A NEW FRAMEWORK FOR POLYNOMIAL APPROXIMATION TO DIFFERENTIAL EQUATIONS

LUIGI BRUGNANO†, GIANLUCA FRASCA-CACCIA‡, FELICE IAVERNARO§, AND VINCENZO VESPRI¶

Abstract. In this paper we discuss a framework for the polynomial approximation to the solution of initial value problems for differential equations. The framework, initially devised for the approximation of ordinary differential equations, is further extended to cope with constant delay differential equations. Relevant classes of Runge-Kutta methods can be derived within this framework.

Key words. ordinary differential equations, delay differential equations, orthogonal polynomials, local Fourier expansion, polynomial approximations, Runge-Kutta methods.

AMS subject classifications. 65L05, 65L03, 65L06, 65P10.

1. Introduction. In this paper, we shall deal with the definition of a framework to discuss polynomial approximations to the solution of initial value problems for ordinary differential equations (ODEs),

\[
\dot{y}(t) = f(t, y(t)), \quad t \in [t_0, T], \quad y(t_0) = y_0 \in \mathbb{R}^m,
\]

and delay differential equations (DDEs) in the form,

\[
\begin{align*}
\dot{y}(t) &= f(t, y(t), y(t-\tau)), & t \in [t_0, T], \\
y(t) &= \phi(t), & t \in [t_0-\tau, t_0],
\end{align*}
\]

where \(\tau > 0\) is a constant delay and, usually, \(y_0 = \phi(t_0)\). In the sequel, we shall always assume that \(f\) and \(\phi\) are suitably regular in their respective arguments. As is well known, the two problems are related in many ways but, at the same time, have quite different features, which reflect on their numerical solution. We refer, e.g., to the comprehensive monograph [23], concerning (1.1), and [4] (see also [17]) for (1.2).

In more detail, in this paper we shall fully develop a novel framework for deriving numerical methods for solving (1.1), which is then extended to cope with (1.2).

The framework we are interested in relies on a local expansion of the vector field in (1.1) along an orthonormal basis. Such basis will be, in the present case, the Legendre polynomial basis \(\{P_j\}_{j \geq 0}\):

\[
P_j \in \Pi_j, \quad \int_0^1 P_i(x)P_j(x)dx = \delta_{ij}, \quad i, j = 0, 1, \ldots,
\]

where, as is usual, \(\Pi_j\) is the vector space of polynomials of degree \(j\), and \(\delta_{ij}\) is the Kronecker symbol. The idea is actually not new: early use of this approach are, for example, Hulme [25, 26], Bottasso [6], and Betsch and Steinmann [5]; it is also at the basis of the energy-conserving class of Runge-Kutta methods named HBVMs [11] (see also the monograph [8] and the review paper [9]).
The approach that we shall pursue has been initially devised in [13], where the target was problem (1.1), and its potentialities have been disclosed by using HBVMs as spectral methods in time for efficiently solving highly oscillatory problems [16] and, subsequently, Hamiltonian PDEs [10]. A corresponding error analysis is given in [2]. Moreover, this allows deriving a formulation of HBVMs as continuous-stage Runge-Kutta methods [1]. Starting from this background, in this work we carry out a complete perturbation analysis of problems (1.1) and (1.2), and set up a unique and comprehensive framework to deal with the numerical solution of both problems by exploiting the same discretization procedure. Interestingly, the approach may be suitably adapted to deal with other classes of problems, and this will be the subject of future investigations.

With this premise, the paper is organized as follows: Section 2 concerns the result pertaining to the ODE case; Section 3 contains the corresponding results for the DDE case; at last, some concluding remarks and possible developments are reported in Section 4.

2. The ODE case. Without loss of generality, we shall consider problem (1.1) in the simpler form:

\[(2.1) \dot{y}(t) = f(y(t)), \quad t \in [t_0, T], \quad y(t_0) = y_0 \in \mathbb{R}^m.\]

Having fixed the mesh

\[(2.2) t_n = t_0 + nh, \quad n = 0, \ldots, N, \quad h = \frac{T - t_0}{N},\]

we formally set, for \(n = 1, \ldots, N:\)

\[(2.3) \hat{\sigma}_n(ch) := y(t_{n-1} + ch) \equiv \hat{\sigma}(t_{n-1} + ch), \quad c \in [0, 1],\]

the restriction of the solution of problem (2.1) to the time interval \([t_{n-1}, t_n].\) Consequently, \(\hat{\sigma}_n\) satisfies the differential equation

\[(2.4) \dot{\hat{\sigma}}_n(ch) = \sum_{j \geq 0} P_j(c) \gamma_j(\hat{\sigma}_n), \quad c \in [0, 1], \quad \hat{\sigma}_n(0) = y(t_{n-1}),\]

so that,

\[(2.5) \hat{\sigma}_n(ch) = y(t_{n-1}) + h \sum_{j \geq 0} \int_0^c P_j(x)dx \gamma_j(\hat{\sigma}_n), \quad c \in [0, 1],\]

and, by virtue of (1.3),

\[(2.6) y(t_n) = y(t_{n-1}) + h \gamma_0(\hat{\sigma}_n) \equiv \hat{\sigma}(t_n),\]

where, in general, for any suitably regular function \(z : [0, h] \to \mathbb{R}^m,

\[(2.7) \gamma_j(z) := \int_0^1 P_j(\zeta)f(z(\zeta h))d\zeta.\]

We now look for a piecewise polynomial approximation \(\sigma(t),\) to the solution of (2.1), such that, setting for \(n = 1, \ldots, N,\)

\[(2.8) \sigma_n(ch) \equiv \sigma(t_{n-1} + ch), \quad c \in [0, 1],\]

\(^1\)The function \(\hat{\sigma}(t) \equiv y(t)\) is introduced for notational purposes.
its restriction to the time interval \([t_{n-1}, t_n]\), \(\sigma_n \in \Pi_s\) and satisfies the differential equation:

\[
(2.9) \quad \dot{\sigma}_n(ch) = \sum_{j=0}^{s-1} P_j(c) \gamma_j(\sigma_n), \quad c \in [0, 1], \quad \sigma_n(0) = y_{n-1},
\]

obtained by truncating the infinite series in (2.4) to a finite sum, with

\[
(2.10) \quad y_n := \sigma_n(h) \equiv \sigma(t_n).
\]

Consequently, \(\sigma_n\) can be formally written as:

\[
(2.11) \quad \sigma_n(ch) = y_{n-1} + h \sum_{j=0}^{s-1} \int_0^c P_j(x) dx \gamma_j(\sigma_n), \quad c \in [0, 1],
\]

and (compare with (2.6)),

\[
(2.12) \quad y_n = y_{n-1} + h \gamma_0(\sigma_n).
\]

2.1. Preliminary results. We here provide a few preliminary results, which will be needed to derive the main ones in the following subsections. Some of them are taken from [13] but we also report them here, for sake of completeness.

**Theorem 2.1.** Let \(G : [0, h] \rightarrow V\), with \(V\) a vector space, admit a Taylor expansion at 0. Then, for all \(j \geq 0\):

\[
\int_0^1 P_j(\zeta) G(\zeta h) d\zeta = O(h^j).
\]

**Proof.** By virtue of (1.3), one has:

\[
\int_0^1 P_j(\zeta) G(\zeta h) d\zeta = \int_0^1 P_j(\zeta) \sum_{k \geq 0} \frac{G^{(k)}(0)}{k!} (\zeta h)^k d\zeta = \sum_{k \geq 0} \frac{G^{(k)}(0)}{k!} h^k \int_0^1 P_j(\zeta) \zeta^k d\zeta = \sum_{k \geq j} \frac{G^{(k)}(0)}{k!} h^k \int_0^1 P_j(\zeta) \zeta^k d\zeta = O(h^j). \square
\]

As a straightforward consequence, setting \(G(\zeta h) := f(z(\zeta h))\), the following result is proved.

**Corollary 2.2.** With reference to (2.7), one has: \(\gamma_j(z) = O(h^j)\).

Let us denote by\(^2\)

\[
(2.13) \quad y(t) \equiv y(t, \xi, \eta)
\]

the solution of the problem (compare with (2.1)):

\[
(2.14) \quad \dot{y}(t) = f(y(t)), \quad t \in [\xi, T], \quad y(\xi) = \eta \in \mathbb{R}^m.
\]

The following theorem contains standard perturbation results w.r.t. all the arguments (see, e.g., [23, Section I.14]).

\(^2\)Hereafter, for sake of brevity, we may use either one of the two notations, depending on the needs.
Theorem 2.3. With reference to the solution (2.13) of problem (2.14), one has:
\[ a) \frac{\partial}{\partial t} y(t) = f(y(t)), \quad b) \frac{\partial}{\partial \eta} y(t) = \Phi(t, \eta), \quad c) \frac{\partial}{\partial \xi} y(t) = -\Phi(t, \xi)f(\eta), \]
where \( \Phi(t, \xi) \) is the solution of the variational problem
\[ \dot{\Phi}(t, \xi) = F(y(t))\Phi(t, \xi), \quad t \in [\xi, T], \quad \Phi(\xi, \xi) = I \in \mathbb{R}^{m \times m}, \]
having set
\[ F(y) = \frac{\partial}{\partial y} f(y). \]

From this theorem, the following result readily follows where, hereafter, \( | \cdot | \) will denote any convenient vector norm.

