Improved Rates for Differentially Private Stochastic Convex Optimization with Heavy-Tailed Data∗

Gautam Kamath† Xingtu Liu‡ Huanyu Zhang§

June 4, 2021

Abstract

We study stochastic convex optimization with heavy-tailed data under the constraint of differential privacy. Most prior work on this problem is restricted to the case where the loss function is Lipschitz. Instead, as introduced by Wang, Xiao, Devadas, and Xu [WXDX20], we study general convex loss functions with the assumption that the distribution of gradients has bounded $k$-th moments. We provide improved upper bounds on the excess population risk under approximate differential privacy of $\tilde{O} \left( \sqrt{\frac{d}{n}} + \left( \frac{d}{n} \right)^{\frac{k-1}{k}} \right)$ and $\tilde{O} \left( \frac{d}{n} + \left( \frac{d}{n} \right)^{\frac{2k-2}{k}} \right)$ for convex and strongly convex loss functions, respectively. We also prove nearly-matching lower bounds under the constraint of pure differential privacy, giving strong evidence that our bounds are tight.

1 Introduction

Stochastic convex optimization (SCO) is a classic optimization problem in machine learning. The goal is, given a loss function $\ell$ and a dataset $X_1, \ldots, X_n$ drawn i.i.d. from some unknown distribution $D$, to output a parameter vector $w$ which minimizes the population risk $L_D(w) = \mathbb{E}_{x \sim D}[\ell(w; x)]$. The quality of a solution $\hat{w}$ is measured in terms of the excess risk over the minimizer in the parameter set $W$, $L_D(\hat{w}) - \arg\min_{w \in W} L_D(w)$. We study SCO under the constraint of differential privacy [DMNS06] (DP), a rigorous notion of privacy which guarantees that an algorithm’s output distribution is insensitive to modification of a small number of datapoints.

The field of DP optimization has seen a significant amount of work. Early results focused on differentially private empirical risk minimization (ERM), a non-statistical problem in which the goal is to privately output a parameter vector $w$ which minimizes the loss function $\ell$ over a fixed dataset $X_1, \ldots, X_n$: that is we would like to optimize $\min_w \frac{1}{n} \sum_{i=1}^n \ell(w, X_i)$. See, for example, [CM08, CMS11, RBHT12, KST12, TS13, SCS13, JT14, BST14, TTZ15, KJ16, WLK+17, WYX17, INS+19, WJE19, ZMH21, WZGX21]. The first result to address the statistical problem of DP SCO was [BST14], using generalization properties of differential privacy and regularized ERM. However, the excess risk bounds were suboptimal. [BFTT19] addressed this and closed the gap by providing tight upper bounds on DP SCO. Following this result there has been renewed

interest in DP SCO, with works reducing the gradient complexity and running time [FKT20, KLL21], and deriving results for different geometries [AFKT21, BGN21].

Despite the wealth of work in this area, a significant restriction in almost all results is that the loss function is assumed to be Lipschitz. This assumption bounds the magnitude of each datapoint’s gradient, a very convenient property for restricting the sensitivity in the design of differentially private algorithms. While convenient, it is often an unrealistic assumption which does not hold in practice, and DP optimizers resort to heuristic clipping of gradients to enforce a bound on their magnitude [ACG+16]. One can remove the strong Lipschitz assumption by instead assuming that the distribution of gradients is somehow well-behaved. In this vein, [WXDX20] introduces and studies the problem of DP SCO with heavy-tailed data. Their work removes the requirement that the loss function is Lipschitz, and instead assumes that the distribution of the gradient has bounded second moments. However, they leave open the question of whether the rates of their algorithms can be improved.

1.1 Results

We answer this question affirmatively, giving algorithms with much better rates for DP SCO with heavy-tailed gradients. We also prove lower bounds which provide strong evidence that these algorithms can not be significantly improved.

Our main upper bound is the following.

**Theorem 1.1** (Informal, see Theorems 4.7 and 4.8). Suppose we have a loss function \( \ell : W \times \mathbb{R}^d \rightarrow \mathbb{R} \) and there exists a distribution \( \mathcal{D} \) over \( \mathbb{R}^d \) such that for any parameter vector \( w \in W \), when \( x \sim \mathcal{D} \), the \( k \)-th moment of \( \nabla \ell(w, x) \) is bounded. Then there exists a computationally efficient \( \varepsilon^2 \)-zero-concentrated differentially private algorithm which, given \( x_1, \ldots, x_n \sim \mathcal{D} \), outputs a parameter vector \( w^{\text{priv}} \) satisfying the following:

\[
\mathbb{E}[L_{\mathcal{D}}(w^{\text{priv}}) - L_{\mathcal{D}}(w^*)] \leq \tilde{O} \left( \sqrt{\frac{d}{n}} + \left( \frac{d}{\varepsilon n} \right)^{\frac{k+1}{2}} \right),
\]

where \( w^* = \arg \min_w L_{\mathcal{D}}(w) \). Furthermore, if \( \ell \) is strongly convex and smooth, a similar algorithm guarantees the following:

\[
\mathbb{E}[L_{\mathcal{D}}(w^{\text{priv}}) - L_{\mathcal{D}}(w^*)] \leq \tilde{O} \left( \frac{d}{n} + \left( \frac{d}{\varepsilon n} \right)^{\frac{2(k-1)}{k}} \right).
\]

This theorem is stated under the constraint of \( \varepsilon^2 \)-concentrated differential privacy, which also implies the more common notion of \( (O(\varepsilon \sqrt{\log(1/\delta)}), \delta) \)-differential privacy for any \( \delta > 0 \) (see Lemma 2.3). Thus, ignoring factors which are logarithmic in \( 1/\delta \), the same rates in Theorem 1.1 also hold under the weaker notion of \( (\varepsilon, \delta) \)-differential privacy.

Prior work on DP SCO with heavy tailed data is due to [WXDX20]. Their main results are algorithms for a case with bounded second moments \( (k = 2) \), guaranteeing excess risk bounds of \( \tilde{O} \left( \frac{d^2}{\varepsilon n} \right)^{1/3} \) and \( \tilde{O} \left( \frac{d^2}{\varepsilon^2 n} \right) \) for the convex and strongly convex cases, respectively. We comment that their bounds are not immediately comparable to ours, due to differences in assumptions. Namely, they assume that the second moment is bounded only in axis-aligned directions, whereas we assume that it is bounded in all directions. While our assumption is stronger, we chose it as the focus of our work since it is rotation invariant, and thus we consider it to be more natural.
Nonetheless, a slight variant of our analysis (described in Appendix B) allows us to similarly derive excess risk bounds under their bounded moment assumption. These bounds are \( \tilde{O}\left(\sqrt{d n / \varepsilon n}\right) \) and 
\( \tilde{O}\left(\frac{d^{3/2}}{\varepsilon n}\right) \) for the convex and strongly convex cases, respectively, which significantly improves upon their excess risk bound for both cases. In addition to improving their error and refining their moment bound, we also derive results that are applicable to distributions with bounded moment conditions of all orders \( k \), while [WXDX20] only applies to distributions with bounded second moments \( (k = 2) \). Finally, while it may appear that one advantage of our upper bounds is that they hold under the stronger notion of concentrated DP, the results of [WXDX20] could easily be analyzed under concentrated DP as well.

To complement our upper bounds, we provide lower bounds with rates which match our upper bounds up to polylogarithmic factors.

**Theorem 1.2** (Informal, see Theorems 5.1 and 5.4). Let \( \ell : \mathcal{W} \times \mathbb{R}^d \to \mathbb{R} \) be a convex loss function and \( \mathcal{D} \) be a distribution over \( \mathbb{R}^d \), such that for any parameter vector \( w \in \mathcal{W} \), when \( x \sim \mathcal{D} \), the \( k \)-th moment of \( \nabla \ell(w, x) \) is bounded. Suppose there exists an \( \varepsilon \)-differentially private algorithm which is given \( x_1, \ldots, x_n \sim \mathcal{D} \) and outputs a parameter vector \( w_{\text{priv}} \). Then there exists a choice of convex loss function \( \ell \) and distribution \( \mathcal{D} \) such that

\[
\mathbb{E}[L_{\mathcal{D}}(w_{\text{priv}}) - L_{\mathcal{D}}(w^*)] \geq \Omega \left( \sqrt{\frac{d}{n}} + \left( \frac{d}{\varepsilon n} \right)^{\frac{k-1}{k}} \right),
\]

where \( w^* = \arg \min_w L_{\mathcal{D}}(w) \). Furthermore, there exists a choice of strongly convex loss function \( \ell \) and distribution \( \mathcal{D} \) such that

\[
\mathbb{E}[L_{\mathcal{D}}(w_{\text{priv}}) - L_{\mathcal{D}}(w^*)] \geq \Omega \left( \frac{d}{n} + \left( \frac{d}{\varepsilon n} \right)^{\frac{2(k-1)}{k}} \right).
\]

We note that our upper bounds are for \( (\varepsilon, \delta) \)-DP, whereas our lower bounds are for \( (\varepsilon, 0) \)-DP. Thus while the rates match, there is still a gap with respect to the privacy notions. However, the same gap exists in the current literature even for the simplest DP SCO problem of private mean estimation. Specifically, [KSU20] similarly shows \( (\varepsilon, \delta) \)-DP upper bounds, \( (\varepsilon, 0) \)-DP upper bounds,\(^1\) and \( (\varepsilon, 0) \)-DP lower bounds for private heavy-tailed mean estimation, all of which match. They conjecture that a matching \( (\varepsilon, \delta) \)-DP lower bound should also exist, appealing to results [KLSU19, BKSW19] showing that private Gaussian mean estimation (which can be seen as a limiting case of heavy tails when \( k = \infty \)) enjoys the same rate under either \( (\varepsilon, \delta) \)-DP or \( (\varepsilon, 0) \)-DP. Thus, we conjecture the same, and in fact a positive resolution to their conjecture would imply the same for us.

1.2 Techniques

Our upper bounds operate using a gradient-descent-based method, relying upon an algorithm for private mean estimation. In particular, we instantiate an oracle which can output an estimate of the true gradient at a point. This oracle is based on the algorithms of [KSU20], which address the problem of private mean estimation of heavy-tailed distributions. That said, for several reasons,
First, the accuracy guarantees in [KSU20] give a prescribed \( \ell_2 \)-error with high probability. While such guarantees for an oracle allow one to achieve non-trivial rates for DP SCO, they are far from optimal. Instead, we can get better results when the estimator is known to have low bias. This is where the intersection of privacy and heavy-tailed data gives rise to a new technical challenge: no unbiased mean estimation algorithm for this setting is known to exist. To deal with these issues, we explicitly derive bounds on the bias and variance of the estimator. While this was implicitly done in [KSU20], the terms were balanced to minimize the \( \ell_2 \)-error in a high-probability bound, whereas we need to decouple the bias and the variance for our application. Even with these changes in place, the bound would still be lossy – as a final modification, we find that a different bias-variance tradeoff is required in each iteration to achieve the best possible error. Namely, if we tolerate additional variance to reduce the bias of each step, this results in an improved final accuracy.

