R \in \operatorname{Trc}$.
Our next objective consists in showing how we can associate a family of tractable trees to any $R \in G D F$, so that, roughly speaking, we can reduce the estimate of $\sigma(\mathrm{DB})$ to estimating the Haar coefficients of $\mathcal{R} \mu$ from below on such family of tractable cubes. First we need the following lemma.

Lemma 5.5. Let $R \in$ MDW be such that $\mathcal{T}\left(e^{\prime}(R)\right)$ is not tractable. Then there exists a family $\mathrm{GH}(R) \subset \mathrm{HD}_{1}\left(e^{\prime}(R)\right) \cap$ MDW satisfying:
(a) The balls $B\left(e^{\prime \prime}(Q)\right)$, with $Q \in \mathrm{GH}(R)$ are pairwise disjoint.
(b) For every $Q \in \mathrm{GH}(R), \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \geq \sigma\left(\mathrm{HD}_{1}(Q)\right) \geq B^{1 / 2} \sigma(Q)$.
(c)

$$
B^{1 / 4} \sum_{Q \in \mathrm{GH}(R)} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \gtrsim \sigma\left(\mathrm{HD}_{2}\left(e^{\prime}(R)\right)\right) .
$$

This lemma is proven in the same way as [DT, Lemma 4.6] and so we omit the proof again.

Remark that the property (c) and the fact that $R \notin \operatorname{Trc}$ yield

$$
\begin{equation*}
\sum_{Q \in \mathrm{GH}(R)} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \gtrsim B^{3 / 4} \sigma\left(\mathrm{HD}_{1}(e(R))\right), \tag{5.8}
\end{equation*}
$$

which will be suitable for iteration in the arguments below.
Given $R \in \mathrm{GDF}$, we will construct now a subfamily of cubes from $\mathcal{D}_{\mu}^{\mathcal{P}}$ generated by $R$, which we will denote by $\operatorname{Gen}(R)$, by iterating the construction of Lemma 5.5. We follow the next algorithm. Given $R \in$ GDF, we denote

$$
\operatorname{Gen}_{0}(R)=\{R\} .
$$

If $R \in \operatorname{Trc}$, we set $\operatorname{Gen}_{1}(R)=\varnothing$, and otherwise

$$
\operatorname{Gen}_{1}(R)=\mathrm{GH}(R),
$$

where $\mathrm{GH}(R)$ is defined in Lemma 5.5. For $j \geq 2$, we set

$$
\operatorname{Gen}_{j}(R)=\bigcup_{Q \in \operatorname{Gen}_{j-1}(R) \backslash \operatorname{Trc}} \mathrm{GH}(Q),
$$

where $\mathrm{GH}(Q)$ is defined in Lemma 5.5. For $j \geq 0$, we also set

$$
\operatorname{Trc}_{j}(R)=\operatorname{Gen}_{j}(R) \cap \operatorname{Trc}
$$

and

$$
\operatorname{Gen}(R)=\bigcup_{j \geq 0} \operatorname{Gen}_{j}(R), \quad \operatorname{Trc}(R)=\bigcup_{j \geq 0} \operatorname{Trc}_{j}(R)
$$

From the construction above, we get the following lemma, which is proven in the same way as [DT, Lemma 4.7] and so we omit the proof.

Lemma 5.6. For $R \in G D F$, we have

$$
\bigcup_{Q \in \operatorname{Gen}(R) \cup \operatorname{Trc}(R)} Q \subset B\left(e^{\prime \prime}(R)\right)
$$

Also,

$$
\begin{equation*}
\sigma\left(\mathrm{HD}_{1}(e(R))\right) \leq \sum_{j \geq 0} B^{-j / 2} \sum_{Q \in \operatorname{Trc}_{j}(R)} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \tag{5.9}
\end{equation*}
$$

## 6. The layers $\mathrm{F}_{j}^{h}$ and $\mathrm{L}_{j}^{h}$ and the typical tractable trees

We denote

$$
\mathrm{F}_{j}=\left\{R \in \mathrm{GDF}: \Theta(R)=A_{0}^{n j}\right\}
$$

so that

$$
\mathrm{GDF}=\bigcup_{j \in \mathbb{Z}} \mathrm{~F}_{j} .
$$

Next we split $\mathrm{F}_{j}$ into layers $\mathrm{F}_{j}^{h}, h \geq 1$, which are defined as follows: $\mathrm{F}_{j}^{1}$ is the family of maximal cubes from $\mathrm{F}_{j}$, and by induction $\mathrm{F}_{j}^{h}$ is the family of maximal cubes from $\mathrm{F}_{j} \backslash \bigcup_{k=1}^{h-1} \mathrm{~F}_{j}^{h-1}$. So we have the splitting

$$
\mathrm{GDF}=\bigcup_{j \in \mathbb{Z}} \bigcup_{h \geq 1} \mathrm{~F}_{j}^{h} .
$$

Our next objective is to choose a suitable subfamily $\mathrm{L}_{j}^{h} \subset \mathrm{~F}_{j}^{h}$, for each $j, h$. By Theorem 9.31 from To5, there is a family $J_{0} \subset \mathrm{~F}_{j}^{h}$ such that1]

1) no ball $B\left(e^{(4)}(Q)\right)$, with $Q \in J_{0}$, is contained in any other ball $B\left(e^{(4)}\left(Q^{\prime}\right)\right)$, with $Q^{\prime} \in \mathrm{F}_{j}^{h}, Q^{\prime} \neq Q$,
2) the balls $B\left(e^{(4)}(Q)\right)$, with $Q \in J_{0}$, have finite superposition, and
3) every ball $B\left(e^{(4)}(Q)\right)$, with $Q \in \mathrm{~F}_{j}^{h}$ is contained in some ball $\left(1+8 A_{0}^{-1}\right) B\left(e^{(4)}(R)\right)$, with $R \in J_{0}$. Consequently,

$$
\bigcup_{Q \in \mathrm{~F}_{j}^{h}} B\left(e^{(4)}(Q)\right) \subset \bigcup_{R \in J_{0}}\left(1+8 A_{0}^{-1}\right) B\left(e^{(4)}(R)\right) .
$$

From the finite superposition property 2), by rather standard arguments which are analogous to the ones in the proof of Besicovitch's covering theorem in [Ma, Theorem 2.7], say, one deduces that $J_{0}$ can be split into $m_{0}$ subfamilies $J_{1}, \ldots, J_{m_{0}}$ such that, for each $k$, the balls $\left\{B\left(e^{(4)}(Q)\right): Q \in J_{k}\right\}$ are pairwise disjoint, with $m_{0} \leq C\left(A_{0}\right)$.

[^1]By the condition 3), we get

$$
\begin{aligned}
\sum_{Q \in \mathrm{~F}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(Q)\right) & =\Lambda^{2} A_{0}^{2 n j} \sum_{Q \in \mathrm{~F}_{j}^{h}} \sum_{P \in \mathrm{HD}_{1}(Q)} \mu(P) \\
& \leq \Lambda^{2} A_{0}^{2 n j} \sum_{R \in J_{0}} \sum_{\substack{Q \in \mathrm{~F}_{j}^{h}: \\
B\left(e^{(4)}(Q)\right) \subset\left(1+8 A_{0}^{-1}\right) B\left(e^{(4)}(R)\right)}} \sum_{P \in \mathrm{HD}_{1}(Q)} \mu(P) .
\end{aligned}
$$

Observe that, for $R \in J_{0}$ and $Q \in \mathrm{~F}_{j}^{h}$ such that $B\left(e^{(4)}(Q)\right) \subset\left(1+8 A_{0}^{-1}\right) B\left(e^{(4)}(R)\right)$, any cube $P \in \mathrm{HD}_{1}(Q)$ is contained in some cube from $\mathrm{HD}_{1}\left(e^{(10)}(R)\right)$ since supp $\mu \cap(1+$ $\left.8 A_{0}^{-1}\right) B\left(e^{(4)}(R)\right) \subset e^{(10)}(R)$, by Lemma 5.3. Using also that the cubes from $\mathrm{F}_{j}^{h}$ are disjoint and Lemma 5.2, we deduce that

$$
\begin{aligned}
\sum_{Q \in \mathrm{~F}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(Q)\right) & \leq \Lambda^{2} A_{0}^{2 n j} \sum_{R \in J_{0}} \sum_{P \in \mathrm{HD}_{1}\left(e^{(10)}(R)\right)} \mu(P) \\
& =\sum_{R \in J_{0}} \sigma\left(\mathrm{HD}_{1}\left(e^{(10)}(R)\right)\right) \leq B^{1 / 4} \sum_{R \in J_{0}} \sigma\left(\mathrm{HD}_{1}(e(R))\right)
\end{aligned}
$$

Next we choose $\mathrm{L}_{j}^{h}=J_{k}$ to be the family such that

$$
\sum_{Q \in J_{k}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right)
$$

is maximal among $J_{1}, \ldots, J_{m_{0}}$, so that

$$
\sum_{Q \in \mathrm{~F}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(Q)\right) \leq m_{0} B^{1 / 4} \sum_{Q \in \mathrm{~L}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) .
$$

So we have:
Lemma 6.1. The family $\mathrm{L}_{j}^{h}$ satisfies:
(i) no ball $B\left(e^{(4)}(Q)\right)$, with $Q \in \mathrm{~L}_{j}^{h}$, is contained in any other ball $B\left(e^{(4)}\left(Q^{\prime}\right)\right)$, with $Q^{\prime} \in \mathrm{F}_{j}^{h}, Q^{\prime} \neq Q$,
(ii) the balls $B\left(e^{(4)}(Q)\right)$, with $Q \in \mathrm{~L}_{j}^{h}$, are pairwise disjoint, and (iii)

$$
\sum_{Q \in \mathrm{~F}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(Q)\right) \leq m_{0} B^{1 / 4} \sum_{Q \in \mathrm{~L}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) .
$$

We denote

$$
\mathrm{L}_{j}=\bigcup_{h \geq 1} \mathrm{~L}_{j}^{h}, \quad \mathrm{~L}=\mathrm{L}(\mathrm{GDF})=\bigcup_{j \in \mathbb{Z}} \mathrm{~L}_{j}=\bigcup_{j \in \mathbb{Z}} \bigcup_{h \geq 1} \mathrm{~L}_{j}^{h} .
$$

By Lemma 6.1 (iii), we have

$$
\begin{align*}
\sum_{R \in \mathrm{GDF}} \sigma\left(\mathrm{HD}_{1}(R)\right) & =\sum_{j \in \mathbb{Z}, h \geq 0} \sum_{R \in \mathrm{~F}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(R)\right)  \tag{6.1}\\
& \leq m_{0} B^{1 / 4} \sum_{j \in \mathbb{Z}, h \geq 0} \sum_{R \in \mathrm{~L}_{j}^{h}} \sigma\left(\mathrm{HD}_{1}(e(R))\right)=m_{0} B^{1 / 4} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sigma\left(\mathrm{HD}_{1}(e(R))\right) .
\end{align*}
$$

Our next objective consists of proving the next lemma, which is the main technical achievement in this section. Although the statement looks similar to [DT, Lemma 5.2], the proof is very different. The cubes from the $\operatorname{NDB}(\cdot)$ play an important role in the arguments. In fact, the main reason for the introduction of the stopping condition involving the family $\operatorname{NDB}(\cdot)$ in Section 5 is that it allows to prove the next lemma.

Lemma 6.2. There exists some constant $C_{2}$ such that, for all $P \in \mathcal{D}_{\mu}$ and all $k \geq 0$,

$$
\#\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } P \in \mathcal{T}\left(e^{\prime}(Q)\right)\right\} \leq C_{2}(\log \Lambda)^{2}
$$

Proof. First notice that if $R \in \mathrm{~L}(\mathrm{GDF})$ and $Q \in \operatorname{Trc}_{k}(R)$ are such that $P \in \mathcal{T}\left(e^{\prime}(Q)\right) \backslash$ $\operatorname{Neg}\left(e^{\prime}(Q)\right)$, then there exists some $\mathcal{P}$-doubling cube that contains $P$ and belongs to $\mathcal{T}_{\text {stop }}\left(e^{\prime}(Q)\right)$, by the definition of the family $\operatorname{Neg}\left(e^{\prime}(Q)\right)$. We denote by $\widetilde{P}$ be the smallest one. This satisfies

$$
\delta_{0} \Theta(Q) \lesssim \Theta(\widetilde{P}) \leq \Lambda^{2} \Theta(Q)
$$

or equivalently, $\Lambda^{k} \Theta(R) \in\left[\Lambda^{-2} \Theta(\widetilde{P}), C \delta_{0}^{-1} \Theta(\widetilde{P})\right]$. Hence, if $\Theta(R)=A_{0}^{n j}$, it follows that

$$
-C \log \Lambda \leq j+c k \log \Lambda-c^{\prime} \log \Theta(\widetilde{P}) \leq C\left|\log \delta_{0}\right|=C^{\prime} \log \Lambda .
$$

Thus, $R$ belongs at most to $C^{\prime \prime} \log \Lambda$ families $\mathrm{L}_{j}$ such that there exists $Q \in \operatorname{Trc}_{k}(R)$ such that $P \in \mathcal{T}\left(e^{\prime}(Q)\right) \backslash \operatorname{Neg}\left(e^{\prime}(Q)\right)$

Suppose now that there exists $Q \in \operatorname{Trc}_{k}(R)$ such that $P \in \operatorname{Neg}\left(e^{\prime}(Q)\right) \subset \mathcal{T}\left(e^{\prime}(Q)\right)$. In this case, by Lemma 5.4, $\ell(P) \gtrsim \delta_{0}^{-2} \ell(Q)$. Hence, there are at most $C\left|\log \delta_{0}\right| \approx \log \Lambda$ cubes $Q$ such that $P \in \mathcal{T}\left(e^{\prime}(Q)\right) \cap \operatorname{Neg}\left(e^{\prime}(Q)\right.$ ), which in turn implies that again there are at most $C^{\prime \prime \prime} \log \Lambda$ families $\mathrm{L}_{j}$ such that there exists $Q \in \operatorname{Trc}_{k}(R)$ satisfying $P \in \mathcal{T}\left(e^{\prime}(Q)\right) \cap$ $\operatorname{Neg}\left(e^{\prime}(Q)\right)$.

By the previous discussion, to prove the lemma, it is enough to show that, for each $j \in \mathbb{Z}, P \in \mathcal{D}_{\mu}, k \geq 0$,

$$
\begin{equation*}
\# \mathrm{~L}_{j}(P, k) \leq C_{3} \log \Lambda, \tag{6.2}
\end{equation*}
$$

where

$$
\mathrm{L}_{j}(P, k)=\left\{R \in \mathrm{~L}_{j}: \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } P \in \mathcal{T}\left(e^{\prime}(Q)\right)\right\} .
$$

To prove (6.2), let $R_{0}$ be a cube in $\mathrm{L}_{j}(P, k)$ with maximal side length, and let $h_{0}$ be such that $R_{0} \in \mathrm{~L}_{j}^{h_{0}}(P, k) \equiv \mathrm{L}_{j}(P, k) \cap \mathrm{L}_{j}^{h_{0}}$.

Claim 6.3. Let $R_{1}$ be another cube from $\mathrm{L}_{j}(P, k)$, and let $h_{1}$ be such that $R_{1} \in \mathrm{~L}_{j}^{h_{1}}(P, k)$. Then $h_{1} \geq h_{0}$.

Proof. Suppose that $h_{1}<h_{0}$. Let $R_{0}^{h_{1}}$ be the cube that contains $R_{0}$ and belongs to $\mathrm{F}_{j}^{h_{1}}$. Observe that, by Lemma 5.6.

$$
P \subset B\left(e^{\prime \prime}\left(R_{0}\right)\right) \cap B\left(e^{\prime \prime}\left(R_{1}\right)\right) \subset B\left(x_{R_{0}}, \frac{3}{2} \ell\left(R_{0}\right)\right) \cap B\left(x_{R_{1}}, \frac{3}{2} \ell\left(R_{1}\right)\right)
$$

Since $\ell\left(R_{0}\right) \geq \ell\left(R_{1}\right)$, we infer that

$$
B\left(x_{R_{1}}, \frac{3}{2} \ell\left(R_{1}\right)\right) \subset B\left(x_{R_{0}}, \frac{9}{2} \ell\left(R_{0}\right)\right)
$$

As $x_{R_{0}} \in B\left(x_{R_{0}}^{h_{1}}, \frac{1}{2} \ell\left(R_{0}^{h_{1}}\right)\right)$ and $\ell\left(R_{0}\right) \leq A_{0}^{-1} \ell\left(R_{0}^{h_{1}}\right)$, we deduce that

$$
\begin{aligned}
B\left(x_{R_{0}}, \frac{9}{2} \ell\left(R_{0}\right)\right) & \subset B\left(x_{R_{0}}^{h_{1}}, \frac{1}{2} \ell\left(R_{0}^{h_{1}}\right)+\frac{9}{2} \ell\left(R_{0}\right)\right) \subset B\left(x_{R_{0}}^{h_{1}}, \frac{1}{2} \ell\left(R_{0}^{h_{1}}\right)+\frac{9}{2} A_{0}^{-1} \ell\left(R_{0}^{h_{1}}\right)\right) \\
& \subset B\left(x_{R_{0}}^{h_{1}},\left(\frac{1}{2}+8 A_{0}^{-1}\right) \ell\left(R_{0}^{h_{1}}\right)\right) \subset B\left(e^{(4)}\left(R_{0}^{h_{1}}\right)\right),
\end{aligned}
$$

where the lat inclusion follows from the definition of $B\left(e^{(4)}\left(R_{0}^{h_{1}}\right)\right)$. Then we deduce that

$$
B\left(e^{(4)}\left(R_{1}\right)\right) \subset B\left(x_{R_{1}}, \frac{3}{2} \ell\left(R_{1}\right)\right) \subset B\left(e^{(4)}\left(R_{0}^{h_{1}}\right)\right)
$$

which contradicts the property (i) of the family $\mathrm{L}_{j}^{h_{1}}$ in Lemma 6.1, because $R_{1} \neq R_{0}^{h_{1}}$.
Claim 6.4. Let $R_{1}$ be another cube from $\mathrm{L}_{j}(P, k)$, and let $h_{1}$ be such that $R_{1} \in \mathrm{~L}_{j}^{h_{1}}(P, k)$. Then

$$
\begin{equation*}
h_{1} \leq h_{0}+C \log \Lambda . \tag{6.3}
\end{equation*}
$$

