An Algorithmic Meta-Theorem for Graph Modification to Planarity and FOL*

Fedor V. Fomin† Petr A. Golovach† Giannos Stamoulis‡ Dimitrios M. Thilikos§

Abstract
In general, a graph modification problem is defined by a graph modification operation \( \boxtimes \) and a target graph property \( \mathcal{P} \). Typically, the modification operation \( \boxtimes \) may be vertex removal, edge removal, edge contraction, or edge addition and the question is, given a graph \( G \) and an integer \( k \), whether it is possible to transform \( G \) to a graph in \( \mathcal{P} \) after applying \( k \) times the operation \( \boxtimes \) on \( G \). This problem has been extensively studied for particular instantiations of \( \boxtimes \) and \( \mathcal{P} \). In this paper we consider the general property \( \mathcal{P}_\varphi \) of being planar and, moreover, being a model of some First-Order Logic sentence \( \varphi \) (an FOL-sentence). We call the corresponding meta-problem \textsc{Graph }\( \boxtimes \)-Modification to Planarity and \( \varphi \) and prove the following algorithmic meta-theorem: there exists a function \( f : \mathbb{N}^2 \rightarrow \mathbb{N} \) such that, for every \( \boxtimes \) and every FOL sentence \( \varphi \), the \textsc{Graph }\( \boxtimes \)-Modification to Planarity and \( \varphi \) is solvable in \( f(k,|\varphi|) \cdot n^2 \) time. The proof constitutes a hybrid of two different classic techniques in graph algorithms. The first is the irrelevant vertex technique that is typically used in the context of Graph Minors and deals with properties such as planarity or surface-embeddability (that are not FOL-expressible) and the second is the use of Gaifman’s Locality Theorem that is the theoretical base for the meta-algorithmic study of FOL-expressible problems.

Keywords: Graph Modification Problems, Algorithmic Meta-theorems, First-Order Logic, Irrelevant Vertex Technique, Planar Graphs.

1 Introduction
The term algorithmic meta-theorems was coined by Grohe in his seminal exposition in [20] in order to describe results providing general conditions, typically of logical and/or combinatorial nature, that automatically guarantee the existence of certain types of algorithms for wide families of problems. Algorithmic meta-theorems reveal deep relations between logic and combinatorial structures, which is a fundamental issue of computational complexity. Such theorems not only yield a better understanding of the scope of general algorithmic techniques and the limits of tractability but often

provide (or induce) a variety of new algorithmic results. The archetype of algorithmic meta-theorems is Courcelle’s theorem [5,6] stating that all graph properties expressible in Monadic Second-Order Logic (in short, \textit{MSOL-expressible properties}) are fixed-parameter tractable when parameterized by the size of the sentence and the treewidth of the graph.

Our meta-theorem belongs to the intersection of two algorithmic research directions: Deciding First-Order Logic properties on sparse graphs and graph planarization algorithms.

\textbf{FOL-expressible properties on sparse graphs.} For graph properties expressible in First-Order Logic (in short \textit{FOL-expressible properties}), a rich family of algorithmic meta-theorems were developed within the last decades. Each of these meta-theorems can be stated in the following form: for a graph class \( \mathcal{C} \), deciding FOL-expressible properties is fixed-parameter tractable on \( \mathcal{C} \), i.e. there is an algorithm running in \( f(|\varphi|) \cdot n^{O(1)} \) time, where \( |\varphi| \) is the size of the the input FOL-sentence \( \varphi \) and \( n \) is the number of vertices of the input graph. The starting point in the chain of such meta-theorems is the work of Seese [32] for \( \mathcal{C} \) being the class of graphs of bounded degree [32]. The first significant extension of Seese’s theorem was obtained by Frick and Grohe [16] for the class \( \mathcal{C} \) of graphs of bounded local treewidth [16]. The class of graphs of bounded local treewidth contains graphs of bounded degree, planar graphs, graphs of bounded genus, and apex-minor-free graphs. The next step was done by Flum and Grohe [13], who extended these results up to graph classes excluding some minor. Dawar, Grohe, and Kreutzer [10] pushed the tractability border up to graphs locally excluding a minor. Further extension was due to Dvořák, Král, and Thomas, who proved tractability for the class \( \mathcal{C} \) of being locally bounded expansion [12]. Finally, Grohe, Kreutzer, and Siebertz [22] established fixed-parameter tractability for classes that are effectively nowhere dense. In some sense, the result of Grohe et al. is the culmination of this long line of meta-theorems, because for somewhere dense graph classes closed under taking subgraphs deciding first-order properties is unlikely to be fixed-parameter tractable [12,25].

Notice that the above line of results also shed some light on graph modification problems. In particular, since many modification operations are FOL-expressible, in some situations when the target property \( \mathcal{P} \) is FOL-expressible, the above meta-algorithmic results can be extended to graph modification problems. As a concrete example, consider the problem of removing at most \( k \) vertices to obtain a graph of degree at most 3. All vertices of the input graph of degree at least \( 4 + k \) should be deleted, so we delete them and adapt the parameter \( k \) accordingly. In the remaining graph all vertices are of degree at most \( 3 + k \) and the property of removing at most \( k \) vertices from such a graph to obtain a graph of degree at most 3 is FOL-expressible. Hence the Seese’s theorem implies that there is an algorithm of running time \( f(k) \cdot n^{O(1)} \) solving this problem. However these theories are not applicable with instantiations of \( \mathcal{P} \), like planarity, that are not FOL-expressible.

Another island of tractability for graph modification problems is provided by Courcelle’s theorem and similar theorems on graphs of bounded widths. For example, graph modification problems are fixed-parameter tractable in cases where the target property \( \mathcal{P} \) is MSOL-expressible under the additional assumption that the graphs in \( \mathcal{P} \) have fixed treewidth (or bounded rankwidth, for MSOL\(_1\)-properties, see e.g., [8]).

To conclude, according to the current state of the art, all known algorithmic meta-theorems concerning fixed-parameter tractability of graph modification problems are attainable either when the target property \( \mathcal{P} \) is FOL-expressible and the structure is sparse or when \( \mathcal{P} \) is MSOL/MSOL\(_1\)-expressible and the structure has bounded tree/rank-width. Interestingly, \textit{planarity} is the typical property that escapes the above pattern: it is not FOL-expressible and it has unbounded treewidth.
Graph planarization. The **Planar Vertex Deletion** problem is a generalization of planarity testing. For a given graph $G$ the goal is to find a vertex set of size at most $k$ whose removal makes the resulting graph planar. Planarity is a nontrivial and hereditary graph property, hence by the result of Lewis and Yannakakis [26], the decision version of **Planar Vertex Deletion** is \( \text{NP} \)-complete. The parameterized complexity of this problem has been extensively studied.

The non-uniform fixed-parameter tractability of **Planar Vertex Deletion** (parameterized by $k$) follows from the deep result of Robertson and Seymour in Graph Minors theory [31], that every minor-closed graph class can be recognized in polynomial time. Since the class of graphs that can be made planar by removing at most $k$ vertices is minor-closed, the result of Robertson and Seymour implies that for **Planar Vertex Deletion**, for each $k$, there exists a (non-uniform) algorithm that in time \( O(n^3) \) solves **Planar Vertex Deletion**. Significant amount of work was involved to improve the enormous constants hidden in the big-Oh and the polynomial dependence in $n$. Marx and Schlotter [28] gave an algorithm that solves the problem in time $f(k) \cdot n^2$, where $f$ is some function of $k$ only. Kawarabayashi [24] obtained the first linear time algorithm of running time $f(k) \cdot n$ and Jansen, Lokshtanov, and Saurabh [23] obtained an algorithm of running time $O(2^{O(k \log k)} \cdot n)$. For the related problem of contracting at most $k$ edges to obtain a planar graph, **Planar Edge Contraction**, an $f(k) \cdot n^{O(1)}$ time algorithm was obtained by Golovach, van ’t Hof and Paulusma [19]. Approximation algorithms for **Planar Vertex Deletion** and for **Planar Edge Deletion** were studied in [2–4].

**Our results.** Let $\Box$ be one of the following operations on graphs: Vertex removal, edge removal, edge contraction, or edge addition. We are interested whether, for a given graph $G$ and an FOL-sentence $\varphi$, it is possible to transform $G$ by applying at most $k$ $\Box$-operations, into a planar graph with the property defined by $\varphi$. We refer to this problem as the **Graph $\Box$-Modification to Planarity and $\varphi$** problem. For example, when $\Box$ is the vertex removal operation, then the problem is **Planar Vertex Deletion**. Similarly, **Graph $\Box$-Modification to Planarity and $\varphi$** generalizes **Planar Edge Deletion** and **Planar Edge Contraction**. On the other hand, for the special case of $k = 0$ this is the problem of deciding FOL-expressible properties on planar graphs.

Examples of first-order expressible properties are deciding whether there the input graph $G$ contains a fixed graph $H$ as a subgraph (**H-Subgraph Isomorphism**), deciding whether there is a homomorphism from a fixed graph $H$ to $G$ to (**H-Homomorphism**), satisfying degree constraints (the degree of every vertex of the graph should be between $a$ and $b$ for some constants $a$ and $b$), excluding a subgraph of constant size or having a dominating set of constant size. Thus **Graph $\Box$-Modification to Planarity and $\varphi$** encompasses the variety of graph modification problems to planar graphs with specific properties. For example, can we delete $k$ vertices (or edges) such that the obtained graph is planar and each vertex belongs to a triangle? Reversely, can we delete at most $k$ vertices (or edges) from a graph such that the resulting graph is a triangle-free planar graph? Can we add (or contract) at most $k$ edges such that the resulting graph is 4-regular and planar? Or can we delete at most $k$ edges resulting in a square-free or claw-free planar graph?

Informally, our main result can be stated as follows.

**Theorem (Informal)** **Graph $\Box$-Modification to Planarity and $\varphi$** is solvable in time $f(k, \varphi) \cdot n^2$, for some function $f$ depending on $k$ and $\varphi$ only. Thus the problem is fixed-parameter tractable, when parameterized by $k + |\varphi|$. 

3
Our theorem not only implies that Planar Vertex Deletion is fixed-parameter tractable parameterized by \( k \) (proved in [23,28]) and that deciding whether a planar graph has a first-order logic property \( \varphi \) is fixed-parameter tractable parameterized by \( |\varphi| \) (that follows from [10,12,16,22]). It also implies a variety of new algorithmic results about graph modification problems to planar graphs with some specific properties that cannot be obtained by applying the known results directly. Of course, for some formulas \( \varphi \), Graph \( \otimes \)-Modification to Planarity and \( \varphi \) can be solved by more simple techniques. For example, if \( \varphi \) defines a hereditary property characterized by a finite family of forbidden induced subgraphs \( \mathcal{F} \), then deciding, whether it is possible to delete at most \( k \) vertices to obtain a planar \( \mathcal{F} \)-free graph, can be done by combining the straightforward branching algorithm and, say, the algorithm of Jansen, Lokshtanov, and Saurabh [23] for Planar Vertex Deletion. For this, we iteratively find a copy of each \( F \in \mathcal{F} \) and if such a copy exists we branch on all the possibilities to destroy this copy of \( F \) by deleting a vertex. By this procedure, we obtain a search tree of depth at most \( k \), whose leaves are all \( \mathcal{F} \)-free induced subgraphs of the input graph that could be obtained by at most \( k \) vertex deletions. Then for each leaf, we use the planarization algorithm limited by the remaining budget. However, this does not work for edge modifications, because deleting an edge in order to ensure planarity may result in creating a copy of a forbidden subgraph. For such type of problems, even for very “simple” ones, like deleting \( k \) edges to obtain a claw-free planar graph, or planar graph without induced cycles of length 4, our theorem establishes the first fixed-parameter algorithms. Also our theorem is applicable to the situation when \( \varphi \) defines a hereditary property that requires an infinite family of forbidden subgraphs for its characterization and for non-hereditary properties expressible in FOL.

The price we pay for such generality is the running time. While the polynomial factor in the running time of our algorithm is comparable with the running time of the algorithm of Marx and Schlotter [28] for Planar Vertex Deletion, it is worse than the more advanced algorithms of Kawarabayashi [24] and Jansen et al. [23]. Similarly, the algorithms for deciding first-order logic properties on graph classes [12,16,22] are faster than our algorithm.

The proof of the main theorem is based on a non-trivial combination of the irrelevant vertex technique of Robertson and Seymour [29,30] with the Gaifman’s Locality Theorem [17]. While both techniques were widely used, see [1,9,19,21,23,27] and [10,13,16], the combination of the two techniques requires novel ideas. Following the popular trend in Theoretical Computer Science, an alternative title for our paper could be “Robertson and Seymour meet Gaifman”.

2 Problem definition and preliminaries

In this section we formally define the general Graph \( \otimes \)-Modification to Planarity and \( \varphi \) problem (Subsection 2.1), present the theoretical background around Gaifman’s Locality Theorem (Subsection 2.2), and provide the main algorithm supporting the proof (Subsection 2.3) whose more precise description is postponed till Section 3.

2.1 Modifications on graphs.

We define \( \text{OP} := \{ \text{vr, er, ec, ea} \} \), that is the set of graph operations of removing a vertex, removing an edge, contracting an edge, and adding an edge, respectively. Given an operation \( \otimes \in \text{OP} \), a graph \( G \), and a vertex set \( R \subseteq V(G) \), we define the application domain of the operation \( \otimes \) as
Notice that \( \boxtimes (G, R) \) is either a vertex set or a set of subsets of vertices each of size two.

Given a set \( S \subseteq \boxtimes (G, R) \), we define \( G \boxtimes S \) as the graph obtained after applying the operation \( \boxtimes \) on the elements of \( S \). The vertices of \( G \) that are affected by the modification of \( G \) to \( G \boxtimes S \), denoted by \( A(S) \), are the vertices in \( S \), in case \( \boxtimes = \text{vr} \) or the endpoints of the edges of \( S \), in case \( \boxtimes \in \{ \text{er, ec, ea}\} \).

Given an FOL-sentence \( \varphi \) and some \( \boxtimes \in \text{OP} \), we define the following meta-problem:

<table>
<thead>
<tr>
<th>Graph ( \boxtimes )-Modification to Planarity and ( \varphi ) (In short: ( \text{GMP} \varphi ))</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input:</strong> A graph ( G ) and a non-negative integer ( k ).</td>
</tr>
<tr>
<td><strong>Question:</strong> Is there a set ( S \subseteq \boxtimes (G, V(G)) ) of size ( k ) such that ( G \boxtimes S ) is a planar graph and ( G \boxtimes S \models \varphi )?</td>
</tr>
</tbody>
</table>

Let \( (x_1, \ldots, x_\ell) \in \mathbb{N}^\ell \) and \( f, g : \mathbb{N} \to \mathbb{N} \). We use notation \( f(n) = O_{x_1, \ldots, x_\ell}(g(n)) \) to denote that there exists a computable function \( h : \mathbb{N}^\ell \to \mathbb{N} \) such that \( f(n) = h(x_1, \ldots, x_\ell) \cdot g(n) \). We are ready to give the formal statement of the main theorem of this paper.