2 Preliminaries

2.1 Privacy Preliminaries

In our work we consider a few different variants of differential privacy. The first is the standard notion of differential privacy.

**Definition 2.1 (Differential Privacy (DP) [DMNS06]).** A randomized algorithm \( M : \mathcal{X}^n \mapsto \mathcal{Y} \) satisfies \((\varepsilon, \delta)\)-differential privacy if for every pair of neighbouring datasets \( X, X' \in \mathcal{X}^n \) (i.e., datasets that differ in exactly one entry),

\[
\forall Y \subseteq \mathcal{Y} \quad \mathbb{P}[M(X) \in Y] \leq e^\varepsilon \cdot \mathbb{P}[M(X') \in Y] + \delta.
\]

When \( \delta = 0 \), we say that \( M \) satisfies \( \varepsilon \)-differential privacy or pure differential privacy.

The second is concentrated differential privacy [DR16], and its refinement zero-concentrated differential privacy [BS16]. Since in this work we exclusively concern ourselves with the latter, in a slight overloading of nomenclature, we refer to it more concisely as concentrated differential privacy.

**Definition 2.2 (Concentrated Differential Privacy (CDP) [BS16]).** A randomized algorithm \( M : \mathcal{X}^n \mapsto \mathcal{Y} \) satisfies \( \rho \)-CDP if for every pair of neighboring datasets \( X, X' \in \mathcal{X}^n \),

\[
\forall \alpha \in (1, \infty) \quad D_\alpha(M(X)||M(X')) \leq \rho \alpha,
\]

where \( D_\alpha(M(X)||M(X')) \) is the \( \alpha \)-Rényi divergence between \( M(X) \) and \( M(X') \).

Roughly speaking, concentrated differential privacy lives between pure \((\varepsilon, 0)\)-differential privacy and approximate \((\varepsilon, \delta)\)-differential privacy, formalized in the following lemma.

**Lemma 2.3 ([BS16]).** For every \( \varepsilon > 0 \), if \( M \) is \( \varepsilon \)-DP, then \( M \) is \( \left( \frac{1}{2} \varepsilon^2 \right) \)-CDP. If \( M \) is \( \left( \frac{1}{2} \varepsilon^2 \right) \)-CDP, then \( M \) is \( \left( \frac{1}{2} \varepsilon^2 + \varepsilon \sqrt{2 \log(1/\delta)} \right) \)-DP for every \( \delta > 0 \).

Differential privacy enjoys various nice properties, including post-processing and adaptive composition.

**Lemma 2.4 (Post-Processing [DMNS06, BS16]).** If \( M : \mathcal{X}^n \mapsto \mathcal{Y} \) is \((\varepsilon, \delta)\)-DP, and \( P : \mathcal{Y} \mapsto \mathcal{Z} \) is any randomized function, then the algorithm \( P \circ M \) is \((\varepsilon, \delta)\)-DP. Similarly if \( M \) is \( \rho \)-CDP then the algorithm \( P \circ M \) is \( \rho \)-CDP.
Lemma 2.5 (Composition of DP [DMNS06, DRV10, BS16]). If \( M \) is an adaptive composition of differentially private algorithms \( M_1, \ldots, M_T \), then the following all hold:

- If \( M_1, \ldots, M_T \) are \((\varepsilon_1, 0), \ldots, (\varepsilon_T, 0)\)-DP then \( M \) is \((\varepsilon, 0)\)-DP for \( \varepsilon = \sum_t \varepsilon_t \).
- If \( M_1, \ldots, M_T \) are \( \rho_1, \ldots, \rho_T \)-CDP then \( M \) is \( \rho \)-CDP for \( \rho = \sum_t \rho_t \).

2.2 Optimization Preliminaries

Definition 2.6. A function \( f : \mathcal{W} \mapsto \mathbb{R} \) is \( L \)-Lipschitz if for all \( w_1, w_2 \in \mathcal{W} \) we have \( |f(w_1) - f(w_2)| \leq L||w_1 - w_2||_2 \).

Definition 2.7. A function \( f \) is \( a \)-strongly convex on \( \mathcal{W} \) if for all \( w_1, w_2 \in \mathcal{W} \) we have \( f(w_1) \geq f(w_2) + \langle \nabla f(w_2), w_1 - w_2 \rangle + \frac{a}{2}||w_1 - w_2||_2^2 \).

Definition 2.8. A function \( f \) is \( b \)-smooth on \( \mathcal{W} \) if for all \( w_1, w_2 \in \mathcal{W} \), \( f(w_1) \leq f(w_2) + \langle \nabla f(w_2), w_1 - w_2 \rangle + \frac{b}{2}||w_1 - w_2||_2^2 \).

Definition 2.9. Given a convex set \( \mathcal{W} \), we denote the projection of any \( \theta \in \mathbb{R}^d \) to the convex set \( \mathcal{W} \) by \( \text{Proj}_\mathcal{W}(\theta) = \arg\min_{w \in \mathcal{W}} \| \theta - w \|_2 \).

2.3 Problem Setup

Definition 2.10 (Stochastic Convex Optimization (SCO)). Let \( \mathcal{D} \) be some unknown distribution over \( \mathcal{X} \) and \( X = \{x_1, \ldots, x_n\} \) be i.i.d. samples from \( \mathcal{D} \). Given a convex constraint set \( \mathcal{W} \subseteq \mathbb{R}^d \) and a convex loss function \( \ell : \mathcal{W} \times \mathcal{X} \mapsto \mathbb{R} \), the goal of stochastic convex optimization (SCO) is to find a minimizer \( w^{\text{priv}} \) for the population risk \( L_\mathcal{D}(w^{\text{priv}}) = \mathbb{E}_{x \sim \mathcal{D}}[\ell(w^{\text{priv}}, x)] \). The utility of an algorithm \( \mathcal{A} \) is measured by the expected excess population risk

\[
\mathbb{E}_{x \sim \mathcal{D}^n, \mathcal{A}} \left[ L_\mathcal{D}(w^{\text{priv}}) - \min_{w \in \mathcal{W}} L_\mathcal{D}(w) \right].
\]

We use the following definition to denote that a distribution has bounded moments. Since it enforces a constraint on every univariate projection of the distribution, it is rotation invariant. This is in comparison to the axis-aligned notion studied by [WXDX20], which is less common in the literature.

Definition 2.11. Let \( \mathcal{D} \) be a distribution over \( \mathbb{R}^d \) with mean \( \mu \). We say that for \( k \geq 2 \), the \( k \)-th moment of \( \mathcal{D} \) is bounded by \( \gamma \), if for every unit vector \( v \in S^{d-1} \),

\[
\mathbb{E}[|X - \mu, v|^k] \leq \gamma,
\]

where \( S^{d-1} \) is the surface of a \( d \)-dimensional sphere.

Let \( B_r(\bar{c}) \subset \mathbb{R}^d \) be the ball of radius \( r > 0 \) centered at \( \bar{c} \in \mathbb{R}^d \). All our theorems rely on the following set of assumptions.

Assumption 1. We assume the following:
1. The loss function \( \ell(w, x) \) is non-negative, differentiable and convex for all \( w \in \mathcal{W} \) and \( x \in \mathcal{X} \).
2. The convex constraint set \( \mathcal{W} \) is bounded with diameter \( M \).
3. The gradient of the loss function at the optimum is zero.
4. For any \( w \in \mathcal{W} \), the distribution of the gradient of the loss function has bounded \( k \)-th moments: \( \nabla \ell(w, x) \sim \mathcal{P} \) satisfies Definition 2.11 with \( \gamma = 1 \).
5. For any \( w \in \mathcal{W} \), the distribution of the gradient has bounded mean: \( \mathbb{E}[\nabla \ell(w, x)] \in B_R(\bar{0}) \), where \( R = \Omega(1) \).
The first three points in Assumption 1 are standard when studying convex learning problems. The fourth is a relaxation of the Lipschitz condition in non-heavy-tailed SCO problems, in which the gradient is assumed to be uniformly bounded by a constant $L$. While the gradient in our setting is unbounded, it is realistic to assume that the expected gradient is inside a ball with some radius $R$. In fact, packing lower bounds for private mean estimation necessitate such an assumption under most notions of DP [KV18]. As a direct corollary, $\|\nabla L_D(w)\|_2 \leq R$, so $L_D(w)$ is $R$-Lipschitz.

3 A Framework for Stochastic Convex Optimization

In this section, we present a general framework for DP SCO. Before diving into the details, we first provide some intuition on how we approach this problem, via the classic optimization model.

Let $L_D(\cdot)$ be the expected loss function to minimize. Note that although the data $x \sim X$, the loss function $\ell(\cdot)$, and its gradient $\nabla \ell(\cdot)$ may be heavy-tailed, $L_D(\cdot)$ is well-behaved (it is both convex and $R$-Lipschitz), which directly comes from Assumption 1. Therefore, if $L_D(\cdot)$ were known beforehand, the problem would reduce to a classical convex optimization problem, which could be solved by gradient descent (GD).

Next, we consider the case when $L_D(\cdot)$ is not known to the optimizer. Note that directly applying GD is infeasible, since it is impossible to compute the exact gradient $\nabla L_D(\cdot)$. An alternative way is to estimate $\nabla L_D(\cdot)$ from the samples $X$, which incurs an additional loss due to error in our estimate.

**Algorithm 1** SCO algorithmic framework SCOF$_{\eta,T,\text{MeanOracle}}(X)$

<table>
<thead>
<tr>
<th>Input: $X = {x_1}_{i=1}^n, x_i \in \mathbb{R}^d$, algorithm MeanOracle, parameters $\eta, T$.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1: Initialize $w^0 \in \mathcal{W}$.</td>
</tr>
<tr>
<td>2: for $t = 1, 2, \ldots, T$ do</td>
</tr>
<tr>
<td>3: $\nabla L_D(w^{t-1}) = \text{MeanOracle}({\nabla \ell(w^{t-1}, x_i)}_{i=1}^n)$</td>
</tr>
<tr>
<td>4: $w^t = \text{Proj}<em>W(w^{t-1} - \eta</em>{t-1} \nabla L_D(w^{t-1}))$</td>
</tr>
<tr>
<td>Output: ${w^1, w^2, \ldots, w^T}$.</td>
</tr>
</tbody>
</table>

Our framework, SCOF, is presented in Algorithm 1, where we generally follow the framework of GD. The main difference is in that the updating rule, we replace $\nabla L_D(w^{t-1})$ by its estimate, $\nabla \tilde{L}_D(w^{t-1})$, which is attained by a mean estimation algorithm.

