Proxy-Normalizing Activations to Match Batch Normalization while Removing Batch Dependence

Abstract

We investigate the reasons for the performance degradation incurred with batch-independent normalization. We find that the prototypical techniques of layer normalization and instance normalization both induce the appearance of failure modes in the neural network’s pre-activations: (i) layer normalization induces a collapse towards channel-wise constant functions; (ii) instance normalization induces a lack of variability in instance statistics, symptomatic of an alteration of the expressivity. To alleviate failure mode (i) without aggravating failure mode (ii), we introduce the technique “Proxy Normalization” that normalizes post-activations using a proxy distribution. When combined with layer normalization or group normalization, this batch-independent normalization emulates batch normalization’s behavior and consistently matches or exceeds its performance.

1 Introduction

Normalization plays a critical role in deep learning as it allows the successful scaling to large and deep models. In vision tasks, the most well-established normalization technique is Batch Normalization (BN) [1]. At every layer in the network, BN normalizes the intermediate activations to have zero mean and unit variance in each channel. While undisputably successful when training with large batch size, BN incurs a performance degradation in the regime of small batch size. This performance degradation is commonly attributed to an excessive or simply unwanted regularization stemming from the noise in the approximation of full-batch statistics by mini-batch statistics.

Many techniques have been proposed to avoid this issue while at the same time retaining BN’s benefits. Some techniques mimic BN’s principle while decoupling the computational batch from the normalization batch [2, 3, 4]. Other techniques are “batch-independent” in that they operate independently of the batch in various modalities: through an explicit normalization either in activation space [5, 6, 7, 8, 9, 10, 11, 12, 13, 14] or in weight space [15, 16, 17, 18]; through the use of an analytic proxy to track activation statistics [19, 20, 21]; through a change of activation function [22, 11, 13].

In this paper, we push the endeavour to replace BN with a batch-independent normalization a step further. Our main contributions are as follows: (i) we introduce a novel framework to finely characterize the various neural network properties affected by the choice of normalization; (ii) using this framework, we show that BN’s beneficial properties are not retained when solely using the prototypical batch-independent norms, but are retained when combining some of these norms with Proxy Normalization, a novel batch-independent technique that we hereby introduce; (iii) we demonstrate on an extensive set of experiments that reproducing BN’s beneficial properties using our batch-independent normalization enables to consistently match or exceed BN’s performance.

As a starting point of our analysis, we need to gain a better understanding of those beneficial properties of BN that we aim at reproducing.

Preprint. Under review.
2 Batch Normalization’s beneficial properties

We consider throughout this paper a convolutional neural network with $d=2$ spatial axes. This neural network maps an input $x \in \mathbb{R}^{H \times W \times C}$ sampled from the dataset $D$ to intermediate activations $x' \in \mathbb{R}^{H' \times W' \times C}$ at each layer $l$. The value of $x'$ at spatial position $\alpha \in \{1, \ldots, H\} \times \{1, \ldots, W\}$ and channel $c \in \{1, \ldots, C\}$ is denoted as $x'_{\alpha,c}$, with the dependency on $x$ kept implicit to avoid overloading notations.

The inclusion of BN at layer $l$ leads in the full-batch setting to adding the following operations $\forall \alpha, c$:

$$y_{\alpha,c}' = \left( \frac{x_{\alpha,c}' - \mu_c(x')} {\sigma_c(x')} \right), \quad \tilde{y}_{\alpha,c}' = \gamma_c y_{\alpha,c}' + \beta_c,$$

where $\mu_c(x')$, $\sigma_c(x')$ are the full-batch mean and standard deviation of $x'$ in channel $c$, and $\gamma_c$, $\beta_c$ are the channel-wise scale and shift parameters restoring the degrees of freedom lost in the standardization. In the mini-batch setting, the full-batch statistics $\mu_c(x')$, $\sigma_c(x')$ are approximated with mini-batch statistics. Unless specifically referring to BN’s regularization stemming from this approximation, we keep however assuming the full-batch setting of Eq. (1).

Table 1 summarizes the beneficial properties that result from including BN in the neural network. Below, we provide details on each of these properties, and we discuss whether each property is reproduced with batch-independent norms.

**Scale invariance.** When BN is present, the input-output mapping of the neural network is invariant to the scale of the weights preceding any BN layer. With such scale invariance plus weight decay, the scale of weights during training reaches an equilibrium with an effective learning rate depending on both the learning rate and the weight decay strength [23, 24, 25, 3, 26, 27, 28]. Such mechanism of “auto rate-tuning” has been shown to provide optimization benefits [29, 24, 30].

*This property is already obtained with most existing batch-independent norms.*

**Control of activation scale in residual networks.** To be trainable, residual networks require the scale of activations to remain well-behaved at initialization [31, 32, 33, 18, 34]. While this property naturally arises when BN is present on the residual path, when BN is not present it can also be enforced by a proper scaling decaying with the depth of the residual path. This “dilution” of the residual path with respect to the skip connection path reduces the effective depth of the network and thereby enables to avoid coarse-grained failures modes [35, 36, 37, 38, 33].

*This property is already obtained with most existing batch-independent norms.*

**Regularizing noise.** Due to the stochasticity of the approximation of $\mu_c(x')$, $\sigma_c(x')$ by mini-batch statistics, training a neural network with BN in the mini-batch setting can be seen as equivalent to performing Bayesian inference [39, 40] or as adding a regularizing term to the training of the same network with full-batch statistics [41]. As a result, BN induces a specific form of regularization.

*This regularization is not reproduced with batch-independent norms, but we leave it out of the scope of this paper. To help minimize the bias in our analysis and “subtract away” this effect, we perform all our experiments without and with extra degrees of regularization. This procedure can be seen as a coarse disentanglement of normalization’s effects from regularization’s effects.*

**Avoidance of collapse.** Unnormalized networks with non-saturating nonlinearities are subject to a phenomenon of “collapse”, whereby the distribution with respect to $x$, $\alpha$ of the intermediate activation vectors $(x'_{\alpha,1}, \ldots, x'_{\alpha,C})$ become close to zero- or one-dimensional in deep layers [36, 42, 38, 43, 44, 45, 46]. This means that deep in an unnormalized network: (i) layers tend to have their channels imbalanced; (ii) nonlinearities tend to become pseudo-linear with respect to $x$, $\alpha$ and not add any effective capacity [36, 47, 48]. Consequently, unnormalized networks can neither effectively use their whole width (imbalanced channels) nor effectively use their whole depth (pseudo linearity).

---

1While at first glance this collapse might seem like another facet of the “internal covariate shift” [1, 49], there are important differences between the two concepts. Most notably, the internal covariate shift, as originally defined [1, 49], only has to do with the rate of change of activation distributions and not with “static” failure modes — present at fixed iteration — in these distributions. A problem of the concept of internal covariate shift is therefore to be tied not only to the choice of normalization but also to confounders such as the learning rate.
We specifically aim at designing a batch-independent norm that preserves expressivity.

We outlined the specific properties that we wish to retain in our design of batch-independent normalization: (i) avoidance of collapse: (ii) preservation of expressivity. We now introduce a framework to understand the trade-offs between the two.

Preservation of expressivity. We can always express the identity with Eq. (1) by choosing \( \beta_c^l = \mu_c (x^l) \), \( \gamma_c^l = \sigma_c (x^l) \). Conversely, for any choice of \( \beta_c^l, \gamma_c^l \), we can always “re-absorb” Eq. (1) into a preceding convolution with bias. This means that BN does not alter the expressivity compared to an unnormalized network, i.e. it amounts to a plain reparameterization of the hypothesis space.

The expressivity is, on the other hand, not always preserved with batch-independent norms. In activation space, the dependence of batch-independent statistics on the input \( x \) turns the standardization into a nonlinear operation that cannot be “re-absorbed” into a preceding convolution \cite{17}. This phenomenon is most pronounced when statistics get computed over few components. This means e.g. that Instance Normalization (IN) \cite{6} induces a greater change of expressivity than GN, which itself induces a greater change of expressivity than LN.

In weight space, the expressivity can also be altered, namely by the removal of degrees of freedom. This is the case with Weight Standardization (WS) \cite{17, 18} and Centered Weight Normalization (CWN) \cite{16}, as we show both theoretically and experimentally on commonly found networks in Section 4.

We specifically aim at designing a batch-independent norm that avoids this collapse.

### Table 1: BN’s beneficial properties and their presence (✓) or absence (✗) with various batch-independent norms: Instance Normalization (IN), Layer Normalization (LN), Layer Normalization + Proxy Normalization (LN+PN, cf Section 5). Note that this categorization is still a simplification as e.g. even BN in the mini-batch setting or LN, LN+PN involve slight alterations of the expressivity.

Conversely, when BN is used, the standardization at each layer prevents this collapse from happening. Even deep in the network, layers still have balanced channels and nonlinearities remain nonlinear with respect to \( x, \alpha \). Consequently, networks with BN can effectively use their whole width and depth.