Proof. Suppose that $h_{1}>h_{0}+1$. This implies that there are cubes $\left\{R_{1}^{h}\right\}_{h_{0}+1 \leq h \leq h_{1}-1}$ such that $R_{1}^{h} \in \mathrm{~F}_{j}^{h}$, with

$$
R_{1}^{h_{0}+1} \supset R_{1}^{h_{0}+2} \supset \ldots \supset R_{1}^{h_{1}-1} \supsetneq R_{1}^{h_{1}}=R_{1} .
$$

Observe now that $\ell\left(R_{1}^{h_{0}+1}\right) \leq \ell\left(R_{0}\right)$. Otherwise, there exists some cube $R_{1}^{h_{0}} \in \mathrm{~F}_{j}^{h_{0}}$ that contains $R_{1}^{h_{0}+1}$ with

$$
\ell\left(R_{1}^{h_{0}}\right) \geq A_{0} \ell\left(R_{1}^{h_{0}+1}\right) \geq A_{0} \ell\left(R_{0}\right)
$$

Since $P \subset B\left(e^{\prime \prime}\left(R_{0}\right)\right) \cap B\left(e^{\prime \prime}\left(R_{1}\right)\right)$, arguing as in the previous claim, we deduce that $B\left(e^{(4)}\left(R_{0}\right)\right) \subset B\left(e^{(4)}\left(R_{1}^{h_{0}}\right)\right)$, which contradicts again the property (i) of the family $\mathrm{L}_{j}^{h_{0}}$, as above. So we have

$$
\ell\left(R_{1}^{h}\right) \leq \ell\left(R_{1}^{h_{0}+1}\right) \leq \ell\left(R_{0}\right) \quad \text { for } h \geq h_{0}+1
$$

By the construction of $\operatorname{Trc}_{k}\left(R_{0}\right)$, there exists a sequence of cubes $S_{0}=R_{0}, S_{1}, S_{2}, \ldots, S_{k}=$ $Q$ such that

$$
S_{i+1} \in \mathrm{GH}\left(S_{i}\right) \text { for } i=0, \ldots, k-1,
$$

and $P \in \mathcal{T}\left(e^{\prime}\left(S_{k}\right)\right)$. In case that $P$ is contained in some $Q^{\prime} \in \mathrm{HD}_{1}\left(e^{\prime}(Q)\right)=\mathrm{HD}_{1}\left(e^{\prime}\left(S_{k}\right)\right)$, we write $S_{k+1}=Q^{\prime}$, and we let $\tilde{k}:=k+1$. Otherwise, we let $\tilde{k}:=k$. In any case, obviously we have $\ell\left(S_{i+1}\right)<\ell\left(S_{i}\right)$ for all $i$. So, for each $h$ with $h_{0}+1 \leq h \leq h_{1}$ there is some $i=i(h)$ such that

$$
\begin{equation*}
\ell\left(S_{i}\right)>\ell\left(R_{1}^{h}\right) \geq \ell\left(S_{i+1}\right) \tag{6.4}
\end{equation*}
$$

with $0 \leq i \leq \tilde{k}$, where we understand that $S_{\tilde{k}+1}=P$. We claim that either $i \lesssim 1$ or $i=\widetilde{k}$, with the implicit constant depending on $n$. Indeed, in the case $i<\widetilde{k}$, let $T \in \mathcal{D}_{\mu}$ be such
that $T \supset S_{i+1}$ and $\ell(T)=\ell\left(R_{1}^{h}\right)$. Notice that, since $2 R_{1}^{h} \cap 2 T \neq \varnothing$ (because both $R_{1}^{h}$ and $2 T$ contain $P$ ) and $\ell\left(R_{1}^{h}\right)=\ell(T)$, we have

$$
\begin{equation*}
\mathcal{P}(T) \approx \mathcal{P}\left(R_{1}^{h}\right) \approx \Theta\left(R_{1}^{h}\right)=\Theta\left(R_{0}\right) \tag{6.5}
\end{equation*}
$$

On the other hand,

$$
\begin{equation*}
\Theta(T) \geq \delta_{0} \Theta\left(S_{i}\right) \tag{6.6}
\end{equation*}
$$

because otherwise either $T \in \operatorname{LD}\left(S_{i}\right)$ or it is contained in some cube from $\operatorname{LD}\left(S_{i}\right) \cup \mathrm{NDB}\left(S_{i}\right)$. In any case, this would imply that $S_{i+1}$ does not belong to $\mathrm{HD}_{1}\left(e^{\prime}\left(S_{i}\right)\right)$. Thus, from (6.5) and (6.6) we derive that

$$
\Theta\left(R_{0}\right) \gtrsim \delta_{0} \Theta\left(S_{i}\right)=\delta_{0} \Lambda^{i} \Theta\left(R_{0}\right)
$$

Hence $\Lambda^{i} \lesssim \delta_{0}^{-1}$, which yields $i \lesssim_{n} 1$ if $i<\widetilde{k}$, as claimed.
The preceding discussion implies that, in order to prove (6.3), it suffices to show that, for each fixed $i=0, \ldots, \tilde{k}$, there are at most $C \log \Lambda$ cubes $R_{1}^{h}$ satisfying (6.4). To this end, suppose first that $i<\tilde{k}$. It is easy to check that there is at most one cube $R_{1}^{h}$ satisfying (6.4) such that

$$
\begin{equation*}
\ell\left(R_{1}^{h}\right) \leq \lambda \ell\left(S_{i}\right) \tag{6.7}
\end{equation*}
$$

Indeed, if otherwise $R_{1}^{h}$ and $R_{1}^{h^{\prime}}$ are such that

$$
\begin{equation*}
\lambda \ell\left(S_{i}\right) \geq \ell\left(R_{1}^{h}\right)>\ell\left(R_{1}^{h^{\prime}}\right)>\ell\left(S_{i+1}\right) \tag{6.8}
\end{equation*}
$$

then, by Lemma 4.6, there exist $T_{a} \in \mathrm{DB}$ and $T_{b} \in \mathcal{D}_{\mu}$ such that $T_{b} \subset 9 T_{a}, \ell\left(T_{a}\right)=\ell\left(T_{b}\right)$ and $R_{1}^{h} \supsetneq T_{b} \supsetneq R_{1}^{h^{\prime}}$. Now, let $T_{c} \in \mathcal{D}_{\mu}$ be such that $T_{c} \supset S_{i+1}$ and $\ell\left(T_{c}\right)=\ell\left(T_{a}\right)$. Since $T_{a} \in \mathrm{DB}$, we infer that $T_{c} \in \operatorname{NDB}\left(S_{i}\right)$, taking into account that $2 T_{b} \cap 2 T_{c} \neq \varnothing$, $T_{b} \subset 9 T_{a}$, and $\ell\left(T_{c}\right)>\lambda \ell\left(S_{i}\right)$. This is a contradiction, because this would imply that either $T_{c} \in \operatorname{Stop}\left(e^{\prime}\left(S_{i}\right)\right)$ or $T_{c}$ is contained in some cube from $\operatorname{Stop}\left(e^{\prime}\left(S_{i}\right)\right)$, which ensures that $S_{i+1} \notin \mathrm{GH}\left(S_{i}\right)$ (notice that we are using the fact that $i<\tilde{k}$ ). So (6.7) holds. Clearly this implies that there are at most $C|\log \lambda| \approx \log \Lambda$ cubes $R_{1}^{h}$ satisfying (6.4).

In the case $i=\tilde{k}$, the same argument as above shows that if $R_{1}^{h}$ and $R_{1}^{h^{\prime}}$ satisfy (6.8), then the cube $T_{c}$ in the preceding paragraph belongs to $\operatorname{NDB}\left(S_{\tilde{k}}\right)$ again. So again either $T_{c} \in \operatorname{Stop}\left(e^{\prime}\left(S_{\tilde{k}}\right)\right)$ or $T_{c}$ is contained in some cube from $\operatorname{Stop}\left(e^{\prime}\left(S_{\tilde{k}}\right)\right)$. As a consequence, by the definition of the family $\operatorname{End}\left(e^{\prime}(R)\right)$ and Lemma 3.2, if we denote by $T_{m}$ the $m$-th descendant of $T_{c}$ which contains $P$, it follows that

$$
\Theta\left(T_{m}\right) \lesssim A_{0}^{-m / 2} \mathcal{P}\left(T_{c}\right) \approx A_{0}^{-m / 2} \mathcal{P}\left(T_{b}\right) \leq A_{0}^{-m / 2} \mathcal{P}\left(R_{1}^{h^{\prime}}\right) \quad \text { for all } m \geq 1
$$

The last inequality follows from the fact that we can assume that $R_{1}^{h^{\prime}} \in G\left(T_{a}, M\right)$, for some $M \geq M_{0}$, by Lemma 4.6. Since any cube $R_{1}^{h^{\prime \prime}}$ with $h^{\prime \prime}>h^{\prime}$ is contained in a cube $2 T_{m}$ with $\ell\left(T_{m}\right) \approx \ell\left(R_{1}^{h^{\prime \prime}}\right)$ for some $m \geq h^{\prime}-h^{\prime \prime}-1$, we deduce that

$$
\begin{aligned}
\Theta\left(R_{1}^{h^{\prime \prime}}\right) & \lesssim \Theta\left(2 T_{m}\right) \lesssim \Theta\left(T_{m-1}\right) \lesssim A_{0}^{-(m-1) / 2} \mathcal{P}\left(R_{1}^{h^{\prime}}\right) \\
& \lesssim A_{0}^{-\left(h^{\prime}-h^{\prime \prime}\right) / 2} \mathcal{P}\left(R_{1}^{h^{\prime}}\right) \approx A_{0}^{-\left(h^{\prime}-h^{\prime \prime}\right) / 2} \Theta\left(R_{1}^{h^{\prime}}\right)
\end{aligned}
$$

Since $\Theta\left(R_{1}^{h^{\prime}}\right)=\Theta\left(R_{1}^{h^{\prime \prime}}\right)$, we get $\left|h^{\prime}-h^{\prime \prime}\right| \lesssim 1$. Consequently, in the case $i=\tilde{k}$ there are again at most $C|\log \lambda| \approx \log \Lambda$ cubes $R_{1}^{h}$ satisfying (6.4).

To prove the lemma, notice that each family $\mathrm{L}_{j}^{h}(P, k)$ consists of a single cube, at most. Indeed, if $R \in \mathrm{~L}_{j}^{h}(P, k)$, then $P \subset B\left(e^{\prime \prime}(R)\right)$. Thus if $R, R^{\prime} \in \mathrm{L}_{j}^{h}(P, k)$, then $B\left(e^{\prime \prime}(R)\right) \cap$ $B\left(e^{\prime \prime}\left(R^{\prime}\right)\right) \neq \varnothing$, which cannot happen if $R \neq R^{\prime}$. From this fact and the preceding claims, we infer that $\# \mathrm{~L}_{j}(P, k) \leq C \log \Lambda$, so that (6.2) holds.

For $R \in \mathrm{~L}(\mathrm{GDF}), Q \in \operatorname{Trc}_{k}(R)$, we write $P \sim \mathcal{T}\left(e^{\prime}(Q)\right)$ if there exists some $P^{\prime} \in \mathcal{T}\left(e^{\prime}(Q)\right)$ such that

$$
\begin{equation*}
A_{0}^{-2} \ell(P) \leq \ell\left(P^{\prime}\right) \leq A_{0}^{2} \ell(P) \quad \text { and } \quad 20 P^{\prime} \cap 20 P \neq \varnothing \tag{6.9}
\end{equation*}
$$

We say that $\mathcal{T}\left(e^{\prime}(Q)\right)$ is a typical tractable tree, and we write $Q \in$ Ty if

$$
\begin{equation*}
\sum_{P \in \mathrm{DB}: P \sim \mathcal{T}\left(e^{\prime}(Q)\right)} \mathcal{E}_{\infty}(9 P) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \tag{6.10}
\end{equation*}
$$

Lemma 6.5. We have

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{\frac{-1}{2 n}}(\log \Lambda)^{2} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}_{y}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) .
$$

Proof. By Lemmas 4.3 and 5.1, we have

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{-\frac{1}{2 n}} \sum_{R \in \mathrm{GDF}} \sigma\left(\mathrm{HD}_{1}(R)\right) .
$$

Also, by (6.1) and Lemma 5.6.

$$
\begin{aligned}
\sum_{R \in \mathrm{GDF}} \sigma\left(\mathrm{HD}_{1}(R)\right) & \leq m_{0} B^{1 / 4} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sigma\left(\mathrm{HD}_{1}(e(R))\right) \\
& \leq m_{0} B^{1 / 4} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R)} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) .
\end{aligned}
$$

Therefore,

$$
\begin{align*}
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim & m_{0} B^{1 / 4} \Lambda^{-\frac{1}{2 n}} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R)} \sigma\left(\mathrm{HD}_{1}(e(Q))\right)  \tag{6.11}\\
= & m_{0} B^{1 / 4} \Lambda^{-\frac{1}{2 n}} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Ty}_{y}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \\
& +m_{0} B^{1 / 4} \Lambda^{-\frac{1}{2 n}} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \backslash \mathrm{Ty}_{y}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right) \\
= & S_{1}+S_{2} .
\end{align*}
$$

By definition, for $Q \in \operatorname{Trc}_{k}(R) \backslash \mathrm{Ty}$, we have

$$
\sigma\left(\mathrm{HD}_{1}(e(Q))\right) \leq \Lambda^{\frac{1}{3 n}} \sum_{P \in \mathrm{DB}: P \sim \mathcal{T}\left(e^{\prime}(R)\right)} \mathcal{E}_{\infty}(9 P) .
$$

Hence, the term $S_{2}$ in (6.11) does not exceed

$$
\begin{aligned}
& m_{0} B^{1 / 4} \Lambda^{-\frac{1}{2 n}} \Lambda^{\frac{1}{3 n}} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \backslash \operatorname{Ty}} \sum_{P \in \mathrm{DB}: P \sim \mathcal{T}\left(e^{\prime}(Q)\right)} \mathcal{E}_{\infty}(9 P) \\
& \lesssim m_{0} B^{1 / 4} \Lambda^{-\frac{1}{6 n}} \sum_{P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P) \sum_{k \geq 0} B^{-k / 2} \# A(P, k)
\end{aligned}
$$

where

$$
A(P, k)=\left\{R \in \mathrm{~L}(\mathrm{GDF}): P \sim \mathcal{T}\left(e^{\prime}(Q)\right) \text { for some } Q \in \operatorname{Trc}_{k}(R)\right\}
$$

From the definition (6.9) and Lemma 6.2, it follows that

$$
\begin{align*}
\# A(P, k) \leq & \sum_{\substack{P^{\prime} \in \mathcal{D}_{\mu}: 20 P^{\prime} \cap 20 P \neq \varnothing \\
A_{0}^{-2} \ell(P) \leq \ell\left(P^{\prime}\right) \leq A_{0}^{2} \ell(P)}} \#\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } P^{\prime} \in \mathcal{T}\left(e^{\prime}(Q)\right)\right\}  \tag{6.12}\\
& \lesssim \sum_{\substack{P^{\prime} \in \mathcal{D}_{\mu}: 20 P^{\prime} \cap 20 P \neq \varnothing \\
A_{0}^{-2} \ell(P) \leq \ell\left(P^{\prime}\right) \leq A_{0}^{2} \ell(P)}}(\log \Lambda)^{2} \lesssim(\log \Lambda)^{2} .
\end{align*}
$$

Therefore, the term $S_{2}$ in (6.11) satisfies
$S_{2} \lesssim m_{0} B^{1 / 4} \Lambda^{-\frac{1}{6 n}}(\log \Lambda)^{2} \sum_{P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P) \sum_{k \geq 0} B^{-k / 2} \lesssim m_{0} B^{1 / 4} \Lambda^{-\frac{1}{6 n}}(\log \Lambda)^{2} \sum_{P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P)$.
Assuming that $B \leq \Lambda^{\frac{1}{2 n}}$, say, we deduce that ${ }^{2}$

$$
S_{2} \leq \frac{1}{2} \sum_{P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P)
$$

if $\Lambda$ is big enough. So we get

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \leq 2 S_{1}
$$

which proves the lemma.
7. Lower estimates for the Riesz transform of the approximating measure $\eta$ IN A TYPICAL TRACTABLE TREE

In this section, for a given $R \in \mathrm{MDW}$ such that $\mathcal{T}\left(e^{\prime}(R)\right)$ is tractable, we will define a suitable measure $\eta$ that approximates $\mu$ at the level of the cubes from $\mathcal{T}\left(e^{\prime}(R)\right)$ and we will get a lower bound for $\|\mathcal{R} \eta\|_{L^{p}(\eta)}$. In the next section we will transfer these estimates to $\mathcal{R} \mu$.

[^2]Let $R$ be a fixed cube from MDW $\cap \operatorname{Trc}$. Recall that the family $\mathcal{T}\left(e^{\prime}(R)\right)$ was constructed by stopping time conditions involving the families $\operatorname{LD}(\cdot), \operatorname{HD}(\cdot)$, and $\operatorname{NDB}(\cdot)$. Next we need to define some regularized family of stopping cubes. First we consider the function

$$
d_{R}(x)=\inf _{Q \in \mathcal{T}\left(e^{\prime}(R)\right)}(\operatorname{dist}(x, Q)+\ell(Q))
$$

Given $0<\ell_{0} \ll \ell(R)$, we denote

$$
\begin{equation*}
d_{R, \ell_{0}}(x)=\max \left(\ell_{0}, d_{R}(x)\right) . \tag{7.1}
\end{equation*}
$$

Notice that both $d_{R}$ and $d_{R, \ell_{0}}$ are 1-Lipschitz.
For each $x \in e^{\prime}(R)$ we take the largest cube $Q_{x} \in \mathcal{D}_{\mu}$ such that $x \in Q_{x}$ and

$$
\begin{equation*}
\ell\left(Q_{x}\right) \leq \frac{1}{60} \inf _{y \in Q_{x}} d_{R, \ell_{0}}(y) . \tag{7.2}
\end{equation*}
$$

We consider the collection of the different cubes $Q_{x}, x \in e^{\prime}(R)$, and we denote it by $\operatorname{Reg}\left(e^{\prime}(R)\right)$ (this stands for "regularized cubes"). Observe that the cubes from Reg are disjoint by construction, and they cover $e^{\prime}(R)$.

The constant $\ell_{0}$ is just an auxiliary parameter that prevents $\ell\left(Q_{x}\right)$ from vanishing. Eventually $\ell_{0}$ will be taken extremely small. In particular, we assume $\ell_{0}$ small enough so that

$$
\begin{equation*}
\mu\left(\bigcup_{Q \in \mathrm{HD}_{1}(e(R)): \ell(Q) \geq \ell_{0}} Q\right) \geq \frac{1}{2} \mu\left(\bigcup_{Q \in \mathrm{HD}_{1}(e(R))} Q\right) \tag{7.3}
\end{equation*}
$$

We let $\mathcal{T}_{\operatorname{Reg}}\left(e^{\prime}(R)\right)$ be the family of cubes made up of $R$ and all the cubes of the next generations which are contained in $e^{\prime}(R)$ but are not strictly contained in any cube from $\operatorname{Reg}\left(e^{\prime}(R)\right)$.