**Theorem 1.** There exists a function \( f : \mathbb{N}^2 \to \mathbb{N} \) such that, for every FOL-sentence \( \varphi \) and for every \( \boxtimes \in \text{OP} \), \( \text{GMP} \varphi \) is solvable in \( O_{k,|\varphi|}(n^2) \) time.

### 2.2 Gaifman’s theorem

For vertices \( u, v \) of graph \( G \), we use \( d_G(u, v) \) to denote the distance between \( u \) and \( v \) in \( G \). We also use \( N^{(r)}_G(v) \) to denote the set of vertices of \( G \) at distance at most \( r \) from \( v \).

Gaifman’s locality theorem is an important ingredient of our proof. We use the shortcut \( \text{FOL-formula/sentence} \) for logical formulas/sentences in First-Order Logic. Given an FOL-formula \( \psi(x) \) with one free variable \( x \), we say that \( \psi(x) \) is \( r \)-local if the validity of \( \psi(x) \) depends only on the \( r \)-neighborhood of \( x \), that is for every graph \( G \) and \( v \in V(G) \) we have

\[
G \models \psi(v) \iff G[N^{(r)}_G(v)] \models \psi(v).
\]

Observe that there exists an FOL-formula \( \delta_r(x, y) \) such that for every graph \( G \) and \( v, u \in V(G) \), we have \( d_G(u, v) \leq r \iff G \models \delta_r(v, u) \) (see [14, Lemma 12.26]).

We say that an FOL-sentence \( \varphi \) is a Gaifman sentence when it is a Boolean combination of sentences \( \varphi_1, \ldots, \varphi_m \) such that, for every \( h \in [m] \),

\[
\varphi_h = \exists x_1 \ldots \exists x_{\ell_h} \left( \bigwedge_{1 \leq i < j \leq \ell_h} d(x_i, x_j) > 2r_h \land \bigwedge_{i \in [\ell_h]} \psi_h(x_i) \right),
\]

where \( \ell_h, r_h \geq 1 \) and \( \psi_h \) is an \( r_h \)-local formula with one free variable. We refer to the variables \( x_1, \ldots, x_{\ell_h} \) for each \( h \in [m] \) as the basic variables of \( \varphi \). Moreover, for every \( h \in [m] \), we call \( \varphi_h \) a basic sentence of \( \varphi \) and the formula \( \psi_h \) a basic local formula of \( \varphi \).

**Proposition 2** (Gaifman’s Theorem [17]). Every first-order sentence \( \varphi \) is equivalent to a Gaifman sentence \( \varphi' \). Furthermore, \( \varphi' \) can be computed effectively.
2.3 Equivalent formulations

Given a Gaifman sentence $\varphi$ combined from sentences $\varphi_1, \ldots, \varphi_m$ and a unary relation symbol $R$, we define $\tilde{\varphi}$ as the sentence that is the same Boolean combination of sentences $\tilde{\varphi}_1, \ldots, \tilde{\varphi}_m$ such that, for every $h \in [m]$, 

$$\tilde{\varphi}_h = \exists x_1 \ldots \exists x_{\ell_h} \left( \bigwedge_{i \in \ell_h} x_i \in R \land \bigwedge_{1 \leq i < j \leq \ell_h} d(x_i, x_j) > 2r_h \land \bigwedge_{i \in \ell_h} \psi_h(x_i) \right),$$

(2)

where $\ell_h, r_h \geq 1$ and $\psi_h$ is an $r_h$-local formula with one free variable. Notice that $\tilde{\varphi}$ is evaluated on annotated graphs of the form $(G, R)$.

Let $(G, k)$ be an instance of the $G\Box \text{MP}_{\varphi}$ problem. We may assume, because of Proposition 2, that $\varphi$ is a Gaifman sentence. We consider an enhanced version of the $G\Box \text{MP}_{\varphi}$ problem as follows. Let $(G, R, k)$ be a triple, where $G$ is a graph, $R \subseteq V(G)$, and $k \in \mathbb{N}$. We say that $(G, R, k)$ is a $(\varphi, \Box)-$triple if there exists set $S \subseteq \Box(G, R)$ such that $|S| \leq k$, $G \Box S$ is a planar graph, and $(G, R, k) \models \tilde{\varphi}$. It is easy to observe that the property that $(G, R, k)$ is a $(\varphi, \Box)-$triple can be expressed in MSOL. This is easy in case $\Box \in \{\text{vr}, \text{er}, \text{ec}\}$. In the case where $\Box = \text{ea}$, we use some syntactic interpretation argument, given in Section 4 (Lemma 7).

Also, we say that a set $S \subseteq \Box(G, V(G))$ is a $\Box$-planarizer of $G$ if $G \Box S$ is planar. Theorem 1 is a consequence of the following lemma.

**Lemma 3.** Given a Gaifman sentence $\varphi$ and a $\Box \in \text{OP}$, there exists a function $f_1 : \mathbb{N}^2 \to \mathbb{N}$, and an algorithm with the following specifications:

**Reduce Instance**($k, G, S, R$)

Input: an integer $k \in \mathbb{N}$, a graph $G$, a set $R \subseteq V(G)$, and a set $S \subseteq R$ that is a vr-planarizer of $G$ of size at most $k$.

Output: One of the following:

1. if $\Box \in \{\text{er}, \text{ec}, \text{ea}\}$: a report that $(G, k)$ is a no-instance of $G\Box \text{MP}_{\varphi}$.

   - if $\Box = \text{vr}$: a vertex $u \in S$ such that $S \setminus \{u\}$ is a vr-planarizer of $G \setminus u$ of size at most $k - 1$ and $(G, k)$ and $(G \setminus u, k - 1)$ are equivalent instances of $G\Box \text{MP}_{\varphi}$.

2. a vertex set $X \subseteq V(G)$ and a vertex $v \in X$ such that $S \subseteq R \setminus X$ and $(G, R, k)$ is a $(\varphi, \Box)$-triple if and only if $(G \setminus v, R \setminus X, k)$ is a $(\varphi, \Box)$-triple.

3. a tree decomposition of $G$ of width at most $f_1(k, |\varphi|)$.

Moreover, this algorithm runs in $O_{k,|\varphi|}(n)$ steps.

We postpone the formal definitions of a tree decomposition and treewidth till Section 4. Given Lemma 3, Theorem 1 can be proved as follows.

**Proof of Theorem 1.** Let $\varphi$ be an FOL-formula. By Proposition 2, $\varphi$ is equivalent to a Gaifman sentence $\varphi'$. Using the planarization algorithm from [23], we compute, in $O_{k}(n)$ steps, a vr-planarizer $S$ of $G$ of size at most $k$. If $\Box = \text{ea}$, then $S := \emptyset$, while if $\Box \in \{\text{vr}, \text{er}, \text{ec}\}$, then if such a set does not exist the we safely return a negative answer (for the case of $\Box = \text{er}, \text{ec}$, this is due to the fact that if there exists an ec- or an er-planarizer of $G$ of size at most $k$ then also a vr-planarizer...
of $G$ of size at most $k$ exists, see [19, Lemma 1]). We are now in position to apply recursively the algorithm \textbf{Reduce Instance}($k, G, S, R$) of Lemma 3 until either an answer or the third case appears. In the first case, we either return a negative answer, if $\Xi \in \{er, ec, ea\}$, or set $(k, G, S, R) := (k - 1, G \setminus v, S \setminus v, R)$ if $\Xi = vr$, while in the second case we set $(k, G, S, R) := (k, G \setminus v, S, R \setminus X)$. In the third case we have that $tw(G) \leq f_1(k, |\varphi'|)$. Recall that the property that $(G, R, k)$ is a $(\varphi, \Xi)$-triple can be expressed in MSOL, thus the status of the final equivalent instance $(G, R, k)$ can be evaluated in $O_{k,|\varphi|}(n)$ steps by applying Courcelle’s theorem. As the recursion takes at most $n$ steps, we obtain the claimed running time. 

3 The algorithm

In this section, we aim to present the proof of Lemma 3. In Subsection 3.1, we present the two main lemmata (Lemma 4 and Lemma 5) that support the proof of Lemma 3 and in Subsection 3.2 we sketch the proof of Lemma 5, which contains the core of the arguments of this paper.

3.1 Two main lemmata

We now give two lemmata, whose combination gives the proof of Lemma 3. Before we state them, we give a series of definitions. Some of them will be given on an intuitive level, while their formal versions are postponed to Section 4. The proofs of the two lemmata are postponed to Section 5 and Section 6, respectively.

Let $\Xi \in \Omega P$, $G$ be a graph, $k \in \mathbb{N}$, and let $S$ be a $\Xi$-planarizer of $G$. We say that $S$ is an \textit{inclusion-minimal $\Xi$-planarizer} of $G$ if none of its proper subsets is a $\Xi$-planarizer of $G$. Notice that, in the special case where $\Xi = ea$, the unique inclusion-minimal $\Xi$-planarizer of $G$ is the empty set of edges. We say that a set $Q \subseteq V(G)$ is $\Xi$-planarization irrelevant if for every inclusion-minimal $\Xi$-planarizer $S$ of $G$ that has size at most $k$, it holds that $A(S) \cap Q = \emptyset$. We say that a graph $G$ is \textit{partially disk-embedded in some closed disk $\Delta$}, if there is some subgraph $K$ of $G$ that is embedded in $\Delta$ whose boundary, denoted by $bd(\Delta)$, is a cycle of $K$ and no vertex in the interior of $\Delta$ is adjacent to a vertex not in $\Delta$. We use the term \textit{partially $\Delta$-embedded graph} $G$ to denote that a graph $G$ is partially disk-embedded in some closed disk $\Delta$. We also call the graph $K$ \textit{compass} of the partially $\Delta$-embedded graph $G$ and we always assume that we accompany a partially $\Delta$-embedded graph $G$ together with an embedding of its compass in $\Delta$ that is the set $G \cap \Delta$.

The concept of $q$-wall, where $q$ is odd, is visualized in Figure 1. In the same figure are depicted the \textit{layers} (in red and blue) and the \textit{perimeter} (the outermost layer) of a $q$-wall (the formal definitions are postponed in Section 4). Also the \textit{branch vertices} are depicted in yellow. Let $W$ be a wall of a graph $G$. We use $\text{perim}(W)$ to denote the perimeter of $W$ and we call \textit{central vertices} the two branch vertices of $W$ that do not belong to any layer and are connected by a path that does not intersect any layer, which we denote by $\text{center}(W)$ (depicted by two orange squared vertices in Figure 1). Let $K'$ be the connected component of $G \setminus \text{perim}(W)$ that contains $W \setminus \text{perim}(W)$. The \textit{compass} of $W$, denoted by $\text{comp}(W)$, is the graph $G[V(K') \cup V(\text{perim}(W))]$. Observe that $W$ is a subgraph of $\text{comp}(W)$ and $\text{comp}(W)$ is connected. In what follows we will always consider walls that are drawn inside the disk of a partially $\Delta$-embedded graph. Therefore, we can see the compass of $W$ as the part of the graph that is drawn inside the closed disk boundary the perimeter of $W$. We are now in position to state the following two lemmata.

7
Lemma 4. Given a $\square \in \text{OP}$, there exist two functions $f_1, f_2 : \mathbb{N}^2 \to \mathbb{N}$, and an algorithm with the following specifications:

**Find Area** $(k, q, G, S)$

Input: a $k \in \mathbb{N}$, an odd $q \in \mathbb{N}_{\geq 1}$, a graph $G$, and a set $S \subseteq V(G)$ that is a $\vr$-planarizer of $G$ of size at most $k$.

Output: One of the following:

1. if $\square \in \{\text{er, ec, ea}\}$: a report that $(G, k)$ is a no-instance of $G \varpi \text{MP}_\varphi$.
   - if $\square = \text{vr}$: a vertex $u \in S$ such that $S \setminus u$ is a $\vr$-planarizer of $G \setminus u$ of size at most $k - 1$ and $(G, k)$ and $(G \setminus u, k - 1)$ are equivalent instances of $G \varpi \text{MP}_\varphi$.

2. a $q$-wall $W$ of $G$ and a closed disk $\Delta$ such that
   - the compass of $W$ has treewidth at most $f_2(k, q)$,
   - $G$ is partially $\Delta$-embedded, where $G \cap \Delta = \text{comp}(W)$, $\text{bd}(\Delta) = \text{perim}(W)$,
   - $V(\text{comp}(W))$ is $\square$-planarization irrelevant, and
   - $N_G(S) \cap V(\text{comp}(W)) = \emptyset$, or

3. a tree decomposition of $G$ of width at most $f_1(k, q)$.

Moreover, this algorithm runs in $O_{k,q}(n)$ steps.

By $N_G(S)$ we denote the vertices not in $S$ adjacent, in $G$, with vertices in $S$. In the first possible output of the algorithm of Lemma 4 we have either a negative answer to the $G \varpi \text{MP}_\varphi$ problem or an equivalent instance of $G \varpi \text{MP}_\varphi$ with reduced value of $k$.

The proof of Lemma 4 is in Section 5 and its main steps are the following. In case, $\square = \text{ea}$ we first check whether $G$ is planar. If not, we report a negative answer, otherwise we find a wall $W$ in $G$ whose size is a “big-enough” function of $k$ and whose compass has “small-enough” treewidth using [18, Lemma 4.2]. This wall contains an (also “big-enough”) subwall of $W$ whose compass is not affected by $S$. In case $\square = \{\text{vr, er, ec}\}$, we consider the neighbors of $S$ in the planar graph $G'$, that is the set $N := N_G(S)$. Moreover, we consider a big enough triangulated grid $\Gamma$ as a contraction of $G'$ (using [15, Theorem 3]) and the set $N_{\Gamma}$ of the “contraction-heirs” of the vertices of $N$ in $\Gamma$. If
$|N_r|$ is “big-enough”, then we prove, using the main technical result of [11], that some of the vertices of $S$ should be affected by every possible solution, in case $\mathbb{X} = \mathbb{v}r$, or that we have a no-instance, in case $\mathbb{X} \in \{\mathbb{e}r, \mathbb{e}c\}$. If $|N_r|$ is “small-enough”, then we can find a “big-enough” wall $W$ in $G$ whose compass is not affected by $S$ (again using the previously mentioned result of [18]). The proof is completed by proving that this wall contains some “big-enough” subwall that is not affected by any inclusion-minimal $\mathbb{e}$-planarizer.

The next lemma deals with the second possible output of the algorithm of Lemma 4 and contains the “core arguments” of this paper.

