Gravitational analogue of Faraday rotation in the magnetized Kerr and Reissner-Nordström spacetimes

Chandrachur Chakraborty*

South-Western Institute for Astronomy Research, Yunnan University, Kunming 650500, China

It is known that the gravitational analogue of the Faraday rotation arises in the rotating spacetime due to the non-zero gravitomagnetic field. In this paper, we show that it also arises in the ‘non-rotating’ Reissner-Nordström spacetime, if it is immersed in a uniform magnetic field. The non-zero angular momentum (due to the presence of electric charge and magnetic field) of the electromagnetic field acts as the twist potential to raise the gravitational Faraday rotation in the said spacetime. The twisting can still exist even if the mass of the spacetime vanishes. In other words, the massless charged particle(s) immersed in a uniform magnetic field, able to twist the spacetime in principle, and responsible for the rotation of the plane of polarization of light. This, in fact, could have some applications in the basic physics and the analogue models of gravity. Here, we also study the effect of magnetic fields in the Kerr and Reissner-Nordström spacetimes, and derive the exact expressions for the gravitational Faraday rotation in the magnetized Kerr and Reissner-Nordström spacetimes. Considering the correction due to the magnetic field in the lowest possible order, we show that the logarithm correction of the distance of the source and observer in the gravitational Faraday rotation for the said spacetimes is an important consequence of the presence of magnetic field. From the astrophysical point of view, our result could be helpful to study the effects of (gravito-)magnetic fields on the propagation of polarized photons in the strong gravity regime of the rapidly rotating collapsed object.

I. INTRODUCTION

Faraday effect is a magneto-optical phenomenon discovered by Michael Faraday in 1845. It arises due to the interaction between the light and magnetic field of the medium. If a beam of plane polarized light is passed through a magnetic field, the plane of polarization is rotated by an angle proportional to the field intensity, which is known as the Faraday effect or Faraday rotation. Einstein’s General Relativity predicts that the light rays passing a massive object bend towards it, i.e., the light is affected by the gravitational field. Not only that, it has also been shown [1, 2] that the plane of polarization of the light rays is rotated by some finite angle depending on the angular momentum of the black hole, even if there is no magnetic field. This means that one can see the gravitational analogue of the Faraday rotation in a rotating spacetime, and the gravitomagnetic field (gravitational analogue of the magnetic field) is responsible for this phenomenon. The plane of polarization of the light rays are rotated due to this gravitomagnetic field. Therefore, this new Faraday rotation is called as the gravitational analogue of the Faraday rotation or the so-called gravitational Faraday rotation [1-4]. Note that, the gravitational Faraday rotation is not related to the magnetic field. It is only related to the gravitomagnetic field, i.e, the rotation of the spacetime. One cannot see the gravitational Faraday rotation in a non-rotating spacetime like the Schwarzschild spacetime. Thus, as of now, one can expect the gravitational Faraday rotation in the Kerr spacetime. The Taub-NUT spacetime has no intrinsic rotation [5] but it has a sense of rotation due to the presence of NUT charge. However, it has been shown [4] that no gravitational Faraday rotation is occurred in the Taub-NUT spacetime.

In a stark contrast, we show in this paper that the gravitational Faraday rotation can occur in the non-rotating Reissner-Nordström (RN) spacetime, if it is immersed in a uniform magnetic field. The RN spacetime is the electrovacuum solution of the Einstein-Maxwell equation with mass and electric charge only. If it is immersed in the magnetic field, its electric field and magnetic field together constitutes a non-zero electromagnetic angular momentum in the magnetized RN spacetime. This electromagnetic angular momentum acts as the gravitomagnetic field, and, therefore, it shows the gravitational Faraday rotation, i.e., if the light passes through this spacetime, the plane of polarization of the light or the electromagnetic wave rotates. Note that in a very recent paper, the exact solution of the magnetized Reissner-Nordström solution was investigated by [6].

The magnetic field plays an important role in the many astrophysical phenomena, e.g., the MHD simulation for the accretion mechanism [7], imaging of the black hole shadow [8, 9], magnetic Penrose process [10, 11] etc. Although the magnetic Penrose process was proposed assuming the magnetic field to be asymptotically uniform [10], the Blandford-Znajek (BZ) mechanism [12] is generally considered for the MHD simulation and to deduce the polarization of the photon ring [8]. However, the exact electrovacuum solution of the Einstein-Maxwell equation for the Kerr metric placed in a uniform magnetic field was first found by Wald [13]. In the next year, Ernst [14] presented a general procedure for transforming an asymptotically flat axially symmetric electrovacuum solution to an exact magnetized solution of the same. Later, the effect of a plasma in the force-free approximation was considered by Blandford and Znajek [12]. For the lacking of the direct measurements of the exact shapes of the magnetic field configurations around a realistic collapsed objects, many other numerical techniques are used to show the strong connections between the shape of magnetosphere and the characteristics of accretion mechanism [15, 16]. In this paper, we consider the Wald [13] and/or Ernst [14] solution as this is the exact electrovacuum solution of the Einstein-Maxwell equation. Secondly, the uniform magnetic field configuration assumed in the magnetic Penrose process [10, 11] seems more efficient than the magnetic field configuration of the BZ mechanism for the electromagnetic extraction of the rotational energy from a rotating black hole.

There was a draw back of the Ernst solution: it produces the conical singularities at the polar axis [17], which was removed by the Ernst-Wild (see [18]) solution in order to obtain a physically meaningful solution [19]. Later, Aliev and Galtsov [20] applied this solution to observe the magnetic precession (see also [21, 22]) in black hole systems with magnetized accretion disks. It is known that the gravitational energy is much greater than the electromagnetic energy, but those are comparable if the strength of the magnetic field ($B$) surrounding a collapsed object with mass $M$ is the order of $[19, 23]$

$$B \approx B_{\text{max}} \sim 2.4 \times 10^{19} \frac{M_{\odot}}{M}$$

(1)

where $M_{\odot}$ is the solar mass. The strength of the magnetic field surrounding black holes is considered much smaller than the value of $B_{\text{max}}$ (i.e., $B << B_{\text{max}}$) but the investigations suggest that the surrounding spacetimes around a black hole could be highly distorted for $B \sim B_{\text{max}}$. Thus, this magnetic field is very important as a background field testing of the geometry around a collapsed object [24].
The primary purpose of this paper is to study the effect of the magnetic field on the gravitational analogue of the Faraday rotation in the exact magnetized Kerr and Reissner-Nordström spacetimes. The scheme of the paper is as follows. In Sec. II, we revisit the formalism of the gravitational analogue of the Faraday rotation and derive the relation of it with the so-called spin precession of a test gyroscope. In Sec. III, we study the effect of magnetic field on the gravitational Faraday rotation. Sec. IV and Sec. V are devoted to study the effect of magnetic field on the gravitational Faraday effect in the magnetized Reissner-Nordström spacetime and the massless charged spacetime, respectively. Finally, we conclude in Sec. VI.

