Minkowski spacetime and non-Ricci-flat compactification in heterotic supergravity

Abstract

We consider compactifying the ten-dimensional spacetime in heterotic supergravity leaving four-dimensional Minkowski spacetime. We search for non-supersymmetric, non-Ricci-flat solutions of the equations of motion, also satisfying the conditions for anomaly cancellation and flux quantization. Three types of solutions are found. The extra-dimensional spaces are direct products of 2-manifolds; \( S^2 \times T^2 \times H^2/\Gamma, S^2 \times H^2/\Gamma \times H^2/\Gamma \) and \( S^2 \times S^2 \times H^2/\Gamma \), where \( H^2/\Gamma \) denotes a compact hyperbolic manifold.

1 Introduction

There are several problems in the Standard Model of particle physics; it does not contain gravity; it cannot explain the origin of gauge groups and the number of generations. These problems would be explained by more fundamental theories, and prominent candidates for them are superstring theories. Superstring theories reside in ten-dimensional spacetime. Dimensions beyond four have not been observed [1–4], so the additional six dimensions need to be small enough. In the context of string phenomenology, the six-dimensional space is often assumed to be a Calabi-Yau manifold [5] or a toroidal or bifold [6, 7]. These spaces are Ricci-flat, so it is easy to show that they satisfy the equations of motion.

The purpose of this paper is to find non-supersymmetric, non-Ricci-flat compactifications in the supergravity theory as the low-energy limit of the heterotic superstring theory [8]. Without supersymmetry, we need to solve equations of motion. We assume that the ten-dimensional spacetime is a direct product of Minkowski spacetime and three 2-manifolds. The advantage of 2-manifolds is that the condition for Green-Schwarz anomaly cancellation mechanism [9] can be satisfied [10] without assuming the equality between curvatures and gauge field strengths (“standard embedding”). In addition, such submanifolds allow us to suppose Freund-Rubin-like configuration for gauge fields [11]. In the heterotic supergravity Lagrangian, the necessity for a quadratic curvature term was shown later in Ref. [12]. Obtaining four-dimensional theories with non-Ricci-flat manifolds has, of course, long history [11, 13–27]. Our study differs from previous works for the quadratic curvature term and the above ansatze.

To search for explicit solutions, we assume the two-dimensional submanifolds are spaces of constant curvature. The six-dimensional manifold solutions that we find here are; \( S^2 \times \)

*tsuyuki@cc.kogakuin.ac.jp
$T^2 \times H^2/\Gamma$, $S^2 \times H^2/\Gamma \times H^2/\Gamma$ and $S^2 \times S^2 \times H^2/\Gamma$, where $S^2$, $T^2$, $H^2/\Gamma$ are a two-dimensional sphere, a torus, and a compact hyperbolic manifold \cite{14,18}, respectively. By the flux quantization condition, a finite number of solutions for the curvature of the first $S^2$ are found.

This paper is organized as follows. In section 2, we describe the Lagrangian and field equations that we solve in this paper. In section 3, explicit configurations of gauge fields and curvature tensors that satisfy the field equations are shown. In section 4, we summarize the result of this paper.

2 Lagrangian and equations of motion

We consider the bosonic part of Lagrangian for heterotic supergravity \cite{12,24}

$$L = \sqrt{-g} e^{-2\phi} \left[ R + 4(\nabla \phi)^2 - \frac{1}{12} H_{MNP} H^{MNP} + \frac{\alpha'}{8} R_{MNPQ} R^{MNPQ} - \frac{\alpha'}{8} \text{tr}(F_{MN} F^{MN}) \right],$$

(1)

where $g$ is the determinant of the metric $g_{MN}$, and the indices run $M, N, P, Q = 0, ..., 9$. $R_{MNPQ}$ is the Riemann tensor, and the Ricci scalar $R$ and the Ricci tensor $R_{MN}$ are defined as

$R = g^{NQ} R_{NQ} = g^{MP} g^{NQ} R_{MNPQ}.$

The gauge field strength $F_{MN}$ is

$$F_{MN} = \partial_M A_N - \partial_N A_M + [A_M, A_N],$$

(2)

$$F_{MN} = F_{MN}^A T^A, \quad A_M = A_M^A T^A, \quad \text{tr}(T^A T^B) = \delta^{AB},$$

(3)

where $A_M^A$ is a gauge field and $T^A$ is a generator of gauge groups $E_8 \times E_8$ or $SO(32)$.