**Lemma 5.** Given a Gaifman sentence $\varphi$ and a $\mathbb{X} \in \mathbb{O}P$, there exist a function $f_3 : \mathbb{N}^2 \rightarrow \mathbb{N}$, whose images are odd integers, and an algorithm with the following specifications:

**Find_Vertex**($k, \Delta, G, R, \mathbb{W}$)

*Input:* a $k \in \mathbb{N}$, a partially $\Delta$-embedded graph $G$, a set of (annotated) vertices $R \subseteq V(G)$, and a $q$-wall $W$ of $G$ such that

- $q = f_3(k, |\varphi|)$,
- the compass of $\mathbb{W}$ has treewidth at most $f_2(k, q)$,
- $G \cap \Delta = \text{comp}(\mathbb{W})$, $\text{bd}(\Delta) = \text{perim}(\mathbb{W})$,
- $V(\text{comp}(\mathbb{W}))$ is $\mathbb{X}$-planarization irrelevant, and

*Output:* a vertex set $X \subseteq V(\text{comp}(\mathbb{W}))$ and a vertex $v \in X$ such that $(G, R, k)$ is a $(\varphi, \mathbb{X})$-triple if and only if $(G \setminus v, R \setminus X, k)$ is a $(\varphi, \mathbb{X})$-triple.

Moreover, this algorithm runs in $O_{k, |\varphi|}(n)$ steps.

Notice that the above algorithm produces a $(\varphi, \mathbb{X})$-triple where both $R$ and $G$ are reduced. To see why Lemma 3 follows from Lemma 4 and Lemma 5, observe that in the second possible output of the algorithm **Find_Area**($k, q, G, S$) we can call the algorithm **Find_Vertex**($k, \Delta, G, R, \mathbb{W}$), where $\mathbb{W} := W$, which outputs a vertex set $X \subseteq V(\text{comp}(\mathbb{W}))$ and a vertex $v \in X$ such that $(G, R, k)$ is a $(\varphi, \mathbb{X})$-triple if and only if $(G \setminus v, R \setminus X, k)$ is a $(\varphi, \mathbb{X})$-triple. Observe that since $N_G(S) \cap V(\text{comp}(W)) = \emptyset$, then $S \subseteq R \setminus X$. We insist that the algorithm **Find_Vertex**($k, \Delta, G, R, \mathbb{W}$) does not use the fact that $N_G(S) \cap V(\text{comp}(\mathbb{W})) = \emptyset$ but we use the latter to guarantee that $S \subseteq R \setminus X$. For the running time of Lemma 3, recall that the two algorithms of Lemma 4 and Lemma 5 run in $O_{k, |\varphi|}(n)$ steps.

### 3.2 Sketch of the proof of Lemma 5

In order to prove Lemma 5, we first find a collection $\mathcal{W}$ of “many-enough” subwalls of $\mathbb{W}$ each with $\rho$ layers (where $\rho$ is “big-enough”), whose compasses are pairwise vertex-disjoint. We keep in mind that every wall in $\mathcal{W}$ has height $2\rho + 1$ and $\rho$ layers.

The key idea is to define a “characteristic” of each wall $W \in \mathcal{W}$ that encodes all possible ways that a $\mathbb{X}$-planarizer $S$ of $G$ affects $\text{comp}(W)$ along with the ways that the fact that $G \mathbb{X} S \models \varphi$ is certified by a vertex assignment to the basic variables of the Gaifman formula $\varphi$ in $\text{comp}(W)$. Recall that $\bar{\varphi}$ is a Boolean combination of sentences $\bar{\varphi}_1, \ldots, \bar{\varphi}_m$, so that for every $h \in [m]$,

$$
\bar{\varphi}_h = \exists x_1 \ldots \exists x_{\ell_h} ( \bigwedge_{i \in [\ell_h]} x_i \in R \wedge \bigwedge_{1 \leq i < j \leq \ell_h} d(x_i, x_j) > 2r_h \wedge \bigwedge_{i \in [\ell_h]} \psi_h(x_i)),
$$
where } ℓ_h, r_h \geq 1 \text{ and } \psi_h \text{ is an } r_h\text{-local formula with one free variable and that } \bar{\varphi} \text{ is evaluated on annotated graphs of the form } (G, R). \text{ Clearly, } \bar{\varphi} \text{ is a sentence in Monadic Second Order Logic, in short, a } \text{MSOL-sentence. We set } r := \max_{h \in [m]} \{ r_h \}, \ell := \sum_{h \in [m]} ℓ_h, \text{ and } d := 2(r + (\ell + 1)r + r).

As a first step, let } \text{SIG} = 2^{[\ell]} \times \cdots \times 2^{[\ell]} \times [r]. \text{ Also, for every wall } W \in \mathcal{W}, \text{ let } K := \text{comp}(W), \text{ for every } t \in [r], \text{ let } K^{(t)} := \text{comp}(W(2t+1)) \text{ and } P^{(t)} := V(\text{perim}(W(2t+1))). \text{ Here, by } W^{(t)} \text{ we denote the subwall of } W \text{ that has height } t, \text{ its layers are the last } \frac{t}{2} \text{ layers of } W, \text{ and has the same center as } W. \text{ We set } K = (V(K^{(1)}), \ldots, V(K^{(\rho)})). \text{ We call the tuple } \mathfrak{R}_W = (K, K) \text{ the } \text{extended compass} \text{ of the wall } W \text{ in } G. \text{ Given the extended compass } \mathfrak{R}_W \text{ of a wall } W \in \mathcal{W}, \text{ a set } R \subseteq V(\text{comp}(W)), \text{ an integer } z \in [d, \rho], \text{ and a set } S \subseteq \mathcal{X}(K, R) \text{ such that } A(S) \subseteq V(K^{(z-d+1)}) \cap R, \text{ we define}

\[ \sigma_{\varphi, \mathcal{X}}(\mathfrak{R}_W, R, z, S) = \{(Y_1, \ldots, Y_m, t) \in \text{SIG} \mid t \leq z \text{ and } \exists (\tilde{X}_1, \ldots, \tilde{X}_m) \text{ such that } \forall h \in [m] X_h = \{x_i^h \mid i \in Y_h\}, \quad \tilde{X}_h \subseteq V((K^{(t-r+1)} \otimes S) \setminus P^{(t-r+1)}) \cap R, \quad \tilde{X}_h \text{ is } (|Y_h|, r_h)\text{-scattered in } K^{(t)} \otimes S, \text{ and } K^{(t)} \otimes S \models \bigwedge_{x \in \tilde{X}_h} \psi_h(x). \]

In the above definition, a set } X \text{ of vertices is } (\alpha, \beta)\text{-scattered, if } |X| = \alpha \text{ and there are no two vertices in } X \text{ within distance } \leq 2\beta. \text{ Intuitively, } (Y_1, \ldots, Y_m, t) \in \sigma_{\varphi, \mathcal{X}}(\mathfrak{R}_W, R, z, S) \text{ if the application of the operation } \otimes \text{ on } G \text{ as defined by } S \text{ gives rise to the existence of a collection of scattered sets } (\tilde{X}_1, \ldots, \tilde{X}_m) \text{ in } (K^{(t-r+1)} \otimes S) \setminus P^{(t-r+1)} \text{ (one scattered set for each basic sentence } \varphi_h) \text{ so that when the vertices of } \tilde{X}_h \text{ are assigned to the basic variables of } \varphi_h \text{ corresponding to } Y_h, \text{ the local basic formula } \psi_h \text{ is satisfied for each } x \in \tilde{X}_h \text{ in the modified graph. Also, notice that } (Y_1, \ldots, Y_m, t) \in \sigma_{\varphi, \mathcal{X}}(\mathfrak{R}_W, R, z, S) \text{ only if } t \leq r, \text{ and, in particular, for every } h \in [m], \tilde{X}_h \subseteq V(K^{(z)} \otimes S) \text{ (since, otherwise, } K^{(z)} \otimes S \text{ can not be a model of } \bigwedge_{x \in \tilde{X}_h} \psi_h(x)). \text{ It is now time to define the characteristic of a wall } W \in \mathcal{W}. \text{ Given the extended compass } \mathfrak{R}_W \text{ of a wall } W \in \mathcal{W} \text{ in } G \text{ and a set } R \subseteq V(\text{comp}(W)), \text{ we define the } (\varphi, \otimes)\text{-characteristic of } (\mathfrak{R}_W, R) \text{ as follows}

\[ (\varphi, \otimes)\text{-char}(\mathfrak{R}_W, R) = \{(z, \sigma, s) \in [d, \rho] \times 2^{\text{SIG}} \times [0, k] \mid \exists S \subseteq \mathcal{X}(K, R) \text{ such that}, \quad A(S) \subseteq V(K^{(z-d+1)}) \cap R, \quad |S| = s, \ K \otimes S \text{ is planar, and} \quad \sigma_{\varphi, \mathcal{X}}(\mathfrak{R}, R, z, S) = \sigma \}. \]

Notice that all queries in the definition of } (\varphi, \otimes)\text{-char}(\mathfrak{R}_W, R) \text{ can be expressed in MSOL. Indeed, this is easy to see when } \mathcal{X} \in \{ \text{vr, er, ec} \}, \text{ as in this case the query "comp}(W) \otimes S \text{ is planar" is trivially true, since } V(\text{comp}(W)) \text{ is } \mathcal{X}\text{-planarization irrelevant. In the case where } \mathcal{X} = \text{ea, the MSOL expressibility is proved in Section 4 (Lemma 7). As each } W \in \mathcal{W} \text{ has treewidth bounded by a function of } k \text{ and } |\varphi|, \text{ it follows by the theorem of Courcelle that } (\varphi, \otimes)\text{-char}(\mathfrak{R}_W, R) \text{ can be computed in } O_{k, |\varphi|}(n) \text{ time.
For every wall $W_i \in W$, we set $K_i := \text{comp}(W_i)$, for every $j \in [\rho]$, $K^{(j)}_i := \text{comp}(W_{i}^{(j+1)})$ and $P^{(j)}_i := V(\text{perim}(W_{i}^{(j+1)}))$, $\mathfrak{A}_i := \mathfrak{R}_W$ and $R_i := R \cap V(\text{comp}(W_i))$. We say that two walls $W_1, W_2$ are $(\varphi, \mathfrak{A})$-equivalent if $(\mathfrak{A}_1, R_1)$ and $(\mathfrak{A}_2, R_2)$ have the same $(\varphi, \mathfrak{A})$-characteristic. Since the collection $W$ contains “many-enough” walls, then we can find a collection $W' \subseteq W$ of also “many-enough” walls that are pairwise equivalent. We fix a wall $W_1 \in W'$ and we set $X := \text{comp}(W_1^{(r)})$, where $r = \max_{h \in [\rho]} \{r_h\}$, and $v \in \text{center}(W_1)$.

In what follows, we highlight the ideas of the proof of the fact that if $(G, R, k)$ is a $(\varphi, \mathfrak{A})$-triple, then $(G \setminus v, R \setminus X, k)$ is a $(\varphi, \mathfrak{A})$-triple. We first consider a set $S \subseteq \mathfrak{A}(G, R)$ of size at most $k$ that certifies that $(G, R, k)$ is a $(\varphi, \mathfrak{A})$-triple. Then, we pick a wall $W_2 \in W' \setminus \{W_1\}$ whose compass is not affected by $S$. We are allowed to pick this wall since there are “many-enough” walls equivalent to $W_1$ in $W'$. Our strategy is to use the fact that $W_1$ and $W_2$ are $(\varphi, \mathfrak{A})$-equivalent in order to state a “replacement argument”: we can find a $z \in [\rho]$, such that the subset $S_{in}$ of $S$ that affects $K^{(z)}_1$ and the set $X$ of vertices of $K^{(z)}_1$ that are assigned to the basic variables of $\varphi$ in order to certify that $G \boxdot S \models \varphi$, can be replaced by their “equivalent” sets $\tilde{S}$ and $\tilde{X}$ in $K^{(z)}_2$. As a consequence of this, for every possible solution $S$ and vertex assignment to the basic variables of $\varphi$, we can find both a new solution and a new vertex assignment that “avoid” the “inner part” of $W_1$. This implies that the validity of any basic local formula of $\varphi$ does not depend on the central vertices of $W_1$. Thus, we can declare one of them “irrelevant” and safely remove it from $G$, while storing (by reducing $R$ to $R \setminus X$) the fact that every possible solution $S$ and vertex assignment to the basic variables of $\varphi$ can “avoid” the “inner part” of $W_1$.

To further inspect how this “replacement” is achieved, we need to dive deeper into the technicalities of the proof (through an intuitive perspective). Given a wall $W$, we refer to a wall-annulus of $W$ as the subgraph of $W$ that is obtained from $W$ after removing from $W$ all its layers, except a fixed number of consecutive layers. We think of every wall $W \in W$ as divided in consecutive wall-annuli of fixed size. Since $\rho$ is “big-enough”, then we can find also “many enough” such wall-annuli. We denote each one of them by $A_i(W)$. Given a $W \in W$, every wall-annulus $A_i(W)$ is divided in some regions as depicted in Figure 2. The regions depicted in purple and green are consisting of $r$ layers of the wall $W$ (recall that $r = \max_{h \in [\rho]} \{r_h\}$). The regions depicted in yellow and orange are both “big-enough” so as to be able to find, in each one of them, an also “big-enough” wall-annulus that “avoids” a given vertex assignment to the basic variables of $\varphi$.

![Figure 2](image-url)
Since \( \rho \) is “big-enough”, then we can find a wall-annulus \( A_i(W_1) \) that is not affected by \( S \). This allows us to partition \( S \) in two sets, \( S_\text{in} \) and \( S_\text{out} \) in the obvious way. The fact that \( W_1 \) and \( W_2 \) are \((\varphi, \Xi)\)-equivalent implies the existence of a set \( S \) in \( W_2 \) certifying that these two walls have the same characteristic. Thus, by setting \( S' := \tilde{S} \cup S_\text{out} \), we have that \( S' \subseteq \Xi(G, R') \), \( |S'| = |S| \), and \( G \Xi S' \) is planar. The latter is guaranteed by the fact that \( V(\comp(W)) \) is \( \Xi \)-planarization irrelevant, in the case \( \Xi \in \{v_r, e_r, ec\} \), while in the case that \( \Xi = ea \), the existence of the outer purple buffer of \( A_i(W_1) \) (resp. \( A_i(W_2) \)) allows us to treat \( S_\text{in} \) (resp. \( \tilde{S} \)) and \( S_\text{out} \) separately, while not spoiling planarity. The last part of the proof requires to prove that \((G \Xi S, R') \models \tilde{\varphi} \iff (G \Xi S', R') \models \tilde{\varphi} \).