Lemma 7.1. The cubes from $\operatorname{Reg}\left(e^{\prime}(R)\right)$ are pairwise disjoint and satisfy the following properties:
(a) If $P \in \operatorname{Reg}\left(e^{\prime}(R)\right)$ and $x \in B\left(x_{P}, 50 \ell(P)\right)$, then $10 \ell(P) \leq d_{R, \ell_{0}}(x) \leq c \ell(P)$, where $c$ is some constant depending only on $n$.
(b) There exists some absolute constant $c>0$ such that if $P, P^{\prime} \in \operatorname{Reg}\left(e^{\prime}(R)\right)$ satisfy $B\left(x_{P}, 50 \ell(P)\right) \cap B\left(x_{P^{\prime}}, 50 \ell\left(P^{\prime}\right)\right) \neq \varnothing$, then

$$
c^{-1} \ell(P) \leq \ell\left(P^{\prime}\right) \leq c \ell(P)
$$

(c) For each $P \in \operatorname{Reg}\left(e^{\prime}(R)\right)$, there are at most $N$ cubes $P^{\prime} \in \operatorname{Reg}\left(e^{\prime}(R)\right)$ such that

$$
B\left(x_{P}, 50 \ell(P)\right) \cap B\left(x_{P^{\prime}}, 50 \ell\left(P^{\prime}\right)\right) \neq \varnothing
$$

where $N$ is some absolute constant.
The proof of this lemma is standard. See for example [To4, Lemma 6.6].
Next we introduce a measure $\eta$ which approximates $\left.\mu\right|_{e^{\prime}(R)}$ at the level of the cubes from $\operatorname{Reg}\left(e^{\prime}(R)\right)$. We let

$$
\eta=\sum_{Q \in \operatorname{Reg}\left(e^{\prime}(R)\right)} \mu(Q) \frac{\left.\mathcal{L}^{n+1}\right|_{2} B(Q)}{\mathcal{L}^{n+1}\left(\frac{1}{2} B(Q)\right)} .
$$

Then we have:

Lemma 7.2. Let $R \in \mathrm{MDW} \cap \operatorname{Trc}$ and let $\eta$ be as above. Assume $\Lambda>0$ big enough and let $c_{2} \in(0,1)$ be small enough (depending at most on the parameters of the David-Mattila lattice). Then there is a subset $V_{R} \subset \operatorname{supp} \eta$ satisfying

$$
\begin{equation*}
\operatorname{dist}\left(Q, \operatorname{supp} \mu \backslash e^{\prime}(R)\right) \gtrsim \ell(R) \quad \text { for all } Q \in \operatorname{Reg}\left(e^{\prime}(R)\right) \text { such that } B_{Q} \cap V_{R} \neq \varnothing \tag{7.4}
\end{equation*}
$$

such that

$$
\int_{V_{R}}\left|\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta(x) \gtrsim \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}(e(R))\right)
$$

for any $p \in(1,2]$, where $p^{\prime}=p /(p-1)$ and the implicit constant depends on $p$.
Recall that, for $\mathcal{I} \subset \mathcal{D}_{\mu}$,

$$
\sigma_{p}(\mathcal{I})=\sum_{P \in \mathcal{I}} \Theta(P)^{p} \mu(P) .
$$

In the lemma $\mathcal{R} \eta(x)$ is well defined by an absolutely convergent integral for all $x \in \mathbb{R}^{n+1}$ because $\eta$ is absolutely continuous with respect to Lebesgue measure in $\mathbb{R}^{n+1}$ and it has a bounded density function, since the cubes from the family Reg have side length bounded away from 0 , thanks to the parameter $\ell_{0}$.

The proof Lemma 7.2 is the same as the one in [DT, Lemma 6.14] and so we omit it here. Remark that the construction of the tractable tree $\mathcal{T}\left(e^{\prime}(R)\right)$ in that work does not involve the stopping condition $\operatorname{NDB}(\cdot)$. However, the reader can check that this type of cubes do not play any role in the proof of [DT, Lemma 6.14], and exactly the same verbatim arguments are valid here.

The proof of the previous lemma is one main key points in the [DT]. The arguments to prove this are partially inspired by related results from [ENV], [RT], and [JNRT].

## 8. Lower estimates for the Hatar coefficients of $\mathcal{R} \mu$ for cubes near a typical tractable tree

In all this section we assume that $R \in$ MDW is such that $R \in \operatorname{Trc} \cap \operatorname{Ty}$, i.e., $\mathcal{T}\left(e^{\prime}(R)\right)$ is tractable and typical, and we consider the measure $\eta$ constructed in Section 7. Roughly speaking, our objective is to transfer the lower estimate we obtained for $\mathcal{R} \eta$ in Lemma 7.2 to the Haar coefficients of $\mathcal{R} \mu$ for cubes close to $\mathcal{T}\left(e^{\prime}(R)\right)$. Recall that $\mathcal{R} \mu(x)$ exists $\mu$-a.e. as a principal value under the assumptions of Proposition 3.7.
8.1. The operators $\mathcal{R}_{\mathcal{T}_{\text {Reg }}}, \mathcal{R}_{\widetilde{\mathcal{T}}}$, and $\Delta_{\tilde{\mathcal{T}}} \mathcal{R}$. To simplify notation, in this section we will write

$$
\text { End }=\operatorname{End}\left(e^{\prime}(R)\right), \quad \operatorname{Reg}=\operatorname{Reg}\left(e^{\prime}(R)\right), \quad \mathcal{T}=\mathcal{T}\left(e^{\prime}(R)\right), \quad \text { and } \quad \mathcal{T}_{\operatorname{Reg}}=\mathcal{T}_{\operatorname{Reg}}\left(e^{\prime}(R)\right)
$$

We need to consider an enlarged version of the generalized tree $\mathcal{T}$, due to some technical difficulties that arise because the cubes from $\operatorname{Neg}:=\operatorname{Neg}\left(e^{\prime}(R)\right) \cap$ End are not $\mathcal{P}$-doubling. To this end, denote by $\operatorname{Reg}_{\mathrm{Neg}}$ the family of the cubes from Reg which are contained in some cube from Neg. Let $\mathrm{D}_{\mathrm{Neg}}$ be the subfamily of the cubes $P \in \operatorname{Reg}_{\mathrm{Neg}}$ for which there exists some $\mathcal{P}$-doubling cube $S \in \mathcal{T}_{\text {Reg }}$ that contains $P$. By the definition of Neg , such cube $S$ should be contained in the cube from $Q \in \operatorname{Neg}$ such that $P \subset Q$. We also denote by $\mathrm{M}_{\text {Neg }}$ the family of maximal $\mathcal{P}$-doubling cubes which belong to $\mathcal{T}_{\text {Reg }}$ and are contained in some cube from Neg, so that, in particular, any cube from $D_{\text {Neg }}$ is contained in another from $M_{\text {Neg }}$.

We define

$$
\widetilde{\text { End }}=(\text { End } \backslash N e g) \cup M_{N e g},
$$

and we let $\widetilde{\mathcal{T}}=\widetilde{\mathcal{T}}\left(e^{\prime}(R)\right)$ be the family of cubes that belong to $\mathcal{T}_{\text {Reg }}$ but are not strictly contained in any cube from End. Further, we write

$$
\begin{equation*}
Z=Z\left(e^{\prime}(R)\right)=e^{\prime}(R) \backslash \bigcup_{Q \in \text { End }} Q \quad \text { and } \quad \widetilde{Z}=\widetilde{Z}\left(e^{\prime}(R)\right)=e^{\prime}(R) \backslash \bigcup_{Q \in \widetilde{\text { End }}} Q \tag{8.1}
\end{equation*}
$$

Then we denote

$$
\begin{aligned}
\mathcal{R}_{\mathcal{T}_{\text {eg }}} \mu(x) & =\sum_{Q \in \operatorname{Reg}} \chi_{Q}(x) \mathcal{R}\left(\chi_{2 R \backslash 2 Q} \mu\right)(x), \\
\mathcal{R}_{\widetilde{\mathcal{T}}} \mu(x) & =\sum_{Q \in \overparen{\text { End }}} \chi_{Q}(x) \mathcal{R}\left(\chi_{2 R \backslash 2 Q} \mu\right)(x),
\end{aligned}
$$

and

$$
\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu(x)=\sum_{Q \in E \text { End }} \chi_{Q}(x)\left(m_{\mu, Q}(\mathcal{R} \mu)-m_{\mu, 2 R}(\mathcal{R} \mu)\right)+\chi_{Z}(x)\left(\mathcal{R} \mu(x)-m_{\mu, 2 R}(\mathcal{R} \mu)\right) .
$$

Remark that the cubes from Reg have the advantage over the cubes from End that their size changes smoothly so that, for example, neighboring cubes have comparable side lengths. However, they need not be $\mathcal{P}$-doubling or doubling, unlike the cubes from End. In particular, it is not clear how to estimate their energy $\mathcal{E}_{\infty}$ in terms of the condition DB (recall that the cubes from DB are asked to be $\mathcal{P}$-doubling).

For $Q \in \mathcal{D}_{\mu}$, we define

$$
\mathcal{Q}_{\mathrm{Reg}}(Q)=\sum_{P \in \operatorname{Reg}} \frac{\ell(P)}{D(P, Q)^{n+1}} \mu(P)
$$

where

$$
D(P, Q)=\ell(P)+\operatorname{dist}(P, Q)+\ell(Q)
$$

The coefficient $\mathcal{Q}_{\text {Reg }}(Q)$ will be used to bound some "error terms" in our transference arguments. We will see later how they can be estimated in terms of the coefficients $\mathcal{P}(Q)$. Notice that, unlike $\mathcal{P}(Q)$, the coefficients $\mathcal{Q}_{\operatorname{Reg}}(Q)$ depend on the family Reg.

The next three lemmas are proven in the same way as Lemmas 7.1, 7.2, and 7.3 from DT].
Lemma 8.1. For any $Q \in \operatorname{Reg}$ such that $\left(Q \cup \frac{1}{2} B(Q)\right) \cap V_{R} \neq \varnothing$ and $x \in Q, y \in \frac{1}{2} B(Q)$,

$$
\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(x)-\mathcal{R} \eta(y)\right| \lesssim \Theta(R)+\mathcal{P}(Q)+\mathcal{Q}_{\operatorname{Reg}}(Q)
$$

Lemma 8.2. For any $Q \in \widetilde{\text { End }}$ and $x, y \in Q$,

$$
\left|\mathcal{R}_{\tilde{\mathcal{T}}} \mu(x)-\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu(y)\right| \lesssim \mathcal{P}(R)+\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2}+\mathcal{P}(Q)+\left(\frac{\mathcal{E}(2 Q)}{\mu(Q)}\right)^{1 / 2}
$$

Lemma 8.3. Let $1<p \leq 2$. For any $Q \in \widetilde{\text { End }}$ such that $\ell_{0} \leq \ell(Q)$,,

$$
\int_{Q}\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu-\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu\right|^{p} d \mu \lesssim \mathcal{E}(2 Q)^{p / 2} \mu(Q)^{1-\frac{p}{2}}
$$

8.2. Estimates for the $\mathcal{P}$ and $\mathcal{Q}_{\text {Reg }}$ coefficients of some cubes from End and Reg. We will transfer the lower estimate obtained for the $L^{p}(\eta)$ norm of $\mathcal{R} \eta$ in Lemma 7.2 to $\mathcal{R}_{\mathcal{T}} \mu, \mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu$, and $\Delta_{\mathcal{T}} \mathcal{R} \mu$ by means of Lemmas 8.1, 8.2, and 8.3. To this end, we will need careful estimates for the $\mathcal{P}$ and $\mathcal{Q}_{\text {Reg }}$ coefficients of cubes from End and Reg. This is the task we will perform in this section.

Given $R \in \mathrm{MDW}$, recall that $\mathrm{HD}_{1}\left(e^{\prime}(R)\right)=\mathrm{HD}(R) \cap \operatorname{Stop}\left(e^{\prime}(R)\right)$. To shorten notation, we will write $\mathrm{HD}_{1}=\mathrm{HD}_{1}\left(e^{\prime}(R)\right)$ in this section. Notice also that, by (5.6), we have

$$
\begin{equation*}
\widetilde{\mathrm{End}}=\mathrm{LD}_{1} \cup \mathrm{NDB}_{1} \cup \mathrm{LD}_{2} \cup \mathrm{NDB}_{2} \cup \mathrm{HD}_{2} \cup \mathrm{M}_{\mathrm{Neg}}, \tag{8.2}
\end{equation*}
$$

where we introduced the following notations:

- LD ${ }_{1}$ is the subfamily of $\widetilde{\text { End }}$ of those maximal $\mathcal{P}$-doubling cubes which are contained both in $e^{\prime}(R)$ and in some cube from $\mathrm{LD}(R) \cap \mathrm{Stop}_{1}\left(e^{\prime}(R)\right) \backslash$ Neg.
- $\mathrm{NDB}_{1}$ is the subfamily of End of those maximal $\mathcal{P}$-doubling cubes which are contained both in $e^{\prime}(R)$ and in some cube from $\operatorname{NDB}(R) \cap \operatorname{Stop}_{1}\left(e^{\prime}(R)\right) \backslash$ Neg.
- $\mathrm{LD}_{2}$ is the subfamily of End of those maximal $\mathcal{P}$-doubling cubes which are contained in some cube $Q \in \mathrm{LD}\left(Q^{\prime}\right) \cap \operatorname{Stop}\left(Q^{\prime}\right) \backslash \mathrm{Neg}$ for some $Q^{\prime} \in \mathrm{HD}_{1}$.
- $\mathrm{NDB}_{2}$ is the subfamily of End of those maximal $\mathcal{P}$-doubling cubes which are contained in some cube $Q \in \operatorname{NDB}\left(Q^{\prime}\right) \cap \operatorname{Stop}\left(Q^{\prime}\right)$ for some $Q^{\prime} \in \mathrm{HD}_{1}$.
- $\mathrm{HD}_{2}=\bigcup_{Q^{\prime} \in \mathrm{HD}_{1}}\left(\mathrm{HD}\left(Q^{\prime}\right) \cap \operatorname{Stop}\left(Q^{\prime}\right)\right)$.

Remark that the splitting in (8.2) is disjoint. Indeed, notice that, by the definition of $M_{\text {Neg }}$, the cubes from $N D B_{2} \cup H D_{2}$ do not belong to $M_{\text {Neg }}$, since they are strictly contained in some cube from $\mathrm{HD}_{1}$, which is $\mathcal{P}$-doubling, in particular.

For $i=1,2$, we also denote by $\operatorname{Reg}_{\mathrm{LD}_{i}}$ the subfamily of the cubes from Reg which are contained in some cube from $\mathrm{LD}_{i}$, and we define $\mathrm{Reg}_{\mathrm{NDB}_{i}}, \mathrm{Reg}_{\mathrm{HD}_{2}}, \mathrm{Reg}_{\mathrm{Neg}}$, and $\mathrm{Reg}_{\mathrm{M}_{\text {Neg }}}$ analogously 3 We let Regot be the "other" cubes from Reg: the ones which are not contained in any cube from End (which, in particular, have side length comparable to $\ell_{0}$ ). Also, we let $\operatorname{Reg}_{\mathrm{DB}}$ be the subfamily of the cubes from Reg which are contained in some cube from $\widetilde{\text { End }} \cap \mathrm{DB}$. Notice that we have the splitting

$$
\begin{equation*}
\operatorname{Reg}=\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{NDB}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}} \cup \operatorname{Reg}_{\mathrm{NDB}_{2}} \cup \operatorname{Reg}_{\mathrm{HD}_{2}} \cup \operatorname{Reg}_{\mathrm{Neg}} \cup \operatorname{Reg}_{\mathrm{Ot}} \tag{8.3}
\end{equation*}
$$

The families above may intersect the family $\mathrm{Reg}_{\mathrm{DB}}$.
Given a family $\mathcal{I} \in \mathcal{D}_{\mu}$ and $1<p \leq 2$, we denote

$$
\Sigma_{p}^{\mathcal{P}}(\mathcal{I})=\sum_{Q \in \mathcal{I}} \mathcal{P}(Q)^{p} \mu(Q), \quad \Sigma_{p}^{\mathcal{Q}}(\mathcal{I})=\sum_{Q \in \mathcal{I}} \mathcal{Q}_{\operatorname{Reg}}(Q)^{p} \mu(Q)
$$

We also write $\Sigma^{\mathcal{P}}(\mathcal{I})=\Sigma_{2}^{\mathcal{P}}(\mathcal{I}), \Sigma^{\mathcal{Q}}(\mathcal{I})=\Sigma_{2}^{\mathcal{Q}}(\mathcal{I})$.

[^3]Lemma 8.4. For any $Q \in \widetilde{\text { End }}$,

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Reg} \cap \mathcal{D}_{\mu}(Q)\right) \lesssim \mathcal{P}(Q)^{2} \mu(Q)+\mathcal{E}(2 Q)
$$

This is proven in the same way as Lemma 7.4 from [DT].
Lemma 8.5. We have:
(i) If $Q \in \mathrm{LD}_{1}$, then $\mathcal{P}(Q) \lesssim \delta_{0}^{\frac{1}{n+1}} \Lambda^{\frac{n}{n+1}} \Theta(R)$.
(ii) If $Q \in \mathrm{LD}_{2}$, then $\mathcal{P}(Q) \lesssim \delta_{0}^{\frac{1}{n+1}} \Lambda^{1+\frac{n}{n+1}} \Theta(R)$.
(iii) If $Q \in \operatorname{NDB}_{1}$, then $\mathcal{P}(Q) \lesssim \Lambda \Theta(R)$.
(iv) If $Q \in \mathrm{NDB}_{2} \cup \mathrm{HD}_{2}$, then $\mathcal{P}(Q) \lesssim \Lambda^{2} \Theta(R)$.
(v) If $Q \in \operatorname{Neg} \cup \mathrm{M}_{\mathrm{Neg}}$, then $\mathcal{P}(Q) \lesssim\left(\frac{\ell(Q)}{\ell(R)}\right)^{1 / 3} \Theta(R)$.

Proof. The statement (i) is proven as in Lemma 3.2 (c) in [RT]. The statement (ii) follows in the same way as (i), replacing $\Theta(R)$ by $\Lambda \Theta(R)$.