The equation of motion for the three-form field $H$ is

$$\partial^M (e^{-2\phi} H_{MNP}) = 0.$$  (4)

We take dilaton $\phi$ constant and $H$ to vanish,

$$\partial_M \phi = 0, \quad H_{MNP} = 0,$$

(5)

then the equation of motion for $H$ \cite{11} is satisfied. Such a configuration with unbroken supersymmetry leads to Ricci-flat compactification \cite{5}. In this paper, we do not assume low-energy supersymmetry. The other equations of motion become

$$R + \frac{\alpha'}{8} R_{MNPQ} R^{MNPQ} - \frac{\alpha'}{8} \text{tr}(F_{MN} F^{MN}) = 0,$$

(6)

$$R_{MN} + \frac{\alpha'}{4} R_{MNPQR} R^{NPR} - \frac{\alpha'}{4} \text{tr}(F_{MP} F^{NP}) = 0,$$

(7)

$$\nabla_M F^{MN} + [A_M, F^{MN}] = 0.$$  (8)

Eq. (6) can be made much simpler. By multiplying Eq. (7) with $g^{MN}$, we obtain

$$R + \frac{\alpha'}{4} R_{MNPQ} R^{MNPQ} - \frac{\alpha'}{4} \text{tr}(F_{MN} F^{MN}) = 0.$$  (9)

Comparing with Eq. (6), we find

$$R = 0.$$  (10)
This is a result of the constant dilaton and vanishing $H$ \(\text{[5]}\). We use this equation instead of the dilaton equation \(\text{[6]}\). Vanishing of the Ricci scalar does not mean that the ten-dimensional manifold is Ricci-flat $R_{MN} = 0$, as we will see in the next section.

In addition to the above equations of motion, the curvature form and the gauge field have to satisfy

$$0 = dH = \frac{\alpha'}{4}(\text{tr} R \wedge R - \text{tr} F \wedge F)$$  \(\text{(11)}\)

for the Green-Schwarz anomaly cancellation mechanism \[9\]. To satisfy this condition, “standard embedding” $R_{MNab} = F_{MN}^A T_{ab}^A$ has often been assumed. Such a relation and Eq. \(\text{(7)}\), however, allow only Ricci-flat solution $R_{MN} = 0$. We need

$$R_{MNab} \neq F_{MN}^A T_{ab}^A$$  \(\text{(12)}\)

for some components to find nontrivial solutions.

3 Compactification

3.1 Ansätze

We are going to solve the Eqs. \(\text{(7)}, \text{(8)}, \text{(10)}, \text{(11)}\). We assume that the ten-dimensional manifold is a product of four manifolds

$$M^{10} = M_0 \times M_1 \times M_2 \times M_3,$$  \(\text{(13)}\)

where $M_0$ is the four-dimensional Minkowski spacetime, and $M_i$ ($i = 1, 2, 3$) are two-dimensional spaces of constant curvature. The metric of $M^{10}$ is block-diagonal and depends only on the coordinates of corresponding manifolds $g^{(i)}_{mn} = g^{(i)}_{mn}(x^{(i)})$, where the indices $m, n$ are tangent to $M_i$. The nonzero Riemann tensor components are then

$$R^{(i)}_{mnpq} = \lambda_i (g_{mp} g_{nq} - g_{mq} g_{np}),$$  \(\text{(14)}\)

where $\lambda_i$ is a constant called sectional curvature. The other components with indices of $M_0$ (like $R_{0123}$) or mixed manifolds (like $R_{4568}$) are zero.