First, we note that Algorithm 1 is differentially private if the mean estimator MeanOracle is differentially private, a consequence of the composition and post-processing properties of differential privacy. Furthermore, in Theorems 3.1 and 3.2, we describe the relationship between the population risk of Algorithm 1 and the accuracy of MeanOracle. In Theorem 3.1, we consider a general class of convex loss functions, while in Theorem 3.2, we consider a less general class of functions, by assuming they are both smooth and strongly convex. Although the proof techniques are standard and similar to the previous work, e.g., [ASY+18], we include the analysis for completeness. The proofs are in Appendix C.1 and Appendix C.2, respectively.

**Theorem 3.1** (Convex). Suppose that MeanOracle guarantees that, for any $w \in \mathcal{W}$, $\mathbb{E}[\nabla \tilde{L}_D(w)] - \nabla L_D(w) \leq B$ and $\mathbb{E}[\|\nabla L_D(w) - \nabla L_D(w)\|_2^2] \leq G^2$. Under Assumption 1, for any $\eta > 0$ the output $w^{priv} = \frac{1}{T} \sum_{t \in [T]} w^t$ produced by SCOF satisfies

$$\mathbb{E}_{X \sim D^n, A} \left[ L_D(w^{priv}) - L_D(w^*) \right] \leq \frac{M^2}{2\eta T} + \frac{\eta R^2}{2} + \frac{\eta G^2}{2} + MB,$$
where \( w^* = \arg \min_w L_D(w) \).

**Theorem 3.2** (Strongly convex and smooth). Suppose that MeanOracle guarantees that, for any \( w \in \mathcal{W} \), \( \mathbb{E}[\|\nabla L_D(w) - \nabla L_D(w^*)\|_2] \leq G \). Under Assumption 1, and the further assumption that the population risk is \( a \)-strongly convex and \( b \)-smooth, if \( \eta = \frac{1}{a+b} \), the output \( w_{\text{priv}} = w^T \) produced by SCO satisfies

\[
\mathbb{E}_{X \sim D^n, A} [L_D(w_{\text{priv}}) - L_D(w^*)] \leq \left( 1 - \frac{ab}{(a+b)^2} \right)^T M + \frac{(a+b)G}{ab}.
\]

Specifically, if \( T = \log \left( \frac{(a+b)G}{ab} \right) / \max \left( \frac{a^2+b^2+ab}{(a+b)^2} \right) \), the output \( w_{\text{priv}} \) satisfies

\[
\mathbb{E}_{X \sim D^n, A} [L_D(w_{\text{priv}}) - L_D(w^*)] \leq \frac{(a+b)^2(M+1)^2G^2}{2a^2b},
\]

where \( w^* = \arg \min_w L_D(w) \).

### 4 Algorithms for SCO with Heavy-Tailed Data

We present our algorithms for \( \rho \)-CDP SCO. We first introduce our mean estimation oracle in Section 4.1. Then we leverage it to obtain our main algorithms, which are presented in Section 4.2.

#### 4.1 Mean Estimation Oracle

Generally speaking, we leverage CDPHDME as our oracle, proposed in [KSU20] to privately estimate the mean of a heavy-tailed distribution. However, it is insufficient to use it as a black box, as this would result in loose bounds for DP SCO. Therefore, we provide a novel analysis of this algorithm, which differs from theirs in two crucial aspects.

First, their analysis only applies for a specific choice of the truncation parameter (\( \tau \) in Theorem 4.1), which is selected to be optimal for their one-round algorithm. However, note that our problem is different from theirs, since GD requires multiple steps instead of only one round. If we naively follow the same parameter setting as they do, we will get a loose bound on the excess risk. Therefore, we generalize their analysis to accommodate a range of values for \( \tau \) to fit our needs.

Second, while their analysis provides \( \ell_2 \)-error guarantees which hold with constant probability, our results for the stochastic oracle model require us to instead derive bounds on the expectation and variance of the estimator. At the same time, we must refine their approach so that most steps in the algorithm fail with exponentially small probability, as compared to constant probability in their analysis.

Our new analysis can be summarized by Theorem 4.1, which reveals a trade-off between the bias and variance of the estimator. Note that by choosing different values for the truncation parameter \( \tau \), we can achieve a different balance between the bias and variance. The proof appears in Appendix C.4. The algorithm is described in Algorithm 3, for which Algorithm 2 is a key subroutine.

**Theorem 4.1.** Let \( D \) be a distribution over \( \mathbb{R} \) with mean \( \mu \in B_R(\bar{0}) \) and \( k \)-th moment bounded by 1. Let \( \tau \geq 60 \), there exists a polynomial-time, \( \rho \)-CDP algorithm CDPHDME(\( \rho, \tau \)) that takes \( \mathcal{N} \geq O\left( \sqrt{\frac{d \log R}{\rho}} + \log R \right) \) samples from \( D \), and outputs \( \hat{\mu} \in \mathbb{R}^d \), such that the following conditions hold:
4.1 Algorithm Subroutine

In this section, we overview the key components in the proof of Theorem 4.1. While the proof is based on the original approach in [KSU20], we crucially sharpen and simplify their analysis at several points.

The first step of Algorithm 3 coarsely estimates the mean of the distribution, using a histogram-based approach described in Algorithm 2. The guarantees of this procedure are described in Theorem 4.2, and proven in Appendix C.3. A weaker statement is proved in [KSU20] for a fixed threshold \( \tau \) and a constant probability of success, we generalize it to handle arbitrary thresholds \( \tau \) and to have sharp exponential tail bounds.

**Theorem 4.2.** Let \( D \) be a distribution over \( \mathbb{R} \) with mean \( \mu \in [-R,R] \) and \( k \)-th moment bounded by 1. There exists an \( \rho \)-CDP algorithm that takes samples from \( D \), and outputs \( I \subset \mathbb{R} \), such that with probability at least \( 1 - 2 \cdot (\frac{L}{K} + 2) \cdot e^{-\frac{\mu^2}{2D^2}} - e^{-\frac{\mu^2}{2D^2}} \), \( |\mu - \frac{D^2}{2D^2}I| \leq 3\tau \).

After performing coordinatewise coarse mean estimation, Algorithm 3 truncates points based on the magnitude of their \( \ell_2 \)-norm. While the algorithm simply discards points which are too far...
from the coarse estimate of the mean, we consider an alternative notion of truncation which sets these distant points to the true (unknown) mean of the distribution. Since the mean is unknown, this is clearly not implementable, but it serves as a useful tool in the analysis.

**Definition 4.3** (Definition 4.2 in [KSU20]). Let \( \bar{c}, x \in \mathbb{R}^d \), and \( r > 0 \). Then we define \( \text{trunc}(\bar{c}, r, x) \) as follows.

\[
\text{trunc}(\bar{c}, r, x, \mu) = \begin{cases} 
  x & \text{if } \|\bar{c} - x\|_2 \leq r, \\
  \mu & \text{if } \|\bar{c} - x\|_2 > r.
\end{cases}
\]

Similarly, for a dataset \( X = (X_1, \ldots, X_n) \in \mathbb{R}^{n \times d} \), we define \( \text{trunc}(\bar{c}, r, S, \mu) \) as the dataset \( (X'_1, \ldots, X'_n) \), where for each \( 1 \leq i \leq n \), \( X'_i = \text{trunc}(\bar{c}, r, X_i, \mu) \).

The following lemma quantifies the bias induced if this (fictional) truncation were performed.

**Lemma 4.4** (Fictional truncation, Lemma 4.3 in [KSU20]). Let \( D \) be a distribution over \( \mathbb{R}^d \) with mean \( \mu \), and \( k \)-th moment bounded by 1, where \( k \geq 2 \). Let \( \bar{c} \in \mathbb{R}^d \), and \( \tau \geq 1 \). Let \( x \sim D \), and \( Z \) be the following random variable:

\[
Z = \text{trunc}(\bar{c}, \tau \sqrt{d}, x, \mu).
\]

If \( \|\mu - \bar{c}\|_2 \leq \frac{\tau \sqrt{d}}{2} \), then \( \|\mu - \mathbb{E}[Z]\|_2 \leq \left(\frac{C}{\tau}\right)^{k-1} \) for a constant \( C \).

We use Lemma 4.5 to quantify the bias induced by the actual truncation procedure. The proof relies upon bounding the bias introduced by the fictional truncation, as quantified in Lemma 4.4. The statement of Lemma 4.5 is similar to Lemma 4.5 in [KSU20], but the proof is novel. We consider both to be cleaner than the equivalents in [KSU20], and thus more broadly applicable.

**Lemma 4.5.** Let \( \tau \geq 20 \), and \( D \) be a distribution over \( \mathbb{R}^d \) with mean \( \mu \) and \( k \)-th moment bounded by 1. Suppose \( x \sim D \), and \( \|\mu - \bar{c}\|_2 \leq \frac{\tau \sqrt{d}}{2} \).

\[
\left\| \mu - \mathbb{E}\left[ x \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right] \right\|_2 \leq 3 \cdot \left(\frac{C}{\tau}\right)^{k-1}.
\]

**Proof.** Let \( Z = \text{trunc}(\bar{c}, \tau \sqrt{d}, x, \mu) \). Note that when \( x \notin B_{\tau \sqrt{d}}(\bar{c}) \), \( Z = \text{trunc}(\bar{c}, \tau \sqrt{d}, x, \mu) = \mu \).

\[
\mathbb{E}[Z - \mu] = \mathbb{P}(x \in B_{\tau \sqrt{d}}(\bar{c})) \cdot \mathbb{E}\left[ x - \mu \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right] + \mathbb{P}(x \notin B_{\tau \sqrt{d}}(\bar{c})) \cdot (\mu - \mu).
\]

\[
= \mathbb{P}(x \in B_{\tau \sqrt{d}}(\bar{c})) \cdot \mathbb{E}\left[ x - \mu \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right].
\]

Therefore,

\[
\left\| \mathbb{E}[Z] - \mathbb{E}\left[ x \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right] \right\|_2 = \left\| \mathbb{E}[Z - \mu] - \mathbb{E}\left[ x - \mu \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right] \right\|_2
\]

\[
= \left( \frac{1}{\mathbb{P}(x \in B_{\tau \sqrt{d}}(\bar{c}))} - 1 \right) \cdot \left\| \mathbb{E}[Z - \mu] \right\|_2
\]

\[
\leq 2 \cdot \mathbb{P}(x \notin B_{\tau \sqrt{d}}(\bar{c})) \cdot \left\| \mathbb{E}[Z - \mu] \right\|_2,
\]

where the second equality comes from (1), and the last inequality comes from the fact that \( \forall \alpha < \frac{1}{2}, \frac{1}{\alpha - 1} \leq 1 + 2\alpha \).