Corollary 2.4. With reference to (2.14), and assuming that \( \xi \in [t_{n-1}, t_n] \), one has:
\[ y(t, \xi, \eta + \delta \eta) = y(t, \xi, \eta) + \Phi(t, \xi)\delta \eta + (t - \xi)O(|\delta \eta|^2), \quad t \in [t_{n-1}, t_n]. \]

2.2. Main results (ODE case). With reference to (2.2)–(2.12), we are now in the position of stating the results concerning the approximation error at the grid points,
\[ y(t_n) - y_n = \hat{\sigma}_n(h) - \sigma_n(h), \quad n = 1, \ldots, N, \]
and, more in general, on each subinterval \([t_{n-1}, t_n]\):
\[ \delta \sigma_n(ch) := \hat{\sigma}_n(ch) - \sigma_n(ch) = \hat{\sigma}(t_{n-1} + ch) - \sigma(t_{n-1} + ch), \quad c \in [0, 1]. \]

For the first step of the approximation procedure, the following theorem holds true, the proof being similar to that of [13, Theorem 1].

Theorem 2.5. With reference to (2.16) and (2.17), one has:
\[ y(t_{n+1}) - y_{n+1} = O(h^{2r+1}), \quad \| \delta \sigma_1 \| := \max_{c \in [0, 1]} |\hat{\sigma}_1(ch) - \sigma_1(ch)| = O(h^{r+1}). \]

Proof. By virtue of Corollary 2.2 and Theorem 2.3, one has:
\[ \dot{\sigma}_1(ch) = y(t_0 + ch, t_0, y_0) - y(t_0 + ch, t_0 + ch, \sigma_1(ch)) \]
\[ = y(t_0 + ch, t_0, \sigma_1(0)) - y(t_0 + ch, t_0 + ch, \sigma_1(ch)) = \int_{t_0}^{t_{n+1}} \frac{\partial}{\partial t} y(t_0 + ch, t_0 + t, \sigma_1(t)) dt \]
\[ = \int_{t_0}^{t_{n+1}} \left[ \frac{\partial}{\partial \xi} y(t_0 + ch, t_0 + ch, \sigma_1(t)) \right]_{\xi = t_0 + t} + \left[ \frac{\partial}{\partial \eta} y(t_0 + ch, t_0 + t, \eta) \right]_{\eta = \sigma_1(t)} \dot{\sigma}_1(t) dt \]
\[ = \int_{t_0}^{t_{n+1}} \Phi(t_0 + ch, t_0 + t) \left[ f(\sigma_1(t)) - \dot{\sigma}_1(t) \right] dt \]
\[ = h \int_{t_0}^{t_{n+1}} \Phi(t_0 + ch, t_0 + \zeta h) \left[ f(\sigma_1(\zeta h)) - \dot{\sigma}_1(\zeta h) \right] d\zeta \]
\[ = h \int_{t_0}^{t_{n+1}} \Phi(t_0 + ch, t_0 + \zeta h) \left[ \sum_{j \geq 0} P_j(\zeta) \gamma_j(\sigma_1) - \sum_{j = 0}^{s-1} P_j(\zeta) \gamma_j(\sigma_1) \right] d\zeta \]
\[ = h \sum_{j \geq s} \int_{t_0}^{t_{n+1}} P_j(\zeta) \Phi(t_0 + ch, t_0 + \zeta h) d\zeta \gamma_j(\sigma_1). \]
Consequently, the second part of the statement follows for \( c \in (0, 1) \), whereas, when \( c = 1 \) one deduces, by virtue of Theorem 2.1:

\[
y(t_1) - y_1 = \hat{\sigma}(h) - \sigma_1(h) = h \sum_{j \geq s} \int_0^1 P_j(\zeta) \Phi(t_1, t_0 + \zeta h) d\zeta = G(h) \gamma_j(\sigma_1) = O(h^{2s+1}).
\]

For the remaining steps, the following result holds true.

**Theorem 2.6.** With reference to (2.16) and (2.17), for \( n = 1, \ldots, N \) one has:

\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}), \quad \|\delta \sigma_n\| = \max_{c \in [0, 1]} |\delta \sigma_n(ch)| = O(h^{s+1}).
\]

**Proof.** By induction on \( n \). For \( n = 1 \) the statement follows from the previous Theorem 2.5. Assuming it true for \( n - 1 \), for \( n \) one has:

\[
\hat{\sigma}_n(ch) - \sigma_n(ch) = (t_{n-1} + ch, t_{n-1}, \hat{\sigma}_n(0)) - y(t_{n-1} + ch, t_{n-1} + ch, \sigma_n(ch)) = y(t_{n-1} + ch, t_{n-1}, \sigma_n(0)) - y(t_{n-1} + ch, t_{n-1}, \sigma_n(0)) +
\]

\[
\left\{ \begin{array}{l}
E_{n,1}(ch) = \Phi(t_{n-1} + ch, t_{n-1}) \delta \sigma_n(0) + ch O(|\delta \sigma_n(0)|^2) \\
E_{n,2}(ch) = y(t_{n-1} + ch, t_{n-1}, \sigma_n(0)) - y(t_{n-1} + ch, t_{n-1} + ch, \sigma_n(ch)).
\end{array} \right.
\]

By using similar arguments as those used in the proof of Theorem 2.5, one deduces that

\[
E_{n,2}(ch) = \left\{ \begin{array}{l}
O(h^{s+1}), \quad c \in (0, 1), \\
O(h^{2s+1}), \quad c = 1.
\end{array} \right.
\]

Moreover, considering that, by the induction hypothesis,

\[
\delta \sigma_n(0) = \hat{\sigma}_n(0) - \sigma_n(0) = y(t_{n-1}) - y_{n-1} = (n - 1) O(h^{2s+1}),
\]

from Corollary 2.4, one has:

\[
E_{n,1}(ch) = \Phi(t_{n-1} + ch, t_{n-1}) \delta \sigma_n(0) + ch O(|\delta \sigma_n(0)|^2) = O(h^{2s+2}).
\]

Consequently, for \( c = 1 \) one obtains the first part of the statement, whereas the second part follows by taking \( c \in (0, 1) \).

**Remark 2.7.** We observe that the two equivalent equations (see (2.7), (2.9), and (2.11)):

\[
\hat{\sigma}_n(ch) = \sum_{j=0}^{s-1} P_j(c) \int_0^1 P_j(\zeta) f(\sigma_n(\zeta h)) d\zeta, \quad c \in [0, 1], \quad \sigma_n(0) = y_{n-1},
\]
and

\begin{equation}
\sigma_n(ch) = y_{n-1} + h \sum_{j=0}^{s-1} \int_0^c P_j(x)dx \int_0^1 P_j(\zeta)f(\sigma_n(\zeta h))d\zeta, \quad c \in [0, 1],
\end{equation}

define a so called HBVM($\infty$, $s$) method on the interval $[t_{n-1}, t_n]$ (see [11, 8, 9]). Consequently, such method defines an order $2s$ approximation procedure for all $s \geq 1$, which can be also recast as a continuous-stage Runge-Kutta method [1]. In particular, the case $s = 1$ corresponds to the so called AVF method [31]; the case $s \geq 1$ has been also considered in [22].

An interesting question concerns the difference between the Fourier coefficients of the solution (2.5)-(2.7) and those of the polynomial approximation (2.11) on the interval $[t_{n-1}, t_n]$. The next result clarifies the issue.

**Theorem 2.8.** With reference to (2.5), (2.7), and (2.11), for all $n = 1, \ldots, N$ one has:

\[ \delta \gamma_j^n := \gamma_j(\hat{\sigma}_n) - \gamma_j(\sigma_n) = O(h^{2s-j}), \quad j = 0, \ldots, s - 1. \]

**Proof.** First of all, from (1.3), (2.5), (2.11), and Theorem 2.6 we know that:

\[ y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + h[\gamma_0(\hat{\sigma}_n) - \gamma_0(\sigma_n)] = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}). \]

Consequently, from the last equality one derives:

\[ \delta \gamma_0^n = \gamma_0(\hat{\sigma}_n) - \gamma_0(\sigma_n) = O(h^{2s}). \]

Further, by taking into account (2.15) and (2.17), one obtains:

\[ O(h^{2s}) = \gamma_0(\hat{\sigma}_n) - \gamma_0(\sigma_n) = \int_0^1 \left[ f(\hat{\sigma}_n(\zeta h)) - f(\sigma_n(\zeta h)) \right] d\zeta 
\]

\[ = \int_0^1 \int_0^1 F(\sigma_n(\zeta h)) + c \delta \sigma_n(\zeta h)) dc \delta \sigma_n(\zeta h) d\zeta = \int_0^1 G(\zeta h) \delta \sigma_n(\zeta h) d\zeta. \]