The collapse is, on the other hand, not always avoided with batch-independent norms \cite{36, 17, 46}. Most notably, it is not avoided with Layer Normalization (LN) \cite{5} and Group Normalization (GN) \cite{10}, as we show both theoretically and experimentally on commonly found networks in Section 4.

We specifically aim at designing a batch-independent norm that avoids this collapse.

### 3 Theoretical framework of analysis

We outlined the specific properties that we wish to retain in our design of batch-independent normalization: (i) avoidance of collapse: (ii) preservation of expressivity. We now introduce a framework to quantify the presence or absence of these properties with various choices of normalization.

**Equations of propagation.** For simplicity, we assume in our theoretical analysis that any layer \( l \) up to depth \( L \) consists of the following three steps: (i) convolution step with weights \( \omega^l \in \mathbb{R}^{K_l \times K_l \times C_{l-1} \times C_l} \); (ii) normalization step; (iii) activation step sub-decomposed into an affine transformation with scale and shift parameters \( \gamma^l, \beta^l \in \mathbb{R}^{C_l} \) and an activation function \( \phi \), supposed positive homogeneous and nonzero (e.g. \( \phi = \text{ReLU} \)). If we denote \( x^l, y^l, z^l \in \mathbb{R}^{H \times W \times C_l} \) the intermediate activations situated just after (i), (ii), (iii) , we may write the propagation through layer \( l \) as

\[
\begin{align*}
x^l &= \text{Conv}(z^{l-1}), \\
y^l &= \text{Norm}(x^l), \\
z^l &= \text{Act}(y^l),
\end{align*}
\]

\[
\begin{align*}
\forall \alpha, c : \quad \text{Conv}(z^{l-1})_{\alpha, c} &= (\omega^l \ast z^{l-1})_{\alpha, c}, \\
\forall \alpha, c : \quad \text{Norm}(x^l)_{\alpha, c} &= \frac{x^l_{\alpha, c} - \mu_{I_{x,c}}(x^l)}{\sigma_{I_{x,c}}(x^l)}, \\
\forall \alpha, c : \quad \text{Act}(y^l)_{\alpha, c} &= \phi \left( y^l_{\alpha, c} \right) = \phi \left( \gamma^l_{\alpha, c} y^l_{\alpha, c} + \beta^l_{\alpha, c} \right),
\end{align*}
\]
where \( z^0 \equiv x \) by convention and \( \mu_{x,c}(x^l), \sigma_{I_{x,c}}(x^l) \) denote the mean and standard deviation of \( x^l \) conditionally on \( I_{x,c} \equiv \{c\}, \{x\}, \{x,c\}, \{x,c \mod G\} \) for the respective cases Norm = BN, LN, IN, GN with \( G \) groups.\(^2\)

**Moments.** Extending the previous notations, we use \( \mu, \sigma, P \) indexed with a (possibly empty) subset of variables to denote the operators of conditional mean, standard deviation and power, e.g.

\[
\begin{align*}
\mu_c(y^l) &= \mathbb{E}_{x,c}[y^l_{\alpha,c}], \\
\sigma_c(y^l) &= \sqrt{\text{Var}_{x,c}[y^l_{\alpha,c}]}, \\
P_c(y^l) &= \mathbb{E}_{x,c}\left[\sigma_c(y^l)^2\right] = \frac{\sigma_c(y^l)^2 + \mu_c(y^l)^2}{\sigma_c(y^l)^2 + \mu_c(y^l)^2} \\
\mu_{x,c}(y^l) &= \mathbb{E}_c[y^l_{\alpha,c}], \\
\sigma_{x,c}(y^l) &= \sqrt{\text{Var}_c[y^l_{\alpha,c}]}, \\
P_{x,c}(y^l) &= \mathbb{E}_c\left[\sigma_{x,c}(y^l)^2\right] = \frac{\sigma_{x,c}(y^l)^2 + \mu_{x,c}(y^l)^2}{\sigma_{x,c}(y^l)^2 + \mu_{x,c}(y^l)^2}.
\end{align*}
\]

**Power decomposition.** Using these notations, we may gain important insights by decomposing the power in channel \( c \) of \( y^l \), just after the normalization, as

\[
P_c(y^l) = \underbrace{p^{(1)}_c(y^l)}_{\mu_{x,c}(y^l)} + \underbrace{p^{(2)}_c(y^l)}_{\sigma_{x,c}(y^l)} + \underbrace{p^{(3)}_c(y^l)}_{\text{Var}_c[y^l_{\alpha,c}]} + \underbrace{p^{(4)}_c(y^l)}_{\text{Var}_c[y^l_{\alpha,c}]}.
\]

Since this four-terms power decomposition will be at the core of our analysis, we detail two useful views of it. The first view is that of a hierarchy of scales: \( P^{(1)}_c(y^l) \) measures the power of \( \mu_{x,c}(y^l) \) at the dataset scale; \( P^{(2)}_c(y^l) \) measures the power of \( \sigma_{x,c}(y^l) \) at the instance scale; the sum of \( P^{(3)}_c(y^l), P^{(4)}_c(y^l) \) measures the power of \( y^l_{\alpha,c} - \mu_{x,c}(y^l) \) at the pixel scale. A particular situation where the power would be concentrated at the dataset scale with \( P^{(1)}_c(y^l) \) equal to \( P_c(y^l) \) would thus imply that \( y^l \) has its distribution fully “collapsed” in channel \( c \), i.e. that \( y^l \) is constant in channel \( c \).

The second view is that of a two-level binary tree: on one half of the tree, the sum of \( P^{(1)}_c(y^l) \) and \( P^{(2)}_c(y^l) \) measures the power coming from \( \mu_{x,c}(y^l) \), with the relative proportions of \( P^{(1)}_c(y^l) \) and \( P^{(2)}_c(y^l) \) functions of the inter-x similarity and inter-x variability of \( \mu_{x,c}(y^l) \); on the other half of the tree, the sum of \( P^{(3)}_c(y^l) \) and \( P^{(4)}_c(y^l) \) measures the power coming from \( \sigma_{x,c}(y^l) \), with the relative proportions of \( P^{(3)}_c(y^l) \) and \( P^{(4)}_c(y^l) \) functions of the inter-x similarity and inter-x variability of \( \sigma_{x,c}(y^l) \). A particular situation where \( P^{(2)}_c(y^l), P^{(4)}_c(y^l) \) would be equal to zero would thus imply that \( \mu_{x,c}(y^l), \sigma_{x,c}(y^l) \) have zero inter-x variability, i.e. that \( \mu_{x,c}(y^l), \sigma_{x,c}(y^l) \) are constant for all \( x \).

A version of Eq. (5) at the layer level instead of channel level will be easier to work with. Defining \( P^{(i)}_c(y^l) \) as the averages of \( P^{(i)}_c(y^l) \) over \( c \) for \( i \in \{1, 2, 3, 4\} \), we obtain

\[
P(y^l) = P^{(1)}(y^l) + P^{(2)}(y^l) + P^{(3)}(y^l) + P^{(4)}(y^l).
\]

It should be noted that \( P(y^l) = 1 \) for any choice of Norm \( \in \{BN, LN, IN, GN\} \), as long as the denominator of Eq. (3) is nonzero for all \( x, c \) [C.1]. Consequently, the terms \( P^{(i)}(y^l) \) sum to one, meaning they can be conveniently seen as the proportion of each term \( i \in \{1, 2, 3, 4\} \) into \( P(y^l) \).

**Revisiting BN’s avoidance of collapse.** When BN is used, \( y^l \) is normalized not only layer-wise but also channel-wise with \( P^{(1)}_c(y^l) = 0 \) and \( P_c(y^l) = 1 \). As a first consequence, \( y^l \) (that is only one affine transformation away from \( y^l \)) is unlikely to have its channel-wise distributions collapsed. This means that the nonlinearity \( \phi \) acting on \( y^l \) can be effectively nonlinear with respect to \( y^l \)’s channel-wise distributions. As a result, each layer adds capacity and the network effectively uses its whole depth. This is opposite to the situation where \( y^l \) has its channel-wise distributions collapsed with \( P_c(y^l) \approx P_{x,c}(y^l) \), which results in \( \phi \) being close to linear with respect to \( y^l \)’s channel-wise distributions. This is illustrated in Figure 1 and formalized in Appendix C.2.\(^3\)

\(^2\)We assume that the norm’s numerical stability constant is zero, with the convention \( y^l_{\alpha,c} = 0, \forall \alpha \) if \( \sigma_{I_{x,c}}(x^l) = 0 \).