II. GRAVITATIONAL FARADAY ROTATION IN THE STATIONARY SPACETIME

The general metric of a stationary spacetime can be written as

$$ds^2 = g_{\mu\nu}dx^\mu dx^\nu = g_{00}(dx^0)^2 + 2g_{0i}dx^0dx^i + g_{ij}dx^i dx^j$$

$$= h(dx^0 - g_{ij}dx^i dx^j)$$

where

$$h = g_{00}, \quad g_i = -\frac{g_{0i}}{h}, \quad \gamma_{ij} = -g_{ij} + \frac{g_{0i}g_{0j}}{g_{00}}.$$  \hfill (4)

The Greek indices represent the time and space components, i.e., $x^\mu = (x^0 \equiv t, x^i)$ and the Latin indices represent only the space components, i.e., $i = 1, 2, 3$. We denote

$$g \equiv \det(g_{\mu\nu}), \quad \gamma \equiv \det(\gamma_{ij})$$

and, hence, $-g = \gamma h$. In a static spacetime ($g_i = 0$), the metric $\gamma_{ij}$ reduces to the so-called optical metric $[3, 25]$. Spatial trajectories of light rays are geodesics of the optical metric. Landau and Lifshitz [26] also showed that $\gamma_{ij}$ can be regarded as a metric of space, as opposed to spacetime. This is similar to the $(3+1)$ decomposition of the metric (Eq. 3). They showed that the test bodies following geodesics of spacetime depart from the geodesic of space as if acted on by the gravitational force $F$ which can be expressed as $[27] 1$.

$$F = \frac{m_0}{\sqrt{1 - v^2}} \left( E_g + v \times \sqrt{h} \cdot B_g \right)$$

where

$$E_g = -\nabla \ln \sqrt{h} = -\frac{1}{2} \frac{\nabla h}{h}$$

and

$$B_g = \text{curl} A \equiv \text{curl} g$$

are the gravitoelectric ($E_g$) and gravitomagnetic ($B_g$) fields respectively.

It is needless to say here that $\sqrt{h} B_g$ also appears in the expression of force (Eq. 6), and, the right hand side of Eq. (12) could be considered as an energy current corresponding to the Poynting vector flux of gravitational field energy. Note, all the operations in Eqs. (9-12) are defined in the 3D space with the metric $\gamma_{ij}$.

1 We use the geometrized unit ($G = c = 1$) in this whole paper except Eq. (92)
Now, using the analogy with the flat spacetime, we consider the plane of polarization of an electromagnetic wave consisting two 3-vectors: the wave vector $k$ and the polarization vector $f$. The 4-vectors corresponding to these 3-vectors are related as

$$ k^\sigma k_\sigma = 0, \quad k^\sigma f_\sigma = 0, \quad f^\sigma f_\sigma = 1, \quad \text{with} \quad \sigma = 0, 1, 2, 3. \quad (13) $$

The evolution equations of $k$ and $f$ along the ray were derived as [1],[4]

$$ 3\nabla_k k = L \times k + (E_g,k)k \quad (14) $$

$$ 3\nabla_k f = L \times f \quad (15) $$

where

$$ L = -\frac{1}{2} k_0 \left[ B_g - \frac{1}{2}(B_g,f)f + \frac{1}{|f|}E_g(k \times f)f \right]. \quad (16) $$

If only the second term exists on the RHS of Eq. (14), it would mean, by comparison with the 4D definition of the parallel transport, that the 3-vector $k$ is parallely transported along the projection of the null geodesic, but the presence of the first term indicates that $k$ is rotated by the angular velocity $L$. The same rotation also appears for the polarization vector $f$ (see Eq. 15). Thus, both of the equations together lead to this important fact that the polarization plane rotates with the angular velocity $L$ along the projected null geodesic. However, Ref. [4] derived the angle of rotation ($\chi$) around the tangent vector $\hat{k}$ along the path between the source and the observer as [4]:

$$ \chi = \int_{\text{source}}^{\text{observer}} L \cdot \hat{k} \, d\lambda \quad (17) $$

$$ = -\frac{1}{2} \int_{\text{source}}^{\text{observer}} (k_0 B_g \hat{k}) \, d\lambda \quad (18) $$

where $\lambda$ is the affine parameter along the ray. After some calculations, Ref. [4] reached at

$$ \chi = -\frac{1}{2} \int_{\text{source}}^{\text{observer}} \text{curl} (\sqrt{h} B_g) \, dS \quad (19) $$

where $dS$ represents the small element of surface to perform the surface integration. With the help of Eq. (12), Eq. (19) is reduced to

$$ \chi = -\int_{\text{source}}^{\text{observer}} (E_g \times \sqrt{h} B_g) \cdot dS. \quad (20) $$

Using Eq. (20), Ref. [4] derived the angle of so-called the gravitational analogue of the Faraday rotation ($\chi$) for the NUT as well as the Kerr spacetimes, i.e., both of the expressions of $E_g$ and $B_g$ are derived separately to obtain the expression of $\chi$ for the said spacetimes. But, one can also directly use the expression of Eq. (19) to derive $\Theta$ without using the expression of $E_g$, as done in [3]. Note, there is a basic difference between the formulation of [4] and [3], which we discuss below. Using Eq. (8) and $A \equiv g$ one can rewrite Eq. (19) as

$$ \chi = -\frac{1}{2} \int_{\text{source}}^{\text{observer}} \text{curl} (\sqrt{h} \text{ curl} g) \cdot dS. \quad (21) $$

It was pointed out in [3, 28] that the spin-optical interaction described by the effective force $f_e$ is proportional to ‘$\text{curl} \text{ curl} g$’ (see Eq. 71 of [28]), if one use the definition of $\gamma$ metric as of Eqs. (2) and (6) of [3]. In our case, $f_e$ should be proportional to ‘$h \text{ curl} (\sqrt{h} \text{ curl} g)$’. However, $f_e$ increases when a photon approaches the collapsed object and reaches its maximum near its radial turning point.