Now, considering that $P_0(x) \equiv 1$ and, for all $\zeta \in [0, 1]$,

\begin{equation}
\int_0^\zeta P_j(x)dx = \xi_{j+1}P_{j+1}(\zeta) - \xi_jP_{j-1}(\zeta), \quad j \geq 1,
\end{equation}

with \[ \xi_j = \left(2\sqrt{4j^2 - 1}\right)^{-1}, \]

one has:

\[ \delta \sigma_n(\zeta h) = \hat{\sigma}_n(\zeta h) - \sigma_n(\zeta h) \]

\[ = y(t_{n-1}) - y_{n-1} + h \sum_{j=0}^{s-1} \int_0^\zeta P_j(x)dx \delta \gamma_j^n + h \sum_{j \geq s} \int_0^\zeta P_j(x)dx \gamma_j(\hat{\sigma}_n) 
\]

\[ = y(t_{n-1}) - y_{n-1} + \zeta h \delta \gamma_0^n + h \sum_{j=1}^{s-1} [\xi_{j+1}P_{j+1}(\zeta) - \xi_jP_{j-1}(\zeta)] \delta \gamma_j^n + 
\]

\[ h \sum_{j \geq s} [\xi_{j+1}P_{j+1}(\zeta) - \xi_jP_{j-1}(\zeta)] \gamma_j(\hat{\sigma}_n). \]

\[ \text{Equation (2.18) is named Master Functional Equation in [11].} \]
Consequently, from Theorem 2.1 and Corollary 2.2, one obtains:

\[
O(h^{2s}) = \int_0^1 G(\zeta h) \delta \sigma_n(\zeta h) \, d\zeta = \int_0^1 G(\zeta h) \, d\zeta [y(t_{n-1}) - y_{n-1}] = (n-1)O(h^{2s+1})
\]

\[
+ h \sum_{j=1}^{s-1} \int_0^1 G(\zeta h) [\xi_{j+1} P_{j-1}(\zeta) - \xi_j P_{j-1}(\zeta)] \, d\zeta \delta \gamma^n_j
\]

from which,

\[
O(h^{2s}) = \int_0^1 G(\zeta h) [\xi_{j+1} P_{j+1}(\zeta) - \xi_j P_{j-1}(\zeta)] \, d\zeta \delta \gamma^n_j = O(h^{j-1})
\]

follows and, therefore, one concludes that \( \delta \gamma^n_j = O(h^{2s-j}) , \, j = 0, \ldots, s - 1. \]

2.3. Conservative/dissipative problems. An interesting case \([21, 8, 30]\) is that when problem (2.1) is in the form

\[
\dot{y}(t) = S \nabla H(y(t)), \quad t \in [t_0, T], \quad y(t_0) = y_0 \in \mathbb{R}^m,
\]

with \( S \in \mathbb{R}^{m \times m} \) either a skew-symmetric matrix, \( S^T = -S \), or a negative semidefinite matrix, \( S \leq 0 \), whereas \( \nabla H \) is the gradient of a scalar function usually called the Hamiltonian. As is clear:

- when \( S^T = -S \):
  \[
  \frac{d}{dt} H(y(t)) = \nabla H(y(t))^T \dot{y}(t) = \nabla H(y(t))^T S \nabla H(y(t)) = 0,
  \]

  so that \( H \) is a conserved quantity, and the problem is said to be conservative;

- when \( S \leq 0 \):
  \[
  \frac{d}{dt} H(y(t)) = \nabla H(y(t))^T \dot{y}(t) = \nabla H(y(t))^T S \nabla H(y(t)) \leq 0,
  \]

  and the problem is said to be dissipative.

The next result shows that this behavior is preserved by the approximations (2.9)–(2.12), upon observing that in this case (2.7) can be conveniently rewritten as

\[
\gamma_j(z) = S \int_0^1 P_j(\zeta) \nabla H(z(\zeta h)) \, d\zeta =: S \beta_j(z).
\]

Theorem 2.9. With reference to (2.9)–(2.12) applied for approximating problem (2.20), for all \( n = 1, \ldots, N \) one has:
\[ H(y_n) = H(y_{n-1}), \text{ when } S^T = -S; \]
\[ H(y_n) \leq H(y_{n-1}), \text{ when } S \leq 0. \]

Proof. In fact, by considering that \( y_n = \sigma_n(h), \ y_{n-1} = \sigma_n(0) \), and taking into account (2.21), one has:

\[
H(y_n) - H(y_{n-1}) = H(\sigma_n(h)) - H(\sigma_n(0)) = \int_0^h \frac{d}{dt} H(\sigma_n(t)) dt
\]

\[
= h \int_0^1 \nabla H(\sigma_n(ch))^T \sigma_n(ch) dc = h \int_0^1 \nabla H(\sigma_n(ch))^T \sum_{j=0}^{s-1} P_j(c) \gamma_j(\sigma_n) dc
\]

\[
= h \sum_{j=0}^{s-1} \left[ \int_0^1 \nabla H(\sigma_n(ch)) P_j(c) dc \right] S \beta_j(\sigma_n) = h \sum_{j=0}^{s-1} \beta_j(\sigma_n)^T S \beta_j(\sigma_n) =: \Delta H_n.
\]

Consequently, if \( S^T = -S \), then \( \Delta H_n = 0 \), whereas \( \Delta H_n \leq 0 \), when \( S \leq 0 \). \( \square \)

Remark 2.10. According to Remark 2.7, one then obtains that HBVM(\( \infty, s \)) methods can preserve the conservative/dissipative feature of problem (2.20).

2.4. Discretization and Runge-Kutta formulation. Quoting Dahlquist and Björk [19, p. 521] “as is well known, even many relatively simple integrals cannot be expressed in finite terms of elementary functions, and thus must be evaluated by numerical methods.” In this context, this quite obvious statement means that the approximation procedure defined by (2.9) and (2.7) does not yet provide a “true” numerical method. In fact, the integrals defining the Fourier coefficients,

\[ \gamma_j(\sigma_n) = \int_0^1 P_j(\zeta) f(\sigma_n(\zeta) h) d\zeta, \quad j = 0, \ldots, s - 1, \quad (2.22) \]

need to be numerically approximated by using a quadrature formula. Since we are dealing with a polynomial approximation, it is quite natural to do this by using an interpolatory quadrature with abscissae and weights \((c_i, b_i), i = 1, \ldots, k\).

\[ \gamma_j(\sigma_n) = \sum_{i=1}^k b_i P_j(c_i) f(\sigma_n(c_i h)) + \Delta_j(h), \quad (2.23) \]

where \( \Delta_j(h) \) is the quadrature error. The following straightforward result holds true.

Theorem 2.11. If the quadrature \((c_i, b_i), i = 1, \ldots, k\) has order \( q \), then

\[ \Delta_j(h) = O(h^{q-j}), \quad j = 0, \ldots, s - 1. \]

Remark 2.12. As is well known, since the quadrature (2.23) is based at \( k \) (distinct) abscissae, \( q \in \{k, \ldots, 2k\} \): the lower limit is obtained by a generic choice of the abscissae, whereas the upper one is achieved by placing them at the zeros of \( P_k(c) \).

When using a quadrature, clearly the Fourier coefficients (2.22) may be not exactly evaluated anymore. This implies that we are actually computing a possibly different
piecewise polynomial approximation $u(t)$ such that (compare with (2.7)–(2.12)), for all $n = 1, \ldots, N$:

\begin{equation}
\begin{aligned}
&u_n(ch) \equiv u(t_{n-1} + ch), \quad c \in [0, 1], \\
&\dot{u}_n(ch) = \sum_{j=0}^{s-1} P_j(c) \hat{\gamma}_j(u_n), \quad c \in [0, 1], \quad u_n(0) = y_{n-1},
\end{aligned}
\end{equation}

with (see (2.23))

\begin{equation}
\begin{aligned}
&\hat{\gamma}_j(u_n) := \sum_{i=1}^{k} b_i P_j(c_i) f(u_n(c_i h)) \equiv \gamma_j(u_n) - \Delta_j(h), \quad j = 0, \ldots, s - 1, \\
&u_n(ch) = y_{n-1} + h \sum_{j=0}^{s-1} \int_{c_j}^{c} P_j(x) dx \hat{\gamma}_j(u_n), \quad c \in [0, 1], \\
&u_n(h) =: y_{n} \equiv y_{n-1} + h \hat{\gamma}_0(u_n).
\end{aligned}
\end{equation}

Actually, (2.26)–(2.28) defines the $n$th integration step, by using a timestep $h$, performed with the $k$ stage Runge-Kutta method having stages:

\begin{equation}
\begin{aligned}
&Y_i^n := u_n(c_i h), \quad i = 1, \ldots, k.
\end{aligned}
\end{equation}

In fact, evaluating (2.27) at the abscissae $c_1, \ldots, c_k$, and substituting in it the $s$ approximate Fourier coefficients (2.26), one obtains, after rearranging terms,

\begin{equation}
\begin{aligned}
&Y_i^n = y_{n-1} + h \sum_{i=1}^{k} b_i \sum_{j=0}^{s-1} \int_{c_j}^{c_i} P_j(x) dx P_j(c_i) f(Y_i^n), \quad i = 1, \ldots, n, \\
&=: a_{i\ell} \\
&y_{n} = y_{n-1} + h \sum_{i=1}^{k} b_i f(Y_i^n).
\end{aligned}
\end{equation}

In other words, we have derived the $k$-stage Runge-Kutta method with abscissae and weights $(c_i, b_i)$, $i = 1, \ldots, k$, and Butcher matrix $A = (a_{i\ell}) \in \mathbb{R}^{k \times k}$. Next theorem puts the Butcher tableau in a more compact form [8].