Finally, by Lemma 4.4, \( \left\| \mathbb{E}[Z - \mu] \right\|_2 \leq \left(\frac{C}{\tau}\right)^{k-1} \). By triangle inequality, \( \left\| \mu - \mathbb{E}\left[ x \mid x \in B_{\tau \sqrt{d}}(\bar{c}) \right] \right\|_2 \leq 3 \cdot \left(\frac{C}{\tau}\right)^{k-1} \). \( \square \)
The proof of Theorem 4.1 depends primarily upon Theorem 4.2 and Lemma 4.5, and appears in Section C.4.

4.2 Main Algorithm

With this tool in place, we present our main algorithm in Algorithm 4. This instantiates our oracle framework (SCOF) using the private mean estimation algorithm (CDPHDME in Theorem 4.1) as our oracle (MeanOracle).

**Algorithm 4** CDP-SCO algorithm with heavy-tailed data

| Input: | $X = \{x_i \}_{i=1}^n, x_i \in \mathbb{R}^d$, parameters $\eta, \rho, T$ |
| Output: | $w^{\text{priv}}$ |

1. $\{w_t\}_{t=1}^T = \text{SCOF}_{\eta,T,\text{CDPHDME}(\rho/T,\tau)}(X)$

Since each of the $T$ steps of the algorithm is $\rho/T$-CDP, composition of CDP gives the following privacy guarantee.

**Lemma 4.6.** Algorithm 4 is $\rho$-CDP.

We provide accuracy guarantees of Algorithm 4 in the following two theorems. In Theorem 4.7, we consider a general class of convex loss functions, and in Theorem 4.8, we consider the functions that are both strongly convex and smooth. The proofs follow by appropriately selecting the truncation parameter $\tau$, and balancing the bias and variance in SCOF. We defer the proofs to Appendix C.5 and Appendix C.6, respectively.

**Theorem 4.7** (Convex). Suppose we have a stochastic convex optimization problem which satisfies Assumption 1. Algorithm 4, instantiated on this problem with parameters $T = \frac{1}{4 \log R} \cdot \left(\frac{\sqrt{d} \log R}{\rho}\right)^{\frac{2k-2}{k}}$, $\eta = \frac{M}{R \sqrt{T}}$, and $\tau = \left(\frac{\sqrt{d} \log R}{\rho}\right)^{1/k}$, will output $w^{\text{priv}} = \frac{1}{T} \sum_{t \in [T]} w^t$. If $n \geq O \left(\frac{\sqrt{d} \log R}{\rho} + \log R\right)$, then

$$\mathbb{E}_{X \sim \mathcal{D}^n, A} \left[ L_D(w^{\text{priv}}) - L_D(w^*) \right] \leq M R \sqrt{\log R} \cdot O \left(\sqrt{\frac{d}{n}} + \left(\frac{d}{\sqrt{n}}\right)^{\frac{k-1}{k}}\right),$$

where $w^* = \arg \min_w L_D(w)$.

**Theorem 4.8** (Strongly Convex and Smooth). Suppose we have a stochastic convex optimization problem which satisfies Assumption 1, and additionally, the loss function $\ell$ is $a$-strongly convex and $b$-smooth. Algorithm 4, instantiated on this problem with parameters $T = \log \left(\frac{(a+b)G}{a b}\right) / \log \left(\frac{a^2 b^2}{a+b}\right)$, $\eta = \frac{1}{a+b}$ and $\tau = \left(\frac{\sqrt{d} \log R}{\rho}\right)^{1/k}$, will output $w^{\text{priv}} = w^T$. If $n \geq O \left(\frac{\sqrt{d} \log R}{\rho} + \log R\right)$, then

$$\mathbb{E}_{X \sim \mathcal{D}^n, A} \left[ L_D(w^{\text{priv}}) - L_D(w^*) \right] \leq \left(\frac{M + 1}{a^2 b}\right)^2 \cdot \tilde{O} \left(\frac{d}{n} + \left(\frac{d}{\sqrt{n}}\right)^{\frac{2k-2}{k}}\right),$$

where $w^* = \arg \min_w L_D(w)$. 

10
Remark 4.9. Our non-standard choice of the truncation parameter $\tau$ in Theorem 4.7 is crucial to obtaining our results. If one were to naïvely use the prior setting of $\tau = \left(\frac{\sqrt{n}}{d \sqrt{T}}\right)^{\frac{k}{k-1}}$ from [KSU20], we would achieve much worse bounds. Instead, in order to reduce bias we truncate far less aggressively than they do, which comes at the cost of increased variance. Roughly speaking, if we were to use their choice of $\tau$ for the convex case, the error would be $O\left(\frac{1}{\sqrt{T}} + \left(\frac{1}{\tau}\right)^{k-1}\right) = O\left(\frac{1}{\sqrt{T}} + \left(\frac{d}{\sqrt{n}}\right)^{\frac{k-1}{k}}\right).$

Fixing $T = \left(\frac{\sqrt{n}}{d}\right)^{\frac{k}{2k-2}}$, we obtain the bound $O\left(\left(\frac{d}{\sqrt{n}}\right)^{\frac{k}{2k-2}}\right)$. Considering the case $k = 2$, this gives $O\left(\left(\frac{d}{\sqrt{n}}\right)^{\frac{1}{2}}\right)$ instead of our bound of $O\left(\left(\frac{d}{\sqrt{n}}\right)^{\frac{1}{2}}\right)$ in Theorem 4.7. In the limit as $k \to \infty$, our bound is quadratically better.

5 Lower Bounds for DP SCO with Heavy-Tailed Data

In this section, we present our lower bounds for $\varepsilon$-DP SCO. Our results are generally attained by reducing from DP SCO to DP mean estimation. Similar connections have been explored when proving lower bounds for DP empirical risk minimization [BST14].

5.1 Strongly-Convex Loss Functions

Theorem 5.1 (Strongly convex case). Let $n, d \in \mathbb{N}$ and $\varepsilon > 0$. There exists a strongly convex loss function $\ell : \mathcal{W} \times \mathbb{R}^d$, such that for every $(\varepsilon, 0)$-DP algorithm $A$ (whose output on input $X$ is denoted by $w^{\text{priv}} = A(X)$), there exists a distribution $\mathcal{D}$ on $\mathbb{R}^d$ such that $\forall w \in \mathcal{W}$, $\sup_{v : \|v\|_2 = 1} \mathbb{E}_{X \sim \mathcal{D}} \left[ |\langle \nabla \ell(w, x) - \mathbb{E}[\nabla \ell(w, x)], v \rangle|^k \right] \leq 1$, which satisfies

$$\mathbb{E}_{X \sim \mathcal{D}^n,A} \left[ L_D(w^{\text{priv}}) - L_D(w^*) \right] \geq \frac{d}{n} + \Omega \left( \min \left( 1, \left( \frac{d}{\varepsilon n} \right)^{\frac{2k-2}{k}} \right) \right),$$

where $w^* = \arg \min_w L_D(w)$.

Proof. The following lemma shows a reduction from DP mean estimation to DP SCO. The proof is deferred to Appendix C.7.

Lemma 5.2. Let $n, d \in \mathbb{N}$, and $\varepsilon > 0$. There exists a strongly convex loss function $\ell : \mathcal{W} \times \mathbb{R}^d$, such that for every $(\varepsilon, 0)$-DP algorithm $A$ (whose output on input $X$ is denoted by $w^{\text{priv}} = A(X)$), and every distribution $\mathcal{D}$ on $\mathbb{R}^d$ with $\mathbb{E}[\mathcal{D}] = \mu$,

$$\mathbb{E}_{X \sim \mathcal{D}^n,A} \left[ L_D(w^{\text{priv}}) - L_D(w^*) \right] = \mathbb{E}_{X \sim \mathcal{D}^n,A} \left[ \frac{1}{2} \| w^{\text{priv}} - \mu \|_2^2 \right],$$

where $w^* = \arg \min_w L_D(w)$.

Furthermore, if $\mathbb{E}[\mathcal{D}] = \mu$ and $\sup_{v : \|v\|_2 = 1} \mathbb{E}_{X \sim \mathcal{D}} \left[ |\langle x - \mu, v \rangle|^k \right] \leq 1$, $\ell$ satisfies that

$$\forall w, \sup_{v : \|v\|_2 = 1} \mathbb{E}_{X \sim \mathcal{D}} \left[ |\langle \nabla \ell(w, x) - \mathbb{E}[\nabla \ell(w, x)], v \rangle|^k \right] \leq 1.$$

The following lemma provides lower bounds for DP mean estimation. The first term is the non-private sample complexity, and is folklore for Gaussian mean estimation. The second term is Proposition 4 in [BD14].
Lemma 5.3. Let $n, d \in \mathbb{N}$ and $\varepsilon > 0$. For every $(\varepsilon, 0)$-DP algorithm $A$, there exists a distribution $\mathcal{D}$ on $\mathbb{R}^d$ with $E[\mathcal{D}] = \mu$ and $\sup_{v : \|v\|_2 = 1} \mathbb{E}_{x \sim \mathcal{D}}[|\langle v, x - \mu \rangle|^k] \leq 1$, such that

$$\mathbb{E}_{X \sim \mathcal{D}^n, A} \left[ \|A(X) - \mu\|_2^2 \right] \geq \frac{d}{n} + \Omega \left( \min \left( 1, \left( \frac{d}{\varepsilon n} \right)^{\frac{k-2}{k}} \right) \right).$$

Combining Lemma 5.2 and Lemma 5.3 yields Theorem 5.1.

5.2 Convex Loss Functions

The convex case is more challenging than the strongly convex case, as it can not be reduced to DP mean estimation in a black-box fashion. Technically, we apply a DP version of Fano’s inequality (Theorem 2 in [ASZ21]), based on the packing of distributions employed by [BD14]. The proof appears in Appendix C.8.