For the gauge field strength $F_{MN}^A$, we assume that it is also block-diagonal for $M, N$, and only nonzero for $U(1)$ generators ($A = 1, 2, ..., 12$). The range of $A$ is determined to leave the gauge group $SU(5)$ in $E^8 \times E^8 \supset SU(5) \times U(1)^{12}$. Actually, we will see that not all $U(1)$ need to be broken. For the nonzero components, we take Freund-Rubin-like configuration \[11\]

$$F^{A(i)}_{mn} = \sqrt{|f_i|} f_i^{A(i)} e^{(i)}_{mn},$$  \(\text{(15)}\)

where $g_i = \det(g^{(i)}_{mn})$, $f_i^A$ is a constant, and $e^{(i)}_{mn}$ is a Levi-Civita symbol. Other components are set to zero. This configuration can satisfy the non-standard embedding condition \[12\].

3.2 Field equations and flux quantization

By the above setups, we can show that the equation of motion for $F_{MN}$ \(\text{(8)}\) is satisfied. Consider that $N = n$ is in the direction of the manifold $M_i$. The second term of Eq. \(\text{(8)}\) vanishes

$$[A_M, F^{Mn}] = A_m^{A(i)} F^{Bmn(i)} [T^A, T^B] = 0,$$  \(\text{(16)}\)
since $A^A$ is nonzero only for $U(1)$ components. The covariant derivative term becomes also zero for the Freund-Rubin configuration,

$$\nabla_M F_M^n = \frac{1}{\sqrt{g_i}} \partial_m \left( \sqrt{g_i} f^A_i \epsilon^{mn} \right) T^A = 0. \quad (17)$$

Our ansatze Eqs. (14), (15) can also satisfy the condition for Green-Schwarz mechanism, Eq. (11). Components of the first term is zero [10],

$$R_{[MN} R_{PQ]RS} = \sum_{i=1}^{3} R_{[MN}^{(i)} R_{PQ]^{(i)}} = 0. \quad (18)$$

This is because $\{M, N, P, Q\}$ cannot be all different in each two-dimensional manifold $M_i$. For the same reason, the second term of Eq. (15) is also zero if $M, N, P, Q$ are in the same $M_i$. For different indexes $m, n$ tangent to $M_i$ and $p, q$ tangent to $M_j (i \neq j)$, we need

$$F^A_{[mn} F^A_{pq]} = \frac{1}{3} \sum_A \sqrt{g_i g_j} f^A_i f^A_j = 0. \quad (19)$$

It can be satisfied if $f^A_i$ do not overlap for $A$,

$$f^A_i f^A_j = 0 \ (i \neq j, \text{ no sum over } A). \quad (20)$$

The equations of motion to be solved are Eqs. (7) and (10). They are reduced to

$$\lambda_i + \frac{\alpha'}{2} \left( \lambda_i^2 - \sum_A (f^A_i)^2 \right) = 0, \quad (21)$$

$$\sum_{i=1}^{3} \lambda_i = 0. \quad (22)$$

From Eq. (21), we see that $\lambda_i$ can be positive or negative. This is crucial to obtain non-Ricci-flat solutions. If the quadratic curvature term or gauge field were not for, all $\lambda_i$ are non-positive or non-negative, and Eq. (22) forces them to be zero.