The statement (iii) is due to the fact that, by the stopping conditions, the cubes $Q^{\prime} \in$ Stop $_{1}\left(e^{\prime}(R)\right)$ satisfy $\mathcal{P}\left(Q^{\prime}\right) \lesssim \Lambda \mathcal{P}(R) \approx \Lambda \Theta(R)$. Then it just remains to notice that if $Q$ is a maximal doubling cube contained in $Q^{\prime}$, from Lemma 3.2 it follows that $\mathcal{P}(Q) \lesssim \mathcal{P}\left(Q^{\prime}\right)$.

The property (iv) for the cubes in $\mathrm{NDB}_{2}$ follows by arguments analogous to the ones for (iii), taking into account that such cubes are maximal doubling cubes contained in cubes from $\operatorname{Stop}\left(R^{\prime}\right)$, for some $R^{\prime} \in \mathrm{HD}_{1}$ with $\mathcal{P}\left(R^{\prime}\right) \approx \Theta\left(R^{\prime}\right)=\Lambda \Theta(R)$ On the other hand the cubes $Q \in \mathrm{HD}_{2}$ satisfy $\Theta(Q)=\Lambda^{2} \Theta(R)$ and are $\mathcal{P}$-doubling by construction.

Finally, we turn our attention to (v). By the definitions of Neg and $\mathrm{M}_{\text {Neg }}$ and Lemma 3.2, for all $S \in \mathcal{D}_{\mu}$ such that $Q \subset S \subset R$, we have

$$
\Theta(S) \lesssim\left(\frac{\ell(S)}{\ell(R)}\right)^{1 / 2} \mathcal{P}(R)
$$

Thus,

$$
\begin{aligned}
\mathcal{P}(Q) & \approx \frac{\ell(Q)}{\ell(R)} \mathcal{P}(R)+\sum_{S: Q \subset S \subset R} \frac{\ell(Q)}{\ell(S)} \Theta(S) \\
& \lesssim \frac{\ell(Q)}{\ell(R)} \Theta(R)+\sum_{S: Q \subset S \subset R} \frac{\ell(Q)}{\ell(S)}\left(\frac{\ell(S)}{\ell(R)}\right)^{1 / 2} \Theta(R) \\
& \lesssim \frac{\ell(Q)}{\ell(R)} \Theta(R)+\sum_{S: Q \subset S \subset R}\left(\frac{\ell(Q)}{\ell(R)}\right)^{1 / 2} \Theta(R) \\
& \lesssim \frac{\ell(Q)}{\ell(R)} \Theta(R)+\log \left(\frac{\ell(R)}{\ell(Q)}\right)\left(\frac{\ell(Q)}{\ell(R)}\right)^{1 / 2} \Theta(R) \lesssim\left(\frac{\ell(Q)}{\ell(R)}\right)^{1 / 3} \Theta(R) .
\end{aligned}
$$

[^4]Remark 8.6. We will assume that

$$
\delta_{0} \leq \Lambda^{-(n+2)^{2}} .
$$

With this choice, it follows easily that $\delta_{0}^{\frac{1}{n+1}} \Lambda^{1+\frac{n}{n+1}} \leq \delta_{0}^{\frac{1}{n+2}}$, so that by the preceding lemma

$$
\mathcal{P}(Q) \lesssim \delta_{0}^{\frac{1}{n+2}} \Theta(R) \quad \text { for all } Q \in \mathrm{LD}_{1} \cup \mathrm{LD}_{2}
$$

Lemma 8.7. Suppose that $R \in \operatorname{Trc} \cap \operatorname{Ty}$. Then

$$
\begin{gather*}
\Sigma^{\mathcal{P}}(\widetilde{\text { End }}) \approx \sigma(\widetilde{\text { End }}) \lesssim B \sigma\left(\mathrm{HD}_{1}\right),  \tag{8.4}\\
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right) \lesssim \sum_{Q \in \overleftarrow{\mathrm{End}} \cap \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \leq \sum_{Q \in \mathrm{DB}: Q \sim \mathcal{T}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right),  \tag{8.5}\\
\Sigma^{\mathcal{P}}(\widetilde{\text { End }} \cap \mathrm{DB}) \approx \sigma(\widetilde{\text { End }} \cap \mathrm{DB}) \leq M_{0}^{-2} \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right),  \tag{8.6}\\
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}}\right)+\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right) \lesssim \sum_{Q \in \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right),  \tag{8.7}\\
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}}\right) \lesssim \sum_{Q \in \mathrm{LD}_{1} \cup \mathrm{LD}_{2}} \mathcal{E}_{\infty}(9 Q) \lesssim\left(B M_{0}^{2} \delta_{0}^{\frac{2}{n+2}}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right) . \tag{8.8}
\end{gather*}
$$

Also, for $1<p \leq 2$,

$$
\begin{gather*}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}}\right) \lesssim\left(B \Lambda^{2} \delta_{0}^{\frac{p}{n+2}}+\Lambda^{\frac{-p}{6 n}}\right) \sigma_{p}\left(\mathrm{HD}_{1}\right),  \tag{8.9}\\
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right) \lesssim \Sigma_{p}^{\mathcal{P}}\left(\mathrm{HD}_{2}\right) \approx \sigma_{p}\left(\mathrm{HD}_{2}\right) \lesssim B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right)  \tag{8.10}\\
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right) \lesssim \Lambda^{\frac{-p}{6 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) . \tag{8.11}
\end{gather*}
$$

Proof. To prove (8.4), notice first that $\Sigma^{\mathcal{P}}(\widetilde{\text { End }}) \approx \sigma(\widetilde{(\text { End })}$ because the cubes from End are $\mathcal{P}$-doubling. Also, by (8.2) we have

$$
\Sigma^{\mathcal{P}}(\widetilde{\mathrm{End}})=\Sigma^{\mathcal{P}}\left(\mathrm{LD}_{1}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{LD}_{2}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{NDB}_{1}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{NDB}_{2}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{HD}_{2}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{M}_{\mathrm{Neg}}\right)
$$

By Lemma 8.5 and the subsequent remark, we have

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\mathrm{LD}_{1}\right)+\Sigma^{\mathcal{P}}\left(\mathrm{LD}_{2}\right) \lesssim \delta_{0}^{\frac{2}{n+2}} \Theta(R)^{2} \mu(R)=\delta_{0}^{\frac{2}{n+2}} \sigma(R) \tag{8.12}
\end{equation*}
$$

Again by Lemma 8.5, we have $\mathcal{P}(Q) \lesssim \Theta(R)$ for all $Q \in \mathrm{M}_{\mathrm{Neg}}$ and thus $5^{5}$

$$
\Sigma^{\mathcal{P}}\left(\mathrm{M}_{\mathrm{Neg}}\right) \lesssim \sigma(R) .
$$

[^5]Also, since $\mathcal{T}$ is a tractable tree, we have

$$
\sigma(R) \leq B \sigma\left(\mathrm{HD}_{1}\right) \quad \text { and } \quad \Sigma^{\mathcal{P}}\left(\mathrm{HD}_{2}\right) \approx \sigma\left(\mathrm{HD}_{2}\right) \lesssim B \sigma\left(\mathrm{HD}_{1}\right)
$$

Regarding the family $\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}$, denote

$$
\operatorname{Stop}_{\mathrm{NDB}}=\operatorname{Stop}_{1}\left(e^{\prime}(R)\right) \cap \operatorname{NDB}(R) \cup \bigcup_{S \in \mathrm{HD}_{1}}(\operatorname{Stop}(S) \cap \operatorname{NDB}(S)),
$$

so that the cubes from $P \in \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}$ are maximal $\mathcal{P}$-doubling cubes contained in some cube from Stop ${ }_{\mathrm{NDB}}$. By Lemma 3.2, if $P \in \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}$ is contained in $Q \in$ Stop $_{\mathrm{NDB}}$, then $\mathcal{P}(P) \lesssim \mathcal{P}(Q)$. Also, by the definition of $\operatorname{NDB}(\cdot)$, there exists $Q^{\prime}=Q^{\prime}(Q) \in \mathrm{DB}$ such that $\ell\left(Q^{\prime}\right)=\ell(Q)$ and $Q^{\prime} \subset 20 Q$. In particular, this implies that $Q^{\prime} \sim \mathcal{T}\left(e^{\prime}(R)\right)$ and that $\mathcal{P}(Q) \approx \mathcal{P}\left(Q^{\prime}\right) \approx \sigma\left(Q^{\prime}\right)$, and by the definition of DB,

$$
\begin{equation*}
\mathcal{E}_{\infty}\left(9 Q^{\prime}\right) \gtrsim M_{0}^{2} \sigma\left(Q^{\prime}\right) . \tag{8.13}
\end{equation*}
$$

Thus,

$$
\begin{align*}
\Sigma^{\mathcal{P}}\left(\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}\right) & =\sum_{Q \in \mathrm{Stop}_{\mathrm{NDB}}} \sum_{P \in \operatorname{End} \cap \mathcal{D}_{\mu}(Q)} \mathcal{P}(P)^{2} \mu(P)  \tag{8.14}\\
& \lesssim \sum_{Q \in \mathrm{Stop}_{\mathrm{NDB}}} \mathcal{P}(Q)^{2} \mu(Q) \approx \sum_{Q \in \mathrm{Stop}_{\mathrm{NDB}}} \sigma\left(Q^{\prime}(Q)\right) \\
& \lesssim \frac{1}{M_{0}^{2}} \sum_{Q \in \mathrm{Stop}_{\mathrm{NDB}}} \mathcal{E}_{\infty}\left(9 Q^{\prime}(Q)\right) \lesssim \frac{1}{M_{0}^{2}} \sum_{Q^{\prime} \in \mathrm{DB}: Q^{\prime} \sim \mathcal{T}} \mathcal{E}_{\infty}\left(9 Q^{\prime}\right),
\end{align*}
$$

where in the last estimate we took into account that for each $Q^{\prime}$ there is a bounded number of cubes $Q \in$ Stop $_{\text {NDB }}$ such that $Q^{\prime}=Q^{\prime}(Q)$ (possibly depending on $n$ and $A_{0}$ ). Since $\mathcal{T}$ is a typical tree, by the definition in (6.10), we have

$$
\begin{equation*}
\sum_{Q^{\prime} \in \mathrm{DB}: Q^{\prime} \sim \mathcal{T}} \mathcal{E}_{\infty}\left(9 Q^{\prime}\right) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \tag{8.15}
\end{equation*}
$$

So we have

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}\right) \lesssim M_{0}^{-2} \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \tag{8.16}
\end{equation*}
$$

Gathering the estimates above, the estimate (8.4) follows.
To prove (8.5), we apply Lemma 8.4 and the fact that $\mathcal{T}$ is a typical tree again:

$$
\begin{aligned}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right) & =\sum_{Q \in \widehat{\mathrm{End}} \cap \mathrm{DB}} \Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}} \cap \mathcal{D}_{\mu}(Q)\right) \\
& \lesssim \sum_{Q \in \widehat{\text { End }} \mathrm{DB}}\left(\mathcal{P}(Q)^{2} \mu(Q)+\mathcal{E}(9 Q)\right) \lesssim \sum_{Q \in \widehat{\mathrm{End}} \cap \mathrm{DB}} \mathcal{E}_{\infty}(9 Q)
\end{aligned}
$$

Notice that, by the construction of the family Reg, for each $Q \in \mathrm{M}_{\text {Neg }}$ there exists some cube $Q^{\prime} \in \mathcal{T}$ such that

$$
\begin{equation*}
\ell(Q) \leq \ell\left(Q^{\prime}\right) \leq A_{0}^{2} \ell(S) \quad \text { and } \quad 20 Q^{\prime} \cap 20 Q \neq \varnothing \tag{8.17}
\end{equation*}
$$

Hence, $Q \sim \mathcal{T}($ see (6.9) $)$, and so

$$
\begin{aligned}
\sum_{Q \in \widetilde{\text { End } \cap D B}} \mathcal{E}_{\infty}(9 Q) & =\sum_{Q \in \text { End } \cap \mathrm{DB}} \mathcal{E}(9 Q)_{\infty}+\sum_{Q \in \mathrm{M}_{\text {Neg } \cap \mathrm{DB}}} \mathcal{E}_{\infty}(9 Q) \\
& \lesssim \sum_{S \in \mathrm{DB}: S \sim \mathcal{T}} \mathcal{E}_{\infty}(9 S) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

taking into account that $\mathcal{T}$ is a typical tree, which completes the proof of (8.5). Notice also that (8.6) follows from (8.5) and the fact that the cubes from DB satisfy (8.13).

Next we turn our attention to (8.7). By Lemma 8.4 we have

$$
\begin{aligned}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}} \cup \operatorname{Reg}_{\mathrm{NDB}_{2}}\right) & \lesssim \sum_{Q \in \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}} \mathcal{E}_{\infty}(9 Q) \\
& \leq \sum_{Q \in \in \mathrm{End} \cap \mathrm{DB} \mathcal{E}_{\infty}(9 Q)+\sum_{Q \in\left(\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}\right) \backslash \mathrm{DB}} \mathcal{E}_{\infty}(9 Q)} .
\end{aligned}
$$

By (8.5), the first term on the right hand side above does not exceed $C \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)$. Concerning the second term, we use the fact for the cubes $Q \notin \mathrm{DB}$, we have $\mathcal{E}_{\infty}(9 Q) \lesssim$ $M_{0}^{2} \sigma(Q)$ together with (8.16). Then we get

$$
\sum_{Q \in\left(\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}\right) \backslash \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim M_{0}^{2} \sigma\left(\mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}\right) \lesssim \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
$$

Regarding the estimate (8.8), by (8.12) and Lemma 8.4, we obtain

$$
\begin{aligned}
\Sigma^{\mathcal{P}}\left(\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}}\right) \backslash \operatorname{Reg}_{\mathrm{DB}}\right) & \lesssim \sum_{Q \in\left(\mathrm{LD}_{1} \cup \mathrm{LD} 2\right) \backslash \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim M_{0}^{2} \Sigma^{\mathcal{P}}\left(\mathrm{LD}_{1} \cup \mathrm{LD}_{2}\right) \\
& \lesssim M_{0}^{2} \delta_{0}^{\frac{2}{n+2}} \sigma(R) \leq B M_{0}^{2} \delta_{0}^{\frac{2}{n+2}} \sigma\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

Together with (8.5), this yields (8.8).
To get (8.9), we apply Hölder's inequality in the preceding estimate:

$$
\begin{aligned}
\Sigma_{p}^{\mathcal{P}}\left(\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}}\right) \backslash \operatorname{Reg}_{\mathrm{DB}}\right) & \leq\left(\Sigma^{\mathcal{P}}\left(\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}}\right) \backslash \operatorname{Reg}_{\mathrm{DB}}\right)\right)^{\frac{p}{2}} \mu\left(e^{\prime}(R)\right)^{1-\frac{p}{2}} \\
& \lesssim\left(B M_{0}^{2} \delta_{0}^{\frac{2}{n+2}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}} \mu(R)^{1-\frac{p}{2}}
\end{aligned}
$$

Observe now that, writing $H D_{i}=\bigcup_{Q \in \mathrm{HD}_{i}} Q$,

$$
\begin{equation*}
\mu\left(H D_{1}\right)=\frac{1}{\Lambda^{2} \Theta(R)^{2}} \sigma\left(\mathrm{HD}_{1}\right) \geq \frac{1}{B \Lambda^{2} \Theta(R)^{2}} \sigma(R)=\frac{1}{B \Lambda^{2}} \mu(R) \tag{8.18}
\end{equation*}
$$

Thus, using also that $M_{0} \leq \Lambda$,

$$
\begin{align*}
\Sigma_{p}^{\mathcal{P}}\left(\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}}\right) \backslash \operatorname{Reg}_{\mathrm{DB}}\right) & \lesssim\left(B M_{0}^{2} \delta_{0}^{\frac{2}{n+2}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}}\left(B \Lambda^{2} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}}  \tag{8.19}\\
& \leq B \Lambda^{2} \delta_{0}^{\frac{p}{n+2}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{align*}
$$

On the other hand, if we let $\operatorname{Reg}_{D_{2}}$ be the subfamily of the cubes from $\operatorname{Reg}_{D B}$ which are contained in some cube from $\mathrm{HD}_{1}$, by Hölder's inequality, Lemma 8.4, and (8.15), we get

$$
\begin{aligned}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}_{2}}\right) & \lesssim \Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}_{2}}\right)^{\frac{p}{2}} \mu\left(H D_{1}\right)^{1-\frac{p}{2}} \\
& \lesssim\left(\sum_{Q^{\prime} \in \mathrm{DB}: Q^{\prime} \sim \mathcal{T}} \mathcal{E}_{\infty}\left(9 Q^{\prime}\right)\right)^{\frac{p}{2}} \mu\left(H D_{1}\right)^{1-\frac{p}{2}} \\
& \lesssim\left(\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}} \mu\left(H D_{1}\right)^{1-\frac{p}{2}}=\Lambda^{\frac{-p}{6 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

Gathering (8.19) and the last estimate, we get (8.9).
To prove (8.10), recall that $\Theta(Q) \leq \Lambda^{2} \Theta(R)$ for all $Q \in \mathcal{T}$. This implies that also $\mathcal{P}(Q) \lesssim \Lambda^{2} \Theta(R)$ for all $Q \in$ Reg, by Lemma 3.2. Consequently,

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right) \lesssim \Lambda^{2 p} \Theta(R)^{p} \mu\left(H D_{2}\right)=\sigma_{p}\left(\mathrm{HD}_{2}\right) \approx \Sigma_{p}^{\mathcal{P}}\left(\mathrm{HD}_{2}\right)
$$

On the other hand, since $R \in \operatorname{Trc}$,

$$
\begin{aligned}
\sigma_{p}\left(\mathrm{HD}_{2}\right) & =\Theta\left(\mathrm{HD}_{2}\right)^{p-2} \sigma\left(\mathrm{HD}_{2}\right) \leq B \Theta\left(\mathrm{HD}_{2}\right)^{p-2} \sigma\left(\mathrm{HD}_{1}\right) \\
& =B \frac{\Theta\left(\mathrm{HD}_{2}\right)^{p-2}}{\Theta\left(\mathrm{HD}_{1}\right)^{p-2}} \sigma_{p}\left(\mathrm{HD}_{1}\right)=B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

which completes the proof of (8.10).
Finally, observe that (8.11) follows (8.7) using Hölder's inequality and the fact that the cubes from $\operatorname{Reg}_{\mathrm{NDB}_{2}}$ are contained in cubes from $\mathrm{HD}_{1}$ :