For simplicity, here we only argue why \((G \Xi S, R) \models \tilde{\varphi}_h \iff (G \Xi S', R') \models \tilde{\varphi}_h \) holds, as the arguments in the proof of the inverse direction are completely symmetrical. Therefore, given an \((\ell_h, r_h)\)-scattered set \( X \) such that \( \varphi_h \) is satisfied if the vertices of \( X \) are assigned to the basic variables of \( \varphi_h \), we aim to find a \( t \in [\rho] \) in order to “replace” the vertices in \( X \cap V(K_1^{t(h)}) \) with a set \( \tilde{X} \) of vertices in \( K_2^{(t)} \) such that the resulting vertex set \( X^* \) is \((\ell_h, r_h)\)-scattered and \( \varphi_h \) is satisfied if the vertices of \( X^* \) are assigned to the basic variables of \( \varphi_h \). Notice that for every \( h \in [m] \) such that \((G \Xi S, R) \models \tilde{\varphi}_h \), these “replacement arguments” are pairwise independent.

We first deal with the possibility that the given scattered set \( X \) intersects some “inner part” of \( \comp(W_2) \). Thus, in order to “clean” the “inner part” of \( \comp(W_2) \), we find a wall \( W_3 \in W' \setminus \{W_1, W_2\} \) that “avoids” both \( S \) and \( X \) (for different \( h \in [m] \), the choice of \( W_3 \) may coincide). Also, we consider a \( t \in [\rho] \) corresponding to a layer in the yellow region of the wall-annulus \( A_i(W_2) \) such that the annulus of the wall-annulus of \( A_i(W_2) \) bounded by the \((t - r + 1)\)-th and \( t\)-th layer of \( W_2 \) is not intersected by \( X \). Then, we “replace” the vertices of \( X \) in \( K_2^{(t-r+1)} \setminus P_2^{(t-r+1)} \), call it \( X'_\text{in} \), with an “equivalent” vertex set \( \tilde{X} \) in \( K_3^{(t-r+1)} \setminus P_3^{(t-r+1)} \) (notice that this is achieved by arguing for \( S := \emptyset \) in the notion of \((\varphi, \Xi)\)-characteristic). This results to an \((\ell_h, r_h)\)-scattered set \( X' \) that does not intersect \( K_2^{(t)} \) and \( G \Xi S \models \bigwedge_{x \in X'} \psi_h(x) \) (see Figure 3).

```
Figure 3: The “cleaning” of the “inner part” of \( \comp(W_2) \). Left: The set \( A(S) \) is depicted in cross vertices, the set \( X \setminus X'_\text{in} \) is depicted in blue, and the set \( X' \) is depicted in red. Right: The set \( A(S) \) is depicted in cross vertices, the set \( X' \setminus X'_\text{in} \) is depicted in blue, and the set \( \tilde{X} \) is depicted in red.
```

Now, we are allowed to pick a \( t \in [\rho] \) corresponding to an “orange” layer of \( A_i(W_1) \) such that the annulus of the wall-annulus of \( A_i(W_1) \) bounded by the \((t - r + 1)\)-th and \( t\)-th layer of \( W_1 \) is not intersected by \( X \). If we set \( Z \) to be the set of vertices of \( X' \) in \( K_1^{(t'-r+1)} \setminus P_1^{(t'-r+1)} \) \( (P_1^{(t'-r+1)}) \) is an “extremal” cycle of \( A_i(W_1) \) and therefore \( X' \) does not intersect it), then since \( \text{sig}_{\varphi, \Xi}(z_1, R_1, z, S') = \text{sig}_{\varphi, \Xi}(z_2, R_2, z, \tilde{S}) \), then there exists a set \( \tilde{Z} \) in \( K_2^{(t'-r+1)} \setminus P_2^{(t'-r+1)} \) that is “equivalent” to \( Z \) (see Figure 4).
Figure 4: The last part of the proof. Left: The set \( A(S_{\text{out}}) \) is depicted in red cross vertices, the set \( A(S_{\text{in}}) \) is depicted in green cross vertices, the set \( Y \setminus Y_{\text{in}} \) is depicted in blue, and the set \( Y_{\text{in}} \) is depicted in red. Right: The set \( A(S_{\text{out}}) \) is depicted in red cross vertices, the set \( A(S) \) is depicted in green cross vertices, the set \( X' \setminus Z \) is depicted in blue, and the set \( Z \) is depicted in red.

Therefore, since \( \tilde{Z} \) is in the orange region of \( \text{comp}(W_2) \) and \( X' \) is “avoiding” \( K_2^{(\tilde{r})} \), then we can derive that \( X' \) and \( \tilde{Z} \) are “separated” by a green and a purple region of \( Z \). Moreover, \( \varphi_h \) is satisfied given that the vertices of \( X^* \) of \( G \otimes S' \) are assigned to the basic variables of \( \varphi_h \). The proof is concluded.

4 Definitions and Preliminaries

We denote by \( \mathbb{N} \) the set of all non-negative integers. Given an \( n \in \mathbb{N} \), we denote by \( \mathbb{N}_{\geq n} \) the set containing all integers equal or greater than \( n \). Given two integers \( x \) and \( y \), we define \( [x, y] = \{x, x+1, \ldots, y-1, y\} \). Given an \( n \in \mathbb{N}_{\geq 1} \), we also define \([n] = [1, n]\). For a set \( S \), we denote by \( 2^S \) the set of all subsets of \( S \).

4.1 Graphs, Walls, Wall-annuli, and Treewidth

Basic concepts on Graphs. All graphs in this paper are undirected, finite, and they do not have loops or multiple edges. Given a graph \( G \), we denote by \( V(G) \) and \( E(G) \) the set of its vertices and edges, respectively. If \( S \subseteq V(G) \), then we denote by \( G \setminus S \) the graph obtained by \( G \) after removing from it all vertices in \( S \), together with their incident edges. Also, we denote by \( G \setminus \{v\} \) the graph \( G \setminus \{v\} \), for some \( v \in V(G) \). We also denote by \( G[S] \) the graph \( G \setminus (V(G) \setminus S) \). Given a graph \( G \), we say that a pair \( (A, B) \in 2^{V(G)} \times 2^{V(G)} \) is a separation of \( G \) if \( A \cup B = V(G) \) and there is no edge in \( G \) with one endpoint in \( A \setminus B \) and the other in \( B \setminus A \). A path (cycle) in a graph \( G \) is a connected subgraph with all vertices of degree at most (exactly) 2. Given a graph \( G \), we define the distance \( d_G(u, v) \) between two vertices \( u, v \) of \( G \), as the minimum length of a path between \( u \) and \( v \) in \( G \). For \( r \in \mathbb{N}_{\geq 1} \) and \( u \in V(G) \) we define the \( r \)-neighborhood \( N_G^{(r)}(u) \) of \( u \) in \( G \) by \( N_G^{(r)}(u) := \{v \in V(G) \mid d_G(u, v) \leq r\} \). We say that a set \( S \subseteq V(G) \) is \((\ell, r)\)-scattered if \( |S| = \ell \) and for every \( u, v \in V(G), u \neq v \) it holds that \( d_G(u, v) > 2r \). An annotated graph is a pair \((G, R)\) where \( G \) is a graph and \( R \subseteq V(G) \).

Disks, annuli and partially disk-embedded graphs. In this paper, we consider embeddings or partial embeddings of graphs on the plane and several subsets of it. We define a closed disk (resp. open disk) to be a subset of the plane homeomorphic to the set \( \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 \leq 1\} \) (resp. \( \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 < 1\} \)) and a closed annulus (resp. open annulus) to be a subset of the plane that
is homeomorphic to the set \( \{(x, y) \in \mathbb{R}^2 | 1 \leq x^2 + y^2 \leq 2\} \) (resp. \( \{(x, y) \in \mathbb{R}^2 | 1 < x^2 + y^2 < 2\} \)).

Given a closed disk or a closed annulus \( X \), we use \( \text{bd}(X) \) to denote the boundary of \( X \) (i.e., the set of points of \( X \) for which every neighborhood around them contains some point not in \( X \)). Notice that if \( X \) is a closed disk then \( \text{bd}(X) \) is a subset of the plane homeomorphic to the set \( \{(x, y) \in \mathbb{R}^2 | x^2 + y^2 = 1\} \), while if \( X \) is a closed annulus then \( \text{bd}(X) = \{C_1, C_2\} \) where \( C_1, C_2 \) are two disjoint subsets of the plane, each one homeomorphic to the set \( \{(x, y) \in \mathbb{R}^2 | x^2 + y^2 = 1\} \). We call these sets boundaries of \( X \). Also given a closed disk (resp. closed annulus) \( X \), we use \( \text{int}(X) \) to denote the open disk \( X \setminus \text{bd}(X) \). When we embed a graph \( G \) in a closed disk or in a closed annulus, we treat \( G \) as a set of points. This permits us to make set operations between graphs and sets of points.

We say that a graph \( G \) is partially disk-embedded in some closed disk \( \Delta \), if there is some subgraph \( K \) of \( G \) that is embedded in \( \Delta \) such that \( \text{bd}(\Delta) \) is a cycle of \( K \) and \( (V(G) \cap \Delta, V(G) \setminus \text{int}(\Delta)) \) is a separation of \( G \). From now on, we use the term partially \( \Delta \)-embedded graph \( G \) to denote that a graph \( G \) is partially disk-embedded in some closed disk \( \Delta \). We also call the graph \( K \) compass of the partially \( \Delta \)-embedded graph \( G \) and we always assume that we accompany a partially \( \Delta \)-embedded graph \( G \) together with an embedding of its compass in \( \Delta \), that is the set \( G \cap \Delta \).

**Grids and walls.** Let \( k, r \in \mathbb{N} \). The \((k \times r)\)-grid is the Cartesian product of two paths on \( k \) and \( r \) vertices respectively. We use the term \( k \)-grid for the \((k \times k)\)-grid. An elementary \( r \)-wall, for some odd integer \( r \geq 3 \), is the graph obtained from a \((2r \times r)\)-grid with vertices \((x,y), x \in [2r] \times [r] \), after the removal of the “vertical” edges \( \{(x,y), (x,y+1)\} \) for odd \( x+y \), and then the removal of all vertices of degree one. Notice that, as \( r \geq 3 \), an elementary \( r \)-wall is a planar graph that has a unique (up to topological isomorphism) embedding in the plane \( \mathbb{R}^2 \) such that all its finite faces are incident to exactly six edges. The perimeter of an elementary \( r \)-wall is the cycle bounding its infinite face, while the cycles bounding its finite faces are called bricks. Given an elementary wall \( \overline{W} \), a vertical path of \( \overline{W} \) is one whose vertices, in ordering of appearance, are \((i,1), (i,2), (i+1,2), (i+1,3), (i,3), (i,4), (i+1,4), (i+1,5), \ldots, (i, r-2), (i, r-1), (i+1, r-1), (i+1,r)\), for some \( i \in \{1,3,\ldots,2r-1\} \). Also an horizontal path of \( \overline{W} \) is the one whose vertices, in ordering of appearance, are \((1,j), (2,j), \ldots, (2r,j)\), for some \( j \in [2, r-1] \), or \((1,1), (2,1), \ldots, (2r-1,1) \) or \((2,r), (2,r), \ldots, (2r,r)\).

An \( r \)-wall is any graph \( W \) obtained from an elementary \( r \)-wall \( \overline{W} \) after subdividing edges (see Figure 1). We call the vertices that where added after the subdivision operations subdivision vertices, while we call the rest of the vertices (i.e., those of \( \overline{W} \)) branch vertices. The perimeter of \( W \), denoted by \( \text{perim}(W) \), is the cycle of \( W \) whose non-subdivision vertices are the vertices of the perimeter of \( \overline{W} \). Also, a vertical (resp. horizontal) path of \( W \) is a subdivided vertical (resp. horizontal) path of \( \overline{W} \).

A graph \( W \) is a wall if it is an \( r \)-wall for some odd integer \( r \geq 3 \) and we refer to \( r \) as the height of \( W \). Given a graph \( G \), a wall of \( G \) is a subgraph of \( G \) that is a wall. We insist that, for every \( r \)-wall, the number \( r \) is always odd.

Let \( W \) be a wall of a graph \( G \) and \( K' \) be the connected component of \( G \setminus \text{perim}(W) \) that contains \( W \setminus \text{perim}(W) \). The compass of \( W \), denoted by \( \text{comp}(W) \), is the graph \( G[V(K') \cup V(\text{perim}(W))] \). Observe that \( W \) is a subgraph of \( \text{comp}(W) \) and \( \text{comp}(W) \) is connected.

The layers of an \( r \)-wall \( W \) are recursively defined as follows. The first layer of \( W \) is its perimeter. For \( i = 2, \ldots, (r-1)/2 \), the \( i \)-th layer of \( W \) is the \((i-1)\)-th layer of the subwall \( W' \) obtained from
after removing from \( W \) its perimeter and all occurring vertices of degree one. Notice that each \((2r + 1)\)-wall has \( r \) layers (see Figure 1). The central vertices of \( W \), denoted by \( \text{center}(W) \), are the two branch vertices of \( W \) that do not belong to any of its layers.

**Treewidth.** A tree decomposition of a graph \( G \) is a pair \((T, \chi)\) where \( T \) is a tree and \( \chi : V(T) \to 2^{V(G)} \) such that

1. \( \bigcup_{t \in V(T)} \chi(t) = V(G) \),
2. for every edge \( e \) of \( G \) there is a \( t \in V(T) \) such that \( \chi(t) \) contains both endpoints of \( e \), and
3. for every \( v \in V(G) \), the subgraph of \( T \) induced by \( \{ t \in V(T) \mid v \in \chi(t) \} \) is connected.

The width of \((T, \chi)\) is defined as \( w(T, \chi) := \max \{ |\chi(t)| - 1 \mid t \in V(T) \} \). The treewidth of \( G \) is defined as \( \text{tw}(G) := \min \{ w(T, \chi) \mid (T, \chi) \text{ is a tree decomposition of } G \} \).

The following result from [18] intuitively states that given an odd \( q \in \mathbb{N} \geq 3 \) and a graph \( G \) of “big enough” treewidth, we can find a \( q \)-wall of \( G \) whose compass has “small enough” treewidth.

**Proposition 6** ([18]). There exists a constant \( c_1 \) and an algorithm with the following specifications:

**Find\_Wall(G, q)**

**Input:** a planar graph \( G \) and an odd \( q \in \mathbb{N} \geq 3 \).

**Output:**

1. A \( q \)-wall \( W \) of \( G \) whose compass has treewidth at most \( c_1 \cdot q \) or
2. A tree decomposition of \( G \) of width at most \( c_1 \cdot q \).

Moreover, this algorithm runs in \( O_q(n) \) steps.

### 4.2 Some logic

**Formulas.** In this paper we deal with logic formulas on graphs. In particular we deal with formulas of first-order logic (FOL) and monadic second-order logic (MSOL). The syntax of FOL-formulas includes the logical connectives \( \lor, \land, \lnot \), a set of variables for vertices, the quantifiers \( \forall, \exists \) that are applied to these variables, the predicate \( u \sim v \), where \( u \) and \( v \) are vertex variables and whose interpretation is that \( u \) and \( v \) are adjacent, and the equality of variables representing vertices. A MSOL-formula, in addition to the variables for vertices of FOL-formulas, may also contain variables for subsets of vertices or subsets of edges. The syntax of MSOL-formulas is obtained after enhancing the syntax of FOL-formulas so to further allow quantification on subsets of vertices or subsets of edges and introduce the predicates \( v \in S \) (resp. \( e \in F \)) whose interpretation is that the vertex \( v \) belongs in the vertex set \( S \) (resp. the edge \( e \) belongs in the edge set \( F \)).