Theorem 5.4 (Convex case). Let $n, d \in \mathbb{N}$ and $\varepsilon > 0$. There exists a convex loss function $\ell : \mathcal{W} \times \mathbb{R}^d$, such that for every $(\varepsilon, 0)$-DP algorithm (whose output on input $X$ is denoted by $w^{priv} = A(X)$), there exists a distribution $\mathcal{D}$ on $\mathbb{R}^d$ with $\forall w, \sup_{v : \|v\|_2 = 1} \mathbb{E}_{x \sim \mathcal{D}} \left[ |\langle \nabla \ell(w, x) - \mathbb{E}[\nabla \ell(w, x)], v \rangle|^k \right] \leq 1$, which satisfies

$$\mathbb{E}_{X \sim \mathcal{D}^n, A} \left[ L_{\mathcal{D}}(w^{priv}) - L_{\mathcal{D}}(w^*) \right] \geq \sqrt{\frac{d}{n}} + \Omega \left( \min \left( 1, \left( \frac{d}{\varepsilon n} \right)^{\frac{k-1}{k}} \right) \right),$$

where $w^* = \arg\min_w L_{\mathcal{D}}(w)$.

A Useful Inequalities

Lemma A.1 (Chebyshev’s Inequality). Let $\mathcal{D}$ be a distribution over $\mathbb{R}$ with mean $\mu$, and $k$-th moment bounded by $M$. Then the following holds for any $a > 1$.

$$\mathbb{P}_{X \sim \mathcal{D}}[|X - \mu| > aM^{\frac{1}{k}}] \leq \frac{1}{a^k}.$$

Lemma A.2 (Gaussian Empirical Variance Concentration). Let $(X_1, \ldots, X_m) \sim \mathcal{N}(0, \sigma^2)$ be independent. If $m \geq \frac{8}{\tau^2} \ln(2/\beta)$, for $\tau \in (0, 1)$, then

$$\mathbb{P}\left[\left|\frac{1}{m} \sum_{i=1}^{m} X_i^2 - \sigma^2\right| > \tau \sigma^2\right] \leq \beta.$$

Lemma A.3 (Laplace Concentration). Let $Z \sim \text{Lap}(t)$. Then $\mathbb{P}[|Z| < t \cdot \ln(1/\beta)] \leq \beta$.

Lemma A.4 (Concentration in High Dimensions [ZJS19]). Let $\mathcal{D}$ be a distribution over $\mathbb{R}^d$ with mean $\mu$ and $k$-th moment bounded by $M$. Then the following holds for any $t > 0$,

$$\mathbb{P}_{X \sim \mathcal{D}}[\|X\|_2 > t] \leq M \left(\frac{\sqrt{d}}{t}\right)^k.$$

B Algorithms under Axis-Aligned Bounded Moments

In this section, we discuss the alternate moment condition of [WXDX20], which we denote as axis-aligned bounded moments, and sketch that our approach can achieve better rates than their algorithms. Roughly speaking, a distribution $\mathcal{D}$ over $\mathbb{R}^d$ with mean $\mu$ has axis-aligned bounded $k$-th moments if for all $i \in [d]$, we have

$$\mathbb{E}[|\langle X - \mu, e_i \rangle|^k] \leq 1,$$
where $e_i$ is the standard unit basis vector in coordinate $i$. Compare this with Definition 2.11, which bounds the $k$-th moment in every projection, rather than just the coordinate axes. Since [WXDX20] restrict their attention to the case $k = 2$, as do we for the sake of this comparison. Furthermore, to allow for the cleanest comparison, we elide the dependence on parameters $M$ and $R$.

The first observation is that axis-aligned bounded moments is a weaker notion that that of Definition 2.11. This can be easily observed by considering the distribution which places probability 0.5 on the all 0’s vector and probability 0.5 on the all 1’s vector. In any axis-aligned direction this distribution is Bernoulli with parameter 0.5, thus satisfying the definition of axis-aligned bounded moments. However, in the direction connecting these two points, the bound will only satisfy Definition 2.11 with $\gamma = d$. Since a weaker assumption requires an algorithm to handle a broader set of inputs, we expect the rates for DP SCO with axis-aligned bounded moments to degrade in comparison to general bounded moments. Nonetheless, we will show that the a similar approach can outperform [WXDX20], simply by changing the mean estimation algorithm.

Specifically, we will modify Algorithm 3. The main difference will be, rather than truncating and noising the dataset based on an $\ell_2$-ball, we will instead use an $\ell_\infty$-ball. This is a natural alteration given the axis-aligned nature of the alternative moment bound. Given the tools we have already developed, this algorithm can be succinctly described as the invocation of Algorithm 3 on each one-dimensional ($d = 1$) axis-aligned problem with privacy parameter $\rho/d$. Composition of CDP gives that this overall procedure will be $\rho$-CDP. For dimension $i$, Theorem 4.1 tells us that

$$|E[\hat{\mu}_i] - \mu_i| \leq O\left(\sqrt{\frac{1}{n} + \frac{1}{\tau}}\right)$$

$$E[(\hat{\mu}_i - \mu_i)^2] \leq O\left(\frac{1}{n} + \frac{\tau^2 d}{\rho n^2} + \left(\frac{1}{\tau}\right)^2\right)$$

By combining these coordinatewise guarantees, we get a $\rho$-DP mean estimation algorithm under axis-aligned bounded moments with the following guarantees, which will be plugged into our SCO framework.

$$\|E[\hat{\mu}] - \mu\|_2 \leq O\left(\sqrt{\frac{d}{n} + \frac{\sqrt{d}}{\tau}}\right)$$

$$E[\|\hat{\mu} - \mu\|^2] \leq O\left(\frac{d}{n} + \frac{\tau^2 d^2}{\rho n^2} + \left(\frac{\sqrt{d}}{\tau}\right)^2\right)$$

To derive bounds for the strongly convex and smooth case, we employ Theorem 3.2, setting $G^2$ to be the above variance bound and balancing the terms by setting truncation parameter $\tau = \left(\frac{n^2 \rho}{d}\right)^{1/4}$. This produces an expected excess risk bound of $\tilde{O}\left(\frac{d^{3/2}}{\sqrt{\rho n}}\right)$, which roughly corresponds to an $(\varepsilon, \delta)$-differential privacy guarantee of $\tilde{O}\left(\frac{d^{3/2}}{\varepsilon n}\right)$. This improves upon the $\tilde{O}\left(\frac{d^2}{\varepsilon^2 n}\right)$ guarantee of [WXDX20] in both $d$ and $\varepsilon$.

For the convex case, we use Theorem 3.1, setting $B$ and $G^2$ to be the above bias and variance bounds. We set parameters $T = \frac{d^{3/2} R^2}{\rho^{1/2} n}, \tau = \left(\frac{n^2 \rho}{d}\right)^{1/4}, \eta = \frac{M}{R\sqrt{T}}$, giving an excess risk bound of $\tilde{O}\left(\sqrt{\frac{d^{3/2}}{\varepsilon n}}\right)$. Again, this roughly corresponds to a guarantee of $\tilde{O}\left(\sqrt{\frac{d^{3/2}}{\varepsilon n}}\right)$ under $(\varepsilon, \delta)$-differential privacy, improving upon the $\tilde{O}\left(\left(\frac{d}{\varepsilon n}\right)^{1/3}\right)$ bound of [WXDX20].
C Omitted Proofs

C.1 Proof of Theorem 3.1

We let $L_D(w^t) = \mathbb{E}_{x \sim D}\left[\ell(w^t, x)\right]$. By Assumption 1, for all $t$,

$$\|\nabla L_D(w^t)\|_2 = \left\| \nabla \mathbb{E}_{x \sim D}\left[\ell(w^t, x)\right]\right\|_2 = \left\| \mathbb{E}_{x \sim D}[\nabla \ell(w^t, x)]\right\|_2 \leq R.$$ 

Let $\hat{w}^t = w^{t-1} - \eta \nabla \tilde{L}_D(w^{t-1})$, and $w^t$ denotes its projection to $W$. By the convexity of $L_D(\cdot)$ (see, e.g., Section 14.1.1 in [SSBD14]), we have

$$\mathbb{E}_{A,X \sim D^n}\left[ L_D(w_{\text{priv}}) - L_D(w^*) \right] = \mathbb{E}_{A,X \sim D^n}\left[ L_D\left( \frac{1}{T} \sum_{t=1}^{T} w^t \right) - L_D(w^*) \right] \leq \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}_{A,X \sim D^n}\left[ \langle \eta \nabla L_D(w^t), w^t - w^* \rangle \right] \leq \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}_{A,X \sim D^n}\left[ \langle \eta \nabla L_D(w^t), \nabla \tilde{L}_D(w^t) - \nabla \tilde{L}_D(w^*) \rangle \right].$$

where (2) is by the Jensen’s inequality and (3) is by the convexity of $L_D$. Continuing the proof,

$$\mathbb{E}_{A,X \sim D^n}\left[ L_D(w_{\text{priv}}) - L_D(w^*) \right] \leq \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}_{A,X \sim D^n}\left[ \langle \eta \nabla L_D(w^t), w^t - w^* \rangle \right] \leq BM.$$

We bound the first term, note that $\|w^t - w^*\|_2 \leq M$, and $\|\nabla \tilde{L}_D(w) - \nabla L_D(w)\|_2 \leq B$,

$$\mathbb{E}_{A,X \sim D^n}\left[ \frac{1}{T} \sum_{t=1}^{T} \langle \nabla L_D(w^t) - \nabla \tilde{L}_D(w^t), w^t - w^* \rangle \right] = \frac{1}{T} \sum_{t=1}^{T} \langle \nabla L_D(w^t) - \nabla \tilde{L}_D(w^t), w^t - w^* \rangle \leq BM.$$
Then we move to the second term.

\[
\mathbb{E}_{X \sim D^n} \left[ \frac{1}{T} \sum_{t=1}^{T} \frac{1}{\eta} \left( \eta \nabla \tilde{L}_D(w_t), w_t - w^* \right) \right]
\]

\[
= \mathbb{E}_{X \sim D^n} \left[ \frac{1}{T} \sum_{t=1}^{T} \left( \frac{1}{2\eta} \left( \|w_t - w^* - \eta \nabla \tilde{L}_D(w_t)\|^2 + \|w_t - w^*\|^2 \right) + \frac{\eta}{2} \|\nabla \tilde{L}_D(w_t)\|^2 \right) \right]
\]

\[
= \frac{1}{T} \sum_{t=1}^{T} \left( \frac{1}{2\eta} \left( -\mathbb{E} \left[ \|w_t^{t+1} - w^*\|^2 \right] + \mathbb{E} \left[ \|w_t - w^*\|^2 \right] \right) + \frac{\eta}{2} \mathbb{E} \left[ \|\nabla \tilde{L}_D(w_t)\|^2 \right] \right)
\]

\[
\leq \frac{1}{T} \sum_{t=1}^{T} \left( \frac{1}{2\eta} \left( -\mathbb{E} \left[ \|w_t^{t+1} - w^*\|^2 \right] + \mathbb{E} \left[ \|w_t - w^*\|^2 \right] \right) + \frac{\eta}{2} \mathbb{E} \left[ \sum_{t=1}^{T} \|\nabla \tilde{L}_D(w_t')\|^2 \right] \right)
\]

\[
\leq \frac{M^2}{2\eta T} + \frac{\eta}{2T} \cdot \mathbb{E} \left[ \sum_{t=1}^{T} \|\nabla \tilde{L}_D(w_t')\|^2 \right].
\] (9)

where (5) comes from the fact that \( \forall a, b \in \mathbb{R}^d, \langle a, b \rangle = \frac{1}{2} \left( \|a\|^2 + \|b\|^2 - \|a - b\|^2 \right) \), and (6) is by the updating rule, (7) comes from the fact that \( \|w_t^{t+1} - w^*\|_2 \geq \|w_t^{t+1} - w^*\|_2 \), and (8) is by the telescopic sum.