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right) \leq \Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right)^{\frac{p}{2}} \mu\left(H D_{1}\right)^{1-\frac{p}{2}} \lesssim\left(\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}} \mu\left(H D_{1}\right)^{1-\frac{p}{2}}=\Lambda^{\frac{-p}{6 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

For the record, notice that (8.14) also shows that the family Stop ${ }_{N D B}$ defined just above (8.13) satisfies

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Stop}_{\mathrm{NDB}}\right)=\sum_{Q \in \mathrm{Stop}_{\mathrm{NDB}}} \mathcal{P}(Q)^{2} \mu(Q) \lesssim \frac{1}{M_{0}^{2}} \sum_{Q^{\prime} \in \mathrm{DB}: Q^{\prime} \sim \mathcal{T}} \mathcal{E}_{\infty}\left(9 Q^{\prime}\right)
$$

which together with (8.15) yields

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\text { Stop }_{\mathrm{NDB}}\right) \lesssim M_{0}^{-2} \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \tag{8.20}
\end{equation*}
$$

Lemma 8.8. Suppose that $R \in \operatorname{Trc} \cap \mathrm{Ty}$. Then

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\mathrm{M}_{\mathrm{Neg}}\right) \lesssim \Sigma^{\mathcal{P}}(\mathrm{Neg}) \lesssim\left(\delta_{0} B \Lambda^{5}+B \Lambda^{-3}+M_{0}^{-2} \Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right) \tag{8.21}
\end{equation*}
$$

and

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) \lesssim \Sigma^{\mathcal{P}}(\mathrm{Neg})+\sum_{Q \in \mathrm{M}_{\mathrm{Neg}}} \mathcal{E}_{\infty}(9 Q) \lesssim\left(\delta_{0} B \Lambda^{7}+B \Lambda^{-1}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right) \tag{8.22}
\end{equation*}
$$

Proof. By Lemma 5.4, the cubes from Neg belong either to $\mathrm{LD}(R)$ or to $\mathrm{NDB}(R)$. Thus, if we denote

$$
\operatorname{Neg}_{\mathrm{LD}}=\operatorname{Neg} \cap \mathrm{LD}(R) \cap \operatorname{Stop}\left(e^{\prime}(R)\right), \quad \operatorname{Neg}_{\mathrm{NDB}}=\operatorname{Neg} \cap \operatorname{NDB}(R) \cap \operatorname{Stop}\left(e^{\prime}(R)\right)
$$

it is clear that

$$
N e g=\operatorname{Neg}_{\mathrm{LD}} \cup \text { Neg }_{\text {NDB }} .
$$

We can split $\operatorname{Reg}_{\text {Neg }}$ in an analogous way:

$$
\operatorname{Reg}_{N e g}=\operatorname{Reg}_{\mathrm{Neg}_{\mathrm{LD}}} \cup \operatorname{Reg}_{\mathrm{Neg}_{\mathrm{NDB}}} .
$$

Recall that the cubes from Neg are not $\mathcal{P}$-doubling and that $\mathcal{P}(Q) \lesssim\left(\frac{\ell(Q)}{\ell(R)}\right)^{1 / 3} \Theta(R)$ for all $Q \in$ Neg.

To estimate $\Sigma^{\mathcal{P}}\left(\operatorname{Neg}_{\mathrm{LD}}\right)$, we split $\operatorname{Neg}_{\mathrm{LD}}$ into two subfamilies $\mathcal{I}$ and $\mathcal{J}$ so that the cubes from $\mathcal{I}$ have side length at least $\Lambda^{-5} \ell(R)$, opposite to the ones from $\mathcal{J}$. We have

$$
\begin{aligned}
\Sigma^{\mathcal{P}}(\mathcal{I}) & =\sum_{Q \in \mathcal{I}} \mathcal{P}(Q)^{2} \mu(Q) \lesssim \Theta(R)^{2} \sum_{Q \in \mathcal{I}} \mu(Q) \\
& \lesssim \Theta(R)^{2} \sum_{Q \in \mathcal{I}} \Theta(Q) \ell(Q)^{n} \lesssim \delta_{0} \Theta(R)^{3} \sum_{Q \in \mathcal{I}} \ell(Q)^{n} .
\end{aligned}
$$

Using now that the balls $\frac{1}{2} B(Q)$, with $Q \in \mathcal{I}$, are disjoint and that $\ell(Q) \geq \Lambda^{-5} \ell(R)$, we get

$$
\sum_{Q \in \mathcal{I}} \ell(Q)^{n} \leq \sum_{Q \in \mathcal{I}} \frac{\Lambda^{5} \ell(Q)^{n+1}}{\ell(R)} \lesssim \frac{\Lambda^{5} \ell(R)^{n+1}}{\ell(R)}=\Lambda^{5} \ell(R)^{n}
$$

Therefore,

$$
\Sigma^{\mathcal{P}}(\mathcal{I}) \lesssim \delta_{0} \Lambda^{5} \Theta(R)^{3} \ell(R)^{n} \approx \delta_{0} \Lambda^{5} \sigma(R) \lesssim \delta_{0} B \Lambda^{5} \sigma\left(\mathrm{HD}_{1}\right) .
$$

In connection with the family $\mathcal{J}$, we have

$$
\begin{aligned}
\Sigma^{\mathcal{P}}(\mathcal{J}) & =\sum_{Q \in \mathcal{J}} \mathcal{P}(Q)^{2} \mu(Q) \lesssim \Theta(R)^{2} \sum_{Q \in \mathcal{J}}\left(\frac{\ell(Q)}{\ell(R)}\right)^{2 / 3} \mu(Q) \\
& \leq \Lambda^{-10 / 3} \Theta(R)^{2} \sum_{Q \in \mathcal{J}} \mu(Q) \leq \Lambda^{-3} \sigma(R) \leq B \Lambda^{-3} \sigma\left(\mathrm{HD}_{1}\right) .
\end{aligned}
$$

Hence,

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Neg}_{\mathrm{LD}}\right) \lesssim\left(\delta_{0} B \Lambda^{5}+B \Lambda^{-3}\right) \sigma\left(\mathrm{HD}_{1}\right)
$$

To estimate $\Sigma^{\mathcal{P}}\left(\right.$ Neg $\left._{\text {NDB }}\right)$ we just take into account that $\operatorname{Neg}_{\text {NDB }} \subset$ Stop $_{\text {NDB }}$, and then by (8.20) we have

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Neg}_{\mathrm{NDB}}\right) \leq \Sigma^{\mathcal{P}}\left(\text { Stop }_{\mathrm{NDB}}\right) \lesssim M_{0}^{-2} \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
$$

Gathering the estimates obtained for $\Sigma^{\mathcal{P}}\left(\mathrm{Neg}_{\mathrm{LD}}\right)$ and $\Sigma^{\mathcal{P}}\left(\mathrm{Neg}_{\mathrm{NDB}}\right)$ we get

$$
\Sigma^{\mathcal{P}}(\mathrm{Neg}) \lesssim\left(\delta_{0} B \Lambda^{5}+B \Lambda^{-3}+M_{0}^{-2} \Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right)
$$

as wished. The fact that $\Sigma^{\mathcal{P}}\left(\mathrm{M}_{\mathrm{Neg}}\right) \lesssim \Sigma^{\mathcal{P}}(\mathrm{Neg})$ follows from the fact that if $P \in \mathrm{M}_{\mathrm{Neg}}$ satisfies $P \subset Q \in \operatorname{Neg}$, then $\mathcal{P}(P) \lesssim \mathcal{P}(Q)$ because $P$ is a maximal $\mathcal{P}$-doubling cube contained in $Q$.

Next we deal with (8.22). We split

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right)=\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{M_{\text {Neg }}}\right)+\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}} \backslash \operatorname{Reg}_{\mathrm{M}_{\text {Neg }}}\right)
$$

Notice that, for all $P \in \operatorname{Reg}_{N_{\text {eg }}} \backslash \operatorname{Reg}_{\mathrm{M}_{\mathrm{Neg}}}$ such that $P \subset Q \in \operatorname{Neg}$, by Lemma $3.2, \mathcal{P}(P) \lesssim$ $\mathcal{P}(Q)$. Then it follows that

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}} \backslash \operatorname{Reg}_{\mathrm{M}_{\mathrm{Neg}}}\right) \lesssim \Sigma^{\mathcal{P}}(\mathrm{Neg})
$$

To estimate $\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{M_{\text {Neg }}}\right)$, we apply Lemma 8.4:

$$
\begin{align*}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{M}_{\text {Neg }}}\right) & =\sum_{S \in \mathrm{M}_{\text {Neg }}} \Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{M}_{\text {Neg }}} \cap \mathcal{D}_{\mu}(S)\right) \lesssim \sum_{S \in \mathrm{M}_{\text {Neg }}} \mathcal{E}_{\infty}(9 S)  \tag{8.23}\\
& \leq \sum_{S \in \mathrm{M}_{\text {Neg }} \backslash \mathrm{DB}} \mathcal{E}_{\infty}(9 S)+\sum_{S \in \mathrm{DB} \cap \widehat{\mathrm{End}}} \mathcal{E}_{\infty}(9 S) .
\end{align*}
$$

By the definition of DB and the fact that $\Theta(S) \lesssim \mathcal{P}(Q)$ whenever $S \subset Q \in$ Neg, we derive

$$
\sum_{S \in \mathrm{M}_{\mathrm{Neg}} \backslash \mathrm{DB}} \mathcal{E}_{\infty}(9 S) \lesssim M_{0}^{2} \sum_{S \in \mathrm{M}_{\mathrm{Neg}} \backslash \mathrm{DB}} \sigma(S) \lesssim M_{0}^{2} \Sigma^{\mathcal{P}}(\mathrm{Neg})
$$

On the other hand, by (8.5),

$$
\sum_{S \in \mathrm{DB} \cap \widetilde{\mathrm{End}}} \mathcal{E}_{\infty}(9 S) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
$$

Therefore,

$$
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{M}_{\mathrm{Neg}}}\right) \lesssim M_{0}^{2} \Sigma^{\mathcal{P}}(\mathrm{Neg})+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
$$

Gathering the estimates above, and taking into account that $M_{0}<\Lambda$ (by (4.2)), we deduce

$$
\begin{aligned}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) & \lesssim M_{0}^{2} \Sigma^{\mathcal{P}}(\mathrm{Neg})+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \\
& \lesssim\left(\delta_{0} B M_{0}^{2} \Lambda^{5}+B \Lambda^{-3} M_{0}^{2}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \\
& \leq\left(\delta_{0} B \Lambda^{7}+B \Lambda^{-1}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

Next lemma deals with $\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\right)$.
Lemma 8.9. For $1 \leq p \leq 2$, we have

$$
\begin{equation*}
\limsup _{\ell_{0} \rightarrow 0} \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)\right) \lesssim \Lambda^{2 p} \Theta(R)^{p} \mu(Z) \tag{8.24}
\end{equation*}
$$

Consequently, if $\mu(Z) \leq \varepsilon_{Z} \mu(R)$, then

$$
\begin{equation*}
\limsup _{\ell_{0} \rightarrow 0} \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)\right) \lesssim B \Lambda^{4} \varepsilon_{Z} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.25}
\end{equation*}
$$

Above we wrote $\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)$ to recall the dependence of the family $\operatorname{Reg}_{\mathrm{Ot}}$ on the parameter $\ell_{0}$ in (7.1).

Proof. If $x \in Q \in$ End with $\ell(Q) \geq \ell_{0}$, then

$$
d_{R, \ell_{0}}(x) \leq \max \left(\ell_{0}, \ell(Q)\right)=\ell(Q)
$$

(recall that $d_{R, \ell_{0}}$ is defined in (7.1)), and thus $x$ is contained in some cube $Q^{\prime} \in \operatorname{Reg}$ with $\ell\left(Q^{\prime}\right) \leq \ell(Q)$, by the definition of the family Reg. So $Q^{\prime} \subset Q$ and then $Q^{\prime} \in \operatorname{Reg} \backslash \operatorname{Reg} \mathrm{Rot}^{\text {. }}$ Therefore,

$$
\begin{equation*}
\bigcup_{P \in \operatorname{Reg}_{O t}} P \subset e^{\prime}(R) \backslash \bigcup_{Q \in \text { End }: \ell(Q)>\ell_{0}} Q, \tag{8.26}
\end{equation*}
$$

and so

$$
\begin{equation*}
\limsup _{\ell_{0} \rightarrow 0} \mu\left(\bigcup_{P \in \operatorname{Reg}_{0_{0}( }\left(\ell_{0}\right)} P\right) \leq \mu\left(e^{\prime}(R) \backslash \bigcup_{Q \in \mathrm{End}} Q\right)=\mu(Z) \tag{8.27}
\end{equation*}
$$

To complete the proof of (8.24) it just remains to notice that, using the fact that $\mathcal{P}(P) \lesssim$ $\Lambda^{2} \Theta(R)$ for all $P \in \operatorname{Reg}$, we have

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)\right) \lesssim \Lambda^{2 p} \Theta(R)^{p} \mu\left(\bigcup_{P \in \operatorname{Reg}_{\mathrm{ot}^{( }\left(\ell_{0}\right)}} P\right)
$$

Regarding the second statement of the lemma recall that, as in (8.18), $\mu\left(H D_{1}\right) \geq$ $\frac{1}{B \Lambda^{2}} \mu(R)$, which implies that

$$
\mu(Z) \leq B \Lambda^{2} \varepsilon_{Z} \mu\left(H D_{1}\right)
$$

Plugging this estimate into (8.24), we get

$$
\limsup _{\ell_{0} \rightarrow 0} \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)\right) \lesssim B \Lambda^{2+p} \varepsilon_{Z} \Theta\left(\mathrm{HD}_{1}\right)^{p} \mu\left(H D_{1}\right) \leq B \Lambda^{4} \varepsilon_{Z} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

Remark 8.10. By Lemma 8.7, for $p \in(1,2)$, if $\Lambda \gg B \gg 1$ and $\delta_{0} \ll \Lambda^{-1}$, we have

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right) \ll \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

Analogously, by Lemma 8.9, if $\varepsilon_{Z} \ll\left(B \Lambda^{4}\right)^{-1}$ and $\ell_{0}$ is small enough,

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{O t}\right) \ll \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

To transfer the lower estimates for the $L^{p}(\eta)$ norm of $\mathcal{R} \eta$ in Lemmal7.2 to $\mathcal{R}_{\mathcal{T}} \mu, \mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu$, and $\Delta_{\mathcal{T}} \mathcal{R} \mu$, it would be useful to have estimates for $\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}}\right), \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right)$, and $\Sigma_{p}^{\mathcal{P}}(\mathrm{Neg})$ analogous to the ones above. However, we have not been able to get them. This fact originates some technical difficulties, which will be solved in the next lemmas.

Remark 8.11. By Lemma 8.7, for $1<p \leq 2$, and $\ell_{0}$ small enough we have

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right) \lesssim\left(B \Lambda^{2} \delta_{0}^{\frac{1}{n+2}}+\Lambda^{\frac{-1}{6 n}}\right) \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

Also, by Lemma 8.9, for $\ell_{0}$ small enough, if $\mu(Z) \leq \varepsilon_{Z} \mu(R)$,

$$
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\left(\ell_{0}\right)\right) \lesssim B \Lambda^{4} \varepsilon_{Z} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

From now on we will assume that $\ell_{0}$ small enough so that this holds,. Remember also that we chose

$$
B=\Lambda^{\frac{1}{100 n}} .
$$

We assume also $\delta_{0}$ and $\varepsilon_{Z}$ small enough so that

$$
\begin{equation*}
B \Lambda^{2} \delta_{0}^{\frac{1}{n+2}}+B \Lambda^{4} \varepsilon_{Z}+B \Lambda^{7} \delta_{0} \leq \Lambda^{\frac{-1}{3 n}} \tag{8.28}
\end{equation*}
$$

In this way, we have

$$
\begin{equation*}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\right) \lesssim \Lambda \frac{-1}{6 n} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.29}
\end{equation*}
$$ under the assumption that $\mu(Z) \leq \varepsilon_{Z} \mu(R)$. Also, from (8.22), it follows that

$$
\begin{equation*}
\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) \lesssim\left(\delta_{0} B \Lambda^{7}+B \Lambda^{-1}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right) \lesssim \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \tag{8.30}
\end{equation*}
$$

Lemma 8.12. Suppose that $R \in \operatorname{Trc} \cap \operatorname{Ty}$ and that $\mu(Z) \leq \varepsilon_{Z} \mu(R)$. We have

$$
\Sigma^{\mathcal{P}}(\mathrm{Reg}) \lesssim B \sigma\left(\mathrm{HD}_{1}\right)
$$

For $p_{0}=2-\frac{1}{18 n}$, we have

$$
\Sigma_{p_{0}}^{\mathcal{P}}(\mathrm{Reg}) \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)
$$

Proof. By (8.29) and (8.10), for $1<p \leq 2$,

$$
\begin{aligned}
& \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\right) \\
& \lesssim\left(\Lambda^{\frac{-1}{6 n}}+B \Lambda^{p-2}\right) \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

Also, by (8.5), (8.7), and (8.30),
$\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}}\right)+\Sigma^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) \lesssim\left(\delta_{0} B \Lambda^{7}+B \Lambda^{-1}+\Lambda^{\frac{-1}{3 n}}\right) \sigma\left(\mathrm{HD}_{1}\right) \lesssim \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)$, by the assumptions on $\delta_{0}, \Lambda$, and $B$ in Remarks 8.6 and 8.11. Choosing $p=2$ above and adding the preceding estimates, we get the first statement in the lemma.

To get the second inequality in the lemma, we apply by Hölder's inequality and (8.18) in the last estimate, and we get

$$
\begin{align*}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) & \lesssim\left(\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}} \mu(R)^{1-\frac{p}{2}}  \tag{8.31}\\
& \lesssim\left(\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}}\left(B \Lambda^{2} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}} \\
& \leq \Lambda^{\frac{-1}{6 n}}\left(\Lambda^{3}\right)^{1-\frac{p}{2}} \sigma_{p}\left(\mathrm{HD}_{1}\right) .
\end{align*}
$$

For $p=2-\frac{1}{18 n}$, we have

$$
\left(\Lambda^{3}\right)^{1-\frac{p}{2}}=\Lambda^{\frac{1}{12 n}}
$$

and thus

$$
\begin{equation*}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{1}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Neg}}\right) \lesssim \Lambda^{\frac{-1}{12 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.32}
\end{equation*}
$$

Also,

$$
B \Lambda^{p-2}=\Lambda^{\frac{1}{100 n}} \Lambda^{\frac{-1}{18 n}}=\Lambda^{\frac{-41}{900 n}}<\Lambda^{\frac{-1}{25 n}}
$$

and thus

$$
\begin{aligned}
\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{1}} \backslash \operatorname{Reg}_{\mathrm{DB}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{LD}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{NDB}_{2}}\right)+\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right)+ & \Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{Ot}}\right) \\
& \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{aligned}
$$

Gathering the estimates above, the lemma follows.