The equations of motion (21), (22) have a trivial flat solution $M_1 = M_2 = M_3 = T^2$ ($\lambda_1 = \lambda_2 = \lambda_3 = 0$ with no gauge fields, $f^A_1 = f^A_2 = f^A_3 = 0$). We are interested in non-flat solutions here. The manifold with $\lambda_i > 0$ is a two-sphere $S^2$ and $\lambda_i < 0$ is a compact hyperbolic manifold $H^2/\Gamma$ [14][18]. For $M_i = S^2, H^2/\Gamma$, gauge field strength satisfy flux quantization conditions [10][26]

$$\int_{M_i} F^A = \text{vol}(M_i) f^A_i = 2\pi n^A_i, \quad (23)$$

where $\text{vol}(M_i)$ is a volume of $M_i$, and $n^A_i$ is an integer. On the other hand, the Ricci scalar is also related to an integer by Gauss-Bonnet theorem

$$\int_{M_i} R = \text{vol}(M_i) 2\lambda_i = 4\pi \chi_i, \quad (24)$$
where $\chi_i$ is the Euler characteristic ($\chi_i = 2$ for $S^2$ and a negative even number for $H^2/\Gamma$). Dividing Eq. (23) by Eq. (24), we find

$$f_i^A = \frac{n_i^A}{\chi_i} \lambda_i.$$  \hspace{1cm} (25)

Substituting it to the equation of motion (21), we obtain

$$\lambda_i = \begin{cases} 
\frac{1}{c_i} - \frac{2}{1 + \alpha'} & (c_i \neq 1) \\
0 & (c_i = 1)
\end{cases},$$  \hspace{1cm} (26)

$$c_i \equiv \frac{1}{\lambda_i^2} \sum_A (n_i^A)^2.$$  \hspace{1cm} (27)

### 3.3 Solutions

For simplicity, we put $\alpha' = 2$ below. To find solutions for the Eqs. (22), (26), (27), it is useful to derive the range of $\lambda_i$. In the region $c_i < 1$ and $c_i > 1$, $\lambda_i$ is monotonically decreasing with $c_i$. By the definition, $c_i \geq 0$ and the minimal $c_i > 1$ is $\frac{5}{4}$, then

$$\lambda_i \leq \begin{cases} 
4 & \text{(for } S^2) \\
-1 & \text{(for } H^2/\Gamma)
\end{cases}.$$  \hspace{1cm} (28)

Without loss of generality, we can set $\lambda_1 \geq \lambda_2 \geq \lambda_3$. For non-flat solutions, Eq. (22) implies $\lambda_1 > 0$, $\lambda_3 < 0$. We discuss three cases with zero, negative, and positive $\lambda_2$. We can find many solutions, and two sample solutions for each case are summarized in Tab. 1. We pick up some solutions below.

#### Case (i): $M_1 = S^2, M_2 = T^2, M_3 = H^2/\Gamma$. This manifold corresponds to $\lambda_2 = f_2^A = 0$. The condition of vanishing Ricci scalar (22) is

$$\frac{1}{c_1 - 1} + \frac{1}{c_3 - 1} = 0.$$  \hspace{1cm} (29)

Table 1: Sample solutions for the equations of motion (21), (22), satisfying the conditions for anomaly cancellation (20) and flux quantization (25). The constants $\lambda_i$, $f_i^A$ are defined in Eqs. (11), (15). For each $M_2 = T^2, H^2/\Gamma, S^2$ cases, solutions with minimal numbers of broken $U(1)$ and another example are shown. $\chi_i$ and $f_i^A$ are proportional to $2/\alpha'$, and $m, n$ are arbitrary natural numbers. For all cases, $\chi_1 = 2$.

</tr>
</tbody>
</table>
It has four solutions,

\[(c_1, c_3) = \left( \frac{5}{4}, \frac{3}{4} \right), \left( \frac{3}{2}, \frac{1}{2} \right), \left( \frac{7}{4}, \frac{1}{4} \right), (2, 0), \]

(corresponding to

\[\lambda_1 = -\lambda_3 = 4, 2, \frac{4}{3}, 1.\]

One of the solutions \((\lambda_1, \lambda_3) = (1, -1)\) can be realized if non-zero parameters are (we choose \(f_i^A \geq 0\))

\[n_1^2 = n_2^2 = 2, f_1^2 = f_1^2 = 1.\]

The number of broken \(U(1)\) is two, and it is minimal for case (i). The condition for anomaly cancellation Eq. (20) is satisfied.