An FOL-formula \( \varphi \) is in prenex normal form if it is written as \( \varphi = Q_1 x_1 \ldots Q_n x_n \psi \) such that for every \( i \in [n] \), \( Q_i \in \{ \forall, \exists \} \) and \( \psi \) is a quantifier-free formula on the variables \( x_1, \ldots, x_n \). Then \( Q_1 x_1 \ldots Q_n x_n \) is referred as the prefix of \( \varphi \). For the rest of the paper, when we mention the term “FOL-formula”, we mean an FOL-formula on graphs that is in prenex normal form. Given an FOL-formula \( \varphi \), we say that a variable \( x \) is a free variable in \( \varphi \) if it does not occur in the prefix of \( \varphi \). We
Lemma 7. Let $\Xi = ea$, $G$ be a graph, and $S \subseteq \Xi(G, V(G))$ where $S = \{\{v_1, u_1\}, \ldots, \{v_r, u_r\}\}$. Then there exists an MSOL-formula $\varphi_{\mathcal{P}, S}$ that is evaluated on structures of type $(G, x_1, y_1, \ldots, x_r, y_r)$ such that

$$G \Xi S \text{ is a planar graph } \iff (G, v_1, u_1, \ldots, v_r, u_r) \models \varphi_{\mathcal{P}, S}. $$

Proof. Notice that there exists an MSOL-formula $\varphi_{\mathcal{P}}$ on graphs such that $G$ is planar if and only if $G \models \varphi_{\mathcal{P}}$ (this holds since planarity is characterized by a finite set of forbidden topological minors, see also [7, Corollary 1.15]).

Now, modify the formula $\varphi_{\mathcal{P}}$ in order to transform it to a formula evaluated on structures of type $(G, v_1, u_1, \ldots, v_r, u_r)$. We define a new predicate $x \sim' y$, where $x, y$ are vertex variables such that

$$x \sim' y := (x \sim y) \lor \bigvee_{i \in [r]} (x = v_i \land y = u_i) \lor (x = u_i \land y = v_i)$$

and replace in $\varphi_{\mathcal{P}}$ every occurrence of the predicate $x \sim y$ with $x \sim' y$. In other words, given two vertices $u, v$ of $G$ and two variables $x, y$ in $\varphi_{\mathcal{P}, S}$, where the variables $x, y$ are interpreted as the vertices $u, v$, the predicate $x \sim' y$ is true if and only if $u, v$ are adjacent or $\{u, v\} \in S$. This implies that $G \Xi S$ is a planar graph $\iff (G, v_1, u_1, \ldots, v_r, u_r) \models \varphi_{\mathcal{P}, S}$. 

5 Proof of Lemma 4

In the proof Lemma 4, the most intriguing part after finding a “big enough” wall $W$ in $G$ such that $G \cap \text{comp}(W)$ is a “flat” part of $G$, is to prove that every inclusion-minimal planarizer of $G$ “avoids” the compass of $W$. In order to prove the latter, we define some notions regarding graphs that are “partially embedded” in an annulus and prove that we can “glue” together two such planar graphs on a way that the resulting graph is planar. This is materialized in Lemma 8 that we state and prove before we proceed to the proof of Lemma 4.

Central subwalls and wall-annuli. Let $W$ be an $r$-wall of $G$, for some odd integer $r \geq 3$, and $L_1, \ldots, L_{(r-1)/2}$ be the layers of $W$. Let $q$ be an odd integer in $[3, r]$. We define the central $q$-subwall of $W$, which we denote by $W^{(q)}$, to be the graph obtained from $W$ after removing from $W$ its first $(r - q)/2$ layers and all occurring vertices of degree one (see Figure 5 for an example).

Let $r \in \mathbb{N}_{\geq 7}$ be an odd integer, $p \in [3, (r - 1)/2]$ and $\ell \in [3, p]$. We define the $(p, \ell)$-wall-annulus of $W$, denoted by $A_p^{(\ell)}(W)$, to be the graph obtained from $W^{(2p+1)}$ after removing the vertices of $W^{(2(p-\ell)+1)}$ and all occurring vertices of degree one (see Figure 5 for an example). Observe that, for every $i \in [p-\ell+1, p]$, $A_p^{(\ell)}(W)$ contains the $i$-th layer of $W$ as a subgraph. A brick of the $(p, \ell)$-wall-annulus $A_p^{(\ell)}(W)$ of $W$ is a subgraph of $A_p^{(\ell)}(W)$ that is also a brick of $W$. A 3-wall-annulus of $W$ is a $(p, 3)$-wall-annulus of $W$ for some $p \in [3, (r - 1)/2]$. Notice that every $(p, \ell)$-wall-annulus contains two “boundary” cycles that we call its extremal cycles. Since $\ell \geq 3$, then $A_p^{(\ell)}(W)$ is a subdivision of a 3-connected graph and therefore has a unique embedding in the plane. Thus, given the embedding
of $A_p^{(f)}(W)$ in the plane, we define the annulus of $A_p^{(f)}(W)$, denoted by $\text{ann}(A_p^{(f)}(W))$, to be the closed annulus in the plane bounded by the two extremal cycles of $A_p^{(f)}(W)$.

**Oriented annuli.** An oriented closed annulus is a triple $A = (A, C_{in}, C_{out})$ where $A$ is a closed annulus and $C_{in}, C_{out}$ are its boundaries, such that the connected component of $\mathbb{R}^2 \setminus C_{in}$ that does not intersect $A$, which we call the inner compass of $A$ and we denote by $\text{comp}_{in}(A)$, is an open disk. Also, we define the outer compass of $A$ as the connected component of $\mathbb{R}^2 \setminus C_{out}$ that intersects $C_{in}$ and denote it by $\text{comp}_{out}(A)$. Given an oriented annulus $A = (A, C_{in}, C_{out})$ we define $\text{rev}(A) = (A, C_{out}, C_{in})$.

**Annulus-boundaried graphs.** An annulus-boundaried graph is a quadruple $(G, K, Y, A)$ (see Figure 6), where

- $G$ is a graph,
- $K$ is a connected subgraph of $G$,
- $Y$ is a 3-wall-annulus that is a subgraph of $K$,
- $A = (A, C_{in}, C_{out})$ is an oriented closed annulus,
- $Y$ is embedded in $A$ such that $C_{in}$ and $C_{out}$ are the two extremal cycles of $Y$, and $G \cap A = K$.

We call the cycle of $Y$ that is identical to $C_{in}$ (resp. $C_{out}$) the inner (resp. outer) cycle of $(G, K, Y, A)$.

**Wall-components of annulus-boundaried graphs** Let $(G, K, Y, A)$ be an annulus-boundaried graph. We now define the notion of a wall-component of $(G, K, Y, A)$. We define two types of wall-components: edges of the form $e = uv \in E(G) \setminus E(Y)$ such that $u, v \in V(Y)$ and subgraphs of $K$ that are maximal connected components of $K \setminus V(Y)$. A wall-component $Q$ is attached to a vertex $v \in V(Y)$ if it has a vertex adjacent to $v$, or (if $Q$ is an edge) one of its endpoints is $v$. We say that a wall-component $Q$ of $(G, K, Y, A)$ is a brick-component if there exists a brick $B$ of $Y$ such that $Q$ is attached only to vertices in $V(B)$. Given a subgraph $H$ of $Y$, let $\text{att}(H)$ denote the subgraph of $G$ induced by the vertices of $H$ and the vertices of the wall-components which are only attached to $H$.

The fact that $Y$ is a subdivision of a 3-connected graph and all embedding of the latter are equivalent implies the following result:
Figure 6: An example of an annulus-boundaried graph \((G, K, Y, A)\). The annulus \(A\) is depicted in blue. Two wall-components of \((G, K, Y, A)\) are depicted in red: An edge attached to \(v \in V(G)\) and a subgraph of \(K\) attached to \(u_1, u_2 \in V(G)\).

**Observation 1.** Let \((G, K, Y, A)\) be an annulus-boundaried graph and let \(H\) be a subgraph of \(Y\). If \(\text{att}(H)\) is planar, then every wall-component of \((G, K, Y, A)\) that is a subgraph of \(\text{att}(H)\) is either attached only to vertices of the inner/outer cycle of \((G, K, Y, A)\) or is a brick-component.

**Annulus-embedded separators.** Let \(G\) be a graph. Let also \((K, Y, A)\) be a triple where \(K\) is a graph, \(Y\) is a subgraph of \(K\) and \(A\) is an oriented closed annulus. We say that \((K, Y, A)\) is an **annulus-embedded separator** of \(G\) if there are two subgraphs \(G_{\text{in}}\) and \(G_{\text{out}}\) of \(G\) such that \(V(G_{\text{in}}) \cup V(G_{\text{out}}) = V(G)\), \(V(G_{\text{in}}) \cap V(G_{\text{out}}) = V(K)\), \((V(G_{\text{in}}), V(G_{\text{out}}))\) is a separation of \(G\), and both \((G_{\text{in}}, K, Y, A)\) and \((G_{\text{out}}, K, Y, \text{rev}(A))\) are annulus-boundaried graphs. We call \(G_{\text{in}}\) (resp. \(G_{\text{out}}\)) the **inner** (resp. **outer** component) of \((K, Y, A)\) in \(G\).

We now prove the following result:

**Lemma 8.** Let \(G\) be a graph and let \((K, Y, A)\) be an annulus-embedded separator of \(G\). Let also \(G_{\text{in}}\) and \(G_{\text{out}}\) be the inner and outer component of \((K, Y, A)\) in \(G\), respectively. Then \(G\) is a planar graph if and only if \(G_{\text{in}}\) and \(G_{\text{out}}\) are planar graphs.

**Proof.** Observe that if \(G\) is a planar graph then, trivially, \(G_{\text{in}}\) and \(G_{\text{out}}\) are planar graphs. We now prove that if \(G_{\text{in}}\) and \(G_{\text{out}}\) are planar graphs, then \(G\) is also planar.

Suppose that \(G_{\text{in}}\) and \(G_{\text{out}}\) are planar graphs and also keep in mind that, since \(G_{\text{in}}\) and \(G_{\text{out}}\) are the inner and outer component of \((K, Y, A)\) in \(G\), both \((G_{\text{in}}, K, Y, A)\) and \((G_{\text{out}}, K, Y, \text{rev}(A))\) are annulus-boundaried graphs. Also, let \(R_{\text{in}}\) (resp. \(R_{\text{out}}\)) be the subgraph of \(G\) induced by the union of the vertex sets of all bricks of \(Y\) that intersect the inner (resp. outer) cycle of \((G, K, Y, A)\).

We begin by fixing a planar embedding \(\theta\) of \(G_{\text{out}}\). Keep in mind that since \(Y\) is a subdivision of a 3-connected planar graph, then all its plane embeddings are equivalent. Observe that \(\theta(R_{\text{out}})\) is...
a region that divides the plane in two other regions (one finite and one infinite). Assume that the graph \( G_{\text{out}} \setminus K \) is embedded in the infinite region.

Let \( Q_{\text{in}} := \text{att}(R_{\text{in}}) \) and let \( U \) denote the vertices of \( Q_{\text{in}} \) that are adjacent to some vertex of \( G_{\text{out}} \setminus V(Q_{\text{in}}) \). For more intuition, notice that \( U \) is a subset of \( V(R_{\text{in}}) \cap V(R_{\text{out}}) \). To prove the latter, suppose towards a contradiction that there is a vertex \( v \in U \) that is not in \( V(R_{\text{in}}) \cap V(R_{\text{out}}) \). Observe that \( v \) is a vertex of a wall-component \( H \) of \( (G_{\text{out}}, K, Y, \text{rev}(\emptyset)) \) that is also a subgraph of \( Q_{\text{in}} \). Since \( v \in U \), there exists a vertex \( u \) of \( G_{\text{out}} \setminus V(Q_{\text{in}}) \) such that \( v \) and \( u \) are adjacent. Notice that by the definition of wall-component, it follows that \( u \in V(Y) \). But then \( H \) is attached to \( u \) and since \( u \notin V(Q_{\text{in}}) \), we arrive to a contradiction to the definition of \( Q_{\text{in}} \) and Observation 1. Observe that the restriction of \( \theta \) to \( G_1 := G_{\text{out}} \setminus V(Q_{\text{in}} \setminus U) \) has a face whose boundary contains \( U \).

Now let \( \varphi \) be a planar embedding of \( G_{\text{in}} \) and let us restrict \( \varphi \) to \( G_2 := G \setminus V(G_1 \setminus U) \). Observe that \( Q_{\text{in}} \subseteq V(G_2) \). Note that \( U \) contains only vertices that are adjacent to some vertex in \( R_{\text{out}} \) or are adjacent to brick-components belonging to a brick of \( R_{\text{out}} \). But \( \varphi \) embeds \( R_{\text{out}} \) and its brick-components also, and therefore the restriction of \( \varphi \) to \( G_2 \) results in a face whose boundary contains \( U \).

Now observe that by combining \( \theta \) and \( \varphi \) in such a way that we embed \( G_1 \) according to \( \theta \) and \( G_2 \) according to \( \varphi \) and then “match” them by identifying \( \theta(u) \) and \( \varphi(u) \) for all \( u \in U \), we get a planar embedding of \( G \).

Before we proceed with the proof of Lemma 4, we need some more definitions.

**Graph contractions.** Let \( G \) and \( H \) be graphs and let \( \rho : V(G) \to V(H) \) be a surjective mapping such that:

1. for every vertex \( v \in V(H) \), its codomain \( \rho^{-1}(v) \) induces a connected graph \( G[\rho^{-1}(v)] \),
2. for every edge \( \{u, v\} \in E(H) \), the graph \( G[\rho^{-1}(u) \cup \rho^{-1}(v)] \) is connected, and
3. for every edge \( \{u, v\} \in E(G) \), either \( \rho(u) = \rho(v) \) or \( \{\rho(u), \rho(v)\} \in E(H) \).

We say that \( H \) is a contraction of \( G \) (via \( \rho \)) and for a vertex \( v \in V(H) \) we call the codomain \( \rho^{-1}(v) \) the model of \( v \) in \( G \).