Note, if one use the definition of the $\gamma$ metric of [3], one obtains the angle of rotation ($\tilde{\chi}$) as $^2$

$$ \tilde{\chi} = -\frac{1}{2} \int_{\text{source}}^{\text{observer}} \text{curl} (\text{curl} g) \cdot dS. \quad (22) $$

$^2$ We follow the definition of $\chi$ and $f_e$ mentioned in Eq. (21) (not of Eq. 22) and Eq. (26), in the whole paper except Eq. (22) and Eq. (25). Eq. (22) as well as Eq. (25) are introduced only to show that both of the formalism eventually gives the same result.
One can take the example of the Kerr spacetime. Considering Eqs. (127-131) of [3] one can obtain from Eq. (22)

\[ \chi_{\text{Kerr}} = -\frac{1}{2} \int_{\text{source}}^{\text{observer}} \frac{4aM^2 \Sigma \sin \theta}{h^2} dr d\theta \]

(23)

\[ = -2aM^2 \int_{\text{source}}^{\text{observer}} \frac{\sin \theta}{(\Sigma - 2Mr)^2} dr d\theta \]

(24)

which is the same as Eq. (23) of [4]. In the weak-field regime \((r \gg M)\), one can obtain from Eq. (24):

\[ \chi_{\text{Kerr}} \sim aM^2/R^3, \]

where \(R\) is the distance between the source and the observer. Actually, \(4aM^2/\Sigma^3 \delta_p\) is substituted for \(\langle \text{curl} \text{ curl } g \rangle_p\) in Eq. (23), and, therefore,

\[ |f_e| \propto |\text{curl} \text{ curl } g| = \frac{4aM^2}{\Sigma^3} \frac{\sqrt{\Delta} \sin \theta}{h} = \frac{4aM^2 \sqrt{\Delta} \sin \theta}{\Sigma^2(\Sigma - 2Mr)}. \]

(25)

In our case, the effective force for the gravitational Faraday effect is obtained as

\[ |f_e| \propto \hbar \text{ curl}(\sqrt{\hbar} \text{ curl } g) \]

\[ = \frac{h}{\sqrt{\hbar} \Sigma(\Sigma - 2Mr)} \frac{4aM^2}{\Sigma^2} \frac{\sqrt{\Delta} \sin \theta}{\sqrt{\hbar}} = \frac{4aM^2 \sqrt{\Delta} \sin \theta}{\Sigma^2(\Sigma - 2Mr)} \]

(26)

which is same as Eq. (25). Far away from a Kerr black hole, this extra force \(f_e\) decreases very rapidly as [28]

\[ |f_e| \sim \frac{4aM^2}{r^5} \sin \theta. \]

(27)

### A. Relation between the gravitational Faraday rotation and the so-called spin precession

For the Kerr spacetime,

\[ g_{00} = h = \left(1 - \frac{2Mr}{\Sigma}\right), \quad g \equiv g_{\phi \phi} = \frac{2aMr \sin^2 \theta}{\Sigma - 2Mr} \]

(28)

and

\[ \gamma_{ij} dx^i dx^j = \frac{\Sigma}{\Delta} dr^2 + \Sigma d\theta^2 + \frac{\Delta}{h} \sin^2 \theta d\phi^2 \]

where, \(a\) is Kerr parameter, defined as \(a = \frac{\Delta}{M}\), the angular momentum per unit mass and

\[ \Sigma = r^2 + a^2 \cos^2 \theta, \quad \Delta = r^2 - 2Mr + a^2. \]

(30)

Considering Eq. (8), one obtains the gravitomagnetic field (in terms of the coordinate basis vectors: \(e_p\)) for the Kerr spacetime as

\[ (\text{curl } g)^p e_p = -2aM \left[ \frac{2r \Delta \cos \theta}{\Sigma^3(\Sigma - 2Mr)^{3/2}} e_r + \left(\frac{r^2 - a^2 \cos^2 \theta}{\Sigma^3(\Sigma - 2Mr)^{3/2}}\right) e_\theta \right]. \]

(31)

To change coordinate basis vectors (\(e_p\)) to the orthonormal basis vectors (\(e_p\)), one can use the following relation \(e_p = e_p/\sqrt{g_{pp}}\) [29], and express Eq. (31) as:

\[ (\text{curl } g)^\hat{p} e_p = -2aM \left[ \frac{2r \sqrt{\Delta} \cos \theta}{\Sigma(\Sigma - 2Mr)^{3/2}} e_r + \left(\frac{r^2 - a^2 \cos^2 \theta}{\Sigma(\Sigma - 2Mr)^{3/2}}\right) e_\theta \right]. \]

(32)

Interestingly, if one multiplies Eq. (32) with \(-\sqrt{\hbar}/2\), one obtains the same expression (Eq. (42) of [5]) which was obtained as the spin precession frequency \(\Omega_s\), or, so-called the Lense-Thirring (LT) precession [30] frequency of a test gyroscope or a test spin (for the detailed spin precession formalism, see [31–33]). So, technically, Eq. (21) leads to the angle of

\[ \chi = \int_{\text{source}}^{\text{observer}} (\text{curl } \Omega_s) \cdot dS. \]

(33)
Although the general expression for the LT precession frequency of a test spin in terms of the coordinate basis vectors was obtained in [34] as
\[ \Omega \equiv - \frac{g_{00}}{2\sqrt{-g}}e_{ijp}g_{i,j}(e_p + g_p e_0) \] (34)
for a general stationary spacetime, we should only consider
\[ \Omega_s = - \frac{1}{2} \sqrt{\frac{h}{\gamma}} \epsilon_{ijp} g_{i,j} e_p = - \frac{1}{2} \sqrt{\hbar} (\text{curl } g) \] (35)
as we deal here only with the $\gamma_{ij}$ metric. $\epsilon_{ijp}$ is the Levi-Civita symbol.

Note, in case of the Taub-NUT spacetime [35, 36], $(\text{curl } g)$ comes as non-zero [4, 5], and, hence the spin of a test gyro can precess [5] in this spacetime. On the other hand, $(\text{curl } (\sqrt{\gamma} \text{ curl } g))$ vanishes, and, therefore, no gravitational Faraday rotation is induced in the Taub-NUT spacetime [4]. This example could be helpful to differentiate between the spin precession and the gravitational Faraday rotation.

**B. Angular separation ($\Theta$) of the right and left circularly polarized beams due to the gravitational Faraday rotation**

In a recent paper, [3] has studied how polarization of photons affects their motion in a gravitational field created by a rotating massive collapsed object. They have shown that the angular separation ($\Theta$) of the right and left circularly polarized beams is deduced using the dimensionless parameter: $\varepsilon = \pm (M\omega)^{-1}$ [28] (with $|\varepsilon| \ll 1$), i.e.,
\[
\Theta = \pm \frac{1}{M\omega} \chi = \pm \frac{1}{2M\omega} \int_{\text{observer}}^{\text{source}} \text{curl}(\sqrt{\gamma} \text{ curl } g) \cdot dS
\] (36)
\[
= \pm \frac{1}{M\omega} \int_{\text{source}}^{\text{observer}} (\text{curl } \Omega_s) \cdot dS
\] (37)
where $\omega$ is the photon frequency and + and − correspond to the right and left circular polarizations, respectively. Eq. (36) depends on $\omega$, and this, in fact, can be used as the final expression to obtain the angle of rotation of the plane of polarization of the light for the gravitational Faraday effect in a particular spacetime. In the next two sections, we study the effects of the gravitational analogue of Faraday rotation in the magnetized Kerr and Reissner-Nordström spacetimes.