**Theorem 2.13.** The Butcher tableau of the Runge-Kutta method (2.30)-(2.31) is given by

\begin{equation}
\begin{array}{c|cccc}
& I_s \mathbf{P} \top \Omega \\
\hline
\mathbf{c} & \mathbf{b} \top
\end{array}
\end{equation}

where

\begin{equation}
\begin{aligned}
&\mathbf{b} = (b_1 \ldots b_k) \top, \quad \mathbf{c} = (c_1 \ldots c_k) \top, \quad \Omega = \text{diag}(\mathbf{b}), \\
&\mathbf{P}_s = \begin{pmatrix} P_0(c_1) & \cdots & P_{s-1}(c_1) \\
\vdots & \ddots & \vdots \\
P_0(c_k) & \cdots & P_{s-1}(c_k) \end{pmatrix}, \quad \mathbf{I}_s = \begin{pmatrix} \int_0^{c_1} P_0(x) dx & \cdots & \int_0^{c_1} P_{s-1}(x) dx \\
\vdots & \ddots & \vdots \\
\int_0^{c_k} P_0(x) dx & \cdots & \int_0^{c_k} P_{s-1}(x) dx \end{pmatrix}.
\end{aligned}
\end{equation}
It is possible to derive an alternative formulation of the Runge-Kutta method \((2.32)\). In fact, using the relation \((2.19)\) between the integrals of the Legendre polynomials and the polynomials themselves, and considering that
\[
\int_0^c P_0(x)dx = \xi_1 P_1(c) + \xi_0 P_0(c), \quad \xi_0 = \frac{1}{2},
\]
one has that \(I_s = P_{s+1} \hat{X}_s\), where
\[
P_{s+1} = \begin{pmatrix} P_0(c_1) & \cdots & P_s(c_1) \\ \vdots & \ddots & \vdots \\ P_0(c_k) & \cdots & P_s(c_k) \end{pmatrix}, \quad \hat{X}_s = \begin{pmatrix} \xi_0 & -\xi_1 \\ \xi_1 & 0 & \ddots \\ \vdots & \ddots & \ddots & -\xi_{s-1} \\ -\xi_{s-1} & \vdots & \ddots & 0 \\ 0 & \cdots & \cdots & \xi_s \end{pmatrix} =: \begin{pmatrix} X_s \\ 0 \cdots 0 \xi_s \end{pmatrix}.
\]

Consequently, the Butcher tableau \((2.32)\) can be rewritten as
\[
\begin{array}{c|c}
\multicolumn{1}{c}{c} & P_{s+1} \hat{X}_s \left[ P_s^T \Omega \right] \\
\hline
b^T & .
\end{array}
\]

When the quadrature \((2.23)\) has order \(q \geq 2s\), it is quite straightforward to prove that
\[
P_s^T \Omega P_s = I_s, \quad P_s^T \Omega P_{s+1} = [I_s, 0] \in \mathbb{R}^{s \times (s+1)},
\]
where in general, hereafter, \(I_r \in \mathbb{R}^{r \times r}\) is the identity matrix.\(^6\) Consequently,
\[
P_s^T \Omega \left[ P_{s+1} \hat{X}_s \left[ P_s^T \Omega \right] \right] P_s = X_s,
\]
which can be regarded as a generalization of the \(W\)-transformation in [24, Theorem 5.6, p. 79]. In addition to this, when \(q \geq 2s\) also the following results hold true.\(^7\)

**Theorem 2.14.** With reference to \((2.1)-(2.7)\) and \((2.24)-(2.28)\), and assuming that the quadrature formula \((2.23)\) has order \(q \geq 2s\), one has:
\[
y(t_1) - y_1 = O(h^{2s+1}), \quad \max_{c \in [0,1]} |\hat{y}_1(ch) - u_1(ch)| = O(h^{s+1}).
\]

**Theorem 2.15.** With reference to \((2.1)-(2.7)\) and \((2.24)-(2.28)\), and assuming that the quadrature formula \((2.23)\) has order \(q \geq 2s\), for \(n = 1, \ldots, N\) one has:
\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}), \quad \max_{c \in [0,1]} |\hat{y}_n(ch) - u_n(ch)| = O(h^{s+1}).
\]

**Theorem 2.16.** With reference to \((2.5)-(2.7)\) and \((2.26)-(2.28)\), and assuming that the quadrature formula \((2.23)\) has order \(q \geq 2s\), for all \(n = 1, \ldots, N\) one has:
\[
\hat{\delta}_{n}^j := \gamma_j (\hat{\sigma}_n) - \hat{\delta}_j (u_n) = O(h^{2s-j}), \quad j = 0, \ldots, s - 1.
\]

Concerning the case of conservative/dissipative problems in the form \((2.20)\), the result of Theorem 2.9 modifies as follows.

\(^6\)When the dimension of the identity matrix is not explicitly indicated, it will be easily deducible from the context.

\(^7\)For sake of brevity, we don’t discuss the case \(q < 2s\), since it has no practical interest.
Theorem 2.17. With reference to (2.24)-(2.28) applied for approximating problem (2.20), and assuming that the quadrature formula (2.23) has order $q \geq 2s$, for all $n=1,\ldots,N$ one has:

- if $H$ is a polynomial of degree not larger than $q/s$, then the result of Theorem 2.9 continues to hold;
- differently,
  \[-H(y_n) = H(y_{n-1}) + O(h^{q/2+1}), \quad \text{when } S^T = -S,\]
  \[-H(y_n) \leq H(y_{n-1}) + O(h^{q+1}), \quad \text{when } S \leq 0.\]

We here provide only the proof of Theorem 2.14 (see also [13, Theorem 4]), since those of Theorem 2.15, Theorem 2.16, and Theorem 2.17 can be similarly obtained by slightly adapting the corresponding proofs of Theorem 2.6, Theorem 2.8, and Theorem 2.9, respectively.

Proof. (of Theorem 2.14) By taking into account the result of Theorem 2.11, one has:

\[
\vartheta_1(ch) - u_1(ch) = y(t_0 + ch, t_0, y_0) - y(t_0 + ch, t_0 + ch, u_1(ch))
\]

\[
= y(t_0 + ch, t_0, u_1(0)) - y(t_0 + ch, t_0 + ch, u_1(ch)) = \int_{ch}^0 \frac{d}{dt} y(t_0 + ch, t_0 + t, u_1(t)) dt
\]

\[
= \int_{ch}^0 \frac{\partial}{\partial \xi} y(t_0 + ch, \xi, u_1(t)) \bigg|_{\xi=t_0+t} + \frac{\partial}{\partial \eta} y(t_0 + ch, t_0 + t, \eta) \bigg|_{\eta=u_1(t)} \dot{u}_1(t) dt
\]

\[
= \int_{0}^{ch} \Phi(t_0 + ch, t_0 + t) \{ f(u_1(t)) - \dot{u}_1(t) \} dt
\]

\[
= h \int_{0}^{c} \Phi(t_0 + ch, t_0 + \zeta h) \{ f(u_1(\zeta h)) - \dot{u}_1(\zeta h) \} d\zeta
\]

\[
= h \int_{0}^{c} \Phi(t_0 + ch, t_0 + \zeta h) \left[ \sum_{j \geq 0} P_j(\zeta) \gamma_j(u_1) - \sum_{j=0}^{s-1} P_j(\zeta) \gamma_j(u_1) \right] d\zeta
\]

\[
= h \sum_{j \geq s} \left[ \int_{0}^{c} P_j(\zeta) \Phi(t_0 + ch, t_0 + \zeta h) d\zeta \right] \gamma_j(u_1) = O(h^s)
\]

\[
+ h \sum_{j=0}^{s-1} \left[ \int_{0}^{c} P_j(\zeta) \Phi(t_0 + ch, t_0 + \zeta h) d\zeta \right] \Delta_j(h) = O(h^{s-1})
\]

Consequently, the second part of the statement follows by considering that, for $c \in (0,1)$, this quantity is

\[
O(h^{s+1}) + O(h^{q-s+2}) = O(h^{s+1}),
\]

since $q \geq 2s$, whereas, when $c = 1$ one deduces, by virtue of Theorem 2.1, and
considering that $t_1 = t_0 + h$:

$$y(t_1) - y_1 \equiv \delta_1(h) - u_1(h) = h \sum_{j \geq s} \int_0^1 P_j(\zeta) \Phi(t_1, t_0 + \zeta h) \, d\zeta \gamma_j(u_1)$$

$$= O(h^s)$$

$$+ h \sum_{j=0}^{s-1} \int_0^1 P_j(\zeta) \Phi(t_1, t_0 + \zeta h) \, d\zeta \Delta_j(h) \equiv O(h^{2s+1} + O(h^{q+1}) = O(h^{2s+1}).$$

**Remark 2.18.** When the $k$ abscissae are placed at the zeros of $P_k(c)$, and $k \geq s$, one obtains a HBVM($k, s$) method, whose order is $2s$ [11, 8, 9]. It is worth mentioning that the HBVM($s, s$) method is nothing but the $s$-stage Gauss method. Moreover, the HBVM($k, 1$) methods correspond to the second-order Runge-Kutta methods described in [18]. Different choices of the quadrature have been also considered in [27, 28, 29, 14].