Remark that in order to transfer the lower estimates for $\mathcal{R} \eta$ to $\mathcal{R} \mu$ we will need to take $p$ very close to 1 below, in particular with $p<p_{0}$.

Next lemma shows how one can estimate the $\mathcal{Q}_{\text {Reg }}$ coefficients in terms of the $\mathcal{P}$ coefficients. This is proven in [DT, Lemma 7.12].

Lemma 8.13. For all $p \in(1, \infty)$,

$$
\Sigma_{p}^{\mathcal{Q}}(\operatorname{Reg}) \lesssim \Sigma_{p}^{\mathcal{P}}(\mathrm{Reg})
$$

8.3. Transference of the lower estimates for $\mathcal{R} \eta$ to $\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu$. Denote

$$
F=e^{\prime}(R) \backslash \bigcup_{Q \in \operatorname{Reg}_{\mathrm{HD}_{2}}} Q
$$

By the splitting (8.3), it is clear that $F$ coincides with the union of the cubes in the family

$$
\operatorname{Reg}_{F}:=\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}} \cup \operatorname{Reg}_{\mathrm{NDB}_{1}} \cup \operatorname{Reg}_{\mathrm{NDB}_{2}} \cup \operatorname{Reg}_{\mathrm{Neg}} \cup \operatorname{Reg}_{\mathrm{Ot}} .
$$

We also write

$$
F_{\eta}=\bigcup_{Q \in \operatorname{Reg}_{F}} \frac{1}{2} B(Q)
$$

so that the measure $\left.\mu\right|_{F}$ is well approximated by $\left.\eta\right|_{F_{\eta}}$, in a sense.
Recall that in Lemma 7.2 we showed that

$$
\int_{V_{R}}\left|\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta(x) \gtrsim \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}(e(R))\right)
$$

for any $p \in\left(1,2\right.$ ], with $c_{2}$ be as in Lemma [7.2] We will show below that a similar lower estimate holds if we restrict the integral on the left side to $H D_{2}$. The first step is the next lemma.

We let $\widetilde{V}_{R}$ be the union of the balls $\frac{1}{2} B(Q)$, with $Q \in \operatorname{Reg}$, that intersect $V_{R}$.
Lemma 8.14. Suppose that $R \in \operatorname{Trc} \cap \operatorname{Ty}$ and also that $\mu(Z) \leq \varepsilon_{Z} \mu(R)$ and

$$
\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \leq \Lambda^{-1} \sigma\left(\mathrm{HD}_{1}\right)
$$

Then, for $p_{0}=2-\frac{1}{18 n}$, assuming $\varepsilon_{Z} \leq \Lambda^{-72 n}$ and $\ell_{0}$ small enough,

$$
\int_{F_{\eta} \cap \tilde{V}_{R}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \eta \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) .
$$

Remark that the proof of this lemma takes advantage of the good estimates we have obtained for $\Sigma_{p_{0}}^{\mathcal{P}}($ Reg $)$ in Lemma 8.12, Later on we will show that an analogous estimate holds for all $p \in\left(1, p_{0}\right)$ (see Lemma 8.15 below).

Proof. Denote
so that $F=F_{a} \cup F_{b} \cup F_{\text {Ot }}$. Write also

$$
\operatorname{End}_{a}=\mathrm{LD}_{1} \cup \mathrm{LD}_{2} \cup \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2} \cup \mathrm{M}_{\mathrm{Neg}}
$$

and

$$
\operatorname{Reg}_{a}=\operatorname{Reg}_{\mathrm{LD}_{1}} \cup \operatorname{Reg}_{\mathrm{LD}_{2}} \cup \operatorname{Reg}_{\mathrm{NDB}_{1}} \cup \operatorname{Reg}_{\mathrm{NDB}_{2}} \cup \operatorname{Reg}_{\mathrm{M}_{\text {Neg }^{2}}},
$$

so that

$$
F_{a}=\bigcup_{Q \in \mathrm{End}_{a}} Q=\bigcup_{Q \in \operatorname{Reg}_{a}} Q .
$$

We also consider
so that these sets approximate $F_{a}, F_{b}, F_{\mathrm{Ot}}$ at the level of the family Reg, in a sense. Moreover, we have $F_{\eta}=F_{a, \eta} \cup F_{b, \eta} \cup F_{\mathrm{Ot}, \eta}$.

We split
$\int_{F_{\eta} \cap \widetilde{V}_{R}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \eta=\int_{F_{a, \eta} \cap \tilde{V}_{R}} \cdots+\int_{F_{b, \eta} \cap \tilde{V}_{R}} \cdots+\int_{F_{\mathrm{Ot}, \eta} \cap \tilde{V}_{R}} \ldots=: I_{a}+I_{b}+I_{\mathrm{Ot}}$, where ". .." stands for $\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \eta$.
Estimates for $I_{b}$. We claim that $I_{b}=0$. Indeed, given $Q \in \operatorname{Reg}_{N_{\text {eg }}} \backslash \operatorname{Reg}_{M_{\text {Neg }}}$, notice that all the cubes $S$ such that $Q \subset S \subset R$ satisfy

$$
\Theta(S) \lesssim\left(\frac{\ell(S)}{\ell(R)}\right)^{1 / 2} \Theta(R)
$$

and so, for any $x \in Q$,

$$
\begin{aligned}
|\mathcal{R} \eta(x)| & \lesssim \sum_{S: Q \subset S \subset R} \theta_{\eta}\left(4 B_{S}\right) \lesssim \sum_{S: Q \subset S \subset R} \theta_{\mu}\left(C B_{S}\right) \\
& \lesssim \sum_{S: Q \subset S \subset R}\left(\frac{\ell(S)}{\ell(R)}\right)^{1 / 2} \Theta(R)+\Theta(R) \lesssim \Theta(R) .
\end{aligned}
$$

Hence, for $\Lambda$ big enough, $\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}=0$, which proves our claim.
Estimates for $I_{a}$. By Lemma 8.1, for all $Q \in \operatorname{Reg}_{a}$ such that $\frac{1}{2} B(Q) \subset \widetilde{V}_{R}$, all $x \in \frac{1}{2} B(Q)$, and all $y \in Q$,

$$
|\mathcal{R} \eta(x)| \leq\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu(y)\right|+C \Theta(R)+C \mathcal{P}(Q)+C \mathcal{Q}_{\operatorname{Reg}}(Q) .
$$

Thus, for $\Lambda$ big enough, since $C \Theta(R)=\Lambda^{-1} \Theta\left(\mathrm{HD}_{1}\right)<\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)$,

$$
\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+} \leq\left(\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(y)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}+C \mathcal{P}(Q)+C \mathcal{Q}_{\mathrm{Reg}}(Q)
$$

Consequently,

$$
\begin{align*}
I_{a} & \lesssim \sum_{Q \in \operatorname{Reg}_{a}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu(y)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu(y)+\sum_{Q \in \operatorname{Reg}_{a}}\left(\mathcal{P}(Q)^{p_{0}}+\mathcal{Q}_{\operatorname{Reg}}(Q)^{p_{0}}\right) \mu(Q)  \tag{8.33}\\
& \lesssim \sum_{S \in \operatorname{End}_{a}} \int_{S}\left|\left(\left|\mathcal{R}_{\mathcal{T e g}} \mu\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu+\Sigma_{p_{0}}^{\mathcal{P}}(\operatorname{Reg}),
\end{align*}
$$

where, in the last inequality, we used the fact that all the cubes from $\operatorname{Reg}_{a}$ are contained in some cube $S \in \operatorname{End}_{a}$ and we applied Lemma 8.13.

For each $S \in \operatorname{End}_{a}$, by the triangle inequality and the fact that $(\cdot)_{+}$is a $1-L i p s c h i t z$ function, we get

$$
\begin{aligned}
\int_{S}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu \lesssim & \int_{S}\left|\left(\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu \\
& +\int_{S}\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu-\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu\right|^{p_{0}} d \mu
\end{aligned}
$$

By Lemma 8.3, the last integral does not exceed $C \mathcal{E}(2 S)^{\frac{p_{0}}{2}} \mu(S)^{1-\frac{p_{0}}{2}}$, and thus we deduce that

$$
\begin{equation*}
I_{a} \lesssim \sum_{S \in \operatorname{End}_{a}} \int_{S}\left|\left(\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu+\sum_{S \in \mathrm{End}_{a}} \mathcal{E}(2 S)^{\frac{p_{0}}{2}} \mu(S)^{1-\frac{p_{0}}{2}}+\Sigma_{p_{0}}^{\mathcal{P}}(\mathrm{Reg}) \tag{8.34}
\end{equation*}
$$

Next we apply Lemma 8.2, which ensures that for any $S \in \operatorname{End}_{a} \subset \widetilde{\text { End }}$ and all $x \in S$,

$$
\begin{equation*}
\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu(x)\right| \leq\left|\Delta_{\widetilde{\mathcal{T}}} \mathcal{R} \mu(x)\right|+C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2}+C\left(\frac{\mathcal{E}(2 S)}{\mu(S)}\right)^{1 / 2} \tag{8.35}
\end{equation*}
$$

In case that $R \notin \mathrm{DB}$, recalling that $\Lambda=M_{0}^{\frac{8 n-1}{8 n-2}} \gg M_{0}$ by (4.2), for $\Lambda$ big enough we obtain

$$
\begin{equation*}
C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2} \leq C M_{0} \Theta(R) \leq \frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right) \tag{8.36}
\end{equation*}
$$

In case that $R \in \mathrm{DB}$, since $R \in \mathrm{Ty}$, we have

$$
\mathcal{E}(4 R) \lesssim \sum_{Q \in \mathrm{DB}: Q \sim \mathcal{T}} \mathcal{E}_{\infty}(9 Q) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)
$$

and so we also get

$$
\begin{equation*}
C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2} \leq C\left(\frac{\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)}{\mu(R)}\right)^{1 / 2} \leq C \Lambda^{\frac{-1}{6 n}} \Theta\left(\mathrm{HD}_{1}\right) \leq \frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right) \tag{8.37}
\end{equation*}
$$

Thus, in any case,

$$
\left(\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu(x)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+} \leq\left|\Delta_{\widetilde{\mathcal{T}}} \mathcal{R} \mu(x)\right|+C\left(\frac{\mathcal{E}(2 S)}{\mu(S)}\right)^{1 / 2}
$$

Plugging this estimate into (8.34), we get

$$
\begin{equation*}
I_{a} \lesssim \sum_{S \in \mathrm{End}_{a}} \int_{S}\left|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right|^{p_{0}} d \mu+\sum_{S \in \operatorname{End}_{a}} \mathcal{E}(2 S)^{\frac{p_{0}}{2}} \mu(S)^{1-\frac{p_{0}}{2}}+\Sigma_{p_{0}}^{\mathcal{P}}(\mathrm{Reg}) \tag{8.38}
\end{equation*}
$$

We deal with each term on the right hand side of the preceding inequality separately. First, by Hölder's inequality and the assumptions in the lemma, we have

$$
\int\left|\Delta_{\widetilde{\mathcal{T}}} \mathcal{R} \mu\right|^{p_{0}} d \mu \lesssim\left\|\Delta_{\widetilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p_{0}} \mu(R)^{1-\frac{p_{0}}{2}} \leq \Lambda^{-\frac{p_{0}}{2}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}} \mu(R)^{1-\frac{p_{0}}{2}}
$$

Regarding the second term in (8.38), by Hölder's inequality again,

$$
\begin{aligned}
\sum_{S \in \operatorname{End}_{a}} \mathcal{E}(2 S)^{\frac{p_{0}}{2}} \mu(S)^{1-\frac{p_{0}}{2}} & \leq\left(\sum_{S \in \operatorname{End}_{a}} \mathcal{E}(2 S)\right)^{\frac{p_{0}}{2}}\left(\sum_{S \in \operatorname{End}_{a}} \mu(S)\right)^{1-\frac{p_{0}}{2}} \\
& \lesssim\left(\sum_{S \in \operatorname{End}_{a}} \mathcal{E}(2 S)\right)^{\frac{p_{0}}{2}} \mu(R)^{1-\frac{p_{0}}{2}}
\end{aligned}
$$

We estimate the first factor on the right hand side using (8.7), (8.8), and (8.22):

$$
\begin{aligned}
\left(\sum_{S \in \operatorname{End}_{a}} \mathcal{E}(2 S)\right)^{\frac{p_{0}}{2}} & \leq\left(\sum_{S \in \mathrm{NDB}_{1} \cup \mathrm{NDB}_{2}} \mathcal{E}_{\infty}(9 S)+\sum_{S \in \mathrm{LD}_{1} \cup \mathrm{LD}_{2}} \mathcal{E}_{\infty}(9 S)+\sum_{S \in \mathrm{M}_{\text {Neg }}} \mathcal{E}_{\infty}(9 S)\right)^{\frac{p_{0}}{2}} \\
& \lesssim\left(B \Lambda^{-1}+\Lambda^{\frac{-1}{3 n}}+B M_{0}^{2} \delta_{0}^{\frac{2}{n+2}}+B \Lambda^{7} \delta_{0}\right)^{\frac{p_{0}}{2}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}} \leq \Lambda^{\frac{-1}{6 n}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}}
\end{aligned}
$$

by the assumption (8.28) on $\delta_{0}$. In connection with the last summand on the right hand side of (8.38), by Lemma 8.12 we have

$$
\Sigma_{p_{0}}^{\mathcal{P}}(\mathrm{Reg}) \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)
$$

Therefore,

$$
I_{a} \lesssim \Lambda^{\frac{-1}{6 n}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}} \mu(R)^{1-\frac{p_{0}}{2}}+\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) .
$$

From (8.18) we derive that $\mu\left(H D_{1}\right) \geq \Lambda^{-3} \mu(R)$, and then

$$
\begin{equation*}
\Lambda^{\frac{-1}{6 n}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}} \mu(R)^{1-\frac{p_{0}}{2}} \leq \Lambda^{\frac{-1}{6 n}}\left(\Lambda^{3}\right)^{1-\frac{p_{0}}{2}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)=\Lambda^{\frac{-1}{12 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) \leq \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) \tag{8.39}
\end{equation*}
$$

So we get

$$
\begin{equation*}
I_{a} \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) \tag{8.40}
\end{equation*}
$$

Estimate of $I_{\mathrm{Ot}}$. By the same arguments as in (8.33), just replacing $\mathrm{Reg}_{a}$ by $\mathrm{Reg}_{\mathrm{Ot}}$, we obtain
$I_{\mathrm{Ot}} \lesssim \sum_{Q \in \operatorname{Reg}_{\mathrm{Ot}}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu(y)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu(y)+\sum_{Q \in \operatorname{Reg}_{\mathrm{Ot}}}\left(\mathcal{P}(Q)^{p_{0}}+\mathcal{Q}_{\operatorname{Reg}}(Q)^{p_{0}}\right) \mu(Q)$.
Thus, using again Lemmas 8.13 and 8.12 we get

$$
\begin{align*}
I_{\mathrm{Ot}} & \lesssim \sum_{Q \in \operatorname{Reg}_{O \mathrm{t}}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(y)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu(y)+\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)  \tag{8.41}\\
& =: \widetilde{I}_{\mathrm{Ot}}+\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) .
\end{align*}
$$

To estimate the integral $\widetilde{I}_{\text {Ot }}$ on the right hand side, we split

$$
\begin{aligned}
\widetilde{I}_{\mathrm{Ot}}= & \sum_{Q \in \operatorname{Reg}_{\mathrm{Ot}_{t}} \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu(x)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu(x) \\
& +\sum_{Q \in \operatorname{Reg}_{\mathrm{g}_{\mathrm{t}} \cap \operatorname{Neg}\left(e^{\prime}(R)\right)}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T R e g}} \mu(x)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \mu(x) \\
= & \widetilde{I}_{\mathrm{Ot}, 1}+\widetilde{I}_{\mathrm{Ot}, 2} .
\end{aligned}
$$

Notice that, by definition we have $\operatorname{Reg}_{\mathrm{Ot}} \subset \mathcal{T}$. Recall that $\operatorname{Neg}=\operatorname{Neg}\left(e^{\prime}(R)\right) \cap$ End and thus we may have $\operatorname{Reg}_{\mathrm{Ot}} \cap \operatorname{Neg}\left(e^{\prime}(R)\right) \neq \varnothing$. In this case, we have $\operatorname{Reg}_{\mathrm{Ot}} \cap \operatorname{Neg}\left(e^{\prime}(R)\right) \subset$ $\mathcal{T}_{\text {Stop }}\left(e^{\prime}(R)\right)$ (because $\operatorname{Neg}\left(e^{\prime}(R)\right) \subset \mathcal{T}_{\text {Stop }}\left(e^{\prime}(R)\right)$ by construction).

The same argument used to show that $I_{b}=0$ shows that

$$
\widetilde{I}_{\mathrm{Ot}, 2}=0 .
$$

To estimate $\widetilde{I}_{\mathrm{Ot}, 1}$, denote by $\mathrm{M}_{\mathrm{Ot}}$ the family of maximal $\mathcal{P}$-doubling cubes which are contained in some cube from $\operatorname{Reg}_{\mathrm{Ot}} \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)$ and let

$$
N_{\mathrm{Ot}}=\bigcup_{Q \in \operatorname{Reg}_{\mathrm{ot}} \mid \operatorname{Neg}\left(e^{\prime}(R)\right)} Q \backslash \bigcup_{P \in \mathrm{M}_{\mathrm{Ot}}} P .
$$

We claim that

$$
\begin{equation*}
\mathrm{M}_{\mathrm{Ot}} \subset \mathcal{T} \quad \text { and } \quad N_{\mathrm{Ot}} \subset Z \tag{8.42}
\end{equation*}
$$

To check this, for a given $P \in \mathrm{M}_{\mathrm{Ot}}$ with $P \subset Q \in \operatorname{Reg}_{\mathrm{Ot}} \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)$, suppose there exists $S \in$ End such that $S \supset P$. As $P$ is a contained in some $Q \in \operatorname{Reg}_{\mathrm{Ot}} \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)$, we have $S \notin$ Neg. Further, $S \subsetneq Q$ because $Q \in \operatorname{Reg}_{\mathrm{Ot}}$ implies that $Q \not \subset S$. Since $S$ is $\mathcal{P}$-doubling, we deduce that $P=S$, by the maximality of $P$ as $\mathcal{P}$-doubling cube contained in $Q$. An analogous argument shows that $N_{\mathrm{Ot}} \subset Z$.