**III. GRAVITATIONAL FARADAY ROTATION IN THE MAGNETIZED KERR SPACETIME**

**A. Brief discussion on the Kerr spacetime immersed in the uniform magnetic field**

The exact electrovacuum solution of the Einstein-Maxwell equation for the magnetized Kerr spacetime is written as [17, 19]
\[
ds^2 = \left( \frac{\Delta}{A} dt^2 - \frac{db^2}{\Delta} - d\theta^2 \right) \Sigma |\Lambda|^2 - \frac{A \sin^2 \theta}{\Sigma |\Lambda|^2} |\Lambda_0|^2 d\phi - \omega dt^2
\] (38)
where
\[
\Delta = r^2 + a^2 - 2Mr, \quad \Sigma = r^2 + a^2 \cos^2 \theta, \\
A = (r^2 + a^2)^2 - \Delta a^2 \sin^2 \theta, \quad \omega = \frac{\alpha - \beta \Delta}{r^2 + a^2}.
\] (39)
Λ(r, θ) is a complex quantity and it has two parts, the real part of Λ: Re Λ and the imaginary part of Λ: Im Λ. So, one can express it as:

\[
\Lambda \equiv \Lambda(r, \theta) = \text{Re } \Lambda + i \text{ Im } \Lambda
\]

\[
= 1 + \frac{B^2 \sin^2 \theta}{4} \left[ \left( \frac{r^2 + a^2}{\Sigma} \right) \right] - i \frac{aB^2 M \cos \theta}{2} \frac{1}{\Sigma} \left( 3 - \cos^2 \theta + \frac{a^2 \sin^4 \theta}{\Sigma} \right)
\]

(41)

where \(i\) stands for the imaginary quantity. In the expression of \(\omega\) (Eq. 40),

\[
\alpha = a(1 - a^2 M^2 B^4)
\]

(42)

and,

\[
\beta = \frac{a\Sigma}{A} + \frac{aMB^4}{16} \left[ -8r \cos^2 \theta(3 - \cos^2 \theta) - 6r \sin^4 \theta + \frac{2a^2 \sin^6 \theta}{A} \left( 2Ma^2 + r(a^2 + r^2) \right) \right]
\]

\[
+ \frac{4a^2 \cos^2 \theta}{A} \left[ (r^2 + a^2)(3 - \cos^2 \theta)^2 - 4a^2 \sin^2 \theta \right]
\]

(43)

It was first pointed out in [37] that ‘magnetic’ transformation of the Kerr spacetime is only locally valid, as it produces the conical singularities at the polar axis. This conical singularities on the polar axis generate some singular stress energy tensor on the right hand side of the Einstein equation in addition to the Maxwellian term. This deficiency can be removed by changing the interval of variation of the azimuthal angle \(\phi\) from \(2\pi\) to \(2\pi|\Lambda_0|^2\) [17, 19], where

\[
|\Lambda_0|^2 = |\Lambda(r, 0)|^2 = 1 + a^2 M^2 B^4
\]

(44)

is the Harrison-Ernst function \(\Lambda(r, \theta)\) at the polar axis \(\theta = 0\). That is the reason, \(|\Lambda_0|^2\) appears just before \(d\phi\) in Eq. (38). Without the factor \(|\Lambda_0|^2\) before \(d\phi\), the magnetized Kerr metric is not really a solution of the Einstein-Maxwell equations elsewhere, as it produces the Ricci tensor singular at the polar axis [17, 19]. Such a singularity is similar to that of the cosmic string [38], which has positive energy density and negative tension by analogy with the physical string. Note, the horizon radii

\[
r_{\pm} = M \pm \sqrt{M^2 - a^2}
\]

(45)

are same for the ordinary Kerr metric and the magnetized Kerr metric, as it do not depend on the value of \(B\). On the other hand, the ergoradii in the magnetized Kerr metric depend on the value of \(B\). Therefore, the expressions of ergoradii for the magnetized Kerr metric cannot be same with the ordinary Kerr metric.

B. Gravitational Faraday rotation in the magnetized Kerr spacetime

For the magnetized Kerr spacetime, one can deduce

\[
g_{00} = h = \left( \frac{\Delta \Sigma |\Lambda|^2}{A} - \frac{A \omega^2 \sin^2 \theta}{\Sigma |\Lambda|^2} \right), \quad g = g_{\phi} = -\frac{\omega A^2 |\Lambda_0|^2 \sin^2 \theta}{\Delta \Sigma^2 |\Lambda|^4} - A^2 \omega^2 \sin^2 \theta
\]

(46)

and

\[
\gamma_{ij} dx^i dx^j = \frac{\Sigma |\Lambda|^2}{\Delta} dr^2 + \Sigma |\Lambda|^2 d\theta^2 + \frac{\Delta |\Lambda_0|^4}{h} \sin^2 \theta d\phi^2
\]

(47)
from Eq. (38). Now, using Eq. (47), we obtain

\[
(curl \, g)^p = \frac{4aM\Delta \cos \theta}{\Sigma^{3/2}(\Sigma - 2Mr)^{3/2}} \left( 1 - \frac{B^2 \sin^2 \theta}{32\Sigma(\Sigma - 2Mr)} C_1 \right) \delta_r^p - \frac{2aM \sin \theta}{\Sigma^{3/2}(\Sigma - 2Mr)^{3/2}} \left( r^2 - a^2 \cos^2 \theta \right) + \frac{B^2 \sin^2 \theta}{128\Sigma(\Sigma - 2Mr)} C_2 \right) \delta_\theta^p + O(B^3)
\]

and,

\[
(curl \, (\sqrt{\mu} \, curl \, g))^p = \left[ \frac{4aM^2}{\Sigma^{3/2}(\Sigma - 2Mr)^{3/2}} - \frac{3aMB^2}{64\Sigma^{5/2}(\Sigma - 2Mr)^{5/2}} C_3 + O(B^3) \right] \delta_r^p
\]

where \(C_1, C_2, C_3\) all are functions of \(r\) and \(\theta\):