\(^3\)Note that BN only guarantees an intra-task nonlinearity. If there are several modes in the task (e.g. in contexts such as adversarial training [51, 52] or conditional GANs [53]), there is still no guarantee of intra-mode nonlinearity unless the modes are decoupled in BN’s computation [54, 55, 56, 57, 58].
With our theoretical framework in hand, we now turn to showing that the prototypical batch-
alter the expressivity

As an additional consequence, $y^l$ is guaranteed to have its channels well balanced with equal power $P_c(y^l)$ for all $c$. As a result, the network effectively uses its whole width. This is opposite to the situation where a single channel $c$ becomes overly dominant over the others with $P_c(y^l) \gg P_{c'}(y^l)$ for $c' \neq c$, which results in downstream layers only “seeing” this channel $c$ and the network behaving as if it had a width equal to one at layer $l$.

**Revisiting BN’s preservation of expressivity.** When BN is used, $P_c^{(1)}(y^l) = 0$ implies for all $c$ that the terms $P_c^{(2)}(y^l), P_c^{(3)}(y^l), P_c^{(4)}(y^l)$ sum to one. Apart from that, BN does not impose any particular constraints on the relative proportions of each term into the sum. This means that the relative proportions of $P_c^{(1)}(y^l)$ and $P^{(i)}(y^l)$ for $i \in \{2, 3, 4\}$ are free to evolve as naturally dictated by the task and the optimizer during learning.

This absence of constraints seems sensible. Indeed, imposing constraints on these relative proportions would alter the expressivity, which would not have any obvious justification in general and could even be detrimental in some cases, as we discuss in Section 4.

### 4 Failure modes with batch-independent normalization

With our theoretical framework in hand, we now turn to showing that the prototypical batch-independent norms are subject to failures modes opposite to BN’s beneficial properties.

In the case of LN, the failure mode does not manifest in an absolute sense but rather as a “soft” inductive bias, i.e., as a preference or a favoring in the hypothesis space. This “soft” inductive bias is quantified by Theorem 1 in the context of networks with random model parameters.

**Definition 1** (random network). We define a “random network” as a neural network having an input sampled from the dataset $D$ and implementing Eq. (2), (3) and (4) in its first $L$ layers with the components of $\omega^l, \gamma^l, \beta^l$ at each layer $l \in \{1, \ldots, L\}$ sampled i.i.d. from the fixed distributions $\nu_\omega, \nu_\gamma, \nu_\beta$ (up to a fan-in’s square root scaling for $\omega^l$).

In such networks, we assume that: (i) $D$ is composed of a finite number of elements, none of which being identically zero; (ii) $\nu_\omega, \nu_\beta, \nu_\gamma$ have well-defined moments, with strictly positive associated root mean squares $\omega, \gamma, \beta > 0$; (iii) $\nu_\omega, \nu_\beta$ are symmetric around zero.

**Theorem 1** (layer-normalized networks collapse (informal)). [D.3] Fix a layer $l \in \{1, \ldots, L\}$ and $\nu_\omega, \nu_\beta, \nu_\gamma, D$ in Definition 1. Further suppose Norm = LN and suppose that the convolution of Eq. (2) uses periodic boundary conditions.

Then for random networks of Definition 1, it holds that

$$P(y^l) - P^{(1)}(y^l) \lesssim \rho^{l-1},$$

$$P(y^l) \simeq 1,$$

where $\rho \equiv \gamma^2 / (\gamma^2 + \beta^2) < 1$, and $\lesssim$ and $\simeq$ denote inequality and equality up to arbitrarily small constants with probability arbitrarily close to 1 for $\min_{0 \leq k \leq L} C_k$ large enough.
Discussion on LN’s failure mode. Theorem 1 implies that, with high probability, \( y^l \) is subject to channel-wise collapse in deep layers \( l \gg 1 \) with \( \mathcal{P}(y^l) - \mathcal{P}^{(1)}(y^l) \ll \mathcal{P}(y^l) \). This means that \( \tilde{y}^l \) (that is only one affine transformation away from \( y^l \)) is likely to have its channel-wise distributions collapsed with \( \mathcal{P}_c(\tilde{y}^l) - \mathcal{P}_c^{(1)}(y^l) \ll \mathcal{P}_c(\tilde{y}^l) \) for most \( c \). As a result, the nonlinearity \( \phi \) acting on \( \tilde{y}^l \) is likely to be close to linear with respect to \( \tilde{y}^l \)'s channel-wise distributions [C.2]. Being pseudo-linear in deep layers, layer-normalized networks are unable to effectively use their whole depth.

Since the inequality \( \ll \) can be replaced by an equality \( \simeq \) in the case \( \phi = \text{identity} \) of Theorem 1 [D.4], the aggravation at each layer \( l \) of the upper bound of Eq. (6) does not stem from the activation function itself but rather by the preceding affine transformation. The phenomenon of channel-wise collapse — also known under the terms of “domain collapse” [36] or “elimination singularity” [17] — is therefore not only induced by a “mean-shifting” activation function such as \( \phi = \text{ReLU} \) [44, 18], but also by the injection of non-centeredness through the application of the channel-wise shift parameter \( \beta^l \) at each layer \( l \). The fact that the general case of positive-homogeneous \( \phi \) is upper-bounded by the case \( \phi = \text{ReLU} \) in Eq. (6) still means that the choice \( \phi = \text{ReLU} \) can only be an aggravating factor.

Crucially, in the context of random networks of large width, LN’s operation at each layer \( l \) does not compensate this “mean shift”. This stems from the fact that LN’s mean and variance statistics can be approximated by zero and a constant value independent of \( x \), respectively. This means that LN’s operation can be approximated by a layer-wise constant scaling independent of \( x \).

The predominance of LN’s failure mode in the hypothesis space — implied by its predominance in random networks — is expected to have at least two negative effects on the actual learning and final performance: (i) being expected to “linger” along the training trajectory and being associated with reduced effective capacity, the failure mode is expected to cause degraded performance on the training loss; (ii) even if avoided to some extent during training, the failure mode is still expected to be present in the vicinity of the training trajectory, implying an ill-conditioning of the loss landscape and a prohibition of large learning rates that could have led otherwise to generalization benefits.

After detailing LN’s failure mode, we now detail IN’s failure mode.

Theorem 2 (instance-normalized networks lack variability in instance statistics). [E] Fix a layer \( l \in \{1, \ldots, L\} \). Further suppose Norm = IN and suppose that model parameters are chosen such that the denominator of Eq. (3) at layer \( l \) is nonzero for all inputs \( x \) and channels \( c \).

Then it holds that

- \( y^l \) is normalized in each channel \( c \) with
  \[ \mathcal{P}_c^{(1)}(y^l) = 0, \quad \mathcal{P}_c(y^l) = 1; \]

- \( y^l \) lacks variability in instance statistics in each channel \( c \) with
  \[ \mathcal{P}_c^{(2)}(y^l) = 0, \quad \mathcal{P}_c^{(3)}(y^l) = 1, \quad \mathcal{P}_c^{(4)}(y^l) = 0. \]

Discussion on IN’s failure mode. Theorem 2 directly implies two constraints that are not present in unnormalized networks: \( \mathcal{P}^{(2)}(y^l) = 0 \) and \( \mathcal{P}^{(4)}(y^l) = 0 \). By contrapositive, this necessarily means that the expressivity is altered since it would always be possible to achieve the same behavior of \( \mathcal{P}^{(3)}(y^l), \mathcal{P}^{(4)}(y^l) \) if the expressivity was preserved.

Another way of recognizing this alteration of the expressivity is by noting that some network mappings that are possible to express without normalization are not possible to express with IN. Let us take the example of a mapping that would provide in channel \( c \) through \( y_{\tilde{c}} \), just before the nonlinearity, a “detector” of a given concept at position \( \alpha \) in the input \( x \). With IN, the lack of variability in instance statistics implies that the mean \( \mu_{x,c}(\tilde{y}^l) \) and standard deviation \( \sigma_{x,c}(\tilde{y}^l) \) of the feature map in channel \( c \) are necessarily constant for all \( x \), equal to \( \beta_c \) and \( \gamma_c \), respectively. This does not allow to express for some inputs \( x \) the presence of the concept at some position \( \alpha \): \( \mu_{x,c}(\tilde{y}^l) > 0, \sigma_{x,c}(\tilde{y}^l) > 0 \); and for other inputs \( x \) the absence of the concept: \( \mu_{x,c}(\tilde{y}^l) = 0, \sigma_{x,c}(\tilde{y}^l) = 0 \). Such an example is not just anecdotal. Indeed, it is accepted that networks trained on high-level conceptual tasks have their initial layers related to low-level features and their deep layers related to increasingly imbalanced channels with depth. This phenomenon would be driven not only by the succession of affine transformations and activation functions, but also by the succession of convolutions [32, 59, 45].

\[4\] In this view, we would expect layer-normalized networks to be equally subject to a phenomenon of increasingly imbalanced channels with depth. This phenomenon would be driven not only by the succession of affine transformations and activation functions, but also by the succession of convolutions [32, 59, 45].
high-level concepts \([60, 61]\). This view explains the success of IN on the specific task of style transfer with fixed “style” input, IN being then incorporated inside a generator network that only acts on the low-level features of the “content” input \([6, 62, 63, 64]\). On high-level conceptual tasks, on the other hand, this view hints at a harmful tension between IN’s constraints and the requirement of instance variability to express high-level concepts in deep layers. In short, not only is the expressivity altered with IN, but the alteration of the expressivity results in the exclusion of useful network mappings.