Finally, for all \( t \in [T] \),

\[
\mathbb{E} \left[ \|\nabla \tilde{L}_D(w_t)\|^2 \right] = \mathbb{E} \left[ \|\nabla \tilde{L}_D(w_t) - \nabla L_D(w_t) + \nabla L_D(w_t)\|^2 \right]
\]

\[
\leq \frac{1}{2} \cdot \left( \mathbb{E} \left[ \|\nabla \tilde{L}_D(w_t) - \nabla L_D(w_t)\|^2 \right] + \|\nabla L_D(w_t)\|^2 \right)
\]

\[
\leq \frac{G^2 + R^2}{2},
\] (10)

where we note that \( \mathbb{E}[\|\nabla \tilde{L}_D(w) - \nabla L_D(w)\|^2] \leq G^2 \), and \( \|\nabla L_D(w_t)\|^2 \leq R^2 \).

We conclude the proof by combining (4), (9), and (10).

### C.2 Proof of Theorem 3.2

The argument is broadly similar to the proof of Theorem 5 in [WXDX20], albeit with some minor modifications.

Let \( \tilde{w}^t = w_t^{t-1} - \eta \nabla \tilde{L}_D(w_t^{t-1}) \). Now we have

\[
\|w_t^t - w^*\|_2 = \|w_t^{t-1} - \eta \nabla \tilde{L}_D(w_t^{t-1}) - w^*\|_2
\]

\[
\leq \|w_t^{t-1} - \eta \nabla L_D(w_t^{t-1}) - w^*\|_2 + \eta \|\nabla \tilde{L}_D(w_t^{t-1}) - \nabla L_D(w_t^{t-1})\|_2.
\]

It should be noticed that, the second term is bounded by \( \eta G \) in expectation, since \( \mathbb{E}[\|\nabla \tilde{L}_D(w_t^{t-1}) - \nabla L_D(w_t^{t-1})\|_2] \leq G \). For the first term, by the coercivity of strongly convex functions (Lemma 3.11 in [Bub15])

\[
\langle w_t^{t-1} - w^*, \nabla L_D(w_t^{t-1}) \rangle \geq \frac{ab}{a + b} \|w_t^{t-1} - w^*\|^2 + \frac{1}{a + b} \|\nabla L_D(w_t^{t-1})\|^2
\]
and by taking $\eta = \frac{1}{a+b}$ we have
\[
\|w^{t-1} - \eta \nabla L_D(w^{t-1}) - w^*\|_2^2 = \|w^{t-1} - w^*\|_2^2 + \|\eta \nabla L_D(w^{t-1})\|_2^2 - 2\langle w^{t-1} - w^* , \eta \nabla L_D(w^{t-1}) \rangle \\
\leq \left( 1 - \frac{2ab}{(a+b)^2} \right) \|w^{t-1} - w^*\|_2^2 - \frac{1}{(a+b)^2} \|\nabla L_D(w^{t-1})\|_2^2 \\
\leq \left( 1 - \frac{2ab}{(a+b)^2} \right) \|w^{t-1} - w^*\|_2^2.
\]
Now using the inequality $\sqrt{1 - x} \leq 1 - \frac{x}{2}$ we combine two terms together to have
\[
\mathbb{E}[\|\hat{w}^t - w^*\|_2^2] \leq \left( 1 - \frac{ab}{(a+b)^2} \right) \mathbb{E}[\|w^{t-1} - w^*\|_2^2] + \frac{G}{a+b}.
\]
Recall that $w^t$ is the projection of $\hat{w}^t$ on $\mathcal{W}$, which implies $\|w^t - w^*\|_2 \leq \|\hat{w}^t - w^*\|_2$. Therefore,
\[
\mathbb{E}[\|w^t - w^*\|_2^2] \leq \left( 1 - \frac{ab}{(a+b)^2} \right) \mathbb{E}[\|w^{t-1} - w^*\|_2^2] + \frac{G}{a+b}.
\]
After $T$ multiplications and simplifying the geometric series,
\[
\mathbb{E}[\|w^T - w^*\|_2^2] \leq \left( 1 - \frac{ab}{(a+b)^2} \right)^T + \frac{(a+b)^2}{ab} \frac{G}{a+b}.
\]
Letting $T = \log \left( \frac{(a+b)G}{ab} \right) / \log \left( \frac{a^2+b^2+ab}{(a+b)^2} \right)$,
\[
\mathbb{E}[\|w^T - w^*\|_2^2] \leq \frac{(a+b)(M+1)G}{ab}.
\]
Since $L_D(w)$ is $b$-smooth, we have
\[
\mathbb{E}_{A, X \sim \mathcal{D}^n} [L_D(w^T)] - L_D(w^*) \leq \frac{b}{2} \mathbb{E}[\|w^T - w^*\|_2^2] \leq \frac{(a+b)^2(M+1)^2G^2}{2a^2b},
\]
which concludes the proof.

C.3 Proof of Theorem 4.2
We first prove the privacy guarantees. Note that Algorithm 2 can be viewed as a post-processing of the private histogram. Therefore, it naturally satisfies $\rho$-CDP.

Now we analyze the accuracy.

We define the following two events. We will show that it is highly likely that neither of them happens.

Let $S_1 = \{ i \in [n] : X_i \notin [\mu - \tau, \mu + \tau] \geq \frac{1}{3}n \}$. Given $x \sim \mathcal{D}$, by Lemma A.1,
\[
\Pr (|x - \mu| \geq 10) \leq \frac{1}{10^k}.
\]
Note that $\tau \geq 10$, and $k \geq 1$, we have
\[
\Pr (|x - \mu| \geq \tau) \leq \frac{1}{10}.
\]
Now we can bound the number of samples which fall outside of $[\mu - \tau, \mu + \tau]$. By the Hoeffding’s inequality,

$$\Pr(S_1) = \Pr\left(\{i \in [n] : X_i \notin [\mu - \tau, \mu + \tau]\} \geq \frac{1}{5n}\right) \leq e^{-\frac{4n}{5}}.$$

Then we define the second event. Given $j \in [\frac{R}{\tau} + 2]$, let $N_j$ denote the Gaussian noise added to the $j$-th bucket in the private histogram. We have that $\forall j \in [\frac{R}{\tau} + 2], N_j \sim N\left(0, \frac{1}{\tau}\right)$.

Let $S_2 = \{\exists j \in [\frac{R}{\tau} + 2], |N_j| \geq \frac{n}{16}\}$. Now we bound the probability of event $S_2$.

By the Gaussian tail bound, $\forall j \in [\frac{R}{\tau} + 2], \Pr(|N_j| \geq \frac{n}{16}) \leq 2 \cdot e^{-\frac{n^2}{1024\tau^2}}$. Finally by union bound,

$$\Pr(S_2) \leq 2 \cdot \left(\frac{R}{\tau} + 2\right) \cdot e^{-\frac{en^2}{1024\tau^2}}.$$

In the following proof, we suppose neither event happens. We note that the remaining proof is almost the same as the original analysis in [KSU20], and we keep it here for completeness. First, there must exist a bucket that contains at least $0.5 \cdot (1 - \frac{1}{5})n \geq \frac{2}{5}n$ samples, which implies that the bucket containing the maximum number of points has to contain at least $\frac{n}{10}$. According to the definition of event $S_2$, the noise added to each bucket is no more than $\frac{n}{16n}$. Therefore, the noisy value for the largest bucket has to be at least $\frac{3}{5}n$. Since all these points lie in a single bucket, and include points that are not in the tail of the distribution, the mean lies in either the same bucket, or in an adjacent bucket because the distance from the mean is at most $\tau$. Hence, the interval $[a - 2\tau, b + 2\tau]$ contains the mean and at least $\frac{2}{5}n$ points. Note that the interval has length $6\tau$ and the mid-point is at most $3\tau$ away from $\mu$.

### C.4 Proof of Theorem 4.1

We separate the proofs of privacy and accuracy. We note that the proof of privacy is exactly the same as the original analysis in [KSU20], and we omit it for simplicity.

Next we show the accuracy guarantees. In the first step, the objective of the algorithm is to find a centre $c_i$ for each dimension, such that $|c_i - \mu_i| \leq 30$. Given $i \in [d]$, let $S_1 = \bigcup_{i \in [d]} S_1^i$, where $S_1^i$ is the event that the $i$-th CDPRE succeeds. Note that suppose $S_1$ happens, $||c - \mu||_2 \leq 30\sqrt{d}$.