\[
C_1 = 25a^6 + 72r^5(-2M + r) + a^4r(-46M + 91r) + 16a^2r^2(-3M^2 + 7Mr + 8r^2) \\
+ a^2(35a^4 + 36a^2r(-2M + 3r) + 8r^2(6M^2 - 22Mr + 11r^2)) \cos 2\theta \\
+ a^4(11a^2 + r(-26M + 17r)) \cos 4\theta + a^6 \cos 6\theta,
\]

\[
C_2 = 50a^8 + 32(16M - 3r)(2M - r)r^6 + 2a^6r(-42M + 95r) + 16a^2r^4(44M^2 - 62Mr + 9r^2) \\
+ 4a^2r^3(-12M^2 - 126Mr + 67r^2) + a^2(75a^6 + 96a^2r^3(-7M + 4r) + a^4r(-142M + 275r) \\
+ 16r^4(20M^2 - 46Mr + 19r^2) \cos 2\theta + 2a^4(15a^4 + a^2r(-38M + 49r) \\
+ 2r^2(12M^2 - 42Mr + 29r^2)) \cos 4\theta + a^6(5a^2 + r(-18M + 13r)) \cos 6\theta.
\]

Now, one can calculate the effective force for the gravitational Faraday rotation as

\[
|f_e| \propto h \, curl(\sqrt{h} \, curl \, g) = \frac{4aM^2 \sqrt{\Delta} \sin \theta}{\Sigma^{3/2}(\Sigma - 2Mr)} - \frac{aMB^2 \sqrt{\Delta} \sin \theta}{64\Sigma^{5/2}(\Sigma - 2Mr)^2} C_4 + O(B^3)
\]

where

\[
C_4 = 64(5M - 3r)(2M - r)r^5 + 17a^6(M + 15r) + 8a^4r(-2M^2 - 121Mr + 105r^2) \\
+ 16a^2r^2(-24M^3 + 56M^2r - 129Mr^2 + 57r^3) + 4(16(19M - 9r)(2M - r)r^5 + a^6(M + 93r) \\
+ a^4r(-2M^2 - 251Mr + 190r^2) + 16a^2r^2(4M^3 + 16M^2r - 35Mr^2 + 12r^3)) \cos 2\theta \\
- 4a^2(4(5M - 33r) + 4(4M - r)r^2(8M^2 - 32Mr + 15r^2) - 2a^2r(2M^2 - 71Mr + 39r^2)) \cos 4\theta \\
- 4a^4(M - 3r)(a^2 + r(-2M + r)) \cos 6\theta + 3a^6(M - r) \cos 8\theta.
\]

The second term in the right hand side of Eq. (53) appears as the correction term due to the presence of magnetic field. Far away (\(r >> M\)) from a slowly rotating Kerr black hole (\(a_* \approx a/M << 1\)), \(|f_e|\) decreases as

\[
|f_e|_{(a_* << 1, r >> M)} \sim \sin \theta \left[ \frac{4aM^2}{r^3} - \frac{3aMB^2}{r^5} (1 + 3 \cos 2\theta) \right].
\]

\(^3\) Although we have calculated the exact expressions for \((\sqrt{\mu} \, curl \, g)\) and \((\sqrt{\mu} \, curl \, g)\), we do not show it here as those expressions are very big in size and useless for the current purpose of this paper. Those expressions could be important for the numerical calculations which we suppose to report elsewhere in future. As the magnetic energy is much less than the gravitational energy for a massive magnetized collapsed object (see Sec. 1), considering the order of magnetic field up to \(B^2\) should suffice for the current purpose of this paper. Hence, we show all the required expressions up to the order of \(B^2\).
Eq. (55) shows that although the effective force for the gravitational Faraday effect decreases as $\sim r^{-5}$ for the ordinary Kerr spacetime, the effective force term due to the presence of non-zero magnetic field decreases as $\sim r^{-2}$ in the magnetized Kerr spacetime. Interestingly, one cannot see the effect of magnetic field in $|f_0|$ for $\theta_0 = \frac{\pi}{2} - \frac{1}{2} \cos^{-1} \frac{1}{4} \approx 54.74^\circ$, as the second term in the square bracket of Eq. (55) vanishes for that value.

Now, using Eq. (36) one obtains the angle of rotation due to the gravitational Faraday effect as

$$\Theta = \mp \frac{1}{M\omega} \int_{r_s}^{r_o} \int_{\theta_s}^{\theta_0} \left[ \frac{2aM^2 \sin \theta}{(\Sigma - 2Mr)^2} - \frac{aMB^2 \sin \theta}{32(\Sigma - 2Mr)^3} C_5 \right] d\theta \, dr$$

(56)

where

$$C_5 = 2(8(5M - 3r)(2M - r)r^3 + a^4(5M + 39r) + 4a^2r(-M^2 - 35Mr + 21r^2))$$

$$+ (-3a^4(M - 33r) + 16(19M - 9r)(2M - r)r^3 + 64a^2r^2(-7M + 3r)) \cos 2\theta$$

$$+ 2a^2(a^2(-5M + 9r) + 4r(M^2 - 5Mr + 3r^2)) \cos 4\theta + 3a^4(M - r) \cos 6\theta.$$  

(57)

In Eq. (56), we take the limit of integration of $r$ from $r_s$ (distance of the source from the central object) to $r_0$ (distance of the observer from the central object) and $\theta_s$ (position angle of the source) to $\theta_0$ (position angle of the observer). Here we consider $r$ and $\theta$ as the two independent parameters unlike [4], as our aim is to derive how the gravitational Faraday rotation is affected due to the presence of magnetic field as observed from a particular point.

Note that Eq. (48) reduces to the combinations of the expressions of $B^r_r$ and $B^\theta_\theta$ of Sec. V.B of Ref. [4] for $B \to 0$. There is no discrepancy between Eq. (49) of this paper and Eq. (131) of [3] for $B \to 0$. If one multiplies Eq. (49) with $h^{3/2}$, it reduces to Eq. (131) of [3]. The apparent discrepancy between these two expressions arises due to the different definition of the $\gamma_{ij}$ metric (see Eq. 4 of this paper and Eq. 6 of [3]). Moreover, Eq. (131) of [3] derived $(\text{curl } \text{curl } g)$ whereas we derive $(\text{curl } (\sqrt{h} \text{ curl } g))$. Eventually, the term inside the square bracket of Eq. (56) reduces to Eq. (23) of [4] for $B \to 0$, as the final expression (scalar quantity) for calculating the angle of rotation ($\Theta$) due to the gravitational Faraday rotation.