Case (ii): \(M_1 = S^2, M_2 = M_3 = H^2/\Gamma\). This manifold corresponds to \(\lambda_2 < 0\). The inequality (28) and Eq. (22) give

\[4 \geq \lambda_1 = -\lambda_2 - \lambda_3 \geq 2.\]

There are only two solutions for \(\lambda_1\),

\[\lambda_1 = 4, 2.\]

For \(\lambda_1 = 2\), the others are \(\lambda_2 = \lambda_3 = -1\). This case requires three \(U(1)\) to be broken, and we have checked this is minimal. For \(\lambda_1 = 4\), the ranges of \(\lambda_2, \lambda_3\) are

\[-1 \geq \lambda_2 \geq -2, -2 \geq \lambda_3 \geq -3.\]

The constants \(\lambda_i, f_i^A\) can be calculated as in other cases.

Case (iii): \(M_1 = M_2 = S^2, M_3 = H^2/\Gamma\). The ranges of the sectional curvatures are

\[4 \geq \lambda_1 \geq (\lambda_1 + \lambda_2)/2 = -\lambda_3/2 \geq 1/2,\]
\[-1 \geq \lambda_3 \geq -8.\]

Then eight values of \(\lambda_1\) are possible,

\[\lambda_1 = 4, 2, \frac{4}{3}, 1, \frac{7}{3}, \frac{7}{2}, 2.\]

The minimal number of broken \(U(1)\) is three for the case \((\lambda_1, \lambda_2, \lambda_3) = (\frac{2}{3}, \frac{4}{3}, -1)\). Another nontrivial solution \((\lambda_1, \lambda_2, \lambda_3) = (4, 4, -8)\) can be realized with

\[c_1 = c_2 = \frac{5}{4} = \frac{2^2 + 1^2}{2^2}, \quad c_3 = \frac{7}{8} = \frac{(3n)^2 + (2n)^2 + n^2}{(-4n)^2},\]

where \(n\) is an arbitrary natural number. The Euler characteristic \(\chi_3 = -4n\) is limited to a multiple of four. Non-zero constants \(f_i^A\) are calculated by Eqs. (25), (39) as

\[f_1^1 = f_2^3 = f_3^2 = 4, f_1^2 = f_2^3 = f_3^2 = 2, f_3^1 = 6.\]

The anomaly cancellation condition Eq. (24) is satisfied.
4 Conclusions

We found a new set of non-trivial solutions for the equations of motion in heterotic supergravity. We have assumed the extra six-dimensional space is a product of two-dimensional manifolds (13). Such manifolds enable the gauge field to take Freund-Rubin-like configuration (15), and Green-Schwarz mechanism (11) can happen without assuming the standard embedding. By the quadratic curvature term in the Lagrangian and non-standard embedding, the sectional curvature $\lambda_i$ can be positive or negative, leading to non-Ricci-flat solutions. The sectional curvature and the flux coefficient $f_i^A$ are discretized by the flux quantization condition. The solutions are summarized in Tab. 1.

Our compactifications realize four-dimensional Minkowski spacetime, so they can be applied for phenomenology. For example, if the broken $U(1)$s are suitably embedded in $E^8 \times E^8$, the unbroken gauge symmetry can be $SO(10)$ which is ideal for grand unification with massive neutrinos [28, 29]. We know explicit metrics and gauge field components. They will enable us to calculate not only topological numbers, like the number of generations, but also other continuous parameters in four-dimensional theories. We would further study these phenomenological aspects in the future. We have considered the heterotic supergravity Lagrangian in which the $R^2$ term is kept. It would be also interesting to examine whether the solutions are stable against inclusion of higher curvature terms.