Furthermore, by Theorem 4.2 and union bound,

$$\Pr(S_1) \geq 1 - 2d \cdot \left(\left(\frac{R}{10} + 2\right) \cdot e^{-\frac{d\sigma^2}{1024\tau^2}} + e^{-\frac{n}{50}}\right).$$

We define $S_2$ to be the event that $\ell \geq \frac{3}{5}n$. Suppose $S_1$ happens, by Lemma A.4, $\Pr\left(x \notin B_{\tau\sqrt{d}}(\bar{c}) \mid S_1\right) \leq \frac{1}{10}$, since $\tau \geq 60$. By the Hoeffding’s inequality, $\Pr(S_2 \mid S_1) \geq 1 - e^{-\frac{n}{50}}$. Therefore,

$$\Pr(S_2 \cap S_1) \geq 1 - (2d + 1) \cdot \left(\left(\frac{R}{10} + 2\right) \cdot e^{-\frac{d\sigma^2}{1024\tau^2}} + e^{-\frac{n}{50}}\right).$$

We prove the first part. By triangle inequality, we are able to separate $||E[\hat{\mu}] - \mu||_2$ into the sum of two terms.

$$||E[\hat{\mu}] - \mu||_2 \leq \Pr(S_1 \cap S_2) \cdot ||E[\hat{\mu} - \mu | S_1 \cap S_2]||_2 + (1 - \Pr(S_1 \cap S_2)) \cdot ||E[\hat{\mu} - \mu | \overline{S_1 \cap S_2}]||_2.$$
Now we bound the first term. Note that
\[ \|E[\tilde{\mu} - \mu \mid S_1 \cap S_2]\|_2 \leq E[\|\tilde{\mu} - \mu\|_2 \mid S_1 \cap S_2] \]
\[ \leq E \left[ \left\| \frac{1}{\ell} \sum_{i \in [\ell]} X_i - \mu \right\|_2 \mid \bigcap_{i \in [\ell]} \left( X_i \in B_{r_\sigma(\ell)} \bigcap \left( \ell \geq \frac{3}{4} n \right) \right) \right] \]
\[ \leq 2\sqrt{\frac{d}{n}} + 3 \cdot \left( \frac{C}{\tau} \right)^{\frac{k-1}{2}}, \]  
(12)

where the first inequality comes from Jensen’s inequality, and the last inequality comes from Lemma 4.4 in [KSU20] and Lemma 4.5.

Finally, by combining (11) and (12), we have
\[ \|E[\tilde{\mu}] - \mu\|_2 \leq 2\sqrt{\frac{d}{n}} + 3 \cdot \left( \frac{C}{\tau} \right)^{\frac{k-1}{2}} + (4d + 2) \cdot R \cdot \left( \left( \frac{R}{10} + 2 \right) \cdot e^{-\frac{\rho n^2}{1024d}} + e^{-\frac{n}{16}} \right), \]
which concludes the first part.

Next we prove the second part. Note that
\[ E[\|\tilde{\mu} - \mu\|_2^2] \leq \text{Pr}(S_1 \cap S_2) \cdot E[\|\tilde{\mu} - \mu\|_2^2 \mid S_1 \cap S_2] + 4(1 - \text{Pr}(S_1 \cap S_2))R^2 \]
\[ \leq E[\|\tilde{\mu} - \mu\|_2^2 \mid S_1 \cap S_2] + 4(1 - \text{Pr}(S_1 \cap S_2))R^2. \]
(13)

We bound the first term. By triangle inequality,
\[ E[\|\tilde{\mu} - \mu\|_2^2 \mid S_1 \cap S_2] \leq E[\|\tilde{\mu} - E[\tilde{\mu} \mid S_1 \cap S_2]\|_2^2 \mid S_1 \cap S_2] + \|\mu - E[\tilde{\mu} \mid S_1 \cap S_2]\|_2^2 \]
\[ \leq \frac{32r^2d^2}{9\rho n^2} + \frac{8d}{n} + 18 \cdot \left( \frac{C}{\tau} \right)^{2k-2}, \]
(14)

where the last inequality comes from the fact that \( \|E[\tilde{\mu} \mid S_1 \cap S_2] - \mu\|_2 \leq 2\sqrt{\frac{d}{n}} + 3 \cdot \left( \frac{C}{\tau} \right)^{\frac{k-1}{2}}. \)

Finally, we note that \( \text{Pr}(S_1 \cap S_2) \geq 1 - (2d + 1) \cdot \left( \left( \frac{R}{10} + 2 \right) \cdot e^{-\frac{\rho n^2}{1024d}} + e^{-\frac{n}{16}} \right) \). Combined with (13) and (14), we have the intermediate results:

1. \( \|E[\tilde{\mu}] - \mu\|_2 \leq 2\sqrt{\frac{d}{n}} + 3 \cdot \left( \frac{C}{\tau} \right)^{\frac{k-1}{2}} + (4d + 2) \cdot R \cdot \left( \left( \frac{R}{10} + 2 \right) \cdot e^{-\frac{\rho n^2}{1024d}} + e^{-\frac{n}{16}} \right). \)

2. \( E[\|\tilde{\mu} - \mu\|_2^2] \leq \frac{8d}{n} + \frac{32r^2d^2}{9\rho n^2} + 18 \cdot \left( \frac{C}{\tau} \right)^{2k-2} + 4R^2 \cdot (2d + 1) \cdot \left( \left( \frac{R}{10} + 2 \right) \cdot e^{-\frac{\rho n^2}{1024d}} + e^{-\frac{n}{16}} \right). \)

By elementary calculations, we note that when \( n \geq O\left( \frac{\sqrt{d \log(R)}}{\sqrt{p}} + \log R \right) \),
\[ R^3d \max \left\{ e^{-\frac{n}{36}}, e^{-\frac{\rho n^2}{d}} \right\} \leq \frac{d}{n}, \]
which eliminates all exponential terms above and concludes the proof.
C.5 Proof of Theorem 4.7

Theorem 4.1 guarantees the following lemma.

**Lemma C.1.** Consider Algorithm 1 instantiated with CDPHDME\(\rho, \left(\frac{\sqrt{\rho n}}{d}\right)^{1/k}\) as MeanOracle, where we set \(\tau = \left(\frac{\sqrt{\rho n}}{d}\right)^{1/k}\). Under Assumption 1 and with \(n \geq O\left(\frac{\sqrt{d T \log(R)}}{\sqrt{\rho n}} + \log R\right)\), the following holds for all \(w \in \mathcal{W}\):

\[
\|\mathbb{E}[\nabla \tilde{L}_D(w)] - \nabla L_D(w)\|_2 \leq O\left(\sqrt{\frac{d}{n}} + \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}}\right),
\]

and

\[
\mathbb{E}[\|\nabla \tilde{L}_D(w) - \nabla L_D(w)\|^2_2] \leq O\left(\frac{d}{n} + \frac{\tau^2 d^2 T}{\rho n^2} + \left(\frac{1}{\tau}\right)^{2k-2}\right),
\]

where \(\nabla \tilde{L}_D(w)\) is the estimated gradient in Algorithm 1.

The proof now follows by choosing the right \(\eta\) and \(T\) in Theorem 3.1. To balance the first two terms, \(\frac{M^2}{\eta T} + \frac{\eta}{2} R^2\), in Theorem 3.1, we let \(\eta = \frac{M}{R \sqrt{T}}\).

Suppose \(T = \frac{1}{4 \log R} \cdot \left(\frac{\sqrt{\rho n}}{d}\right)^{\frac{2k-2}{k}}\), note that \(\eta = \frac{2M \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}}\) and \(\eta T = \frac{M R}{2 R \sqrt{\log R}}\cdot \left(\frac{\sqrt{\rho n}}{d}\right)^{\frac{k-1}{k}}\), we have

\[
\frac{M^2}{\eta T} = O\left(\frac{MR \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}}\right),
\]

\[
\frac{\eta}{2} R^2 = O\left(\frac{MR \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}}\right),
\]

\[
BM = O\left(M \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}} + M \cdot \sqrt{\frac{d}{n}}\right),
\]

\[
\eta G^2 = \frac{2M \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}} \cdot G^2 \leq \frac{2M \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}} \cdot O\left(\frac{d}{n} + \left(\frac{1}{\tau}\right)^{2k-2} + \frac{\tau^2 d^2 T}{\rho n^2}\right)
\]

\[
= \frac{2M \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}} \cdot O\left(\frac{d}{n} + \left(\frac{d}{n \sqrt{\rho}}\right)^{2k-2} + \frac{M R}{R} \cdot O\left(\frac{d}{n \sqrt{\rho}}\right)^{\frac{k-1}{k}}\right)
\]

\[
\leq O\left(\frac{MR \sqrt{\log R}}{R} \cdot \left(\frac{d}{\sqrt{\rho n}}\right)^{\frac{k-1}{k}}\right).
\]

To justify the last inequality, observe that (3) in the proof of Theorem 3.1 implies that \(M R\) is a vacuous bound on the excess risk, and thus to obtain a non-trivial bound we implicitly have the
condition that the LHS of Theorem 4.7 is bounded by $MR$, i.e.,

$$\sqrt{\log R} \cdot O \left( \sqrt{\frac{d}{n}} + \left( \frac{d}{\sqrt{pn}} \right)^{\frac{k}{k+1}} \right) \leq 1$$

and thus

$$O \left( \frac{d}{n} + \left( \frac{d}{\sqrt{pn}} \right)^{\frac{k}{k+1}} \right) \leq \frac{1}{\log R}.$$ 

Combining this with $R = \Omega(1)$ from Assumption 1 justifies the inequality. Putting the various terms together completes the proof.

### C.6 Proof of Theorem 4.8

Note that Theorem 4.1 immediately guarantees the following accuracy when CDPHDM E is instantiated as MeanOracle in SCOF:

**Lemma C.2.** Consider Algorithm 1 instantiated with CDPHDM $E \left( \frac{d}{T} \left( \frac{\sqrt{p} n}{d \sqrt{T}} \right)^{1/k} \right)$ as MeanOracle.

Under Assumption 1, and with $n \geq O \left( \frac{\sqrt{d T \log(R)}}{\sqrt{p}} + \log R \right)$, the following holds for all $w \in W$:

$$\mathbb{E}[\|\nabla \tilde{L}_D(w) - \nabla L_D(w)\|_2] \leq O \left( \sqrt{\frac{d}{n}} + \left( \frac{d \sqrt{T}}{\sqrt{pn}} \right)^{\frac{k-1}{k}} \right),$$

where $\nabla \tilde{L}_D(w)$ is the estimated gradient in Algorithm 1.

The proof then follows by Theorem 3.2.