**Failure modes with GN.** Group Normalization is a middle ground between the two extremes of LN \((G = 1 \text{ group})\) and IN \((G = C_l \text{ groups at layer } l)\). Networks with GN are consequently affected by both problems of Theorem 1 and Theorem 2, but to a lesser extent than networks with LN and IN. On the one hand, since GN becomes equivalent to a constant scaling when group sizes become large, networks with GN are likely to be subject to channel-wise collapse. On the other hand, since GN can be seen as removing a fraction — with an inverse dependence on the group size — of the depth \(l\), \(P^{(l)}(y^l)\) in between each layer, networks with GN are likely to lack variability in instance statistics.

The balance stricken by GN between the two failure modes of LN and IN could still be beneficial, which would explain GN’s superior performance in practice. It makes sense intuitively that being subject to two failure modes weakly is preferable over being subject to one failure mode strongly.

**Experimental validation.** Figure 3 shows \(P^{(1)}(y^l), P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l)\) as a function of the depth \(l\) during the training of ResNet-50 (v2) \([65]\) with notably BN, LN, GN on ImageNet \([66]\).

With these “power plots”, we confirm: (i) the tendency of networks with LN and — to a lesser extent — GN to be subject to channel-wise collapse as depth increases; (ii) the lack of variability in instance statistics, particularly at low depth, in networks with GN compared to networks with BN and LN.

## 5 Proxy Normalization

With the goal of remedying the failure modes of Section 4, we now introduce our batch-independent normalization approach. The rationale that supports our approach is simple: if convolutions do not play any role in the channel-wise collapse and if LN and GN can be approximated as constant scalings independent of \(x\), then the channel-wise collapse can be altogether avoided by compensating at each layer \(l\) the mean shift associated with the affine transformation and the activation function \(\phi\).

To achieve this mean shift compensation, we introduce “Proxy Normalization” (PN). PN amounts to normalizing \(\phi(\gamma_c y_{\alpha,c} + \beta_c)\) for each channel \(c\) by assimilating it with \(\phi(\gamma_c Y^l_c + \beta_c)\), where \(Y^l_c\) is a Gaussian “proxy” variable with mean \(\bar{\beta}_c\) and variance \((1 + \bar{\gamma}_c^2)\) derived from the additional parameters \(\bar{\beta}_c, \bar{\gamma}_c \in \mathbb{R}^{C_l}\).

While not a primary requirement of PN, we found that letting \(\bar{\beta}_c, \bar{\gamma}_c\) be nonzero but still subject to weight decay, and thus close to zero, was beneficial. This has the advantage of maintaining \(Y^l_c\) close to channel-wise normalized while at the same time leaving flexibility for “error correction”. Combined with the iterative assumption that \(Y^l_c\) itself remains close to channel-wise normalized, this ensures that PN’s mean shift compensation remains effective. Importantly, unlike with IN in activation space or WS in weight space, this mean shift compensation does not come with an alteration of the expressivity.

Formally, PN is incorporated in the network by replacing the activation step of Eq. (4) by the following “proxy-normalized” activation step (cf Figure 2 and Appendix B):

\[
\tilde{z}^l = \text{PN-Act}(y^l), \quad \forall \alpha, c : \quad \text{PN-Act}(y^l)_{\alpha,c} = \left( \frac{\phi(\gamma^l_{\alpha,c} Y^l_{\alpha,c} + \beta^l_{\alpha,c}) - E_{Y^l_c}[\phi(\gamma^l_{\alpha,c} Y^l_{\alpha,c} + \beta^l_{\alpha,c})]}{\sqrt{\text{Var}_{Y^l_c}[\phi(\gamma^l_{\alpha,c} Y^l_{\alpha,c} + \beta^l_{\alpha,c})] + \epsilon}} \right)
\]

where \(Y^l_c \sim \mathcal{N}(\bar{\beta}_c, (1 + \bar{\gamma}_c)^2)\) and \(\epsilon \geq 0\) is the numerical stability constant of PN.

PN can be plugged into any activation function \(\phi\). Unlike previous approaches based on the tracking of activation statistics \([19, 20, 21]\), PN only requires a local tracking of activation statistics around \(\phi\). This makes it “cheap” and tractable even in residual networks. The only required constraint for PN to work optimally is that each activation step should be immediately preceded by a normalization step.
We start by analyzing the effect of adding PN on top of LN, GN, LN+PN, LN+WS (IN is not shown due to numerical stability issues). We show the means (solid lines) as well as $1\sigma$ intervals (shaded regions) over 100 epochs of training on ImageNet. Further experimental details are reported in Appendix A.2.

**Experimental validation.** As visible in Figure 3, the power plots of networks with LN+PN resemble the power plots of networks with BN. This confirms the view that PN remedies LN’s failure mode without incurring IN’s failure mode. Important, this also means that BN’s behavior can be emulated in a fully batch-independent manner with LN+PN or GN+PN.

As also visible in Figure 3, networks with LN+WS are less effective in avoiding the channel-wise collapse. This stems from the implicit reliance of WS on the assumption that different channels have the same channel-wise means after $\phi$. While valid at initialization, this assumption becomes less valid as the affine transformation starts deviating from the identity during training [A.2]. A similar issue would be expected with CWN [16], PreLayerNorm [46] or Normalization Propagation [19]. In short, the properties at initialization should not be considered as fully representative of the whole training.

## 6 Results with Proxy Normalization

We finally evaluate the practical performance of our batch-independent normalization approach. As mentioned in Section 2, we perform all our experiments with two different degrees of regularization to disentangle normalization’s effects from regularization’s effects. While we focus on ImageNet in the main text of this paper, we report additional results on CIFAR in Appendix A.1. We also report in Appendix A.1 all our experiments details as well as our experimental error bars.

We start by analyzing the effect of adding PN on top of various norms in ResNet-50 (v2). As visible in Table 2, PN is mostly beneficial when added on top of LN or on top of GN with a small number of groups $G$. The consequence is that the optimal $G$ gets shifted to lower values in GN+PN compared to GN. This confirms the view that PN’s benefit lies in addressing LN’s failure mode.

It can also be seen in Table 2 that PN does not provide noticeable benefits to BN. This confirms again the view that PN’s benefit lies in addressing the problem — not present with BN — of channel-wise collapse. Importantly, since PN does not entail effects others than normalization that could artificially boost the performance, $\text{GN+PN}$ can be “fairly” compared to $\text{BN}$ when evaluating the effectiveness of normalization. This is unlike WS which has been shown to improve BN’s performance [17]. In our results of Table 2, the high performance of GN+WS without extra regularization and the fact that PN still provides benefits to GN+WS suggests that: (i) on top of its normalization benefits, WS induces a form of regularization; (ii) GN+WS is still not fully optimal in terms of normalization.

Next we turn to comparing GN+PN’s performance to BN’s performance across a broad range of models trained on ImageNet. As visible in Figure 4 and Tables 3 and 4, GN+PN outperforms BN in

![Figure 3: $P^{(1)}(y^l)$, $P^{(2)}(y^l)$, $P^{(3)}(y^l)$, $P^{(4)}(y^l)$ as a function of the depth $l$ in ResNet-50 (v2) with different choices of norm: BN, LN, GN, LN+PN, LN+WS (IN is not shown due to numerical stability issues). We show the means (solid lines) as well as $1\sigma$ intervals (shaded regions) over 100 epochs of training on ImageNet. Further experimental details are reported in Appendix A.2.](image-url)

</table>

To ensure that activation steps are directly preceded by normalization steps (cf Section 5), we always use v2 instantiations of ResNets and instantiations of ResNeXts having the same block reorderings as ResNets v2 [A.1].
ResNet-50 and ResNet-101 [65], matches BN in ResNeXt-50 and ResNeXt-101 [67], and matches BN in EfficientNet-B0 and EfficientNet-B2, both in the original variant with depthwise convolutions and with expansion ratio of 6 [50] and in an approximately parameter-preserving variant with group convolutions of group size 16 and with expansion ratio of 4 [68] (cf Section A.1). In short, our batch-independent normalization approach matches BN not only in behavior but also in performance.