C. Logarithm correction in the gravitational Faraday rotation for the slowly-rotating magnetized Kerr black hole

In case of the slowly rotating black hole ($a_* \equiv a/M << 1$) and for a distant observer ($r >> M$), Eq. (56) reduces to

$$\Theta|_{(a_*,<1,r>>M)} = \mp \frac{1}{M\omega} \int_{r_s}^{r_o} \int_{\theta_s}^{\theta_0} \left[ \frac{2aM^2}{r^4} - \frac{3aMB^2}{2r}(1 + 3 \cos 2\theta) \right] \sin \theta \, dr \, d\theta$$

(58)

$$= \pm \frac{a}{\omega} \int_{\theta_s}^{\theta_0} \left[ \frac{2M}{3} \left( \frac{1}{r_s^2} - \frac{1}{r_o^2} \right) - \frac{3}{2} B^2(1 + 3 \cos 2\theta) \ln \left( \frac{r_s}{r_o} \right) \right] \sin \theta \, d\theta$$

(59)

The first term ($\propto r^{-3}$) in the square bracket are already reported in several papers [1–4, 28, 39–41] but the second term, i.e., the logarithmic correction in the gravitational Faraday rotation due to the presence of magnetic field is completely new. We do not perform the $\theta$ integration in Eq. (59), as it is not so important for our present purpose.
IV. GRAVITATIONAL FARADAY ROTATION IN THE MAGNETIZED REISSNER-NORDSTRÖM SPACETIME

A. Brief discussion on the Reissner-Nordström spacetime immersed in the uniform magnetic field

If the Reissner-Nordström (RN) spacetime is immersed in a uniform magnetic field $B$, the transformed metric can be expressed as [14]

$$ds^2 = |\Lambda|^2 \left[ \frac{\Delta}{r^2} dt^2 - \frac{dr^2}{\Delta} - r^2 d\theta^2 \right] - |\Lambda|^{-2} r^2 \sin^2 \theta (|\Lambda_0|^2 d\phi - \omega dt)^2$$

(60)

where

$$\Delta = r^2 - 2Mr + Q^2, \quad \Lambda = 1 + \frac{1}{4} B^2 \left( r^2 \sin^2 \theta + Q^2 \cos^2 \theta \right) - iBQ \cos \theta$$

(61)

and

$$\omega = \frac{BQ}{2r} \left[ -4 + 2B^2 r^2 + B^2 Q^2 - B^2 \Delta \sin^2 \theta \right].$$

(62)

Here, $M$ and $Q$ are the mass and charge of the spacetime which is immersed in an uniform magnetic field $B$. The magnetized RN spacetime (mRN) will reduce to the ordinary RN spacetime (oRN) for $B = 0$. One should note here that the mRN metric (Eq. 60) is the exact electrovacuum solution of the Einstein-Maxwell equation (with a non-zero magnetic field), similar to the oRN. Another similarity between oRN and mRN is that the locations of the horizons ($r_{\pm}$) occur at the same distance, i.e.,

$$r_{\pm} = M \pm \sqrt{M^2 - Q^2}$$

(63)

where $r_+$ and $r_-$ indicate the locations of the event horizon and Cauchy horizon, respectively. Eq. (63) shows that both of the horizons exist only for $0 < Q \leq M$, whereas the horizons vanish for the overcharged ($Q > M$) RN spacetime. The reason to add

$$|\Lambda_0|^2 = |\Lambda(r, 0)|^2 = \left( 1 + \frac{B^2 Q^2}{4} \right)^2 + B^2 Q^2$$

(64)

before $d\phi$ of Eq. (60) is same as discussed in Sec. IIIA. Thus, we do not repeat it here.

The electric field and magnetic field components in the mRN spacetime can be written as:

$$H_r + iE_r = \Lambda^{-2} \left[ iQ/r^2 \left( 1 - \frac{1}{4} B^2 \left( r^2 \sin^2 \theta + Q^2 \cos^2 \theta \right) \right) \right]$$

$$+ B(1 - 1/2iBQ \cos \theta)(1 - Q^2/r^2) \cos \theta),$$

(65)

$$H_\theta + iE_\theta = -B \Lambda^{-2}(1 - 1/2iBQ \cos \theta) \frac{\Delta}{r} \sin \theta.$$  

(66)

Thus, $\mathbf{E} \times \mathbf{H}$ serves as the source of twist potential in the mRN spacetime as

$$|\mathbf{E} \times \mathbf{H}| = -\frac{BQ \sqrt{\Delta} \sin \theta}{16r^3 \Lambda^4} \left[ 1 - \frac{1}{4} B^2 \left( r^2 \sin^2 \theta + Q^2 \cos^2 \theta \right) \right].$$

(67)

If $B$ and/or $Q$ vanishes, the twist potential becomes zero.

The stark contrast between an oRN and a mRN is that the mRN is an stationary and axisymmetric spacetime whereas the oRN is a static and spherically symmetric spacetime. Which makes this important difference between these two? Of course, the presence of magnetic field. If the magnetic field vanishes, $\omega$ becomes zero. One can see the non-zero gravitational Faraday rotation or the so-called spin precession only because of the presence of $\omega$ or $g_i$ or $B$. It is interesting to see that $\omega$ or $g_i$ can vanish at

$$r_0 = r|_{\omega=0} = \frac{\sqrt{8 - 2B^2 Q^2 + (3B^2Q^2 - 4) \sin^2 \theta + B^2(M^2 - Q^2) \sin^4 \theta} - MB \sin^2 \theta}{B(2 - \sin^2 \theta)}$$

(68)
for a particular radius \( r = r_0 \) even if \( B \neq 0 \). So, one cannot see the gravitational Faraday rotation at this particular orbit whereas the ordinary Faraday rotation can be seen. Note that to obtain a physically realistic \( r_0 \), it must be positive, which satisfies

\[
\sin^2 \theta \geq \left(1 - \frac{4}{B^2 Q^2}\right), \quad \text{i.e.} \quad BQ \leq 2 \sec \theta.
\] (69)

B. Gravitational Faraday rotation in the magnetized Reissner-Nordström spacetime

For the mRN spacetime, one can deduce

\[
g_{00} = h = \left(\frac{\Delta |\Lambda|^2}{r^2} - \frac{r^2 \omega^2 \sin^2 \theta}{|\Lambda|^2}\right), \quad g \equiv g_\phi = -\frac{\omega r^4 |\Lambda_0|^2 \sin^2 \theta}{\Delta |\Lambda|^4 - r^4 \omega^2 \sin^2 \theta}
\] (70)

and

\[
\gamma_{ij} dx^i dx^j = \frac{r^2 |\Lambda|^2}{\Delta} dr^2 + r^2 |\Lambda|^2 d\theta^2 + \frac{\Delta |\Lambda_0|^4}{h} \sin^2 \theta d\phi^2
\] (71)

from Eq. (60). Now, using Eq. (71), we obtain

\[
(curl \ g)^p = \left[\frac{4Q \cos \theta}{r^{1/2}(r - 2M)^{1/2}} \delta^p_\theta - \frac{2Q \sin \theta (r - 4M)}{r^{3/2}(r - 2M)^{3/2}} \delta^p_\phi + O(Q^3)\right] B + O(B^3)
\] (72)

and

\[
(curl (\sqrt{h} \ curl \ g))^p = \left[\frac{4Q(r - 3M)}{r^{3/2}(r - 2M)^{3/2}} \delta^p_\phi + O(Q^3)\right] B + O(B^3).
\] (73)