By Hölder's inequality and (8.27), for $\ell_{0}$ small enough we have

$$
\begin{aligned}
\widetilde{I}_{\mathrm{Ot}} & \leq\left(\sum_{Q \in \operatorname{Reg}_{\mathrm{Ot}}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu(x)\right|-\frac{c_{2}}{8} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{2} d \mu(x)\right)^{\frac{p_{0}}{2}}\left(\sum_{Q \in \operatorname{Reg}_{\mathrm{Ot}}} \mu(Q)\right)^{1-\frac{p_{0}}{2}} \\
& \leq\left(\sum_{P \in \mathrm{M}_{\mathrm{Ot}}} \int_{P}\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu\right|^{2} d \mu+\int_{N_{\mathrm{Ot}}}\left|\mathcal{R}_{\mathcal{T}_{\operatorname{Reg}}} \mu\right|^{2} d \mu\right)^{\frac{p_{0}}{2}}\left(\mu(Z)+o\left(\ell_{0}\right)\right)^{1-\frac{p_{0}}{2}}
\end{aligned}
$$

with $o\left(\ell_{0}\right) \rightarrow 0$ as $\ell_{0} \rightarrow 0$.
Denote

$$
\mathcal{R}_{\mathrm{M}_{\mathrm{tt}}} \mu(x)=\sum_{P \in \mathrm{M}_{\mathrm{Ot}}} \chi_{P}(x) \mathcal{R}\left(\chi_{2 R \backslash 2 P} \mu\right)(x)
$$

and

$$
\Delta_{\mathrm{M}_{\mathrm{Ot}}} \mathcal{R} \mu(x)=\sum_{P \in \mathrm{M}_{\mathrm{Ot}}} \chi_{P}(x)\left(m_{\mu, P}(\mathcal{R} \mu)-m_{\mu, 2 R}(\mathcal{R} \mu)\right)+\chi_{Z}(x)\left(\mathcal{R} \mu(x)-m_{\mu, 2 R}(\mathcal{R} \mu)\right) .
$$

Notice that, for $x \in P \in \mathrm{M}_{\mathrm{Ot}}$ and $Q \in \operatorname{Reg}_{\mathrm{Ot}} \backslash \operatorname{Neg}\left(e^{\prime}(R)\right)$ such that $Q \supset P$, since there are no $\mathcal{P}$-doubling cubes $P^{\prime}$ such that $P \subsetneq P^{\prime} \subset Q$,

$$
\left|\mathcal{R}_{\mathrm{M}_{\mathrm{Ot}}} \mu(x)-\mathcal{R}_{\mathcal{T}_{\mathrm{Reg}}} \mu(x)\right|=\left|\mathcal{R}\left(\chi_{2 Q \backslash 2 P} \mu\right)(x)\right| \lesssim \sum_{P: P \subset P^{\prime} \subset Q} \Theta\left(P^{\prime}\right) \lesssim \mathcal{P}(Q) \lesssim \Lambda \Theta\left(\mathrm{HD}_{1}\right)
$$

Almost the same argument shows also that, for $x \in N_{\mathrm{Ot}}$,

$$
\left|\mathcal{R}\left(\chi_{2 R} \mu\right)(x)-\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(x)\right| \lesssim \Lambda \Theta\left(\mathrm{HD}_{1}\right) .
$$

Remark also that

$$
\int_{N_{\mathrm{Ot}}}\left|\mathcal{R}\left(\chi_{2 R} \mu\right)\right|^{2} d \mu \leq \int_{Z}\left|\mathcal{R}\left(\chi_{2 R} \mu\right)\right|^{2} d \mu
$$

So we deduce that, for $\ell_{0}$ small enough,

$$
\tilde{I}_{\mathrm{Ot}} \lesssim\left(\sum_{P \in \mathrm{M}_{\mathrm{Ot}}} \int_{P}\left|\mathcal{R}_{\mathrm{M}_{\mathrm{Ot}}} \mu\right|^{2} d \mu+\int_{Z}\left|\mathcal{R}\left(\chi_{2 R} \mu\right)\right|^{2} d \mu+\Lambda^{2} \Theta\left(\mathrm{HD}_{1}\right)^{2} \mu(R)\right)^{\frac{p_{0}}{2}}\left(\varepsilon_{Z} \mu(R)\right)^{1-\frac{p_{0}}{2}} .
$$

Almost the same arguments as in Lemma 8.2 show that for $x \in P \in \mathrm{M}_{\mathrm{Ot}}$,

$$
\left|\mathcal{R}_{\mathrm{M}_{\mathrm{Ot}}} \mu(x)-\Delta_{\mathrm{M}_{\mathrm{Ot}}} \mathcal{R} \mu(x)\right| \lesssim \mathcal{P}(R)+\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2}+\mathcal{P}(P)+\left(\frac{\mathcal{E}(2 P)}{\mu(P)}\right)^{1 / 2}
$$

and that, for $x \in Z$,

$$
\left|\mathcal{R}\left(\chi_{2 R} \mu\right)(x)-\Delta_{\mathrm{M}_{\mathrm{Ot}}} \mathcal{R} \mu(x)\right| \lesssim \mathcal{P}(R)+\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2}
$$

Therefore, by (8.36) and (8.37) and taking into account that $\mathcal{P}(P) \lesssim \Lambda \Theta\left(\mathrm{HD}_{1}\right)$ for $P \in$ $\mathrm{M}_{\mathrm{Ot}}$, we deduce

$$
\widetilde{I}_{\mathrm{Ot}} \lesssim\left(\int\left|\Delta_{\mathrm{M}_{\mathrm{Ot}}} \mathcal{R} \mu\right|^{2} d \mu+\sum_{P \in \mathrm{M}_{\mathrm{Ot}}} \mathcal{E}(2 P)+\Lambda^{2} \Theta\left(\mathrm{HD}_{1}\right)^{2} \mu(R)\right)^{\frac{p_{0}}{2}}\left(\varepsilon_{Z} \mu(R)\right)^{1-\frac{p_{0}}{2}}
$$

By the orthogonality of the functions $\Delta_{Q} \mathcal{R} \mu, Q \in \mathcal{D}_{\mu}$, the assumptions in the lemma, and (8.42), it is clear that

$$
\int\left|\Delta_{\mathrm{M}_{\mathrm{Ot}}} \mathcal{R} \mu\right|^{2} d \mu \leq\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \leq \Lambda^{-1} \sigma\left(\mathrm{HD}_{1}\right)
$$

On the other hand, since the tree $\mathcal{T}$ is typical,

$$
\begin{aligned}
\sum_{P \in \mathrm{M}_{\mathrm{ot}}} \mathcal{E}(2 P) & \leq \sum_{P \in \mathrm{M}_{\mathrm{Ot} \backslash \mathrm{DB}}} \mathcal{E}(2 P)+\sum_{P \in \mathcal{T} \cap \mathrm{DB}} \mathcal{E}(2 P) \leq M_{0}^{2} \sigma\left(\mathrm{M}_{\mathrm{Ot}}\right)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \\
& \leq \Lambda^{2} \Theta\left(\mathrm{HD}_{1}\right)^{2} \mu(R)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \lesssim \Lambda^{2} \Theta\left(\mathrm{HD}_{1}\right)^{2} \mu(R)
\end{aligned}
$$

Thus, using also (8.18),

$$
\begin{aligned}
\widetilde{I}_{\mathrm{Ot}} & \lesssim \Lambda^{\frac{-p_{0}}{2}} \sigma\left(\mathrm{HD}_{1}\right)^{\frac{p_{0}}{2}} \mu(R)^{1-\frac{p_{0}}{2}}+\varepsilon_{Z}^{1-\frac{p_{0}}{2}} \Lambda^{p_{0}} \Theta\left(\mathrm{HD}_{1}\right)^{p_{0}} \mu(R) \\
& \lesssim\left(B \Lambda^{2}\right)^{1-\frac{p_{0}}{2}} \Lambda^{\frac{-p_{0}}{2}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)+\varepsilon_{Z}^{1-\frac{p_{0}}{2}} B \Lambda^{2+p_{0}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) .
\end{aligned}
$$

By the choice of $p_{0}, \Lambda$, and $B$ and the assumption $\varepsilon_{Z} \leq \Lambda^{-72 n}$, we have

$$
\widetilde{I}_{\mathrm{Ot}} \lesssim \Lambda^{\frac{-1}{2}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)+\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) \lesssim \Lambda^{\frac{-1}{55 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right) .
$$

Together with (8.41), this yields

$$
I_{\mathrm{Ot}} \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)
$$

Gathering the estimates obtained for $I_{a}$ and $I_{\mathrm{Ot}}$, the lemma follows.

Lemma 8.15. Suppose that $R \in \operatorname{Trc} \cap \operatorname{Ty}$ and also that $\mu(Z) \leq \varepsilon_{Z} \mu(R)$ and

$$
\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \leq \Lambda^{-1} \sigma\left(\mathrm{HD}_{1}\right) .
$$

Assume also that $\varepsilon_{Z} \leq \Lambda^{-72 n}$ and $\ell_{0}$ is small enough. Then

$$
\eta\left(\left\{x \in \widetilde{V}_{R}:|\mathcal{R} \eta(x)|>\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right\}\right) \lesssim \Lambda^{\frac{-1}{25 n}} \mu\left(H D_{1}\right) .
$$

Also, for any $p \in\left(1, p_{0}\right)$,

$$
\int_{F_{\eta} \cap \widetilde{V}_{R}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta \lesssim \Lambda^{\frac{-1}{25 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) .
$$

Proof. Denote

$$
A=\left\{x \in \widetilde{V}_{R}:|\mathcal{R} \eta(x)|>\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right\} .
$$

By the definition of $F_{\eta}$ we can split

$$
\eta(A) \leq \eta\left(A \cap F_{\eta}\right)+\eta\left(\bigcup_{Q \in \mathrm{HD}_{2}} \frac{1}{2} B(Q)\right)
$$

Notice first that

$$
\begin{equation*}
\eta\left(\bigcup_{Q \in \mathrm{HD}_{2}} \frac{1}{2} B(Q)\right)=\frac{1}{\Theta\left(\mathrm{HD}_{2}\right)^{2}} \sigma\left(\mathrm{HD}_{2}\right) \leq \frac{B}{\Lambda^{2} \Theta\left(\mathrm{HD}_{1}\right)^{2}} \sigma\left(\mathrm{HD}_{1}\right) \leq \Lambda^{-1} \mu\left(H D_{1}\right) \tag{8.43}
\end{equation*}
$$

On the other hand, for $x \in A$ we have

$$
\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+} \geq \frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right) .
$$

So, by Chebyshev and Lemma 8.14

$$
\begin{aligned}
\eta\left(A \cap F_{\eta}\right) & \lesssim \frac{1}{\Theta\left(\mathrm{HD}_{1}\right)^{p_{0}}} \int_{F_{\eta} \cap \tilde{V}_{R}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \eta \\
& \lesssim \frac{\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)}{\Theta\left(\mathrm{HD}_{1}\right)^{p_{0}}}=\Lambda^{\frac{-1}{25 n}} \mu\left(H D_{1}\right)
\end{aligned}
$$

which, together with (8.43), proves the first assertion of the lemma.

For the second statement in the lemma we use Hölder and Lemma 8.14 again:

$$
\begin{aligned}
\int_{F_{\eta} \cap \tilde{V}_{R}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta & =\int_{A \cap F_{\eta}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta \\
& \leq\left(\int_{A \cap F_{\eta}}\left|\left(|\mathcal{R} \eta|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p_{0}} d \eta\right)^{\frac{p}{p_{0}}} \eta\left(A \cap F_{\eta}\right)^{1-\frac{p}{p_{0}}} \\
& \lesssim\left(\Lambda^{\frac{-1}{25 n}} \sigma_{p_{0}}\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{p_{0}}}\left(\Lambda^{\frac{-1}{25 n}} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{p_{0}}} \\
& =\Lambda^{\frac{-1}{25 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) .
\end{aligned}
$$

Observe that, given $R \in \mathrm{MDW} \cap \operatorname{Trc} \cap \mathrm{Ty}$, from Lemmas 7.2 and 8.15, under the assumptions in those lemmas, we derive that

$$
\begin{align*}
& \int_{V_{R} \cap H D_{2}}\left|\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta(x)  \tag{8.44}\\
& \geq c \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)-C \Lambda^{\frac{-1}{25 n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) \approx \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
\end{align*}
$$

for $p \in\left(1, p_{0}\right]$, assuming that $\varepsilon_{n}$ and $p$ are chosen so that $p^{\prime} \varepsilon_{n} \ll \frac{1}{25 n}$. This is the main ingredient for the proof of the next lemma, which is the main result of this section.

Lemma 8.16. Let $R \in \operatorname{MDW} \cap \operatorname{Trc} \cap \mathrm{Ty}$. Let $\Lambda>0$ be big enough and suppose that $\varepsilon_{Z} \leq \Lambda^{-72 n}$. Then one of the following alternatives holds:
(a) $\mu(Z)>\varepsilon_{Z} \mu(R)$, or
(b) $\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}>\Lambda^{-1} \sigma\left(\mathrm{HD}_{1}\right)$.

Proof. Suppose that none of the alternatives holds. Then, by Lemmas 7.2 and 8.15, as in (8.44), we have

$$
\begin{equation*}
I_{\mathrm{HD}_{2}}:=\int_{V_{R} \cap H D_{2}}\left|\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \eta(x) \gtrsim \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.45}
\end{equation*}
$$

for all $p \in\left(1, p_{0}\right]$, assuming that $\ell_{0}$ is chosen small enough and that

$$
\begin{equation*}
p^{\prime} \varepsilon_{n} \leq \frac{1}{50 n} . \tag{8.46}
\end{equation*}
$$

The appropriate values of $\varepsilon_{n}$ and $p$ will be chosen at the end of the proof.
By arguments analogous to the ones we used to estimate the integral $I_{a}$ in the proof of Lemma 8.14 we will "transfer" the estimate for $\mathcal{R} \eta$ in (8.45) to $\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu$, so that we will obtain a lower estimate for $\left\|\Delta_{\mathcal{T}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}$ which will contradict the assumption that (b) does not hold. Although some of the estimates below are very similar to the ones to obtain the inequality (8.38) in the proof of Lemma 8.14 we will include the full details here for the reader's convenience. On the other hand, an important differences between the proof of that lemma and the current proof is that in Lemma 8.14 we took advantage of the fact that $p_{0}$ is close to 2 , and the estimates there would not work for the family $\operatorname{Reg}_{\mathrm{HD}_{2}}$, while in the arguments below it is essential the fact that we are taking $p$ close to 1 and the estimates work fine for the family $\operatorname{Reg}_{H_{2}}$, while they would fail for the family $\operatorname{Reg}_{a}$.

By Lemma 8.1, for all $Q \in \operatorname{Reg}_{\mathrm{HD}_{2}}$ such that $\frac{1}{2} B(Q) \subset \widetilde{V}_{R}$, all $x \in \frac{1}{2} B(Q)$, and all $y \in Q$,

$$
|\mathcal{R} \eta(x)| \leq\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(y)\right|+C \Theta(R)+C \mathcal{P}(Q)+C \mathcal{Q}_{\operatorname{Reg}}(Q) .
$$

Thus, for $\Lambda$ big enough, since $\Theta(R)=\Lambda^{-1} \Theta\left(\mathrm{HD}_{1}\right)<\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)$,

$$
\left(|\mathcal{R} \eta(x)|-\frac{c_{2}}{2} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+} \leq\left(\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(y)\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}+C \mathcal{P}(Q)+C \mathcal{Q}_{\operatorname{Reg}}(Q)
$$

Therefore,
$I_{\mathrm{HD}_{2}} \lesssim \sum_{Q \in \operatorname{Reg}_{\mathrm{HD}_{2}}} \int_{Q}\left|\left(\left|\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu(y)\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \mu(y)+\sum_{Q \in \operatorname{Reg}_{\mathrm{HD}_{2}}}\left(\mathcal{P}(Q)^{p}+\mathcal{Q}_{\mathrm{Reg}}(Q)^{p}\right) \mu(Q)$.
By (8.10) and Lemma 8.13, we have

$$
\begin{aligned}
\sum_{Q \in \operatorname{Reg}_{\mathrm{HD}_{2}}}\left(\mathcal{P}(Q)^{p}+\mathcal{Q}_{\operatorname{Reg}}(Q)^{p}\right) \mu(Q) & =\Sigma_{p}^{\mathcal{P}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right)+\Sigma_{p}^{\mathcal{Q}}\left(\operatorname{Reg}_{\mathrm{HD}_{2}}\right) \\
& \lesssim \sigma_{p}\left(\mathrm{HD}_{2}\right)+\Sigma^{\mathcal{Q}}(\operatorname{Reg})^{\frac{p}{2}} \mu\left(H D_{2}\right)^{1-\frac{p}{2}} \\
& \lesssim B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right)+\Sigma^{\mathcal{P}}(\operatorname{Reg})^{\frac{p}{2}} \mu\left(H D_{2}\right)^{1-\frac{p}{2}}
\end{aligned}
$$

Also, recalling that $\sigma\left(\mathrm{HD}_{2}\right) \leq B \sigma\left(\mathrm{HD}_{1}\right)$, we get $\mu\left(H D_{2}\right) \leq B \Lambda^{-2} \mu\left(H D_{1}\right)$. Then, by Lemma 8.12, we obtain

$$
\Sigma^{\mathcal{P}}(\operatorname{Reg})^{\frac{p}{2}} \mu\left(H D_{2}\right)^{1-\frac{p}{2}} \leq\left(B \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}}\left(B \Lambda^{-2} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}}=B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

So, since any cube from $\mathrm{Reg}_{\mathrm{HD}_{2}}$ is contained in some cube $S \in \mathrm{HD}_{2}$ :

$$
I_{\mathrm{HD}_{2}} \lesssim \sum_{S \in \mathrm{HD}_{2}} \int_{S}\left|\left(\left|\mathcal{R}_{\mathcal{R e g}} \mu(y)\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \mu(y)+B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right) .
$$

For each $S \in \mathrm{HD}_{2}$, by the triangle inequality and the fact that $(\cdot)_{+}$is a 1 -Lipschitz function, we obtain

$$
\begin{aligned}
\int_{S}\left|\left(\left|\mathcal{R}_{\mathcal{R}_{\text {Reg }}} \mu\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \mu \lesssim & \int_{S}\left|\left(\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \mu \\
& +\int_{S}\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu-\mathcal{R}_{\mathcal{T}_{\text {Reg }}} \mu\right|^{p} d \mu
\end{aligned}
$$