With regard to matching BN’s performance with alternative norms, various positive results have been reported in ResNets and ResNeXts [3, 4, 8, 9, 13, 18, 34] but only a limited number in EfficientNets [13]. In EfficientNets, we are notably not aware of any other work outlining that BN’s performance can be matched with a batch-independent approach. As a confirmation, we assess the performance of various batch-independent approaches: GN [10], GN+WS [17], Evo-S0 [13], FRN+TLU [69, 11]. Unlike GN+PN, none of these approaches is found in Table 4 to match BN with consistency.

Our results suggest that while an efficient normalization is not sufficient in itself to achieve good performance on ImageNet, it is still a necessary condition, together with regularization. In our results, it is always with extra regularization that PN yields the most benefits. Importantly, the fact that PN consistently leads to large improvements in training accuracy [A.3.2] suggests that additional benefits would be obtained on larger datasets without the requirement of relying on regularization [70, 71].

7 Summary and broader impact

We introduced a novel framework to finely characterize the various neural network properties affected by the choice of normalization. Using this framework, we showed that while BN’s beneficial properties are not retained when solely using the prototypical batch-independent norms, they are retained when combining some of these norms with the technique hereby introduced of Proxy Normalization. We demonstrated on an extensive set of experiments that our batch-independent normalization approach consistently matches BN in both behavior and performance.

This work could potentially have wide implications since it unlocks the possibility to retain the normalization benefits of BN while removing batch dependence. Firstly, our approach could be used to retain BN’s normalization benefits while alleviating the burden of large activation memory stemming from BN’s requirement of large enough batch sizes. This is expected to be important in memory-intensive applications such as object detection or image segmentation, but also when using A.I. accelerators that leverage local memory to provide extra acceleration and energy savings in exchange for tighter memory constraints. Secondly, our approach could be used to retain BN’s normalization benefits while avoiding BN’s regularization when the latter is detrimental. As discussed in Section 6, this is expected to be important in the context — that will likely be prevalent in the future — of large datasets.

A Experimental details

A.1 Experimental setup

Architectures. As stated in Section 6, we use v2 instantiations of ResNets and instantiations of ResNeXts having the same block reorderings as ResNets v2. Practically, our instantiations of ResNeXts are obtained by starting from ResNets v2 and applying the same changes in bottleneck widths and number of groups in $3 \times 3$ convolutions as the ones yielding ResNeXts v1 from ResNets v1, using a cardinality $C = 32$ and a dimension $d = 4$ [67].

As also stated in Section 6, we consider two variants of EfficientNets: (i) the original variant with one depthwise convolution per MBConv block and with expansion ratio of 6 [50], and (ii) a variant with each depthwise convolution replaced by a group convolution of group size 16 and with expansion ratio of 4 [68]. Compared to the original variant, the variant with group convolutions has roughly the same number of parameters and slightly more floating point operations (FLOPs) (cf Table 5), but it can be executed more efficiently on common A.I. accelerators. Interestingly, the fact that GN+WS does not perform well even in this variant (cf Tables 4, 8 and Figure 6) suggests that the problem related to the removal of degrees of freedom by WS goes beyond just depthwise convolutions [18].

Table 5: Number of parameters and number of FLOPs in EfficientNet-B0 (EN-B0) and EfficientNet-B2 (EN-B2), in the variant with depthwise convolutions and with expansion ratio of 6 (left) and in the variant with group convolutions of group size 16 and with expansion ratio of 4 (right).

PN. We set PN’s numerical stability constant to $\epsilon = 0.03$, as we found smaller $\epsilon$ can lead to suboptimal performance. We use 200 samples uniformly sampled in probability in the proxy distribution (cf Section B).

In all networks, we disable the scaling part of PN in the proxy-normalized activation step just before the final mean pooling. This is to avoid an alteration of the effective learning rate that would stem from a change in the scale of the activations at the end of the network. An alternative option would be to altogether remove PN before the final mean pooling.

In EfficientNets: (i) we disable PN in squeeze-excite (SE) blocks as no normalization step precedes each activation step in these blocks; (ii) we replace the final affine transformation of each MBConv block by a single channel-wise scaling (i.e. we only keep the scale parameter in the affine transformation).

WS. We set the numerical stability constant of WS to 0.

In all networks, we disable WS in fully-connected layers and in SE blocks. In ResNets, we add an extra scale parameter after the final convolution of each residual block with WS.

Evo-S0. In EfficientNets, the final norm and affine transformation in each MBConv block are replaced by a single affine transformation.

Experiments with ResNets and ResNeXts on ImageNet. We train for 100 epochs with SGD with a momentum of 0.9 and with a batch size of 256. We start with a learning rate of 0.1 after a linear warmup over the first 5 epochs [72], and we decrease this learning rate four times at the epochs 30, 60, 80 and 90, each time by a factor 10. We apply weight decay with a strength of $10^{-4}$ to all parameters including the additional parameters $\beta^l$, $\gamma^l$ of PN and the channel-wise scale and shift parameters $\beta^l$, $\gamma^l$ (this is sensible as $\phi = \text{ReLU}$ is positive homogeneous).

We set the norm’s numerical stability constant to $10^{-6}$ and, unless otherwise specified, we use $G = 8$ groups when using GN. When using BN, we compute BN’s statistics over 32 inputs $x$ and we compute moving average statistics by exponentially weighted average with decay factor 0.97.
For the preprocessing, we follow [65]. When using extra regularization, we use label smoothing with factor 0.1 [73], dropout with rate 0.1 [74] and stochastic depth with rate 0.05 [75].

While we use float-16 to store and process intermediate activations (except in normalization steps), model parameters are still stored and updated in float-32. Each time we provide a result, the mean and standard deviation are computed over 3 independent runs, at the final epoch of each run. As only exceptions, the mean and 1σ intervals in Figures 3, 5 are computed by “pooling together” either all 100 epochs in 5 independent runs (Figure 3) or the initialization state in 5 independent runs (Figure 5).

Experiments with EfficientNets normalized batch-independently on ImageNet. Our experimental setup closely follows [50]. We train for 350 epochs with RMSProp with a batch size of 768. We start with a learning rate of $768 \times 2^{-14}$ after a linear warmup over the first 5 epochs [72], and we decay the learning rate exponentially by a factor 0.97 every 2.4 epochs. In RMSProp, we use a momentum of 0.9, a decay of $1.0 - (768 \times 2^{-14})$ and a numerical stability constant of $10^{-3}$. We apply weight decay with a strength of $10^{-768}$. We start with a learning rate of $10^{-7}$ after a linear warmup over the first 5 epochs [72], and we decrease this learning rate two times by a factor 10. We apply weight decay with a strength of $10^{-3}$ to all parameters including the additional parameters $\phi$, $\gamma$ of PN and the channel-wise scale and shift parameters $\beta$, $\gamma$ (this is sensible as $\phi$ is not positive homogeneous).

We set the norm’s numerical stability constant to $10^{-3}$ and we use $G = 4$ groups when using GN or Evo-S0.

For the baseline preprocessing, we follow [50]. In terms of regularization, we always use label smoothing with factor 0.1 [73], dropout with rate 0.2 [74] and stochastic depth with rate starting at 0.2 in the first MBCConv block and decaying to zero linearly with the depth of the MBCConv block [75]. When using extra regularization, we use Mixup with strength 0.1 [76] in both EfficientNets-B0 and EfficientNets-B2, and in EfficientNets-B2 we additionally use a variant of CutMix [77] that samples $U_0 \sim \text{Uniform}(0, 1)$ and $U_1 \sim \text{Uniform}(e^{-4}, 1)$ and sets the combination ratio as $\lambda = 1$ if $U_0 \leq 0.435$ and $\lambda = 1 + \frac{1}{4} \log(U_1)$ otherwise.

While we use float-16 to store and process intermediate activations (except in normalization steps), model parameters are still stored and updated in float-32. Each time we provide a result, the mean and standard deviation are computed over 3 independent runs. For each run, performance is evaluated at the final epoch with model parameters obtained by exponentially weighted average over checkpoints from previous epochs with a decay factor of 0.97.

Experiments with EfficientNets normalized with BN on ImageNet. For these experiments, we run the public EfficientNet repository with the settings recommended in the repository.\footnote{https://github.com/tensorflow/tpu/tree/master/models/official/efficientnet} When considering the variant with group convolutions, our only modifications consist in replacing depthwise convolutions with group convolutions of group size 16 and changing the expansion ratio from 6 to 4.

In addition to BN’s specific regularization, these runs always incorporate label smoothing, dropout and stochastic depth. The runs with extra regularization additionally incorporate AutoAugment [78].

Experiments with ResNets on CIFAR-10 and CIFAR-100 (cf Section A.4). We train for 160 epochs with SGD with a momentum of 0.9 and with a batch size of 128. We start with a learning rate of 0.1 after a linear warmup over the first 5 epochs [72], and we decrease this learning rate two times at the epochs 80 and 120, each time by a factor 10. We apply weight decay with a strength of $10^{-3}$ to all parameters including the additional parameters $\beta$, $\gamma$ of PN and the channel-wise scale and shift parameters $\beta$, $\gamma$ (this is sensible as $\phi = \text{ReLU}$ is positive homogeneous).