**Central grids.** Let \( k, r \in \mathbb{N}_{\geq 2} \). We define the perimeter of a \((k \times r)\)-grid to be the unique cycle of the grid of length at least three that does not contain vertices of degree four. Let \( r \in \mathbb{N}_{\geq 2} \) and \( H \) be an \( r \)-grid. Given an \( i \in \left[ \frac{r}{2} \right] \), we define the \( i \)-th layer of \( H \) recursively as follows. The first layer of \( H \) is its perimeter, while, if \( i \geq 2 \), the \( i \)-th layer of \( H \) is the \((i - 1)\)-th layer of the grid created if we remove from \( H \) its perimeter. Given two odd integers \( q, r \in \mathbb{N}_{\geq 3} \) such that \( q \leq r \) and an \( r \)-grid \( H \), we define the central \( q \)-grid of \( H \) to be the graph obtained from \( H \) if we remove from \( H \) its \( \frac{r - q}{2} \) first layers.

**Triangulated grids.** We now define the **triangulated \( k \)-grid** \( \Gamma_k \). Consider a plane embedding of the \( k \)-grid such that all external vertices are on the boundary of the infinite face. We triangulate the internal faces of the \( k \)-grid (the faces that are incident to exactly four edges) such that all internal vertices have degree 4 in the obtained graph and all non-corner external vertices have degree 4.
Finally, one corner of degree 2 is joined by edges with all the extremal vertices and we call this vertex loaded (see example in Figure 7). We refer to the initial $k$-grid as the underlying grid of $\Gamma_k$.

Before we proceed to the proof of Lemma 4, we need two results that will be useful.

**Proposition 9** ([15]). Let $G$ be a connected planar graph and $k$ be a positive integer. There is a constant $c_2$ such that if $\text{tw}(G) > c_2 \cdot k$, then $G$ contains $\Gamma_k$ as a contraction.

**Proposition 10** ([11]). Let $H$ be the $m$-grid and a subset $U$ of vertices in the central $(m-2\ell)$-grid $\bar{H}$ of $H$, where $|U| = s$ and $\ell = \lceil \sqrt{s} \rceil$. Then $H$ contains the $\ell$-grid $R$ as a minor such that the model of each vertex of $R$ intersects $U$.

In the following proof, we use $c_1, c_2$ to denote the constants in Proposition 6 and Proposition 9, respectively.

**Proof of Lemma 4.** We set $m = 3 \cdot (2k + 1)$,

$$
\begin{align*}
r &:= 2 \cdot (2m + q) + 1, \\
\ell &:= 4\lceil \sqrt{k + 1} \rceil - 1, \\
z &:= c_1 \cdot r + 2, \\
f_2(k, q) &:= z - 2, \\
f_1(k, q) &:= \max\{c_2 \cdot b + k, c_1 \cdot q\}.
\end{align*}
$$

We begin with the case where $\bar{\Xi} = \bar{\mathbf{a}}$. Observe that if $G$ is not planar, then $(G, k)$ is a $\mathsf{no}$-instance of $\mathsf{GEMP}_{\bar{\varphi}}$. If $G$ is planar and if it is the case that $\text{tw}(G) > f_1(k, q) \geq c_1 \cdot q$, we call the algorithm $\mathsf{Find\_Wall}(G, q)$ of Proposition 6 and we get a $q$-wall $W$ of $G$ whose compass has treewidth at most $c_1 \cdot q$. Since $c_1 \cdot q < f_2(k, q)$, the claimed bound on the treewidth of $\text{comp}(W)$ follows. We also set $\Delta := \text{perim}(W) \cup J$, where $J$ is the connected component of $\mathbb{R}^2 \setminus \text{perim}(W)$ that contains $W \setminus V(\text{perim}(W))$. Observe that $\Delta$ is a closed disk and therefore $G$ is partially $\Delta$-embedded, where $G \cap \Delta = \text{comp}(W)$ and $\text{bd}(\Delta) = \text{perim}(W)$.

Therefore, in the rest of the proof we consider the case where $\bar{\Xi} \in \{\mathbf{v}, \mathbf{e}, \mathbf{c}\}$. We consider an embedding $\theta$ of $G \setminus S$ in the plane. Suppose that $\text{tw}(G) > f_1(k, q)$. Let $G'$ be a connected component of $G \setminus S$ (if $G \setminus S$ is connected, $G' := G \setminus S$) such that $\text{tw}(G') = \text{tw}(G \setminus S)$. Therefore, we have that $\text{tw}(G') > f_1(k, q) - k \geq c_2 \cdot b$. Then, by Proposition 9, $G'$ contains $\Gamma_b$ as a contraction. Let $H$ be the underlying grid of $\Gamma_b$ and $\bar{H}$ be the central $(b - 2\ell)$-grid of $H$.

For every vertex $u \in S$, let

$$
N_u := \{v \in V(\bar{H}) \mid \text{the model of } v \text{ intersects } N_{G'}(u)\}.
$$
Let $N := \bigcup_{u \in S} N_u$. We consider the following cases, concerning the size of $N$:

**Case 1:** $|N| \geq \ell^4 \cdot k$.

In this case, there exists a vertex $u \in S$ such that $|N_u| \geq \ell^4$. Let $U$ be a subset of $N_u$ such that $|U| = \ell^4$. Then, by Proposition 10, $H$ contains the $\ell$-grid as a minor and every vertex of the latter is adjacent to $u$. This, together with the fact that $\ell = 4\sqrt{K + 1} - 1$, implies that $G$ contains a $(K_5, k + 1)$-star\(^1\) as a minor with $u$ as its central vertex. Observe that if $\Xi = er, ec$, the latter implies that $(G, k)$ is a no-instance (since we cannot eliminate all $k + 1$ copies of $K_5$ from $G$ by removing/contracting $k$ edges), while if $\Xi = vr$, for every vr-planarizer $S'$ of $G$ of size at most $k$ it holds that $u \in S'$ (intuitively, $u$ is an “obligatory” vertex for every vr-planarizer of $G$ of size at most $k$). Also, observe that $S \setminus \{u\}$ is a vr-planarizer of $G \setminus u$ of size at most $k - 1$ and notice that $(G, k)$ and $(G \setminus u, k - 1)$ are equivalent instances of $\Xi\text{MP}\varphi$. The above constitute the first possible output of the algorithm $\text{Find Area}(k, q, G, S)$ of Lemma 4 and this concludes Case 1.

**Case 2:** $|N| < \ell^4 \cdot k$.

In this case, we first argue that the following holds:

**Claim 1:** There exists a wall $\hat{W}$ of $G'$ of height $2m + q$ such that $N_{G'}(S) \cap V(\text{comp}(\hat{W})) = \emptyset$.

**Proof of Claim 1:** Since $|N| < \ell^4 \cdot k$, $\hat{H}$ is a $(b - 2\ell)$-grid, and $b - 2\ell = \sqrt{\ell^4 \cdot k} \cdot z$, there exists a $z$-grid $H'$ that is a subgraph of $\hat{H}$ such that $N \cap V(H') = \emptyset$.

Let $w$ denote some corner of $H'$. Consider a surjective mapping $\rho : V(\Gamma_b) \to V(H')$ that maps every vertex in $V(H')$ to itself and every vertex in $V(\Gamma_b) \setminus V(H')$ to $w$. This results to a graph $R$ that is a contraction of $G'$ (via $\rho$). Notice that $R \cong \Gamma_z$, where the model of its loaded vertex $w$ contains $N_{G'}(S)$, and $\text{tw}(R) \geq z$.

Consider now the set $V_w := \{v \in V(G') \mid v \text{ is in the model of } w\}$, and observe that $G'[V_w]$ is a connected graph. Since $\text{tw}(R) \geq z$, then $\text{tw}(G' \setminus V_w) \geq z - 1 > c_1 \cdot r$. By applying the algorithm $\text{Find Wall}(G, q)$ of Proposition 6 for $G' \setminus V_w$ and $r$, we get a $r$-wall $W'$ of $G' \setminus V_w$ whose compass has treewidth at most $c_1 \cdot r = f_2(k, q)$.

Notice that, since $G'[V_w]$ is connected and $G'$ is planar, then $N_{G'}(S)$ (being a subset of $V_w$) is entirely contained in a unique face of $W'$ (recall that since we fixed an embedding $\theta$ of $G'$, we can treat the vertices of $G'$ as points on the plane). Therefore, since $W'$ has height $r = 2 \cdot (2m + q) + 1$, there exists a subwall $\tilde{W}$ of $W'$ of height $2m + q$ that is a wall of $G'$ and $N_{G'}(S) \cap V(\text{comp}(\tilde{W})) = \emptyset$. Claim 1 follows.

By Claim 1, there exists a wall $\tilde{W}$ of $G'$ of height $2m + q$ such that $N_{G'}(S) \cap V(\text{comp}(\tilde{W})) = \emptyset$. Therefore, by restricting the embedding $\theta$ of $G \setminus S$ in $\text{comp}(\tilde{W})$, we get that $\text{comp}(\tilde{W})$ is a planar graph. Let $W$ be the central $q$-subwall of $\tilde{W}$. We now argue that the following holds:

**Claim 2:** The set $V(\text{comp}(W))$ is $\Xi$-planarization irrelevant.

**Proof of Claim 2:** Suppose, towards a contradiction, that there is a set $Z \subseteq \Xi(G, V(G))$ such that $Z$ is an inclusion-minimal $\Xi$-planarizer and $A(Z) \cap V(\text{comp}(W)) \neq \emptyset$.

Since $\tilde{W}$ is a wall of height $2m + q$, it has at least $m$ layers. For every $i \in [m]$, let $C_i$ be the $i$-th layer of $\tilde{W}$. For every $i \in [m - 2]$, let $A_i$ be the finite region of $\mathbb{R}^2$ bounded by $\varphi(C_i)$ and $\varphi(C_{i+2})$.

\(^1\)Given an $r \geq 1$ we define the graph $(K_5, r)$-star as the graph obtained by taking $r$ copies of $K_4$ (that is the complete graph on 4 vertices) and a vertex $v$ and making $v$ adjacent to all vertices of the $r$ copies of $K_4$. We call $v$ the central vertex of the $(K_5, r)$-star.
(the wall $W$ is a subdivision of a 3-connected graph and therefore all its embeddings in the plane are equivalent) and let $A_i := (A_i, C_i, \ell_i)$.

Since $|A(Z)| \leq 2k$ and $m = 3 \cdot (2k + 1)$, then there exists an $i_Z \in [m - 2]$ and a subgraph $Y$ of $\tilde{W}$ such that $A(Z) \cap A_{i_Z} = \emptyset$ and $Y$ is a 3-wall-annulus whose extremal cycles are $C_{i_Z}, C_{i_Z + 2}$. For simplicity, we denote $A := A_{i_Z}$ and $A := \tilde{A}_{i_Z}$.

Let $K$ be the maximal connected subgraph of $G$ such that $G \cap A = K$. We denote by $G_{in}$ the graph $G[(V(G) \cap \text{comp}_out(A)) \cup V(C_{i_Z + 2})]$ and with $G_{out}$ the graph $G \setminus (V(G) \cap \text{comp}_in(A))$ and consider the annulus-boundaried graphs $(G_{in}, K, Y, A)$ and $(G_{out}, K, Y, \text{rev}(A))$. Notice that $(K, Y, A)$ is an annulus-embedded separator of $G$. Also, since $S$ is a $vr$-planarizer of $G$ and $N_{G'}(S) \cap V(\text{comp}(W)) = \emptyset$, then $G_{in}$ is planar (since $G_{in}$ is a subgraph of $G'$ and $G'$ is planar).

Notice that since $A(Z) \cap A = \emptyset$, $\text{comp}(W)$ is planar and $Y$ is a 3-wall-annulus of $G'$ whose extremal cycles are the boundaries of $A$, then there is no $x \in Z$ that affects vertices of $G$ in both connected components of $\mathbb{R}^2 \setminus A$. In other words, $Z$ is partitioned in two sets $Z_{in}$ and $Z_{out}$, where $A(Z_{in})$ is in $\text{comp}_in(A)$ and $A(Z_{out})$ is in $\mathbb{R}^2 \setminus \text{comp}_out(A)$. Now, observe that since $\text{comp}(W)$ is a graph embedded in a subset of $\text{comp}_in(A)$ and $A(Z) \cap V(\text{comp}(W)) \neq \emptyset$, then $Z_{in} \neq \emptyset$. Thus $Z_{out}$ is a proper subset of $Z$. Also, the fact that $Z$ is a $\mathbb{R}$-planarizer of $G$, implies that $Z_{out}$ is a $\mathbb{R}$-planarizer of $G_{out}$. Hence, $G_{out} \mathbb{R} Z_{out}$ is planar. Moreover, $(K, Y, A)$ is an annulus-embedded separator of $G \mathbb{R} Z_{out}$.

Therefore, since $(K, Y, A)$ is an annulus-embedded separator of $G \mathbb{R} Z_{out}$ and $G_{in}$ and $G_{out} \mathbb{R} Z_{out}$ are planar graphs, by Lemma 8 we have that $G \mathbb{R} Z_{out}$ is a planar graph, a contradiction to the minimality of $Z$. Claim 2 follows.\)

Following Claim 2, $W$ is a $q$-wall of $G$ whose compass has treewidth at most $f_2(k, q)$ and $V(\text{comp}(W))$ is a $\mathbb{R}$-planarization irrelevant. Keep in mind that $\text{comp}(W)$ is a planar graph, since it is a subgraph of the planar graph $\text{comp}(\tilde{W})$. Now, let $J$ be the connected component of $\mathbb{R}^2 \setminus \text{perim}(W)$ that contains $W \setminus \text{perim}(W)$. Observe that $\Delta := \text{perim}(W) \cup J$ is a closed disk and therefore $G$ is partially $\Delta$-embedded, where $G \cap \Delta = \text{comp}(W)$. Therefore, the algorithm $\text{Find \_ Area}(k, q, G, S)$ of Lemma 4 returns $W$ and $\Delta$ and this completes the proof of the lemma. □

6 Proof of Lemma 5

In this section we use $f_2$ to denote the function in Lemma 4, bounding the treewidth of the compass of the wall that the claimed algorithm outputs.

We now proceed with the proof of Lemma 5, that is the main technical result of this paper.

Proof of Lemma 5. Keep in mind that $\varphi$, as a Gaifman sentence, is a Boolean combination of sentences $\varphi_1, \ldots, \varphi_m$ such that, for every $h \in [m],$

$$\varphi_h = \exists x_1 \ldots \exists x_{\ell_h} \left( \bigwedge_{1 \leq i < j \leq \ell_h} d(x_i, x_j) > 2r_h \land \bigwedge_{i \in [\ell_h]} \psi_h(x_i) \right),$$

where $\ell_h, r_h \geq 1$ and $\psi_h(x)$ is $r_h$-local. Let $r := \max_{h \in [m]} \{r_h\}$ and $\ell := \sum_{h \in [m]} \ell_h$. We consider the sentence $\hat{\varphi}$ and recall that it is the same Boolean combination of sentences $\hat{\varphi}_1, \ldots, \hat{\varphi}_m$ such that,
for every $h \in [m]$,

$$
\tilde{\varphi}_h = \exists x_1 \ldots \exists x_{t_h} \left( \bigwedge_{i \in [t_h]} x_i \in R \land \bigwedge_{1 \leq i < j \leq t_h} d(x_i, x_j) > 2r_h \land \bigwedge_{i \in [t_h]} \psi_h(x_i) \right),
$$

and the formulas $\tilde{\varphi}$ and $\tilde{\varphi}_1, \ldots, \tilde{\varphi}_m$ are evaluated on annotated graphs of the form $(G, R)$.