**2.5. Solving the discrete problems.** Sometimes, the number of stages $k$ of the Runge-Kutta method (2.32) can be pretty larger than the degree $s$ of the underlying polynomial approximation (2.26)–(2.28). This is the case, for example, of HBVM($k, s$) methods when used as energy-conserving methods [11, 8, 9] (see also Theorem 2.17 in Subsection 2.3). In such a case, it is clear that the usual implementation of the Runge-Kutta method leads to the solution of a discrete problem having (block) dimension $k$. Nevertheless, for sake of completeness we now recall how the discrete problem to be solved can be actually recast so as to have (block) dimension $s$, independently of $k$. This clearly allows for relatively large values of $k$, thus making possible the use of an arbitrarily high-order quadrature (2.23). Let us then consider the first integration step of the method for solving (2.1) with timestep $h$, (thus, we can skip the index $n$ of the step). Setting $\mathbf{1} = (1 \ldots 1)^T \in \mathbb{R}^k$, and $Y$ the stage vector of (block) dimension $k$, one obtains that the stage equation for (2.32) is given by:

$$Y = \mathbf{1} \otimes y_0 + h \mathcal{I}_s P_s^T \Omega \otimes I_m f(Y),$$

with an obvious meaning of $f(Y)$. However, we observe that [12]

$$P_s^T \Omega \otimes I_m f(Y) =: \hat{\gamma} \equiv \begin{pmatrix} \hat{\gamma}_0(u_1) \\ \vdots \\ \hat{\gamma}_{s-1}(u_1) \end{pmatrix},$$

i.e., the (block) vector with the $s$ coefficients of the polynomial approximation $u_1(ch)$ (see (2.26)-(2.27)). Consequently, (2.33) can be rewritten as

$$Y = \mathbf{1} \otimes y_0 + h \mathcal{I}_s \otimes I_m \hat{\gamma}.$$ By combining the last two equations one eventually obtains:

$$\hat{\gamma} = P_s^T \Omega \otimes I_m f(\mathbf{1} \otimes y_0 + h \mathcal{I}_s \otimes I_m \hat{\gamma}),$$

$$= O(h^2s)$$

$$+ o(h^s).$$

$$= O(h^{2s+1}) + O(h^{q+1}) = O(h^{2s+1}).$$
which is a discrete problem, equivalent to (2.33), having (block) dimension $s$, independently of $k$. Once this equation has been solved, the new approximation is derived, according to (2.28), as

$$y_1 = y_0 + h\hat{\gamma}_0(u_1).$$

It is also worth mentioning that very effective nonlinear iterations have been devised for solving (2.34) [12, 7, 8] (the most effective being that derived from the so called blended iteration introduced in [15]).

3. The DDE case. As for the ODE case, also for DDEs we shall consider, without loss of generality, the simpler problem

$$\dot{y}(t) = f(y(t), y(t - \tau)), \quad t \in [t_0, T], \quad y(t_0) = y_0,$$

in place of (1.2) where, usually, $y_0 = \phi(t_0)$. Moreover, we shall suppose that both the timestep $h$ defining the discrete mesh (2.2) and the width of the integration interval, $T - t_0$, are commensurable with the delay:

$$\tau = \nu h, \quad T - t_0 = K\tau, \quad K, \nu \in \mathbb{N},$$

so that the discrete mesh is now given by:

$$t_n = t_0 + nh, \quad n = -\nu, \ldots, N \equiv K\nu.$$

On one hand, similarly as done in the ODE case, let us denote, for notational purposes, by $\hat{\sigma}(t) \equiv y(t)$ the solution of (3.1), and

$$\hat{\sigma}_n(ch) := \hat{\sigma}(t_{n-1} + ch), \quad c \in [0, 1], \quad n = 1 - \nu, \ldots, N,$$

its restriction to the time interval $[t_{n-1}, t_n]$. Consequently,

$$\hat{\sigma}_n(ch) \equiv \phi(t_{n-1} + ch), \quad c \in [0, 1], \quad n = 1 - \nu, \ldots, 0,$$

whereas, for $n = 1, \ldots, N$, one has (compare with (2.4)–(2.7)):

$$\dot{\hat{\sigma}}_n(ch) = \sum_{j \geq 0} P_j(c)\gamma_j(\hat{\sigma}_n, \hat{\sigma}_{n-\nu}), \quad c \in [0, 1], \quad \hat{\sigma}_n(0) = y(t_{n-1}),$$

so that,

$$\hat{\sigma}_n(ch) = y(t_{n-1}) + h\sum_{j \geq 0} \int_0^c P_j(x)dx \gamma_j(\hat{\sigma}_n, \hat{\sigma}_{n-\nu}), \quad c \in [0, 1],$$

and

$$y(t_n) = y(t_{n-1}) + h\gamma_0(\hat{\sigma}_n, \hat{\sigma}_{n-\nu}) \equiv \hat{\sigma}(t_n),$$

where, in general, for any suitably regular functions $z, w : [0, h] \to \mathbb{R}^m$,

$$\gamma_j(z, w) := \int_0^1 P_j(\zeta)f(z(\zeta h), w(\zeta h))d\zeta.$$
On the other hand, we shall look for a piecewise approximation to $\hat{\sigma}(t)$, i.e. $\sigma(t)$, such that (compare with (2.8)–(2.12))

$$\sigma_n(ch) := \sigma(t_{n-1} + ch), \quad c \in [0,1], \quad n = 1 - \nu, \ldots, N,$$

denotes its restriction to the time interval $[t_{n-1}, t_n]$. Consequently, one has:

$$\sigma_n(ch) \equiv \phi(t_{n-1} + ch), \quad c \in [0,1], \quad n = 1 - \nu, \ldots, 0,$$

whereas, for $n = 1, \ldots, N$, $\sigma_n \in \Pi_s$ satisfies the differential equation

$$\dot{\sigma}_n(ch) = \sum_{j=0}^{s-1} P_j(c) \gamma_j(\sigma_n, \sigma_{n-\nu}), \quad c \in [0,1], \quad \sigma_n(0) = y_{n-1},$$

so that,

$$\sigma_n(ch) = y_{n-1} + h \sum_{j=0}^{s-1} \int_0^c P_j(x) \gamma_j(\sigma_n, \sigma_{n-\nu}), \quad c \in [0,1],$$

and

$$y_n = y_{n-1} + h \gamma_0(\sigma_n, \sigma_{n-\nu}) =: \sigma_n(h),$$

with $\gamma_j(\sigma_n, \sigma_{n-\nu})$ defined according to (3.9). In the sequel, we shall discuss the accuracy of the approximations:

$$y(t_n) - y_n \equiv \hat{\sigma}_n(h) - \sigma_n(h),$$

$$\delta \sigma_n(ch) := \sigma_n(ch) - \sigma_n(ch), \quad c \in (0,1), \quad n = 1, \ldots, N.$$

For this purpose, some preliminary results are given in the next section.

### 3.1. Preliminary results

We start with the generalization of Corollary 2.2 to the present setting.

**Corollary 3.1.** With reference to (3.9), one has: $\gamma_j(z, w) = O(h^j)$.

**Proof.** Immediate from Theorem 2.1, by setting $G(\zeta h) := f(z(\zeta h), w(\zeta h))$. \(\square\)

We also need perturbation results corresponding to those of Theorem 2.3 for ODEs. For this purpose, it is sufficient to discuss them for a local problem defined on two contiguous time subintervals of width $\tau$: the former containing the *memory*, the latter containing the solution to be computed. Without loss of generality, we shall then fix the reference interval $[t_0 - \tau, t_0 + \tau]$, where we consider the following problem, defined for a generic $\xi \in [t_0, t_0 + \tau]$:

$$\dot{y}(t) = f(y(t), y(t - \tau)), \quad t \in [t_0, t_0 + \tau],$$

$$y(t) = \phi(t), \quad t \in [t_0 - \tau, t_0].$$

Problem (3.16) defines a generalization of the localized one associated to (3.1) (obtained for $\xi = t_0$ and $\eta = y_0$), and we shall denote its solution by

$$y(t) \equiv y(t, \xi, \eta, \phi; t_0),$$

As done in the ODE case, for sake of brevity, hereafter we shall use either one of the two notations, depending on the needs.
in order to emphasize its dependence on the first four parameters, whereas the last one refers to the time subinterval. We shall also use the following notation:

\[(3.18) \quad F_1(z, w) = \frac{\partial}{\partial z} f(z, w), \quad F_2(z, w) = \frac{\partial}{\partial w} f(z, w).\]

**Remark 3.2.** It is clear that the function \(\phi\) in (3.16) represents the memory term of the equation, and it is a known function. The same will happen in the subsequent reference interval, \([t_0, t_0 + 2\tau]\), obtained by shifting to the right the previous one by \(\tau\), once the solution of (3.16) has been computed, and so forth.

To begin with, let us state the following straightforward result, whose proof is omitted for brevity.

**Theorem 3.3.** The solution (3.17) of problem (3.16) is defined on the whole time interval \([t_0, t_0 + \tau]\), independently of the point \(\xi \in [t_0, t_0 + \tau]\) where the condition \(\eta\) is given.

The following result then holds true (compare with Theorem 2.3).