We set the norm’s numerical stability constant to $10^{-6}$ and we use $G = 4$ groups when using GN. When using BN, we compute BN’s statistics over 128 inputs $x$ and we compute moving average statistics by exponentially weighted average with decay factor 0.97.

For the preprocessing, we follow [65]. When using extra regularization, we use label smoothing with factor 0.1 [73], dropout with rate 0.25 [74] and stochastic depth with rate 0.1 [75].

We use float-16 to store and process intermediate activations (except in normalization steps) and to store and update model parameters. Each time we provide a result, the mean and standard deviation are computed over 10 independent runs, at the final epoch of each run.
A.2 Additional details on power plots

Additional details of experiments related to power plots. We obtain power plots using the setup of experiments described in Section A.1 with ResNets on ImageNet. At each epoch, we compute the power terms \( P^{(1)}(y^l), P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l) \) for each layer \( l \) and each channel \( c \) using the last mini-batch of 256 inputs \( x \) as a proxy for the full dataset \( \mathcal{D} \).

When looking at each norm separately in residual networks, we noticed artefacts that we attributed to the discrepancy between the computational depth \( l \) and the “effective” depth (that oscillates with \( l \)). Indeed, the effective depth, defined in terms of the statistical properties of the intermediate activations, grows linearly inside each residual block but gets reduced each time a residual path is summed with a skip connection path (since the latter originates from earlier layers). This phenomenon is tightly connected to the property discussed in Section 2 on the control of activation scale in residual networks.

To avoid such an artefact in Figures 3, 5, we report only a single measurement of \( P^{(1)}(y^l), P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l) \) per residual block by “pooling together” all the channels from the three norms inside each block. We also do not report \( P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l) \) for the final norm just before the final mean pooling.

The presence of this artefact confirms the fact that the effective depth evolves more slowly than the computational depth \( l \) in residual networks. This explains why \( y^l \) with LN and GN is not immoderately collapsed even at large \( l \) in Figures 3, 5.

Numerical stability issues with IN. As stated in the caption of Figure 3, we did not succeed at training ResNet-50 v2 with IN. We found that using float-16 to store and process intermediate activations caused divergence in these networks. When replacing float-16 by float-32, even though divergence was avoided, instance-normalized ResNets-50 v2 still did not reach satisfactory performance. We attribute this to a plain incompatibility of IN with v2 instantiations of ResNets that could stem from the presence of a final block of normalization and activation just before the final mean pooling. Intuitively, if we denote this final block as \( L \) and if we subtract away the activation function by supposing \( \phi = \text{identity} \), then \( \mu_{x,c}(z^L) \) in channel \( c \) is constant for all \( x \), equal to \( \beta_c^L \) (cf Section 4). Thus, if we subtract away the activation function, with IN all inputs \( x \) end up mapped to the same channel-wise constants after the final mean pooling, i.e. they become indistinguishable.

Power plots at initialization. Figure 5 reports the same power plots as Figure 3, except with the mean and 1\( \sigma \) intervals of \( P^{(1)}(y^l), P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l) \) computed at initialization.

When comparing Figure 5 to Figure 3, it is clearly visible that the channel-wise collapse with LN+WS gets aggravated during training compared to initialization. This confirms the importance of compensating the mean shift associated with the affine transformation during training.

It is also visible that the difference between GN and LN gets narrower during training compared to initialization. This means that despite a similar behavior of \( P^{(1)}(y^l) \) along the training trajectories with GN and LN, differences could still exist in the vicinity of these trajectories, which could lead to a better conditioning of the loss landscape with GN. A similar argument would make us expect a better conditioning of the loss landscape when enforcing \( y^l \) to be channel-wise normalized via an operation directly embedded in the network mapping as opposed to via an external penalty [79, 46, 80], despite the two approaches potentially leading to the same reduction of \( P^{(1)}(y^l) \).

Figure 5: Same as Figure 3, except the mean and 1\( \sigma \) intervals of \( P^{(1)}(y^l), P^{(2)}(y^l), P^{(3)}(y^l), P^{(4)}(y^l) \) are computed at initialization.
A.3 More detailed results on ImageNet

A.3.1 Error bars

In Tables 6, 7, 8, we complement the results of Tables 2, 3, 4 with error bars. In Figure 6, we also provide a visualization of the results of Tables 4, 8.

A.3.2 Training accuracies

In Tables 9, 10, 11, we complement the results of Tables 2, 3, 4 with training accuracies.

We stress that these training accuracies are highly dependent on the strength of applied regularization. This leads us to: (i) always separate the training accuracies obtained without and with extra regularization; (ii) report only the training accuracies obtained with batch-independent approaches as the training accuracies obtained with BN would not be comparable due to BN’s specific regularization.

As visible in Tables 9, 10, 11, GN+PN outperforms alternative batch-independent approaches in terms of training accuracies on ImageNet. This applies both to training without extra regularization and to training with extra regularization. This suggests that, on larger datasets, GN+PN would outperform these alternative approaches in terms of both training accuracies and validation accuracies [70, 71].

In Table 11, the fact that with extra regularization EfficientNets-B2 reach lower training accuracies than EfficientNets-B0 is explained by the different level of applied regularization (we add CutMix when training EfficientNets-B2).

Table 9: ResNet-50 (RN50) trained on ImageNet with LN, GN, GN+WS with $G$ groups. Results are formatted as $X \pm \sqrt{\text{Var}}$ with $X$ the training accuracies at the final epoch (%). We report separately the results without extra regularization (top) and with extra regularization (bottom).

A.4 Experiments on CIFAR-10 and CIFAR-100

In this section, we report results of experiments with ResNets on CIFAR [81].

We report results on CIFAR-10 in Table 12 and results on CIFAR-100 in Table 13. We further provide a visualization of these results in Figure 7.

While slightly underperforming BN on CIFAR-10, GN+PN tends to slightly outperform BN on CIFAR-100. As a possible reason, BN’s regularization could be more beneficial on the “easy” task of CIFAR-10 than on the “harder” task of CIFAR-100. To the extent that BN’s regularization can be seen as a reduction of the network’s effective capacity, such a reduction of the network’s effective capacity could be more harmful for tasks that require more capacity, i.e. for harder tasks.

Table 12: ResNet-20 (RN20), ResNet-32 (RN32), ResNet-44 (RN44), ResNet-56 (RN56) and ResNet-110 (RN110) trained on CIFAR-10 with BN, GN, GN+PN. Results are formatted as \(X \pm \sqrt{\text{Var}} / Y \pm \sqrt{\text{Var}}\) with \(X, Y\) the validation accuracies (%) without and with extra regularization, respectively.

B Implementation of the proxy-normalized activation step

In this section, we provide a Tensorflow 1 implementation of the proxy-normalized activation step. We refer the reader to Section 5 for the formal details.

```python
import tensorflow as tf
import numpy as np
from scipy.special import erfinv
def uniformly_sampled_gaussian(num_rand):
    rand = 2 * (np.arange(num_rand) + 0.5) / float(num_rand) - 1
    return np.sqrt(2) * erfinv(rand)
```
```python
def proxy_norm_act(y, 
    activation_fn=tf.nn.relu, 
    proxy_epsilon=0.03, 
    num_samples=256):
    
    """ TensorFlow 1 implementation of the proxy normalized activation step. 
    To ease implementation, the scale and shift parameters are applied 
    during this step rather than the normalization step. 
    When a normalization step is not followed by an activation step 
    (as e.g. in the last norm of an MBConv block), 
    the scale parameter should be maintained after the norm. 
    :param y: 4D activation tensor after the normalization step 
    :param activation_fn: Activation function 
    :param proxy_epsilon: PN's numerical stability constant (should not be too low) 
    :param num_samples: Number of samples in proxy distribution 
    :return tilde_z: 4D activation tensor after the proxy-normalized activation step 
    """

def create_channelwise_variable(name, init):
    num_channels = int(y.get_shape()[-1])
    return tf.get_variable(name, 
        dtype=y.dtype, 
        shape=[1, 1, 1, num_channels], 
        initializer=tf.constant_initializer(init))

    # scale and shift parameters after the norm 
    beta = create_channelwise_variable('beta', 0.0) 
    gamma = create_channelwise_variable('gamma', 1.0) 
    # Additional scale and shift parameters subject to weight decay 
    # While these additional parameters are not a primary requirement of PN, 
    # letting them be nonzero but still close to zero was found to be beneficial 
    tilde_beta = create_channelwise_variable('tilde_beta', 0.0) 
    tilde_gamma = create_channelwise_variable('tilde_gamma', 0.0)

    # activation step 
    z = gamma * y + beta  # affine transform 
    z = activation_fn(z)  # activation function 

    # proxy normalization 
    proxy_z = tf.constant(uniformly_sampled_gaussian(num_samples), y.dtype) 
    proxy_z = tf.reshape(proxy_z, [num_samples, 1, 1, 1]) 
    proxy_z = (1 + tilde_gamma) * proxy_z + tilde_beta 
    proxy_z = gamma * proxy_z + beta  # affine transform on proxy distribution 
    proxy_z = activation_fn(proxy_z)  # activation function on proxy distribution 

    # compute proxy statistics 
    proxy_mean, proxy_var = tf.nn.moments(proxy_z, axes=[0], keepdims=True) 
    # normalize z according to proxy statistics 
    tilde_z = (z - proxy_mean) * tf.rsqrt(proxy_var + proxy_epsilon) 
    return tilde_z
```

C Proofs of results others than Theorem 1 and Theorem 2

C.1 Layer-wise power equals one

**Proposition 1.** If $\sigma_{I_{x,c}}(x^l) \neq 0$ for all $x, c$, then it holds that $\mathcal{P}(y^l) = 1$ for any choice of $\text{Norm} \in \{\text{BN}, \text{LN}, \text{IN}, \text{GN}\}$.