We set

$$
d := 2(r + (\ell + 1)r),
$$

$$
\rho := (2k + 1) \cdot d,
$$

$$
w := 2^{(k+1)2^{k\rho}} \cdot (2k + 1)(\ell + 3),
$$

and

$$
f_3(k, |\varphi|) := \lceil (2\rho + 1) \cdot \sqrt{w} \rceil.
$$

Since $q = f_3(k, |\varphi|) = \lceil (2\rho + 1) \cdot \sqrt{w} \rceil$, then there exists a collection $W$ of $w (2\rho + 1)$-subwalls of $\tilde{W}$ whose compasses are pairwise disjoint. Suppose that there is a wall $W \in W$ such that $V(\text{comp}(W)) \cap R = \emptyset$. If we set $X := V(\text{comp}(W^{(0-1)}))$ and $v$ to be a vertex in $\text{center}(W)$ then, since $\text{comp}(W^{(0-1)})$ is a planar graph, and there exist at least $\rho - 1$ layers of $W$ separating a vertex $u \notin V(\text{comp}(W^{(0-1)}))$ and $v$, for every $u \notin V(\text{comp}(W^{(0-1)}))$ it holds that $d(u, v) \geq \rho - 1$. This, together with the fact that $\rho - 1 > r$ and for every $h \in [m]$ $\psi_h(x)$ is $r_h$-local, imply that $(G, R, k)$ is a $(\varphi, \boxtimes)$-triple if and only if $(G \setminus v, R \setminus X, k)$ is a $(\varphi, \boxtimes)$-triple. Therefore, our algorithm can safely return the vertex set $X$ and the vertex $v$. Thus, we may assume that for every $W \in W$ it holds that $V(\text{comp}(W)) \cap R \neq \emptyset$.

Let

$$
\text{SIG} = 2^{[t_1]} \times \cdots \times 2^{[t_m]} \times [\rho].
$$

Let $W \in W$ and keep in mind that $\text{comp}(W)$ is embedded in $\Delta$. We set $K = \text{comp}(W)$, for every $t \in [\rho]$, let $K^{(t)} = \text{comp}(W^{(2t+1)})$, $P^{(t)} = V(\text{perim}(W^{(2t+1)}))$, and let $K = (V(K^{(1)}), \ldots, V(K^{(\rho)}))$. We call the tuple $\mathfrak{R}_W = (K, K)$ the extended compass of the wall $W$ in $G$ (we stress that the embedding of $K$ in $\Delta$ yields a unique extended compass for every wall $W \in W$). Given the extended compass $\mathfrak{R}_W$ of a wall $W \in W$ in $G$, a set $R \subseteq V(\text{comp}(W))$, an integer $z \in [d, \rho]$, and a set $S \subseteq \boxtimes(K, R)$ such that $A(S) \subseteq V(K^{(z-d+1)}) \cap R$, we define

$$
\text{sig}_{\varphi, \boxtimes}(\mathfrak{R}_W, R, z, S) = \{(Y_1, \ldots, Y_m, t) \in \text{SIG} \mid t \leq z \land \exists (\tilde{X}_1, \ldots, \tilde{X}_m) \text{ such that } \forall h \in [m]
$$

$$
\tilde{X}_h = \{x_i^h \mid i \in Y_h\},
$$

$$
\tilde{X}_h \subseteq V((K^{(t-r+1)} \boxtimes S) \setminus P^{(t-r+1)}) \cap R,
$$

$$
\tilde{X}_h \text{ is } (|Y_h|, r_h)\text{-scattered in } K^{(t)} \boxtimes S, \text{ and }
$$

$$
K^{(t)} \boxtimes S \models \bigwedge_{x \in \tilde{X}_h} \psi_h(x).$$

Notice that $(Y_1, \ldots, Y_m, t) \in \text{sig}_{\varphi, \boxtimes}(\mathfrak{R}_W, R, z, S)$ only if for every $h \in [m]$, $\tilde{X}_h \subseteq V(K^{(z-r+1)} \boxtimes S)$ (since, otherwise, $K^{(z)} \boxtimes S$ can not be a model of $\bigwedge_{x \in \tilde{X}_h} \psi_h(x)$). Recall that $\rho = (2k + 1) \cdot d$. Given
We set partitioned into the sets consecutive layers of then the fact that each \(A\) exists a collection of \((\mathfrak{R}_W, R)\) as follows

\[
(\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_W, R) = \{(z, \text{sig}, s) \in [d, \rho] \times 2^{\text{SIG}} \times [0, k] \mid \exists S \subseteq \mathfrak{X}(K, R) \text{ such that, } \\
A(S) \subseteq V(K^{(z-d+1)}) \cap R, \\
|S| = s, K \mathfrak{X} S \text{ is planar, and} \\
\text{sig}_{\varphi, \mathfrak{X}}(\mathfrak{R}, R, z, S) = \text{sig}\}.
\]

Notice that all queries in the definition of \((\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_W, R)\) can be expressed in MSOL. Indeed, this is easy to see when \(\mathfrak{X} \in \{\text{vr, er, ec}\}\), as in this case the query “\(K \mathfrak{X} S\) is planar” is trivially true, since \(V(\mathfrak{comp}(\hat{W}))\) is \(\mathfrak{X}\)-planarization irrelevant. In the case where \(\mathfrak{X} = \text{ea}\), MSOL expressibility follows from Lemma 7. As each \(W \in W\) has treewidth at most \(f_2(k, q)\), it follows by the theorem of Courcelle that \((\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_W, R)\) can be computed in \(O_{k,|\varphi|}(n)\) time.

For every wall \(W_i \in W\), we set \(K_i := \text{comp}(W_i)\), for every \(j \in [\rho]\), \(K_i^{(j)} := \text{comp}(W_i^{(2j+1)})\) and \(P_i^{(j)} := V(\text{perim}(W_i^{(2j+1)}))\), \(\mathfrak{R}_i := \mathfrak{R}_{W_i}\) and \(R_i := R \cap V(\text{comp}(W_i))\). We say that two walls \(W_1, W_2 \in W\) are \((\varphi, \mathfrak{X})\text{-equivalent}\) if \((\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_1, R_1) = (\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_2, R_2)\), and we denote this by \(W_1 \sim_{\varphi, \mathfrak{X}} W_2\).

Since \(w = \varphi^{(k+1)} \cdot 2^{2d\cdot \rho} \cdot (2k + 1)(\ell + 3)\) and for every \(i \in [w]\), \((\varphi, \mathfrak{X})\text{-}\text{char}(\mathfrak{R}_i, R_i) \subseteq [d + 1, \rho] \times 2^{\text{SIG}} \times [0, k]\), we can find, in \(O_{k,|\varphi|}(n)\) time, a collection \(W' \subseteq W\) of \((2k + 1)(\ell + 3)\) walls that are pairwise \((\varphi, \mathfrak{X})\text{-equivalent}\). We fix a wall \(W_1 \in W'\), and set \(X := V(K_1^{(r)})\). Let \(R' := R \setminus X\). We now prove that the following holds:

**Claim:** If \(S\) is a subset of \(\mathfrak{X}(G, R)\), where \(|S| = k\) and \(G \mathfrak{X} S\) is a planar graph, then there exists a set \(S' \subseteq \mathfrak{X}(G, R')\) such that

- \(|S| = |S'|\),
- \(G \mathfrak{X} S'\) is a planar graph, and
- \((G \mathfrak{X} S, R) \models \varphi\) if and only if \((G \mathfrak{X} S', R') \models \varphi\).

**Proof of Claim:** Let \(S\) be a subset of \(\mathfrak{X}(G, R)\), where \(|S| = k\) and \(G \mathfrak{X} S\) is a planar graph. Since the collection \(W'\) of walls that are \((\varphi, \mathfrak{X})\text{-equivalent}\) with \(W_1\) has size \((2k + 1)(\ell + 3)\) and \(|A(S)| \leq 2k\), there exists a collection \(W'' \subseteq W' \setminus \{W_1\}\) of size \((\ell + 2)\), such that for every \(W \in W''\), it holds that \(W \sim_{\varphi, \mathfrak{X}} W_1\) and \(V(\mathfrak{comp}(\hat{W})) \cap A(S) = \emptyset\). Let \(W_2 \in W''\).

Since \(W_1\) has height \(2\rho + 1\), where \(\rho = (2k + 1) \cdot d\), observe that there is a collection of \(2k + 1\) closed annuli \(\{\text{ann}(A_i^{(d)}(W_1)) \mid i \in [2k + 1]\}\) that are pairwise disjoint and keep in mind that each \(\text{ann}(A_i^{(d)}(W_1))\) is a closed annulus that is a subset of \(\Delta\) and, intuitively, “crops” an area of \(d\) consecutive layers of \(W_1\). Therefore, the fact that \(|A(S)| \leq 2k\) implies that there exists an \(i \in [2k+1]\) such that \(A(S)\) does not intersect \(\text{ann}(A_i^{(d)}(W_1))\). Notice that, since \(G \mathfrak{X} S\) is planar and \(d \geq 3\), \(S\) is partitioned into the sets \(S_{in}\) and \(S_{out}\), where \(A(S_{in}) \subseteq V(K_1^{(i+d-d+1)}) \cap R\) and \(A(S_{out}) \cap V(K_1^{(i+d)}) = \emptyset\). We set \(z := i \cdot d\).

Since \(S_{in} \subseteq \mathfrak{X}(K_1, R_1)\), \(A(S_{in}) \subseteq V(K_1^{(z-d+1)}) \cap R = V(K_1^{(z-d+1)}) \cap R_1\), and \(K_1 \mathfrak{X} S\) is planar, then the fact that \(W_1 \sim_{\varphi, \mathfrak{X}} W_2\) implies that there exists a set \(\tilde{S} \subseteq \mathfrak{X}(K_2, R_2)\), such that \(|\tilde{S}| = |S_{in}|\),

24
Notice that \( S' \subseteq \mathbb{R}(G, R') \), \(|S'| = k\), and \( G \times S' \) is planar. As a proof of the latter, in the case where \( \mathbb{R} = vr, er, \) or \( ec \), since \( V(\text{comp}(W)) \) is \( \mathbb{R} \)-planarization irrelevant then every inclusion-minimal \( \mathbb{R} \)-planarizer of \( G \) is a subset of \( S_{\text{out}} \). Also, in the case where \( \mathbb{R} = ea \), \( G \times S' \) is planar since \( (G \setminus V(K_2^{(z-d+1)})) \times S_{\text{out}} \) and \( K_2^{(z)} \times \tilde{S} \) are planar and \( d \geq 3 \) (due to Lemma 8 presented in Section 5). Therefore, our goal now is to prove that \((G \times S, R) \models \varphi \) if and only if \((G \times S', R') \models \varphi \).

Since \((G \times S, R) \models \varphi \) and \( \varphi \) is a Boolean combination of the formulas \( \varphi_1, \ldots, \varphi_m \), then there is a set \( J \subseteq [m] \) such that for every \( j \in J \) it holds \((G \times S, R) \models \varphi_j \) and for every \( j \notin J \) it holds that \((G \times S, R) \models \neg \varphi_j \). In order to show that \((G \times S', R') \models \varphi \), we show that for every \( j \in J \) it holds \((G \times S', R') \models \varphi_j \) and for every \( j \notin J \) it holds that \((G \times S', R') \models \neg \varphi_j \). Therefore, we distinguish the two cases.

Case 1: \( j \in J \). We aim to prove that \((G \times S, R) \models \varphi_j \) if and only if \((G \times S', R') \models \varphi_j \). In other words, we will prove that there exists an \((\ell_j, r_j)\)-scattered set \( X_j \subseteq R \) in \( G \times S \) such that \( G \times S = \cup_{x \in X_j} \psi_j(x) \) if and only if there is an \((\ell_j, r_j)\)-scattered set \( X' \subseteq R' \) in \( G \times S' \) such that \( G \times S' = \cup_{x \in X'} \psi_j(x) \).

Subclaim: There exists a \( t \in [z - \frac{d}{2} + 2r + 1, z - r] \) and an \((\ell_j, r_j)\)-scattered set \( X_j' \subseteq R \) in \( G \times S \) such that \( G \times S = \cup_{x \in X_j} \psi_j(x) \) if and only if \( G \times S = \cup_{x \in X_j'} \psi_j(x) \) and \( X_j \cap V(K_2^{(\ell)}) = \emptyset \).

Proof of Subclaim: Recall that there is a collection \( W' \) of size \( \ell + 2 \) of walls \((\varphi, \mathbb{R})\)-equivalent to \( W_1 \) whose compasses are disjoint from \( A(S) \). Therefore, since \( X_j \) has size at most \( \ell \), there exists a wall \( W_3 \in W' \setminus \{W_2\} \) such that \( V(K_3) \cap (A(S) \cup X_j) = \emptyset \).

We now focus on the closed annulus \( \text{ann}(\mathcal{A}_z^{(d)}(W_2)) \), which, since \( A(S) \cap V(K_2) = \emptyset \), does not intersect \( A(S) \). We have that \( d = 2(r + (\ell + 1)r + r) \) and \( |X_j| \leq \ell \) and therefore there exists a \( t \in [z - \frac{d}{2} + 2r + 1, z - r] \) (see Figure 8) such that \( X_j \) does not intersect \( \text{ann}(\mathcal{A}_t^{(r)}(W_2)) \). Intuitively, we separate the \( d \) layers of \( W_2 \) that are in \( \text{ann}(\mathcal{A}_z^{(d)}(W_2)) \) into two parts, the first \( d/2 \) layers and the second \( d/2 \) layers, and then we find some layer among the “central” \( (\ell + 1)r \) layers of the second part (\( t \) corresponds to a layer in the yellow area of Figure 8). This layer (corresponding to \( t \)) together with its preceding \( r - 1 \) layers define an annulus of size \( r \), \( \text{ann}(\mathcal{A}_t^{(r)}(W_2)) \), which \( X_j \) “avoids”. Since \( \text{ann}(\mathcal{A}_t^{(r)}(W_2)) \subseteq \text{ann}(\mathcal{A}_z^{(d)}(W_2)) \) and \( A(S) \cap \text{ann}(\mathcal{A}_z^{(d)}(W_2)) = \emptyset \), it also holds that \( A(S) \cap \text{ann}(\mathcal{A}_t^{(r)}(W_2)) = \emptyset \).