**Theorem 3.4.** With reference to the solution (3.17) of problem (3.16), one has:

\[a) \quad \frac{\partial}{\partial t} y(t) = f(y(t), y(t - \tau)), \quad b) \quad \frac{\partial}{\partial \eta} y(t) = \Phi(t, \xi; t_0), \quad c) \quad \frac{\partial}{\partial \xi} y(t) = -\Phi(t, \xi; t_0) f(y(\xi), y(\xi - \tau)),\]

where \(\Phi(t, \xi; t_0)\) satisfies (see (3.18)):

\[(3.19) \quad \Phi(t, \xi; t_0) = F_1(y(t), y(t - \tau)) \Phi(t, \xi; t_0), \quad t \in [t_0, t_0 + \tau], \]
\[\Phi(\xi, \xi; t_0) = I \in \mathbb{R}^{m \times m}, \quad \Phi(t, \xi; t_0) = O \in \mathbb{R}^{m \times m}, \quad t \in [t_0 - \tau, t_0).\]

**Proof.** The statement \(a)\) clearly follows from (3.16). From the same equation one also derives that, for \(t \in [t_0, t_0 + \tau]\),

\[(3.20) \quad \frac{d}{dt} \left( \frac{\partial}{\partial \eta} y(t) \right) = \frac{\partial}{\partial \eta} f(y(t), y(t - \tau)) = F_1(y(t), y(t - \tau)) \frac{\partial}{\partial \eta} y(t) + F_2(y(t), y(t - \tau)) \frac{\partial}{\partial \eta} y(t - \tau).\]

Moreover, at \(t = \xi\),

\[\frac{\partial}{\partial \eta} y(\xi) = \frac{\partial}{\partial \eta} \eta = I,\]

and, for \(t \in [t_0 - \tau, t_0)\),

\[\frac{\partial}{\partial \eta} y(t) = \frac{\partial}{\partial \eta} \phi(t) = O.\]

This latter equality implies that, for \(t \in [t_0, t_0 + \tau]\), the term \(F_2(y(t), y(t - \tau)) \frac{\partial}{\partial \eta} y(t - \tau)\) in (3.20) vanishes, thus reducing to the first equation in (3.19), so that \(b)\) eventually follows. Finally, by virtue of Theorem 3.3, let \(t^*\) be a generic point in the interval \([t_0, t_0 + \tau]\), and denote

\[y^* = y(t^*, \xi, \eta, \phi; t_0).\]
Consequently, since $\xi \in [t_0, t_0 + \tau]$ as well, one has:

$$
\eta = y(\xi, t^*, y(t^*, \xi, \eta, \phi; t_0), \phi; t_0),
$$

so that we eventually arrive at the identity

$$
y^* = y(t^*, \xi, y(\xi, t^*, y^*, \phi; t_0), \phi; t_0).
$$

By taking into account the results of the previous points $a)$ and $b)$, one derives:

$$
0 = \left. \frac{d}{d\xi} y(t^*, \xi, y(\xi, t^*, y^*, \phi; t_0), \phi; t_0) \right|_{t = \xi} = \frac{\partial}{\partial \xi} y(t^*, \xi, \eta, \phi; t_0) + \left. \frac{\partial}{\partial \eta} y(t^*, \xi, \eta, \phi; t_0) \right|_{t = \xi} \frac{\partial}{\partial t} y(t, t^*, y^*, \phi; t_0) + \left( \frac{\partial}{\partial \phi} y(t, t^*, y^*, \phi; t_0) \right) f(y(\xi), y(\xi - \tau)).
$$

The statement $c)$ then follows, by taking into account that $t^*$ is generic. \(\square\)

One main difference with the ODE case, stems from the fact that now (3.17) also depends on the memory term $\phi$, which is a functional parameter. Consequently, we now look for a Fréchet derivative such that, for any perturbation $\delta \phi \in C([t_0 - \tau, t_0])$ and $t \in [t_0 - \tau, t_0 + \tau]$:

$$
\lim_{\varepsilon \to 0} \frac{y(t, \xi, \eta, \phi + \varepsilon \delta \phi; t_0) - y(t, \xi, \eta, \phi; t_0)}{\varepsilon} = \int_{t_0 - \tau}^{t_0} \frac{\delta}{\delta \phi(\xi)} y(t, \xi, \eta, \phi; t_0) d\xi,
$$

where

$$
\frac{\delta}{\delta \phi(\xi)} y(t) : (t, \xi) \in [t_0 - \tau, t_0 + \tau] \times [t_0 - \tau, t_0) \to \left( \frac{\delta}{\xi \phi(\xi)} y_i(t) \right) \in \mathbb{R}^{m \times m},
$$

is the functional derivative of (3.17) (see, e.g., [20, Appendix A]), with $y_i$ and $\phi_j$ the respective entries of $y$ and $\phi$. For later use, we recall that, for a given $t \in [t_0 - \tau, t_0)$ and $i, j = 1, \ldots, m$,

$$
\left. \frac{\delta}{\delta \phi_j(\xi)} y_i(t) \right|_{t = \xi} = \lim_{\varepsilon \to 0} \frac{y_i(t, \xi, \eta, \phi + \varepsilon \delta \phi_j; t_0) - y_i(t, \xi, \eta, \phi; t_0)}{\varepsilon} = \int_{t_0 - \tau}^{t_0} \frac{\delta}{\delta \phi_j(\xi)} y_i(t) d\xi,
$$

with $e_j \in \mathbb{R}^m$ the $j$th unit vector and, hereafter, $\delta_i(t)$ is the Dirac delta function centered at $t$. The following result holds true.

**Lemma 3.5.** With reference to (3.21) and (3.22), for any fixed $t \in [\xi, t_0 + \tau] \subseteq [t_0, t_0 + \tau]$ one has:

$$
\frac{\delta}{\delta \phi(\xi)} y(t) = O \in \mathbb{R}^{m \times m}, \quad \forall \xi \in [t_0 - \tau, \xi - \tau) \cup (t - \tau, t_0).
$$

**Proof.** Having fixed $t \in [\xi, t_0 + \tau]$, it follows that $\forall \zeta \in [t_0 - \tau, \xi - \tau) \cup (t - \tau, t_0)$, setting as usual $\delta_i(\zeta)$ the Dirac delta centered at $\zeta$, one has:

$$
y(t, \xi, \eta, \phi + \varepsilon \delta \xi; t_0) = y(t, \xi, \eta, \phi; t_0), \quad \forall \varepsilon \in \mathbb{R}.
$$
In fact, by virtue of (3.16), the solution (3.17) is independent of the values of \( \phi \) outside the interval \([\xi - \tau, t - \tau]\). Consequently, by taking into account (3.23), it follows that:

\[
\frac{\delta}{\delta \phi(\zeta)} y(t) = \lim_{\varepsilon \to 0} \frac{y(t, \xi, \eta, \phi + \varepsilon \delta \zeta; t_0) - y(t, \xi, \eta, \phi; t_0)}{\varepsilon} = O. \quad \blacksquare
\]

Taking into account Lemma 3.5, the following result provides a more practical characterization of the functional derivative (3.21)-(3.22). Figure 1 displays the location of the most relevant points and subintervals involved in Theorem 3.6.

**Theorem 3.6.** With reference to the solution (3.17) of problem (3.16), for any \( \hat{t} \in [\xi - \tau, t_0] \) one has:

\[
(3.24) \quad \frac{\delta}{\delta \phi(\hat{t})} y(t) = \Psi(t, \hat{t}; t_0),
\]

where \( \Psi(t, \hat{t}; t_0) \) satisfies (see (3.18)):

\[
(3.25) \quad \Psi(t, \hat{t}; t_0) = F_1(y(t), y(t - \tau)) \Psi(t, \hat{t}; t_0), \quad t \in (\hat{t} + \tau, t_0 + \tau],
\]

\[
\Psi(\hat{t} + \tau, \hat{t}; t_0) = F_2(y(\hat{t} + \tau), y(\hat{t})),
\]

\[
\Psi(t, \hat{t}; t_0) = \delta \xi(t) I, \quad t \in [t_0 - \tau, \hat{t} + \tau),
\]

with \( O, I \in \mathbb{R}^{m \times m} \) and \( \delta \xi(t) \) the Dirac delta function.

**Proof.** In fact, for \( t \in [t_0, t_0 + \tau] \) one has, by virtue of (3.16):

\[
\frac{d}{dt} \frac{\delta}{\delta \phi(\hat{t})} y(t, \xi, \eta, \phi; t_0) = \frac{\delta}{\delta \phi(\hat{t})} y(t) = \frac{\delta}{\delta \phi(\hat{t})} f(y(t), y(t - \tau))
\]

\[
= F_1(y(t), y(t - \tau)) \frac{\delta}{\delta \phi(\hat{t})} y(t) + F_2(y(t), y(t - \tau)) \frac{\delta}{\delta \phi(\hat{t})} y(t - \tau),
\]

i.e., using the notation (3.24),

\[
(3.26) \quad \dot{\Psi}(t, \hat{t}; t_0) = F_1(y(t), y(t - \tau)) \Psi(t, \hat{t}; t_0) + F_2(y(t), y(t - \tau)) \Psi(t - \tau, \hat{t}; t_0).
\]

Moreover, at \( t = \xi \),

\[
(3.27) \quad \Psi(\xi, \hat{t}; t_0) = \frac{\delta}{\delta \phi(\hat{t})} y(\xi) = \frac{\delta}{\delta \phi(\hat{t})} \eta = O,
\]

since the condition \( y(\xi) = \eta \) is independent of the history \( \phi \). Further, taking into account (3.23), for all \( i, j = 1, \ldots, m \) and for \( t \in [t_0 - \tau, t_0] \), one has:

\[
\frac{\delta}{\delta \phi_j(t)} y_i(t) = \frac{\delta}{\delta \phi_j(t)} \phi_i(t) = \lim_{\varepsilon \to 0} \frac{[\phi_i(t) + \varepsilon \delta_{ij} \delta \xi(t)] - \phi_i(t)}{\varepsilon} = \delta_{ij} \delta \xi(t),
\]

with \( \delta_{ij} \) the Kronecker delta. Consequently,

\[
(3.28) \quad \Psi(t, \hat{t}; t_0) = \frac{\delta}{\delta \phi(\hat{t})} y(t) = \delta \xi(t) I, \quad t \in [t_0 - \tau, t_0).
\]
From (3.26)–(3.28), one then derives, considering that (see Figure 1) \( t_0 - \tau \leq \xi - \tau < \hat{t} \):