### C.7 Proof of Lemma 5.2

Let $x \sim D$, and $\ell(w; x) = \frac{1}{2}\|w - x\|_2^2$. Note that $w^* = \arg \min L_D(w) = \mathbb{E}_{x \sim D} [x] = \mu$. Further using the expansion $\|a - b\|_2^2 = \|a\|_2^2 - 2\langle a, b \rangle + \|b\|_2^2$,

$$L_D(w) - L_D(w^*) = \frac{1}{2} \mathbb{E}_{x \sim D} [\\|w - x\|_2^2 - \|w^* - x\|_2^2]$$

$$= \frac{1}{2} \mathbb{E}_{x \sim D} [\\|w\|_2^2 - 2\langle w, x \rangle + \|x\|_2^2 - \|w^*\|_2^2 + 2\langle w^*, x \rangle - \|x\|_2^2]$$

$$= \frac{1}{2} (\\|w\|_2^2 - 2\langle w, w^* \rangle - \|w^*\|_2^2 + 2\langle w^*, w^* \rangle)$$

$$= \frac{1}{2} (\\|w\|_2^2 - 2\langle w, w^* \rangle + \|w^*\|_2^2)$$

$$= \frac{1}{2} \|w - w^*\|_2^2$$

Notice that $\ell$ is strongly convex and the expected risk of $w^{\text{priv}}$ is

$$\mathbb{E}_{x \sim D_n} [L_D(w^{\text{priv}})] - L_D(w^*) = \mathbb{E}_{x \sim D_n} \left[ \frac{1}{2} \|w^{\text{priv}} - \mu\|_2^2 \right],$$

which implies the result.
Now we prove the second half, note that $\nabla \ell(w, x) = w - x$, and $\mathbb{E} [\nabla \ell(w, x)] = w - \mu$,

$$\sup_{v: \|v\|_2 = 1} \mathbb{E}_{x \sim \mathcal{D}} \left[ |\langle v, \nabla \ell(w, x) - \mathbb{E} [\nabla \ell(w, x)] \rangle|^k \right] = \sup_{v: \|v\|_2 = 1} \mathbb{E}_{x \sim \mathcal{D}} \left[ |\langle v, w - x - (w - \mu) \rangle|^k \right] = \sup_{v: \|v\|_2 = 1} \mathbb{E}_{x \sim \mathcal{D}} \left[ |\langle v, x - \mu \rangle|^k \right] \leq 1.$$

### C.8 Proof of Theorem 5.4

We first prove the private term (the second term) in Theorem 5.4.

We adopt the packing set defined in the proof of Proposition 4 in [BD14]. Given $\nu \in \mathcal{V}$, with $\|\nu\|_2 = 1$, let $Q_{\nu} = (1 - p)P_0 + pP_{\nu}$ for some $p \in [0, 1]$, where $P_0$ is a point mass on $\{D = 0\}$ and $P_{\nu}$ is a point mass on $\{D = p^{-1/k}\nu\}$.

Given $Q_{\nu}$, we define $\mu_{\nu} \in \mathbb{R}^d$ to be the mean of $Q_{\nu}$, i.e., $\mu_{\nu} = \mathbb{E}_{x \sim Q_{\nu}}[x]$. Additionally, we define $w_{\nu}$ to be its normalization, i.e., $w_{\nu} = \frac{\mu_{\nu}}{\|\mu_{\nu}\|_2}$. Note that $w_{\nu}$ is in the same direction as $\mu_{\nu}$, with $\|w_{\nu}\|_2 = 1$.

As a corollary of standard Gilbert-Varshamov bound for constant-weight codes (e.g., see Lemma 6 in [ASZ21]), there exists a set $\mathcal{V}$ with cardinality at least $\|\mathcal{V}\|_2 \geq 2^{\frac{k}{d}}$, with $\|\nu\|_2 = 1$ for all $\nu \in \mathcal{V}$, and with $\|\nu - \nu'\|_2 \geq \frac{1}{k}$ for all $\nu \neq \nu' \in \mathcal{V}$.

Suppose $p = \min\left(1, \frac{k}{4\varepsilon n}\right)$, we first compute the norm of $\mu_{\nu}$. Note that $\forall \nu \in \mathcal{V}$, $\|\mu_{\nu}\|_2$ is the same, which is denoted by $\|\mu\|_2$.

$$\|\mu_{\nu}\|_2 = \|\mathbb{E}_{x \sim Q_{\nu}}[x]\|_2 = \min\left(1, \left(\frac{d}{\varepsilon n}\right)^{\frac{k-1}{k}}\right) = \|\mu\|_2.$$

Without loss of generality, we assume the parameter space $\|W\|_2 = 1$, which is a unit ball. Then we define the loss function $\ell(w; x)$. Given $\nu \in \mathcal{V}$, and $x \sim Q_{\nu}$, we let $\ell(w; x) = -\langle w, x \rangle$, and

$$L_{Q_{\nu}}(w) = \mathbb{E}_{x \sim Q_{\nu}}[\ell(w; x)] = -\langle w, \mu_{\nu} \rangle.$$

Let $x \sim Q_{\nu}$. Note that $\nabla \ell(w, x) = -x$, and $\mathbb{E} [\nabla \ell(w, x)] = -\mu_{\nu}$,

$$\sup_{v: \|v\|_2 = 1} \mathbb{E}_{x \sim Q_{\nu}} \left[ |\langle v, \nabla \ell(w, x) - \mathbb{E} [\nabla \ell(w, x)] \rangle|^k \right] = \sup_{v: \|v\|_2 = 1} \mathbb{E}_{x \sim Q_{\nu}} \left[ |\langle v, -x + \mu_{\nu} \rangle|^k \right] \leq \mathbb{E}_{x \sim Q_{\nu}} \left[ \|x - \mu_{\nu}\|_2^k \right] \leq p \cdot \left( p^{-1/k} \right)^k = 1.$$

Now we are able to bound the error of SCO.
\[
\mathbb{E} \left[ L_D(w^{\text{priv}}) - \min_{\hat{w} \in \mathcal{W}} L_D(\hat{w}) \right] \geq \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ L_{Q_{\nu}}(w^{\text{priv}}) - \min_{\hat{w} \in \mathcal{W}} L_{Q_{\nu}}(\hat{w}) \right] \quad (15)
\]

\[
\geq \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \langle \mu_{\nu}, \mu_{\nu} \rangle_{L^2} - \langle w^{\text{priv}}, \mu_{\nu} \rangle \right] \quad (16)
\]

\[
= \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \|\mu\|_2 - \langle w^{\text{priv}}, \mu_{\nu} \rangle \right]
\]

\[
\geq \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \frac{1}{2} \cdot \|\mu\|_2 \cdot \|w^{\text{priv}} - w_{\nu}\|_2^2 \right], \quad (17)
\]

where (15) comes from the fact that the worst case loss is no smaller than the average loss, (16) comes from \( w_{\nu} = \arg\min_{\hat{w} \in \mathcal{W}} \|w_{\nu} - w^{\text{priv}}\|_2 \). By triangle inequality,

\[
\|w_{\nu} - w^{\text{priv}}\|_2 \leq \|w_{\nu} - w_{\nu'}\|_2 + \|w_{\nu'} - w^{\text{priv}}\|_2 \leq 2 \|w_{\nu} - w^{\text{priv}}\|_2.
\]

Therefore,

\[
\mathbb{E} \left[ L_D(w^{\text{priv}}) - \min_{\hat{w} \in \mathcal{W}} L_D(\hat{w}) \right] \geq \frac{\|\mu\|_2}{8} \cdot \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \|w^{\text{priv}} - w_{\nu}\|_2^2 \right].
\]

Note that \(|\mathcal{V}| \geq 2^\#\). Furthermore, \( \forall \nu \neq \nu' \), \( \|w_{\nu} - w_{\nu'}\|_2 = \Omega(1) \); \( d_{TV}(w_{\nu}, w_{\nu'}) = p \), indicating that there exists a coupling between \( w_{\nu} \) and \( w_{\nu'} \) with a coupling distance \( np \). By DP Fano’s inequality (Theorem 2 in [ASZ21]), it can be shown that

\[
\frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \|w^{\text{priv}} - w_{\nu}\|_2^2 \right] = \Omega(1).
\]

Thus,

\[
\mathbb{E} \left[ L_D(w^{\text{priv}}) - \min_{\hat{w} \in \mathcal{W}} L_D(\hat{w}) \right] \geq \Omega(1) \cdot \|\mu\|_2 = \Omega \left( \min \left( 1, \left( \frac{d}{\varepsilon n} \right)^{\frac{k-1}{k}} \right) \right).
\]

Now we prove the first term. We generally follow the lower bound proof of \( \varepsilon \)-DP estimating Gaussians [ASZ21]. Given \( \nu \in \{0,1\}^d \), we define \( Q_{\nu} = \mathcal{N}(\mu_{\nu}, I_d) \), where \( \mu_{\nu} = \frac{\nu}{\sqrt{d}} \cdot \nu \), for some \( p \in [0,1] \). Similarly, we define \( w_{\nu} = \frac{\nu}{\|\nu\|_2} \).

As a standard Gilbert-Varshamov bound for constant-weight codes (e.g., see Lemma 6 in [ASZ21]), there exists a set \( \mathcal{V} \) with cardinality at least \( \|\nu\|_2 \geq 2^\# \), with \( |\nu|_1 = \frac{d}{2} \) for all \( \nu \in \mathcal{V} \), and with \( d_{\text{Ham}}(\nu, \nu') \geq \frac{d}{2} \) for all \( \nu \neq \nu' \in \mathcal{V} \).

Suppose \( p = \min \left( 1, \sqrt{\frac{d}{n}} \right) \), we can compute the norm of the distribution mean. Note that \( |\nu|_1 = \frac{d}{2} \),

\[
\|\mu_{\nu}\|_2 = \frac{\sqrt{2}}{2} \min \left( 1, \sqrt{\frac{d}{n}} \right) := \|\mu\|_2
\]
By a similar argument with the private case, it can be shown that

$$
\mathbb{E} \left[ L_D(w_{priv}) - \min_{\hat{w} \in \mathcal{W}} L_D(\hat{w}) \right] \geq \frac{\|\mu\|_2}{8} \cdot \frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \|\hat{w}_{priv} - w_{\nu}\|_2^2 \right],
$$

where $\hat{w}_{priv} := \arg \min_{w_{\nu}} \|w_{\nu} - w_{priv}\|_2$.

Note that this is indeed a multi-way classification problem, where $w_{\nu}$’s are well-separated. By classical Fano’s inequality,

$$
\frac{1}{|\mathcal{V}|} \sum_{\nu \in \mathcal{V}} \mathbb{E} \left[ \|\hat{w}_{priv} - w_{\nu}\|_2^2 \right] = \Omega(1).
$$

Thus,

$$
\mathbb{E} \left[ L_D(w_{priv}) - \min_{\hat{w} \in \mathcal{W}} L_D(\hat{w}) \right] \geq \Omega(1) \cdot \|\mu\|_2 = \Omega \left( \min \left( 1, \sqrt{\frac{d}{n}} \right) \right). \quad (19)
$$

Combining (18) and (19), we conclude the proof.