We set \( X_j^* := X_j \cap V(K_2^{(t-r+1)}) \) and \( Y_j \subseteq [\ell_j] \) to be the set of indices of the vertices in \( X_j^* \). Notice that \( X_j^* \subseteq R \cap V(K_2^{(t-r+1)}) \subseteq R_2 \) and that, since \( X_j \) does not intersect \( \text{ann}(\mathcal{A}_t^{(r)}(W_2)) \), also \( X_j^* \) does not intersect \( P_2^{(t-r+1)} \) (that is an extremal cycle of \( \text{ann}(\mathcal{A}_t^{(r)}(W_2)) \)). Also, observe that, since \( A(S) \cap V(K_2) = \emptyset \), we have that \( V(K_2) \subseteq V(G \times S) \) and \( G \times S[V(K_2)] = K_2 \). Therefore, since \( X_j^* \subseteq V(K_2^{(t-r+1)}) \setminus P_2^{(t-r+1)} \), \( \psi_j(x) \) is an \( r_j \)-local formula, and \( r \geq r_j \), we have that \( G \times S \models \ldots \)
\[ \sum_{x \in X_j} \psi_j(x) \iff K_2^{(t)} \models \sum_{x \in X_j} \psi_j(x). \]  

To sum up, we have that the set \( X_j^* \) is a subset of \( V(K_2^{(t-r+1)} \setminus P_2^{(t-r+1)}) \cap R_2 \) and \( \psi_j(x) \)-scattered in \( K_2^{(t)} \) (being a subset of \( X_j \)) and \( K_2^{(t)} \models \sum_{x \in X_j} \psi_j(x) \).

Notice that, since \( A(S) \cap V(K_2) = \emptyset \) and \( W_2 \sim_{\varphi, \emptyset} W_3 \), we have that \( \text{sig}_{\varphi, \emptyset}(R_2, R_2, t', \emptyset) = \text{sig}_{\varphi, \emptyset}(R_3, R_3, t', \emptyset) \) for every \( t' \in [\rho] \). Therefore, we have that \( \text{sig}_{\varphi, \emptyset}(R_2, R_2, t, \emptyset) = \text{sig}_{\varphi, \emptyset}(R_3, R_3, t, \emptyset) \) and this implies that there is a set \( \tilde{X}_j \subseteq V(K_3^{(t-r+1)} \setminus P_3^{(t-r+1)}) \cap R_3 \) such that \( \tilde{X}_j \) is \( (|Y_j|, r_j) \)-scattered in \( K_3^{(t)} \) and \( K_2^{(t)} \models \sum_{x \in \tilde{X}_j} \psi_j(x) \iff K_3^{(t)} \models \sum_{x \in \tilde{X}_j} \psi_j(x) \). Observe that since \( A(S) \cap V(K_3) = \emptyset \) and \( \tilde{X}_j \subseteq V(K_3^{(t-r+1)} \setminus P_3^{(t-r+1)}) \subseteq V(K_3^{(\rho-r)}) \), then for every \( x \in \tilde{X}_j \) it holds that \( N_{G_{\emptyset S}}(x) \cap A(S) = \emptyset \). Thus, since every \( \psi_h(x), h \in [m] \) is \( r_h \)-local, it follows that \( K_3^{(t)} \models \sum_{x \in \tilde{X}_j} \psi_j(x) \iff G \boxtimes S \models \sum_{x \in \tilde{X}_j} \psi_j(x) \).

We now consider the set
\[ X_j' := (X_j \setminus X_j^*) \cup \tilde{X}_j. \]

Since \( V(K_3) \cap (X_j \cup A(S)) = \emptyset \) and \( r \geq r_j \), for every \( x \in X_j \), and thus for every \( x \in X_j \setminus X_j^* \), it holds that \( N_{G_{\emptyset S}}^{(\leq r_j)}(x) \cap V(K_3^{(\rho-r+1)}) = \emptyset \). Also, since \( t \leq \rho - r \) and \( \tilde{X}_j \subseteq V(K_3^{(t-r+1)} \setminus P_3^{(t-r+1)}) \), for every \( x \in \tilde{X}_j \) it holds that \( N_{G_{\emptyset S}}^{(\leq r_j)}(x) \subseteq V(K_3^{(\rho-r+1)}) \). Thus, for every \( x \in X_j \setminus X_j^* \) and \( x' \in \tilde{X}_j \) we have that \( N_{G_{\emptyset S}}^{(\leq r_j)}(x) \cap N_{G_{\emptyset S}}^{(\leq r_j)}(x') = \emptyset \). The latter, together with the fact that the set \( X_j \setminus X_j^* \) is \((\ell_j - |Y_j|, r_j)\)-scattered in \( G \boxtimes S \), \( \tilde{X}_j \) is \((|Y_j|, r_j)\)-scattered in \( K_3^{(t)} \), and \( K_3^{(t)} = G \boxtimes S[V(K_3^{(t)})] \), implies that \( X_j' \) is an \((\ell_j, r_j)\)-scattered set in \( G \boxtimes S \). Moreover, by definition, we have that \( X_j' \subseteq R \) and \( X_j' \) does not intersect \( V(K_2^{(t)}) \), while we already argued why \( G \boxtimes S \models \sum_{x \in X_j'} \psi_j(x) \iff G \boxtimes S \models \sum_{x \in X_j} \psi_j(x) \).

Subclaim follows.

Following the above subclaim, let \( t \in [z - \frac{d}{2} + 2r + 1, z - r] \) and an \((\ell_j, r_j)\)-scattered set \( X_j' \subseteq R \) in \( G \boxtimes S \) such that \( G \boxtimes S \models \sum_{x \in X_j} \psi_j(x) \iff G \boxtimes S \models \sum_{x \in X_j} \psi_j(x) \) and \( X_j' \cap V(K_2^{(t)}) = \emptyset \).
Since $d = 2(r + (\ell + 1)r + r)$ and $|X_j'| \leq \ell$, there exists a $t' \in [z - d + 2r + 1, z - \frac{d}{2} - r]$ such that $X_j'$ does not intersect $\text{ann}(A_P^r(W_1))$ (a $t'$ corresponds to a layer in the orange area in Figure 8).

Now, consider the set $Z := X_j' \cap V(K_1^{(t' - r + 1)} \otimes S_{in})$. Observe that $Z \subseteq R_1$ and therefore $Z \subseteq V(K_1^{(t' - r + 1)} \otimes S_{in}) \cap R_1$. Also, notice that, since $A(S_{in}) \subseteq V(K_1^{z - d + 1})$ and $t' \geq z - d + 2r + 1$, $P_1^{(t' - r + 1)} \subseteq V(K_1^{t' - r + 1} \otimes S_{in})$. Thus, $Z \subseteq V(K_1^{t' - r + 1} \otimes S_{in}) \setminus P_1^{(t' - r + 1)} \cap R_1$. Recall that $R' = R \setminus V(K_1^{(t)})$ and observe that, since $(X_j' \setminus Z) \cap V(K_1^{(t)}) = \emptyset$ and $t' > r$, it holds that $X_j' \setminus Z \subseteq R'$. Let $Y_j' \subseteq \{\ell\}$ be the set of the indices of the vertices of $X_j'$ in $Z$. Also, notice that since $Z \subseteq V(K_1^{(t' - r + 1)} \otimes S_{in}) \setminus P_1^{(t' - r + 1)} \cap R_1$, $Z$ is a subset of $X_j'$, and $X_j'$ is $(\ell_j, r_j)$-scattered in $G \otimes S$, it holds that $Z$ is $(|Y_j'|, r_j)$-scattered in $K^{(t')} \otimes S_{in}$ and $K^{(t')} \otimes S_{in} = \bigwedge_{x \in Z} \psi_j(x)$. As we mentioned before, $\text{sig}_{\varphi, \otimes}(\hat{R}_2, R_2, z, \hat{S}) = \text{sig}_{\varphi, \otimes}(\hat{R}_1, R_1, z, S_{in})$. This implies the existence of a set $\bar{Z} \subseteq V((K_2^{(t' - r + 1)} \otimes \bar{S}) \setminus P_2^{(t' - r + 1)} \cap R_2 \subseteq R' \setminus \{\ell\}$ such that $\bar{Z}$ is $(|Y_j'|, r_j)$-scattered in $K^{(t')} \otimes \bar{S}$ and $K^{(t')} \otimes S_{in} = \bigwedge_{x \in \bar{Z}} \psi_j(x)$. At this point, observe that, since the formula $\psi_j(x)$ is $r_j$-local and $Z \subseteq V((K_1^{(t' - r + 1)} \otimes S_{in}) \setminus P_1^{(t' - r + 1)})$, $N_{G \otimes S}(\varphi) \subseteq V(K_1^{(t')} \otimes S_{in})$, for every $x \in Z$. Also, $A(S_{out}) \cap V(K_2^{(t)}) = \emptyset$, which implies that $K^{(t')} \otimes S_{in} = \bigwedge_{x \in \bar{Z}} \psi_j(x) \iff G \otimes S = \bigwedge_{x \in Z} \psi_j(x)$.

Also, since $S' = \bar{S} \cup S_{out}$, where $A(S_{out}) \cap V(K_2) = \emptyset$, and $\bar{Z}$ is $(|Y_j'|, r_j)$-scattered in $K^{(t')} \otimes \bar{S}$, where $\bar{Z} \subseteq V((K_2^{(t' - r + 1)} \otimes \bar{S}) \setminus P_2^{(t' - r + 1)})$ and $t' \leq \rho - r$, we notice that $\bar{Z}$ is also $(|Y_j'|, r_j)$-scattered in $G \otimes S'$. Moreover, the formula $\psi_j(x)$ is $r_j$-local, so $K^{(t')} \otimes \bar{S} = \bigwedge_{x \in \bar{Z}} \psi_j(x) \iff G \otimes S' = \bigwedge_{x \in \bar{Z}} \psi_j(x)$. Therefore, we have $G \otimes S = \bigwedge_{x \in Z} \psi_j(x) \iff G \otimes S' = \bigwedge_{x \in \bar{Z}} \psi_j(x)$.

Consider the set $X := (X_j' \setminus Z) \cup \bar{Z}$.

Notice that since $X_j' \setminus Z$ is an $(\ell_j - |Y_j'|, r_j)$-scattered set in $G \otimes S$ and it does not intersect neither $V(K_1^{(z - d + 1)})$ (where $A(\bar{S})$ lies), nor $V(K_1^{(t' - r + 1)})$ (where $A(S_{in})$ lies), it is also an $(\ell_j - |Y_j'|, r_j)$-scattered set in $G \otimes S'$. Since $\bar{Z} \subseteq V((K_2^{(t' - r + 1)} \otimes \bar{S}) \setminus P_2^{(t' - r + 1)})$, $X_j' \cap V(K_2^{(t')}) = \emptyset$, and $t' < t - 2r$, then for every $x \in X_j' \setminus Z$ and $x' \in \bar{Z}$ it holds that $N^{(r_j)}_{G \otimes S}(x) \cap N^{(r_j)}_{G \otimes S}(x') = \emptyset$. The latter, together with the fact that $X_j' \setminus Z$ is an $(\ell_j - |Y_j'|, r_j)$-scattered set in $G \otimes S'$ and $\bar{Z}$ is $(|Y_j'|, r_j)$-scattered in $G \otimes S'$, implies that $X \subseteq R'$ is an $(\ell_j, r_j)$-scattered set in $G \otimes S'$. Furthermore, since the formula $\psi_j(x)$ is $r_j$-local, then $G \otimes S' = \bigwedge_{x \in X} \psi_j(x) \iff G \otimes S' = \bigwedge_{x \in X} \psi_j(x)$.

Thus, assuming that there is an $(\ell_j, r_j)$-scattered set $X_j \subseteq R$ in $G \otimes S$ such that $G \otimes S = \bigwedge_{x \in X} \psi_j(x)$, we proved that there is an $(\ell_j, r_j)$-scattered set $X \subseteq R'$ in $G \otimes S'$ such that $G \otimes S' = \bigwedge_{x \in X} \psi_j(x)$. To conclude Case 1, notice that we can prove the inverse implication. That is, by assuming the existence of an $(\ell_j, r_j)$-scattered set $X_j \subseteq R'$ in $G \otimes S'$ such that $G \otimes S' = \bigwedge_{x \in X_j} \psi_j(x)$ and using the same arguments as above (replacing $W_1$ with $W_2$, $S$ with $S'$ and $R$ with $R'$), we can prove the existence of an $(\ell_j, r_j)$-scattered set $X \subseteq R$ in $G \otimes S$ such that $G \otimes S = \bigwedge_{x \in X} \psi_j(x)$.

Case 2: $j \notin J$. We aim to prove that $(G \otimes S, R) \models \neg \varphi_j \iff (G \otimes S', R') \models \neg \varphi_j$.

In other words, we need to prove that for every $(\ell_j, r_j)$-scattered set $X_j \subseteq R$ in $G \otimes S$, $G \otimes S = \neg \psi_j(x)$, for some $x \in X_j$, if and only if for every $(\ell_j, r_j)$-scattered set $X_j \subseteq R'$ in $G \otimes S'$, $G \otimes S' = \neg \psi_j(x)$, for some $x \in X_j$. In Case 1 we argued that there is an $(\ell_j, r_j)$-scattered set $X_j \subseteq R$ in $G \otimes S$ such that $G \otimes S = \bigwedge_{x \in X_j} \psi_j(x)$ if and only if there is an $(\ell_j, r_j)$-scattered set $X_j \subseteq R'$ in $G \otimes S'$ such
that $G \boxtimes S' = \bigwedge_{x \in X_j} \psi_j(x)$. This directly implies that $(G \boxtimes S, R) \models \neg \tilde{\varphi}_j \iff (G \boxtimes S', R') \models \neg \tilde{\varphi}_j$. This concludes Case 2 and completes the proof of Claim.

Let $v \in \text{center}(W^{(r)}_1)$. We conclude the proof of the lemma by proving that $(G, R, k)$ is a $(\varphi, \boxtimes)$-triple if and only if $(G \setminus v, R', k)$ is a $(\varphi, \boxtimes)$-triple. As a proof of the latter, notice that by Claim, we get that $(G, R, k)$ is a $(\varphi, \boxtimes)$-triple if and only if $(G, R', k)$ is a $(\varphi, \boxtimes)$-triple. By the definition of the $(\varphi, \boxtimes)$-triple, $(G, R', k)$ is a $(\varphi, \boxtimes)$-triple if and only if there exists an $S \subseteq \boxtimes \langle G, R' \rangle$ such that $|S| = k$, $G \boxtimes S$ is a planar graph, and $(G \boxtimes S, R') \models \tilde{\varphi}$. Since for every $h \in [m]$ the FOL-formula $\psi_h(x)$ is $r_h$-local, then the validity of $\psi_h(x)$ does not depend on the central vertex $v$ of $W^{(r)}_1$. Therefore, $(G, R', k)$ is a $(\varphi, \boxtimes)$-triple if and only if $(G \setminus v, R', k)$ is a $(\varphi, \boxtimes)$-triple.