(3.29) \[
\Psi(t, \hat{t}; t_0) = \int_{\xi}^{\hat{t}} \Psi(\zeta, \hat{t}; t_0) d\zeta = \begin{cases} 
O, & t \in [t_0, \hat{t} + \tau), \\
F_2(y(\hat{t} + \tau), y(\hat{t})), & t = \hat{t} + \tau.
\end{cases}
\]

From (3.28) and (3.29) the last two equations in (3.25) follow. Consequently, from (3.29), one obtains

\[
\hat{\Psi}(t, \hat{t}; t_0) = F_1(y(t), y(t - \tau)) \Psi(t, \hat{t}; t_0), \quad t \in [\hat{t} + \tau, t_0 + \tau],
\]

which completes the proof of (3.25). \(\square\)

As a straightforward consequence, the following result holds true, which guarantees the regularity of \( \Psi \) w.r.t. its first two arguments (again, for sake of clarity, refer to Figure 1).

**Corollary 3.7.** With reference to the solution (3.17) of problem (3.16), and considering (3.18), (3.19), and (3.25), for any \( t \in (\xi - \tau, t_0) \) one has:

(3.30) \[
\Psi(t, \hat{t}; t_0) = \Phi(t, \hat{t} + \tau; t_0) F_2(y(\hat{t} + \tau), y(\hat{t})), \quad t \in [\hat{t} + \tau, t_0 + \tau].
\]

Finally, the following result holds true (compare with Corollary 2.4 of the ODE case).

**Corollary 3.8.** With reference to the solution (3.17) of problem (3.16), and considering (3.19) and (3.30), for any \( \delta \phi \in C([t_0 - \tau, t_0]) \) one has:

\[
y(t, \xi, \eta + \delta \eta, \phi + \delta \phi; t_0) = y(t, \xi, \eta, \phi; t_0) + \Phi(t, \xi; t_0) \delta \eta + \int_{\xi = \tau}^{t - \tau} \Psi(t, \zeta; t_0) \delta \phi(\zeta) d\zeta \\
+ (t - \xi) O(||\delta \eta|| + ||\delta \phi||)^2, \quad t \in [\xi, t_0 + \tau],
\]

with \( ||\delta \phi|| = \max_{\zeta \in [\xi - \tau, t - \tau]} |\delta \phi(\zeta)| \).

**Proof.** The statement follows from Theorem 3.4, part b), and Theorem 3.6, by taking into account Equation (3.21) and the result of Lemma 3.5. \(\square\)

### 3.2. Main results (DDE case)

We are now in the position of discussing the accuracy of the approximations (3.15). To begin with, the following result holds true.

**Theorem 3.9.** With reference to (3.1)–(3.15), for \( n = 1, \ldots, \nu \) one has:

\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}), \quad ||\delta \sigma_n|| := \max_{c \in [0,1]} |\delta \sigma_n(ch)| = O(h^{s+1}).
\]

**Proof.** The statement follows from Theorem 2.6 by considering that, for \( n = 1, \ldots, \nu \), then \( t \in [t_0, t_0 + \tau] \) in (3.1), so that \( y(t - \tau) \equiv \phi(t - \tau) \), which is a known function, thus obtaining an ODE. \(\square\)

This result allows us to state the following one, which generalizes that of Theorem 2.8 to the present case.

**Theorem 3.10.** With reference to (3.7), (3.9), (3.13), and (3.15) if for \( n \geq 1 \) one has:

\[
y(t_r) - y_r = y(t_{r-1}) - y_{r-1} + O(h^{2s+1}), \quad r = 1, \ldots, n,
\]

then

\[
\delta \gamma_j^n := \gamma_j(\delta \sigma_n, \delta \sigma_{n-\nu}) - \gamma_j(\sigma_n, \sigma_{n-\nu}) = O(h^{2s-j}), \quad j = 0, \ldots, s - 1.
\]
Proof. The proof is by generalized induction. For \( n = 1, \ldots, \nu \) the statement follows from Theorem 2.8 and Theorem 3.9 since, in this case,

\[
\dot{\sigma}_{n-\nu}(ch) \equiv \sigma_{n-\nu}(ch) \equiv \phi(t_{n-1} + ch - \tau), \quad c \in [0, 1],
\]

so that we are dealing with an ODE. Assume now it true up to \( n - 1 \), and prove for \( n \). By hypothesis, and from (3.8) and (3.14), we know that

\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}) \equiv y(t_{n-1}) - y_{n-1} + h\delta\gamma^a_0,
\]

so that \( \delta\gamma^a_0 = O(h^{2s}) \) follows. Then, by taking into account (3.18), it follows that:

\[
O(h^{2s}) = \delta\gamma^a_0 = \gamma_0(\dot{\sigma}_n, \dot{\sigma}_n - \nu) - \gamma_0(\sigma_n, \sigma_n - \nu)
\]

\[
= \int_0^1 [f(\dot{\sigma}_n(\zeta h), \dot{\sigma}_n - \nu(\zeta h)) - f(\sigma_n(\zeta h), \sigma_n - \nu(\zeta h))] d\zeta
\]

\[
= \int_0^1 \int_0^1 [F_1(\sigma_n(\zeta h) + c \delta\sigma_n(\zeta h), \sigma_n - \nu(\zeta h) + c \delta\sigma_n - \nu(\zeta h)) + F_2(\sigma_n(\zeta h) + c \delta\sigma_n(\zeta h), \sigma_n - \nu(\zeta h) + c \delta\sigma_n - \nu(\zeta h))] dc d\zeta
\]

\[
= \int_0^1 \int_0^1 \underbrace{F_1(\sigma_n(\zeta h) + c \delta\sigma_n(\zeta h), \sigma_n - \nu(\zeta h) + c \delta\sigma_n - \nu(\zeta h)) dc d\zeta}_{=: G_1(\zeta h)}
\]

\[
\int_0^1 \int_0^1 \underbrace{F_2(\sigma_n(\zeta h) + c \delta\sigma_n(\zeta h), \sigma_n - \nu(\zeta h) + c \delta\sigma_n - \nu(\zeta h)) dc d\zeta}_{=: G_2(\zeta h)}
\]

\[
= \int_0^1 G_1(\zeta h) \delta\sigma_n(\zeta h) d\zeta + \int_0^1 G_2(\zeta h) \delta\sigma_n - \nu(\zeta h) d\zeta.
\]

Let us discuss in detail the term

\[
\int_0^1 G_1(\zeta h) \delta\sigma_n(\zeta h) d\zeta,
\]

since the remaining one,

\[
\int_0^1 G_2(\zeta h) \delta\sigma_n - \nu(\zeta h) d\zeta = O(h^{2s}),
\]

is similarly discussed, by taking into account the induction hypothesis. By virtue of (2.19), one has:

\[
\delta\sigma_n(\zeta h) = \dot{\sigma}_n(\zeta h) - \sigma_n(\zeta h)
\]

\[
= y(t_{n-1}) - y_{n-1} + \sum_{j=0}^{s-1} \int_0^\zeta P_j(x) dx \dot{\gamma}_j^n + \sum_{j \geq s} \int_0^\zeta P_j(x) dx \gamma_j(\dot{\sigma}_n, \dot{\sigma}_n - \nu)
\]

\[
= y(t_{n-1}) - y_{n-1} + \zeta h\delta\gamma^n_0 + h \sum_{j=1}^{s-1} [\xi_j P_{j+1}(\zeta) - \xi_j P_{j-1}(\zeta)] \delta\gamma^n_j +
\]

\[
h \sum_{j \geq s} [\xi_j P_{j+1}(\zeta) - \xi_j P_{j-1}(\zeta)] \gamma_j(\dot{\sigma}_n, \dot{\sigma}_n - \nu).\]
Consequently, from Theorem 2.1 and Corollary 3.1, one obtains:

\[
O(h^{2s}) = \int_0^1 G_1(\zeta h)\delta\sigma_n(\zeta h) \, d\zeta = \int_0^1 G_1(\zeta h) \, d\zeta \left[ y(t_{n-1}) - y_{n-1} \right] = O(1) = (n-1)O(h^{2s+1})
\]

\[
+ h \int_0^1 G_1(\zeta h) \, d\zeta \delta\gamma^n = O(k^s)
\]

\[
+ h \sum_{j=1}^{s-1} \int_0^1 G_1(\zeta h) \left[ \xi_{j+1} - \xi_j \right] \, d\zeta \delta\gamma^n = O(h^s)
\]

\[
\int_0^1 G_1(\zeta h) \left[ \xi_{j+1} - \xi_j \right] \, d\zeta \delta\gamma^n = O(h^s)
\]

from which,

\[
O(h^{2s}) = h \sum_{j=1}^{s-1} \int_0^1 G_1(\zeta h) \left[ \xi_{j+1} - \xi_j \right] \, d\zeta \delta\gamma^n = O(h^{s-1})
\]

follows and, therefore, one concludes that \( \delta\gamma^n_j = O(h^{2s-j}), \ j = 0, \ldots, s - 1. \)

As a consequence, the following result can be stated.