**Proof.** The proof proceeds by distinguishing each case in $\text{Norm} \in \{\text{BN}, \text{LN}, \text{IN}, \text{GN}\}$.
We further define the linearized post-activations $\tilde{y}_{\alpha,c}$. We immediately get that
$$P_c(y') = \left( \frac{\mathbb{E}_{x,\alpha} \left[ (x'_{\alpha,c} - \mu_c(x'))^2 \right]}{\sigma_c(x')^2} \right) = \frac{\sigma_c(x')^2}{\sigma_c(x')^2} = 1.$$ 

We immediately get that $P(y') = \mathbb{E}_c \left[ P_c(y') \right] = 1$.

**Case of GN.** Let us fix $x \in \mathcal{D}$ and denote $G_i$ for $i \in \{1, \ldots, G\}$ the $G$ groups of channels and $I_x^{(i)} = \{ x, c \in G_i \}$ for $i \in \{1, \ldots, G\}$ the $G$ conditional sets of standardization. The assumption that $\sigma_{I_x^{(i)}}(x') \neq 0$ implies for any $i$ that
$$P_{I_x^{(i)}}(y') = \left( \frac{\mathbb{E}_{x,\alpha}|G_i| \left[ \left( x_{I_x^{(i)}}, c \right) - \mu_{I_x^{(i)}}(x') \right]^2}{\sigma_{I_x^{(i)}}(x')^2} \right) = \frac{\sigma_{I_x^{(i)}}(x')^2}{\sigma_{I_x^{(i)}}(x')^2} = 1.$$ 

This implies that
$$P_x(y') = \frac{1}{C_l} \sum_c P_{x,c}(y') = \frac{1}{C_l} \sum_i \sum_{c \in G_i} P_{x,c}(y') = \frac{1}{C_l} \sum_i |G_i| = 1,$$
where we used $P_{I_x^{(i)}}(y') = \frac{1}{|G_i|} \sum_c P_{x,c}(y')$.

We immediately get that $P(y') = \mathbb{E}_x \left[ P_x(y') \right] = 1$.

**Cases of LN and IN.** The cases of LN and IN immediately follow from the cases of GN with $G = 1$ group and $G = C_l$ groups. □

### C.2 Channel-wise collapse implies pseudo-linearity

Some additional notations are required in this section. We denote $\Theta^l \equiv (\omega^l, \beta^l, \gamma^l, \ldots, \omega^l, \beta^l, \gamma^l)$ the aggregate model parameters up to layer $l$.

We further define the linearized post-activations $\tilde{z}^l$ for any $\mathcal{D}, \Theta^l$ as
\begin{align}
\forall \alpha, c : \quad & \tilde{z}_{\alpha,c}^l = \tilde{y}_{\alpha,c}^l, \quad \text{(7)} \\
\forall c : \quad & \tilde{\lambda}_c = \arg \min_{\lambda_c} \mathbb{E}_{x,\alpha} \left[ (z_{\alpha,c}^l - \lambda_c y_{\alpha,c}^l)^2 \right] = \arg \min_{\lambda_c} \mathbb{E}_{x,\alpha} \left[ (\phi(y_{\alpha,c}^l) - \lambda_c y_{\alpha,c}^l)^2 \right]. \quad \text{(8)}
\end{align}

In each channel $c$, $\tilde{z}_{\alpha,c}^l$ corresponds to the channel-wise linearly transformed version of $y_{\alpha,c}^l$ that best approaches $z_{\alpha,c}^l = \phi(y_{\alpha,c}^l)$.

We start by proving that the inequality $P_c(y^l) - P_c^\dagger(y^l) \leq \tilde{\eta} P_c^\dagger(y^l)$ implies for sufficiently small $\tilde{\eta}$ pseudo-linearity (Proposition 2). We then prove that the inequality $P_c(y^l) - P_c^\dagger(y^l) \leq \tilde{\eta} P_c^\dagger(y^l)$ implies for sufficiently small $\tilde{\eta}$ pseudo-linearity (Proposition 3).

**Proposition 2.** If we fix some $d \in \mathbb{N}^*$, there exists $\tilde{\eta} > 0$ such that for any choice of $(\phi, H, W, \mathcal{D}, \Theta^l)$, it holds that
$$\left( HW \mid D \right) = d \wedge \left( P_c(y^l) - P_c^\dagger(y^l) \leq \tilde{\eta} P_c^\dagger(y^l) \right) \Rightarrow z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall x, \alpha,$$
with $\tilde{z}^l$ the linearized post-activations defined in Eq. (7), (8) and the logical “and”.

**Proof.** Any positive homogeneous $\phi$ satisfies $\phi(r) = r \phi(1)$ and $\phi(-r) = r \phi(-1)$ for any $r \geq 0$. This means that any positive homogeneous $\phi$ is: (i) fully determined by its values at $+1$ and $-1$; (ii) linear on the intervals $(-\infty, 0]$ and $[0, +\infty)$.

A sufficient condition for the linearity in channel $c$ w.r.t. $x, \alpha$ is therefore a constant sign of $y_{\alpha,c}^l$ for all $x, \alpha$. Let us see that this constant sign is implied by a sufficiently severe channel-wise collapse.

We start by proving the result with the two distinct conditionalities: (i) $\sigma_c(y^l) = 0$ and (ii) $\sigma_c(y^l) > 0$. 23
Conditionality $\sigma_c(\tilde{y}^l) = 0$. If $\sigma_c(\tilde{y}^l) = 0$, then $\tilde{y}^l_{a,c} = \mu_c(\tilde{y}^l), \forall x, \alpha$.

Under this conditionality, let us define $\lambda_c$ such that

$$
\lambda_c = \begin{cases} 
0 & \text{if } \mu_c(\tilde{y}^l) = 0, \\
\phi(\mu_c(\tilde{y}^l)) / \mu_c(\tilde{y}^l) & \text{otherwise}.
\end{cases}
$$

For any choice of positive homogeneous $\phi$, it holds that $\phi(0) = 0$. Combined with the definition of $\lambda_c$, this implies $\phi(\mu_c(\tilde{y}^l)) = \lambda_c \mu_c(\tilde{y}^l)$ and thus $\forall x, \alpha$:

$$z^l_{a,c} = \phi(\tilde{y}^l_{a,c}) = \phi(\mu_c(\tilde{y}^l)) = \lambda_c \mu_c(\tilde{y}^l) = \lambda_c \tilde{y}^l_{a,c}.
$$

Given the definition of the linearized post-activations $\tilde{z}^l$, this means

$$
\mathbb{E}_{x, \alpha} \left[ (z^l_{a,c} - \tilde{z}^l_{a,c})^2 \right] \leq \mathbb{E}_{x, \alpha} \left[ (z^l_{a,c} - \lambda_c \tilde{y}^l_{a,c})^2 \right] = 0.
$$

This immediately implies $\forall x, \alpha$: $z^l_{a,c} = \tilde{z}^l_{a,c}$. Thus, it holds for any $(\phi, H, W, D, \Theta^l)$ such that $\sigma_c(\tilde{y}^l) = 0$ that $\forall x, \alpha$: $z^l_{a,c} = \tilde{z}^l_{a,c}$.