Now, one can calculate the effective force for the gravitational Faraday rotation as

\[
|f_e| \propto |h \ curl (\sqrt{h} \ curl \ g)| = \left[\frac{4Q(r - 3M) \sin \theta}{r^{3/2}(r - 2M)^{1/2}} + O(Q^3)\right] B + O(B^3).
\] (74)

Far away \((r >> M)\) from the mRN spacetime, one obtains from Eq. (74) as

\[
|f_e|_{r >> M} \sim \frac{4BQ \sin \theta}{r^2}.
\] (75)

This indicates that \(|f_e|\) is proportional to \(r^{-2}\), as magnetic field is non-zero here, which is similar to the ‘magnetic’ correction term of the magnetized Kerr case. Thus, the angle of rotation due to the gravitational Faraday effect is obtained using Eq. (36) as

\[
\Theta = \mp \frac{1}{M\omega} \int_{r_s}^{r_0} \int_{\theta_1}^{\theta_2} 2BQ \left(\frac{(r - 3M) \sin \theta}{(r - 2M)^2}\right) dr d\theta
\] (76)

Similar to Eq. (59), we perform the integration, and obtain from Eq. (76) for a distant observer \((r >> M)\) as

\[
\Theta = \pm \frac{2BQ}{M\omega} \ln \left(\frac{r_o}{r_s}\right) \left(\cos \theta_o - \cos \theta_s\right).
\] (77)

The angle of rotation \((\Theta)\) depends on the logarithm of the observer’s distance in this case too. This is similar to the magnetized Kerr case. It seems that the presence of a uniform magnetic field in a spacetime is responsible for \(\Theta\) to depend on the logarithm of the distance of the observer.

Note that an unmagnetized Reissner-Nordström spacetime cannot show the gravitational Faraday rotation, which leads to \(\Theta = 0\). On the other hand, a mRN spacetime can show the gravitational Faraday rotation, the spin precession of a test gyro and the frame-dragging effect. In conclusion, the mRN spacetime acts as a perfectly rotating charged collapsed object, although its spin/Kerr parameter is zero. The source of its angular momentum is the Poynting vector or the non-zero twist potential \((E \times H)\).
V. GRAVITATIONAL FARADAY ROTATION IN THE MASSLESS CHARGED REISSNER-NORDSTRÖM-LIKE SPACETIME IMMERSED IN AN UNIFORM MAGNETIC FIELD

If the mass term vanishes ($M \rightarrow 0$) in Eq. (60), it implies a massless charged RN-like spacetime [42]. Now, if the massless charged RN-like spacetime is immersed in an uniform magnetic field $B$, the transformed metric can be expressed as (setting $M \rightarrow 0$ in Eq. 60)

$$ds^2 = |\Lambda|^2 \left[ -\left(1 + \frac{Q^2}{r^2}\right) dt^2 + \frac{dr^2}{1 + \frac{Q^2}{r^2}} + r^2 d\theta^2 \right] + |\Lambda|^{-2} r^2 \sin^2 \theta \left(|\Lambda_0|^2 d\phi - \omega dt\right)^2$$  \hspace{1cm} (78)

where [17, 19]

$$\Lambda = 1 + \frac{1}{4} B^2 \left(r^2 \sin^2 \theta + Q^2 \cos^2 \theta\right) - i B Q \cos \theta,$$

$$|\Lambda_0|^2 = |\Lambda(r, 0)|^2 = \left(1 + \frac{1}{4} B^2 Q^2\right)^2 + B^2 Q^2$$  \hspace{1cm} (80)

and

$$\omega = \frac{B Q}{2 r} \left[-4 + 2 B^2 r^2 + B^2 Q^2 - B^2 r^2 \sin^2 \theta \left(1 + \frac{Q^2}{r^2}\right)\right].$$  \hspace{1cm} (81)

As the horizons do not exist for the metric presented in Eq. (78), it represents a naked singularity, in principle. Now, one can obtain

$$(\text{curl } g)^p = \left[\frac{4 Q \cos \theta}{r} \delta_r^p - \frac{2 Q \sin \theta}{r^2} \delta_\theta^p + O(Q^3)\right] B + O(B^3)$$  \hspace{1cm} (82)

and

$$\left(\text{curl } (\sqrt{h} \text{ curl } g)^p\right) = \left[\frac{4 Q \sin \theta}{r^3} \delta_r^p + O(Q^3)\right] B + O(B^3).$$  \hspace{1cm} (83)

The effective force for the gravitational Faraday rotation can be calculated as

$$|f_e| \propto \left|h \text{ curl}(\sqrt{h} \text{ curl } g)\right| = \left[\frac{4 Q \sin \theta}{r^2} + O(Q^3)\right] B + O(B^3).$$  \hspace{1cm} (84)

Thus, the angle of rotation due to the gravitational Faraday effect is obtained using Eq. (36) as

$$\Theta = -\varepsilon \int_{\text{observer}}^{\text{source}} 2 B Q \left(\frac{\sin \theta}{r}\right) dr d\theta$$  \hspace{1cm} (85)

Although we have, so far, used $\varepsilon = \pm (M \omega)^{-1}$ (see Sec. II B), the same cannot be used in Eq. (85), as $M = 0$ in this particular case. However, by solving the wave equation with the magnetic potential (see Eq. 118 of Ch. 8 of [43]), one obtains a modified plane wave equation due to the presence of magnetic field [44]. From that, one may conclude: $\varepsilon = \pm (\omega^2/B^2)^{-1}$, where $|\varepsilon| << 1$. As the magnetic energy ($\sim B^2$) is much less than the gravitational energy, the contribution of ($\omega^2/B^2)^{-1}$ is negligible compare to $(M \omega)^{-1}$, and, therefore it does not appear in case of the magnetized Kerr and mRN spacetimes. On the other hand, $M$ vanishes in the massless RN spacetime, and this particular term $\varepsilon = \pm (\omega^2/B^2)^{-1}$ becomes important for this case. Note, without solving the wave equation, one may also deduce the term $(\omega^2/B^2)^{-1}$ from the dimension analysis. However, eventually, we obtain from Eq. (85):

$$\Theta = \pm \frac{2 B^3 Q}{\omega^2} \int_{r_s}^{r_o} \int_{\theta_s}^{\theta_o} \left(\frac{\sin \theta}{r}\right) dr d\theta$$  \hspace{1cm} (86)

$$= \pm \frac{2 B^3 Q}{\omega^2} \ln \left(\frac{r_o}{r_s}\right) (\cos \theta_o - \cos \theta_s).$$  \hspace{1cm} (87)