**Theorem 3.11.** With reference to (3.1)–(3.15), for \( n = 1, \ldots, N \equiv K\nu \) one has:

\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}), \quad \|\delta\sigma_n\| := \max_{c\in[0,1]} |\delta\sigma_n(ch)| = O(h^{s+1}).
\]

**Proof.** The proof is done by induction on groups of \( \nu \) consecutive steps. For the first \( \nu \) steps, the statement follows from Theorem 3.9. Assume now, by induction, that it holds true up to \( t_{k\nu} = t_0 + k\nu h \), and let us prove for \( n = k\nu + 1, \ldots, (k+1)\nu \).

For this purpose, for \( k = 1, \ldots, K - 1 \) let us set:

\[
\phi_k(t) \equiv \sigma(t), \quad \hat{\phi}_k(t) \equiv \hat{\sigma}(t) \equiv y(t), \quad t \in [t_{(k-1)\nu}, t_{k\nu}).
\]

Assuming, again, true the statement for \( n - 1 \), and using the notation (3.17), one has:

\[
\delta\sigma_n(ch) = \hat{\sigma}_n(ch) - \sigma_n(ch)
\]

\[
= y(t_{n-1} + ch, t_{n-1}, y(t_{n-1}), \hat{\phi}_k; t_{k\nu}) - y(t_{n-1} + ch, t_{n-1} + ch, \sigma_n(ch), \phi_k; t_{k\nu})
\]

\[
= y(t_{n-1} + ch, t_{n-1} + \hat{\sigma}_n(0), \phi_k; t_{k\nu}) - y(t_{n-1} + ch, t_{n-1} + ch, \sigma_n(ch), \phi_k; t_{k\nu})
\]

\[
= E_{n-1}^{(k)}(ch)
\]

\[
+ y(t_{n-1} + ch, t_{n-1} + \hat{\sigma}_n(0), \hat{\phi}_k; t_{k\nu}) - y(t_{n-1} + ch, t_{n-1} + \hat{\sigma}_n(0), \phi_k; t_{k\nu})
\]

\[
= E_{n-2}^{(k)}(ch)
\]

From Theorem 3.9, it follows that

\[
E_{n,1}^{(k)}(h) = \sigma_n(0) - \sigma_n(0) + O(h^{2s+1}) = O(h^{2s+1}),
\]

\[
\|E_n^{(k)}\| := \max_{c\in[0,1]} |E_n^{(k)}(ch)| = O(h^{s+1}).
\]
Moreover, from Corollary 3.8, and considering that \( h\nu = \tau \), one has:

\[
E_{n,2}^{(k)}(ch) = I + O(ch) = \delta \sigma_n(0)
\]

\[
= \Phi(t_{n-1} + ch, t_{n-1}; t_{kv}) [g(t_{n-1}) - y_{n-1}]
\]

\[
+ h \int_0^1 \Psi(t_{n-1} + ch, t_{n-1} + \zeta h - \tau; t_{kv}) \delta \sigma_{n-\nu}(\zeta h) d\zeta
\]

\[
+ ch O(\|\delta \sigma_n(0)\| + \|\delta \sigma_{n-\nu}\|)^2.
\]

By considering that

\[
|\delta \sigma_n(0)| = (n - 1)O(h^{2s+1}), \quad \|\delta \sigma_{n-\nu}\| = O(h^{s+1}),
\]

one eventually derives

\[
\|E_{n,2}^{(k)}\| := \max_{c \in [0,1]} |E_{n,2}^{(k)}(ch)| = O(h^{s+2}),
\]

from which the second part of the statement follows, by taking into account (3.31). Moreover, when \( c = 1 \) then \( t_{n-1} + h = t_n \) and, by virtue of Theorem 2.1 and Theorem 3.10, one obtains:

\[
\int_0^1 \Psi(t_{n-1} + \zeta h - \tau; t_{kv}) \delta \sigma_{n-\nu}(\zeta h) d\zeta
\]

\[
= \int_0^1 G(\zeta h) \left[ \sum_{j=0}^{s-1} P_j(\zeta) \delta \gamma_j^{n-\nu} + \sum_{j \geq s} P_j(\zeta) \gamma_j(\hat{\sigma}_{n-\nu}, \hat{\sigma}_{n-2\nu}) \right]
\]

\[
= \sum_{j=0}^{s-1} \int_0^1 P_j(\zeta) G(\zeta h) d\zeta \left[ \delta \gamma_j^{n-\nu} = O(h^{2s-j}) \right] + \sum_{j \geq s} \int_0^1 P_j(\zeta) G(\zeta h) d\zeta \gamma_j(\hat{\sigma}_{n-\nu}, \hat{\sigma}_{n-2\nu}) = O(h^j)
\]

Consequently,

\[
E_{n,2}^{(k)}(h) = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}),
\]

and also the first part of the statement follows. \qed

3.3. Discretization. The discretization issue proceeds as in the ODE case. In fact, also in the DDE case, the Fourier coefficients (see (3.9) and (3.12)),

\[
\gamma_j(\sigma_n, \sigma_{n-\nu}) = \int_0^1 P_j(\zeta) f(\sigma_n(\zeta h), \sigma_{n-\nu}(\zeta h)) d\zeta, \quad j = 0, \ldots, s - 1,
\]

need to be approximated by using a (interpolatory) quadrature rule of order \( q \), thus providing a possibly different piecewise approximation \( u(t) \),

\[
u(t) \equiv \phi(t), \quad t < t_0, \quad u_n(ch) := u(t_{n-1} + ch), \quad c \in [0, 1], \quad n = 1 - \nu, \ldots, N,
\]

such that, for \( n \geq 1 \):

\[
\sum_{j=0}^{s-1} P_j(c) \hat{\gamma}_j(u_n, u_{n-\nu}), \quad c \in [0, 1], \quad u_n(0) = y_{n-1}.
\]
Consequently,

\begin{equation}
(3.33) \quad u_n(ch) = y_{n-1} + h \sum_{j=0}^{n-1} \int_0^c P_j(x) dx \hat{\gamma}_j(u_n, u_{n-\nu}), \quad c \in [0, 1],
\end{equation}

and

\begin{equation}
(3.34) \quad y_n = y_{n-1} + h \hat{\gamma}_0(u_n, u_{n-\nu}) =: u_n(h),
\end{equation}

where (see (3.9)),

\begin{equation}
(3.35) \quad \hat{\gamma}_j(u_n, u_{n-\nu}) := \sum_{i=1}^{k} b_i P_j(c_i) f(u_n(c_i h), u_{n-\nu}(c_i h)) = \gamma_j(u_n, u_{n-\nu}) - \Delta_j(h),
\end{equation}

with \((c_i, b_i)\) the abscissae and weights of the quadrature, and \(\Delta_j(h) = O(h^{q-j})\) the quadrature error, where \(q\) is the order of the quadrature. By using standard arguments (which we omit, as done in the ODE case), we can derive the following results, representing the corresponding counterparts of Theorem 3.10 and Theorem 3.11, respectively.

**Theorem 3.12.** With reference to (3.7), (3.9), (3.32)-(3.34), and assuming that the quadrature formula (3.35) has order \(q \geq 2s\), if for \(n \geq 1\) one has:

\[
y(t_r) - y_r = y(t_{r-1}) - y_{r-1} + O(h^{2s+1}), \quad r = 1, \ldots, n,
\]

then

\[
\delta\hat{\gamma}_j := \gamma_j(\hat{\sigma}_n, \hat{\sigma}_{n-\nu}) - \hat{\gamma}_j(u_n, u_{n-\nu}) = O(h^{2s-j}), \quad j = 0, \ldots, s-1.
\]

**Theorem 3.13.** With reference to (3.7), (3.9), (3.32)-(3.34), and assuming that the quadrature formula (3.35) has order \(q \geq 2s\), for \(n = 1, \ldots, N \equiv K\nu\) one has:

\[
y(t_n) - y_n = y(t_{n-1}) - y_{n-1} + O(h^{2s+1}), \quad \max_{c \in [0,1]} |\hat{\sigma}_n(ch) - u_n(ch)| = O(h^{s+1}).
\]

**Remark 3.14.** It is worth mentioning that the result of Theorem 3.13 states that the super-convergence order \(2s\) at the mesh-points \(t_n\) is obtained, even though possibly different Runge-Kutta methods are used at each integration step, provided that they define a polynomial approximation of degree \(s\). This, in turn, represents a generalization of the results in [3] for collocation methods.

We conclude this section, by observing that, concerning the implementation of the resulting Runge-Kutta method used for solving problem (3.1), the arguments in Subsection 2.5, mutatis mutandis, apply as well.

**4. Conclusions.** In this paper we have fully developed a thorough approach for obtaining polynomial approximations to the solution of initial value ODE and DDE problems. It allows to eventually derive a wide class of Runge-Kutta methods, whose properties are easily discussed within the framework, as well as their actual implementation. The present approach allows generalizations along several directions: in particular to different kind of problems, besides the ones considered here. Another relevant direction of investigation consists in looking for approximations belonging to functional subspaces different than polynomials: that is, by considering orthonormal functional bases different from (1.3). Both directions will be the subject of future investigations.