By Lemma 8.3, the last integral does not exceed $C \mathcal{E}(2 S)^{\frac{p}{2}} \mu(S)^{1-\frac{p}{2}}$, and thus

$$
\begin{equation*}
I_{\mathrm{HD}_{2}} \lesssim \sum_{S \in \mathrm{HD}_{2}} \int_{S}\left|\left(\left|\mathcal{R}_{\widetilde{\mathcal{T}}} \mu\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+}\right|^{p} d \mu+\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S)^{\frac{p}{2}} \mu(S)^{1-\frac{p}{2}}+B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.47}
\end{equation*}
$$

Next we apply Lemma 8.2, which implies that for any $S \in \mathrm{HD}_{2}$ and all $x \in S$,

$$
\begin{equation*}
\left|\mathcal{R}_{\tilde{\mathcal{T}}} \mu(x)\right| \leq\left|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu(x)\right|+C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2}+C\left(\frac{\mathcal{E}(2 S)}{\mu(S)}\right)^{1 / 2} \tag{8.48}
\end{equation*}
$$

In case that $R \notin \mathrm{DB}$, recalling that $\Lambda=M_{0}^{\frac{8 n-1}{8 n-2}} \gg M_{0}$ by (4.2), for $\Lambda$ big enough we obtain

$$
C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2} \leq C M_{0} \Theta(R) \leq \frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)
$$

If $R \in \mathrm{DB}$, then we use the fact that $R \in \mathrm{Ty}$, which ensures that

$$
\mathcal{E}(4 R) \lesssim \sum_{P \sim \mathcal{T}: P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P) \leq \Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right),
$$

and so we also get

$$
C\left(\frac{\mathcal{E}(4 R)}{\mu(R)}\right)^{1 / 2} \leq C\left(\frac{\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right)}{\mu(R)}\right)^{1 / 2} \leq C \Lambda^{\frac{-1}{6 n}} \Theta\left(\mathrm{HD}_{1}\right) \leq \frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)
$$

Hence, in any case we have

$$
\left(\left|\mathcal{R}_{\tilde{\mathcal{T}}} \mu(x)\right|-\frac{c_{2}}{4} \Theta\left(\mathrm{HD}_{1}\right)\right)_{+} \leq\left|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu(x)\right|+C\left(\frac{\mathcal{E}(2 S)}{\mu(S)}\right)^{1 / 2}
$$

Plugging this estimate into (8.47), we get

$$
\begin{equation*}
I_{\mathrm{HD}_{2}} \lesssim \int_{H D_{2}}\left|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right|^{p} d \mu+\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S)^{\frac{p}{2}} \mu(S)^{1-\frac{p}{2}}+B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.49}
\end{equation*}
$$

Next we will estimate each term on the right hand side. First, by Hölder's inequality, we have

$$
\begin{aligned}
\int_{H D_{2}}\left|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right|^{p} d \mu & \lesssim\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p} \mu\left(H D_{2}\right)^{1-\frac{p}{2}} \\
& \leq\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p}\left(B \Lambda^{-2} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}} \leq\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p}\left(\Lambda^{-1} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}}
\end{aligned}
$$

Regarding the second term in (8.49), by Hölder's inequality again,

$$
\begin{equation*}
\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S)^{\frac{p}{2}} \mu(S)^{1-\frac{p}{2}} \leq\left(\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S)\right)^{\frac{p}{2}} \mu\left(H D_{2}\right)^{1-\frac{p}{2}} \tag{8.50}
\end{equation*}
$$

We estimate now the first factor on the right hand side:

$$
\begin{aligned}
\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S) & \leq \sum_{S \in \mathrm{HD}_{2} \backslash \mathrm{DB}} \mathcal{E}(2 S)+\sum_{S \sim \mathcal{T}: S \in \mathrm{DB}} \mathcal{E}(2 S) \\
& \lesssim M_{0}^{2} \sum_{S \in \mathrm{HD}_{2} \backslash \mathrm{DB}} \sigma(S)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \\
& \leq M_{0}^{2} \sigma\left(\mathrm{HD}_{2}\right)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \\
& \leq B M_{0}^{2} \sigma\left(\mathrm{HD}_{1}\right)+\Lambda^{\frac{-1}{3 n}} \sigma\left(\mathrm{HD}_{1}\right) \lesssim B M_{0}^{2} \sigma\left(\mathrm{HD}_{1}\right) .
\end{aligned}
$$

Hence, plugging this estimate into (8.50) and using that $\mu\left(H D_{2}\right) \leq B \Lambda^{-2} \mu\left(H D_{1}\right)$,

$$
\sum_{S \in \mathrm{HD}_{2}} \mathcal{E}(2 S)^{\frac{p}{2}} \mu(S)^{1-\frac{p}{2}} \lesssim\left(B M_{0}^{2} \sigma\left(\mathrm{HD}_{1}\right)\right)^{\frac{p}{2}}\left(B \Lambda^{-2} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}}=M_{0}^{p} B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

Altogether, we deduce that

$$
I_{\mathrm{HD}_{2}} \lesssim\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p}\left(\Lambda^{-1} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}}+M_{0}^{p} B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right) .
$$

Recalling the lower estimate for $I_{\mathrm{HD}_{2}}$ in (8.45), we obtain

$$
\begin{equation*}
\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p}\left(\Lambda^{-1} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}} \geq c \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)-C M_{0}^{p} B \Lambda^{p-2} \sigma_{p}\left(\mathrm{HD}_{1}\right) \tag{8.51}
\end{equation*}
$$

Recall now that

$$
M_{0}=\Lambda^{1-\frac{1}{8 n-1}} \ll \Lambda
$$

Notice that for $p$ close enough to 1 , we have $M_{0}^{p} B \Lambda^{p-2} \ll 1$, so that the last term on the right hand side of (8.51) is much smaller than the first one, assuming $\varepsilon_{n}$ close enough to 0 . To be more precise, let us take

$$
p=1+\frac{1}{4(8 n-1)} .
$$

A straightforward calculation gives $M_{0}^{p} \Lambda^{p-2}=\Lambda^{-\frac{1}{2(8 n-1)}-\frac{1}{4(8 n-1)^{2}}}$, so that

$$
B M_{0}^{p} \Lambda^{p-2} \leq \Lambda^{\frac{1}{100 n}} \Lambda^{-\frac{1}{2(8 n-1)}} \leq \Lambda^{-\frac{1}{4(8 n-1)}}
$$

Then we choose $\varepsilon_{n}$ so that, besides (8.46), it satisfies

$$
\varepsilon_{n} \leq \frac{1}{8(8 n-1)}(p-1)=\frac{1}{32(8 n-1)^{2}}
$$

and we derive

$$
\left\|\Delta_{\tilde{\mathcal{T}}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{p}\left(\Lambda^{-1} \mu\left(H D_{1}\right)\right)^{1-\frac{p}{2}} \gtrsim \Lambda^{-p^{\prime} \varepsilon_{n}} \sigma_{p}\left(\mathrm{HD}_{1}\right)
$$

which is equivalent to

$$
\begin{aligned}
\left\|\Delta_{\mathcal{T}} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} & \gtrsim\left(\Lambda^{-p^{\prime} \varepsilon_{n}} \Lambda^{1-\frac{p}{2}} \sigma_{p}\left(\mathrm{HD}_{1}\right) \mu\left(H D_{1}\right)^{\frac{p}{2}-1}\right)^{\frac{p}{2}} \\
& =\Lambda^{-\frac{2 \varepsilon_{n}}{p-1}+\frac{p}{2}-1} \sigma\left(\mathrm{HD}_{1}\right) \gg \Lambda^{-1} \sigma\left(\mathrm{HD}_{1}\right) .
\end{aligned}
$$

This contradicts the assumption that the alternative (b) in the lemma does not hold.

## 9. The proof of Proposition 3.7

We have to show that

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \leq C\left(\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\theta_{0}^{2}\|\mu\|\right)
$$

with $C$ possibly depending on $\Lambda$ and other parameters. Recall that by Lemma 6.5, we have

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda^{\frac{-1}{2 n}}(\log \Lambda)^{2} \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{T}_{y}} \sigma\left(\mathrm{HD}_{1}(e(Q))\right)
$$

Also, by Lemma 6.2, it turns out that, for all $P \in \mathcal{D}_{\mu}$ and all $k \geq 0$,

$$
\#\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } P \in \mathcal{T}\left(e^{\prime}(Q)\right)\right\} \leq C_{2}(\log \Lambda)^{2}
$$

Observe now that, by Lemma 8.16, for each $Q \in \operatorname{Trc}_{k}(R) \cap \operatorname{Ty}$, either

$$
\sigma\left(\mathrm{HD}_{1}(e(Q))\right) \lesssim \theta_{0}^{2} \mu(Q) \leq \theta_{0}^{2} \varepsilon_{Z}^{-1} \mu(Z(Q))
$$

where $Z(Q)$ is the set $Z$ appearing in Lemma 6.5 (replacing $R$ by $Q$ there), or

$$
\sigma\left(\mathrm{HD}_{1}(e(Q))\right) \leq \Lambda\left\|\Delta_{\tilde{\mathcal{T}}\left(e^{\prime}(Q)\right)} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}
$$

Therefore,

$$
\begin{align*}
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim & \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}}\left\|\Delta_{\widetilde{\mathcal{T}}\left(e^{\prime}(Q)\right)} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}  \tag{9.1}\\
& +\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}} \theta_{0}^{2} \varepsilon_{Z}^{-1} \mu(Z(Q)) \\
= & : T_{1}+T_{2} .
\end{align*}
$$

9.1. Estimate of $T_{1}$. Recall that

$$
\begin{aligned}
\Delta_{\tilde{\mathcal{T}}\left(e^{\prime}(Q)\right)} \mathcal{R} \mu(x)= & \sum_{P \in \operatorname{End}\left(e^{\prime}(Q)\right)} \chi_{P}(x)\left(m_{\mu, P}(\mathcal{R} \mu)-m_{\mu, 2 Q}(\mathcal{R} \mu)\right) \\
& +\chi_{Z(Q)}(x)\left(\mathcal{R} \mu(x)-m_{\mu, 2 R}(\mathcal{R} \mu)\right)
\end{aligned}
$$

For $Q \in \mathrm{MDW}$, we write $S \prec Q$ if $S \in \mathcal{D}_{\mu}$ is a maximal cube contained in $e^{\prime}(Q)$. Then we denote

$$
\widehat{\Delta}_{Q} \mathcal{R} \mu=\sum_{S \prec Q}\left(m_{\mu, S}\left(\mathcal{R}_{\mu}\right)-m_{\mu, 2 Q}(\mathcal{R} \mu)\right) \chi_{S}
$$

Then, it is easy to check that

$$
\Delta_{\widetilde{\mathcal{T}}\left(e^{\prime}(Q)\right)} \mathcal{R} \mu=\left(\sum_{P \in \widetilde{\mathcal{T}}\left(e^{\prime}(Q)\right) \backslash \widehat{\operatorname{End}\left(e^{\prime}(Q)\right)}} \Delta_{P} \mathcal{R} \mu+\widehat{\Delta}_{Q} \mathcal{R} \mu\right) \chi_{\widetilde{G}(Q)}
$$

where

$$
\widetilde{G}(Q)=\bigcup_{P \in \widetilde{\operatorname{End}\left(e^{\prime}(Q)\right)}} P \cup Z(Q)
$$

(see [DT, Section 8.1] for the full details). It is also immediate to check that, for a fixed $Q$, all the functions appearing on the right hand side are mutually orthogonal in $L^{2}(\mu)$. Arguing as in (8.17), one sees that the cubes $P \in \widetilde{\mathcal{T}}\left(e^{\prime}(Q)\right)$ satisfy $P \sim \mathcal{T}\left(e^{\prime}(Q)\right)$. So we get

$$
\begin{aligned}
\left\|\Delta_{\tilde{\mathcal{T}}\left(e^{\prime}(Q)\right)} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} & =\sum_{P \in \widetilde{\mathcal{T}}\left(e^{\prime}(Q)\right) \backslash \widehat{\operatorname{End}\left(e^{\prime}(Q)\right)}}\left\|\Delta_{P} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}+\left\|\widehat{\Delta}_{Q} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \\
& \leq \sum_{P \sim \mathcal{T}\left(e^{\prime}(Q)\right)}\left\|\Delta_{P} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}+\left\|\widehat{\Delta}_{Q} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
T_{1} \leq & \sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \operatorname{Ty}} \sum_{P \sim \mathcal{T}\left(e^{\prime}(Q)\right)}\left\|\Delta_{P} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \\
& +\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}}\left\|\widehat{\Delta}_{Q} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \\
= & : T_{1,1}+T_{1,2} .
\end{aligned}
$$

By Fubini, regarding the term $T_{1,1}$, we have

$$
T_{1,1} \leq \sum_{P \in \mathcal{D}_{\mu}}\left\|\Delta_{P} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \sum_{k \geq 0} B^{-k / 2} \# A(P, k),
$$

where

$$
A(P, k)=\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } P \sim \mathcal{T}\left(e^{\prime}(Q)\right)\right\}
$$

As shown in (6.12), it holds

$$
\# A(P, k) \lesssim(\log \Lambda)^{2}
$$

Hence,

$$
T_{1,1} \lesssim \Lambda \sum_{P \in \mathcal{D}_{\mu}}\left\|\Delta_{P} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \lesssim \Lambda\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2} .
$$

Concerning $T_{1,2}$, we argue analogously:

$$
T_{1,2} \leq \sum_{Q \in \mathcal{D}_{\mu}^{\mathcal{P}}}\left\|\widehat{\Delta}_{Q} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} \sum_{k \geq 0} B^{-k / 2} \# \widetilde{A}(Q, k)
$$

where

$$
\widetilde{A}(Q, k)=\left\{R \in \mathrm{~L}(\mathrm{GDF}): Q \in \operatorname{Trc}_{k}(R)\right\} .
$$

Since

$$
\# \widetilde{A}(Q, k) \leq \# A(Q, k) \lesssim(\log \Lambda)^{2}
$$

we deduce that

$$
T_{1,2} \lesssim \Lambda \sum_{Q \in \mathrm{MDW}}\left\|\widehat{\Delta}_{Q} \mathcal{R} \mu\right\|_{L^{2}(\mu)}^{2} .
$$

By Lemma 8.1 from [DT] 6 the right hand side above is also bounded by $C\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}$. So we have,

$$
T_{1} \lesssim \Lambda\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2} .
$$

9.2. Estimate of $T_{2}$. We have

$$
\begin{aligned}
T_{2} & =\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}} \theta_{0}^{2} \varepsilon_{Z}^{-1} \mu(Z(Q)) \\
& =\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \mathrm{Ty}} \int_{Z(Q)} \theta_{0}^{2} \varepsilon_{Z}^{-1} d \mu \\
& =\int \theta_{0}^{2} \varepsilon_{Z}^{-1}\left(\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \operatorname{Ty}^{2}} \chi_{Z(Q)}\right) d \mu .
\end{aligned}
$$

By Fubini, we have

$$
\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \operatorname{Ty}} \chi_{Z(Q)} \leq \sum_{k \geq 0} B^{-k / 2} \# D(x, k),
$$

where

$$
D(x, k)=\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R) \text { such that } x \in Z(Q)\right\}
$$

[^6]Observe now that, given $j \geq 1$, if we let
$D_{j}(x, k)=\left\{R \in \mathrm{~L}(\mathrm{GDF}): \exists Q \in \operatorname{Trc}_{k}(R)\right.$ such that $\mathcal{T}\left(e^{\prime}(Q)\right)$ contains
every $P \in \mathcal{D}_{\mu}$ such that $x \in P$ and $\left.\ell(P) \leq A_{0}^{-j}\right\}$,
then we have

$$
D(x, k)=\bigcup_{j \geq 1} D_{j}(x, k),
$$

and moreover $D_{j}(x, k) \subset D_{j+1}(x, k)$ for all $j$. From Lemma 6.2 we deduce that

$$
\# D_{j}(x, k) \leq C(\log \Lambda)^{2} \quad \text { for all } j \geq 1
$$

Thus, $\# D(x, k) \leq C(\log \Lambda)^{2}$ too. Consequently,

$$
\sum_{R \in \mathrm{~L}(\mathrm{GDF})} \sum_{k \geq 0} B^{-k / 2} \sum_{Q \in \operatorname{Trc}_{k}(R) \cap \operatorname{Ty}} \chi_{Z(Q)} \lesssim \Lambda 1,
$$

and so

$$
T_{2} \lesssim_{\Lambda} \varepsilon_{Z}^{-1} \theta_{0}^{2}\|\mu\| .
$$

Together with the estimate we obtained for $T_{1}$, this yields

$$
\sum_{Q \in \mathrm{DB}} \mathcal{E}_{\infty}(9 Q) \lesssim \Lambda\|\mathcal{R} \mu\|_{L^{2}(\mu)}^{2}+\varepsilon_{Z}^{-1} \theta_{0}^{2}\|\mu\|,
$$

which concludes the proof of Proposition 3.7.

[^1]:    ${ }^{1}$ Actually the property 1 ) is not stated in that theorem, however this can be obtained by preselecting a subfamily of maximal balls from $\mathrm{F}_{j}^{h}$ with respect to inclusion and then applying the theorem to the maximal subfamily.

[^2]:    ${ }^{2}$ Here we are assuming that $\sum_{P \in \mathrm{DB}} \mathcal{E}_{\infty}(9 P)<\infty$. To ensure that this holds, if necessary we may replace the measure $\mu$ by another approximating measure of the form $\mu_{\ell}=\varphi_{\ell} * \mu$, where $\varphi_{\ell}$ is a $C^{\infty}$ bump function supported on $B(0, \ell)$, with $\left\|\varphi_{\ell}\right\|_{1}=1$. Then we prove Proposition 3.7 for $\mu_{\ell}$ with bounds independent of $\ell$, and finally we let $\ell \rightarrow \infty$.

[^3]:    ${ }^{3}$ Notice that $D_{\text {Neg }}=\operatorname{Reg}_{M_{\text {Neg }}}$.

[^4]:    ${ }^{4}$ This arugment shows that, in fact, $\mathcal{P}(Q) \lesssim \Lambda^{2} \Theta(R)$ for all $Q \in \mathcal{T}\left(e^{\prime}(R)\right)$.

[^5]:    ${ }^{5}$ We will obtain better estimates for $\Sigma^{\mathcal{P}}\left(\mathrm{M}_{\mathrm{Neg}}\right)$ below.

[^6]:    ${ }^{6}$ In fact, the family MDW in DT is not the same as the one in the current paper because in DT MDW is a subfamily of roots of a corona decomposition of $\mathcal{D}_{\mu}$. However, the reader can check that the proof of Lemma 8.1 from DT works verbatim in our situation too.