Eq. (87) is also depends on the logarithmic term, which is expected.
A. Spin precession in the massless charged Reissner-Nordström-like spacetime

Using Eq. (35), one can obtain the exact expression for the spin precession in the massless RN spacetime as,

$$\Omega_s \approx \frac{BQ}{r} \left[-2\cos\theta \hat{r} + \sin\theta \hat{\theta}\right] + O(B^3)Q + O(Q^3)$$  \hspace{1cm} (88)

$$= r |E| |B| \left[2\cos(\pi - \theta) \hat{r} + \sin(\pi - \theta) \hat{\theta}\right]$$  \hspace{1cm} (89)

where $|E| \sim Q/r^2$ is the modulus of the electric field. Although we have calculated the exact expression of the above expression (Eq. 88), here we write it up to the order of $B^2$ and $Q^2$. To draw an analogy with the spin (LT) precession ($\Omega_s^{Kerr}$) for a slowly rotating Kerr black hole [5, 29]

$$\Omega_s^{Kerr} = \frac{1}{r^3} [3(J, \hat{r})\hat{r} - J] = \frac{J}{r^3} \left[2\cos\theta \hat{r} + \sin\theta \hat{\theta}\right]$$  \hspace{1cm} (90)

($J = |J|$ is the angular momentum of the Kerr spacetime), we can rewrite Eq. (88) or Eq. (89) as

$$\Omega_s = j \left[2\cos(\pi - \theta) \hat{r} + \sin(\pi - \theta) \hat{\theta}\right]$$  \hspace{1cm} (91)

where $j = |j| \sim r |E| |B|$ (i.e., $E$ is orthogonal to $B$ as well as $E \times B$ is orthogonal to $\hat{r}$) is the modulus of the angular momentum density ($j$) of the electromagnetic field. It is clear from Eq. (91) that the spin precession frequency for the EM field does not follow the inverse cube law of distance. Although $|\Omega_s| \propto j$, the angle is differed by $(\pi - \theta)$. This means that if the direction of angular momentum ($j$) of the electromagnetic field is separated by an angle $\theta$ with the radial direction $\hat{r}$, the direction of spin precession is occurred separated by an angle $(\pi - \theta)$ with $\hat{r}$.

As the massless charged particles have not been observed yet [45, 46] in nature, Sec. V is devoted only for the theoretical purpose. Another problem is that the massless charged RN-like spacetime describes a naked singularity. Thus, as of now, this particular spacetime is completely unrealistic. However, one can notice the sole importance of the magnetic fields and electric charges for the gravitational Faraday rotation without the presence of mass and rotation parameter. Specifically, as all the derivations of Sec. V A is independent of mass, those might be important for the very small massive charged particles, like, electrons, protons etc. The possible applications of this special spin precession derived in this section as well as the gravitational analogue of Faraday rotation may be studied in the laboratory applying it to the analogue models of gravity [47–49]. For example, one may proceed with the same arrangement as mentioned in [50] with some modifications (i.e., submerging the whole system in an uniform magnetic field and adding charges of a ‘very low mass’ at the center of the radial vortex) to visualize the above-mentioned effect.

VI. CONCLUSION AND DISCUSSION

In the original Faraday effect, a plane polarized electromagnetic wave rotates by an angle $(\delta \theta_F)$ [4]:

$$\delta \theta_F = \frac{2\pi e^3}{m_e c^2 \omega^2} \int_0^D n_e(s)B_\parallel(s) ds$$  \hspace{1cm} (92)

where $n_e(s)$ is the density of electrons at each point $s$ along the path, $D$ is the length of the path where the light and magnetic field interact, $B_\parallel(s)$ is the component of the interstellar magnetic field in the direction of propagation at each point $s$ along the path, $e$ is the charge of an electron; $c$ is the speed of light in the vacuum; $m_e$ is the mass of an electron and $\omega$ is the frequency of light.

In contrast, we have shown in this paper that, in case of the gravitational Faraday effect for an ordinary slowly-rotating Kerr black hole, it is proportional to $a$ and $M$ and inversely proportional to $r^3$ and $\omega$ for a distant

---

4 The angular momentum density ($j$) of an electromagnetic (EM) field is written as

$$j \sim r \times (E \times B).$$
observer, whereas, in the presence of magnetic field, the modified term proportional to $aB^2$ and $\ln r$, and is inversely proportional to $\omega$. We show that the gravitational Faraday effect becomes non-zero if the RN spacetime is immersed in a magnetic field. In a stark contrast with the magnetized Kerr spacetime, the gravitational Faraday effect in the magnetized RN spacetime is proportional to $BQ$, $\ln r$ and inversely proportional to $M\omega$ for a distant observer. In case of the massless charged RN spacetime, it depends on $\sim B^2Q \ln r/\omega^2$. Overall, we have shown that the magnetic field has a non-negligible effect on the gravitational Faraday rotation. Although the massless charge(s) cannot be found in nature, our result could be applicable for a very small massive ($M \rightarrow 0$) charged particle. Note, as the exact expressions of the gravitational Faraday rotation derived from our result is shown that the magnetic field has a non-negligible effect on the gravitational Faraday rotation. Although the massless charge(s) cannot be found in nature, our result could be applicable for a very small massive ($M \rightarrow 0$) charged particle. Note, as the exact expressions of the gravitational Faraday rotation derived from our result is applicable inside the ergosphere, as it diverges there. Therefore, we need to modify the current formalism of the gravitational Faraday rotation following the formalism developed in [32], which we plan to report soon in a different article. This approach would allow us to study the polarization-dependent effects for photons which closely approach a (non-)magnetized collapsed object.

It could be interesting to study how the polarization of light due to the gravitational Faraday rotation modifies the black hole shadow of M87* [8, 9] in the presence of magnetic field. If the ‘bright’ radiation behind the rotating collapsed object (such as, M87*) is non-monochromatic, the position of the shadow should depend on the frequency of the radiation ($\omega$), i.e., one may observe a peculiar ‘rainbow effect’ [3] for the shadow of a collapsed object. The polarization splitting might also be detectable in future by the astrophysical observations. Finally, it would be worth to study the possible applications of the gravitational Faraday rotation in the realistic astrophysical problems [51, 52].