More concisely, it holds for any choice of $(\phi, H, W, D, \Theta^l)$ that

$$
\sigma_c(\tilde{y}^l) = 0 \implies z^l_{a,c} = \tilde{z}^l_{a,c} \forall x, \alpha.
$$

Conditionality $\sigma_c(\tilde{y}^l) > 0$. We start by fixing $(\phi, H, W, D, \Theta^l)$. For any given $k > 0$, Chebyshev’s inequality implies

$$
\mathbb{P}_{x, \alpha} \left[ |\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| \geq k \sigma_c(\tilde{y}^l) \right] \leq \frac{1}{k^2},
$$

$$
\mathbb{P}_{x, \alpha} \left[ (\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l))^2 \geq k^2 \sigma_c(\tilde{y}^l)^2 \right] \leq \frac{1}{k^2}.
$$

Thus, if $\mathcal{P}_c(\tilde{y}^l) - \mathcal{P}^{(1)}_c(\tilde{y}^l) \leq \eta \mathcal{P}^{(1)}_c(\tilde{y}^l)$ for some $\eta > 0$, it holds for any given $k > 0$ that

$$
1 - \frac{1}{k^2} \leq \mathbb{P}_{x, \alpha} \left[ (\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l))^2 < k^2 \sigma_c(\tilde{y}^l)^2 \right] = \mathbb{P}_{x, \alpha} \left[ (\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l))^2 < k^2 (\mathcal{P}_c(\tilde{y}^l) - \mathcal{P}^{(1)}_c(\tilde{y}^l)) \right]
$$

$$
\leq \mathbb{P}_{x, \alpha} \left[ (\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l))^2 < k^2 \eta \mathcal{P}^{(1)}_c(\tilde{y}^l) \right] = \mathbb{P}_{x, \alpha} \left[ (\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l))^2 < k^2 \eta \mathcal{P}^{(1)}_c(\tilde{y}^l) \right]
$$

$$
\leq \mathbb{P}_{x, \alpha} \left[ |\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| < k \sqrt{\eta} \mu_c(\tilde{y}^l) |. \right.
$$

Choosing $k = \frac{1}{\sqrt{\eta}}$, we get

$$
\mathbb{P}_{x, \alpha} \left[ |\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| \geq |\mu_c(\tilde{y}^l)| \right] \leq \eta.
$$

Now if we suppose that $\eta$ is such that $\frac{1}{HW|\mathcal{D}|} > \eta > 0$, we get

$$
\mathbb{P}_{x, \alpha} \left[ |\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| \geq |\mu_c(\tilde{y}^l)| \right] < \frac{1}{HW|\mathcal{D}|}. \tag{10}
$$

Eq. (10) could not hold if there existed $x \in \mathcal{D}$ and $\alpha \in \{1, \ldots, H\} \times \{1, \ldots, W\}$ such that $|\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| \geq |\mu_c(\tilde{y}^l)|$. Consequently, $|\tilde{y}^l_{a,c} - \mu_c(\tilde{y}^l)| < |\mu_c(\tilde{y}^l)|$ for all $x, \alpha$, implying that there exists a tensor $r^l \in \mathbb{R}^{H \times W \times |\mathcal{G}|}$ depending on $x$ such that $x, \alpha$:

$$
\tilde{y}^l_{a,c} = r^l_{a,c} \mu_c(\tilde{y}^l), \quad r^l_{a,c} \geq 0. \tag{11}
$$

Now if we combine $\sigma_c(\tilde{y}^l) > 0$ with $\mathcal{P}_c(\tilde{y}^l) - \mathcal{P}^{(1)}_c(\tilde{y}^l) \leq \eta \mathcal{P}^{(1)}_c(\tilde{y}^l)$, we deduce that $\mathcal{P}^{(1)}_c(\tilde{y}^l) > 0$ and thus that $\mu_c(\tilde{y}^l) \neq 0$. Injecting this into Eq. (11), we get $x, \alpha$:

$$
\tilde{z}^l_{a,c} = \phi(\tilde{y}^l_{a,c}) = r^l_{a,c} \phi(\mu_c(\tilde{y}^l)) = \frac{\phi(\mu_c(\tilde{y}^l))}{\mu_c(\tilde{y}^l)} r^l_{a,c} \mu_c(\tilde{y}^l) = \lambda_c \tilde{y}^l_{a,c}.
$$

24
with the definition $\lambda_c \equiv \frac{J(\mu_c(y^l))}{\mu_c(y^l)}$.

Given the definition of the linearized post-activations $\tilde{z}^l$, this means

$$\mathbb{E}_{\mathbf{x}, \alpha} \left[ (z_{\alpha,c}^l - \tilde{z}_{\alpha,c}^l)^2 \right] \leq \mathbb{E}_{\mathbf{x}, \alpha} \left[ (z_{\alpha,c}^l - \lambda_c y_{\alpha,c}^l)^2 \right] = 0.$$  

This immediately implies $\forall \mathbf{x}, \alpha: z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l$.

Thus, if we fix some $d \in \mathbb{N}^+$ and if we define $\tilde{\eta} = \frac{1}{\tilde{z}^l}$, it holds for any choice of $(\phi, H, W, D, \Theta^l)$ such that (i) $HW|D| = d$, (ii) $P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c^{(1)}(y^l)$, (iii) $\sigma_c(y^l) > 0$, that $\forall \mathbf{x}, \alpha: z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l$.

More concisely, it holds for any choice of $(\phi, H, W, D, \Theta^l)$ that

$$\left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c^{(1)}(y^l) \right) \land \left( \sigma_c(y^l) > 0 \right) \Rightarrow z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall \mathbf{x}, \alpha. \tag{12}$$

**General case.** To wrap up, if we fix some $d \in \mathbb{N}^+$ and if we reuse the definition $\tilde{\eta} = \frac{1}{\tilde{z}^l}$, it holds for any choice of $(\phi, H, W, D, \Theta^l)$ that

$$\left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c^{(1)}(y^l) \right) \Rightarrow \left( \tilde{z}_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall \mathbf{x}, \alpha \right) \lor \left( z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall \mathbf{x}, \alpha \right) \tag{13}$$

where Eq. (13) is obtained using Eq. (9) and Eq. (12) and $\land, \lor$ are the logical “and” and “or”.

**Proposition 3.** If we fix some $d \in \mathbb{N}^+$, there exists $\tilde{\eta} > 0$ such that for any choice of $(\phi, H, W, D, \Theta^l)$, it holds that

$$\left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c^{(1)}(y^l) \right) \Rightarrow z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall \mathbf{x}, \alpha,$$

with $\tilde{z}^l$ the linearized post-activations defined in Eq. (7), (8) and $\land$ the logical “and”.

**Proof.** We start by noting that for any $1 > \eta > 0$:

$$P_c(y^l) - P_c^{(1)}(y^l) \leq \eta P_c(y^l) \iff P_c(y^l) - P_c^{(1)}(y^l) \leq \eta \left( P_c(y^l) - P_c^{(1)}(y^l) + P_c^{(1)}(y^l) \right) \iff P_c(y^l) - P_c^{(1)}(y^l) \leq \frac{\eta}{1 - \eta} P_c^{(1)}(y^l).$$

Thus, if we fix some $d \in \mathbb{N}^+$ and if we define $\tilde{\eta} = \frac{1}{\tilde{z}^l}$ and $\tilde{\eta} = \frac{\eta}{1 + \tilde{\eta}}$, it holds for any choice of $(\phi, H, W, D, \Theta^l)$ that

$$\left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c(y^l) \right) \iff \left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \frac{\tilde{\eta}}{1 - \tilde{\eta}} P_c^{(1)}(y^l) \right) \iff \left( HW|D| = d \right) \land \left( P_c(y^l) - P_c^{(1)}(y^l) \leq \tilde{\eta}P_c^{(1)}(y^l) \right) \iff \left( z_{\alpha,c}^l = \tilde{z}_{\alpha,c}^l \forall \mathbf{x}, \alpha \right), \tag{14}$$

where Eq. (14) is obtained using Proposition 2 and $\land$ is the logical “and”. \hfill \Box
D Proof of Theorem 1

D.1 Additional notations

Model parameters. We introduce the notations $\theta^l \equiv (\omega^l, \beta^l, \gamma^l)$ for the model parameters at layer $l$ and $\Theta^l \equiv (\omega^1, \beta^1, \gamma^1, \ldots, \omega^l, \beta^l, \gamma^l)$ for the aggregate model parameters up to layer $l$.

Activation tensors. For each layer $l$, we define the tensors $\hat{z}^{l-1}_{\alpha,c}$, $\hat{x}^l_{\alpha,c}$, $\hat{y}^l_{\alpha,c}$ such that $\forall \alpha, c$:

\begin{align}
\hat{z}^{l-1}_{\alpha,c} &= \sqrt{\frac{P(z^{l-1})}{P_x(z^{l-1})}}z^{l-1}_{\alpha,c}, \\
\hat{x}^l_{\alpha,c} &= \sqrt{\frac{P(z^{l-1})}{P_x(z^{l-1})}}x^l_{\alpha,c} = (\omega^l \ast \hat{z}^{l-1})_{\alpha,c}, \\
\hat{y}^l_{\alpha,c} &= \frac{1}{\omega \sqrt{P(z^{l-1})}}x^l_{\alpha,c}, \\
\hat{y}^l_{\alpha,c} &= \gamma^l \hat{x}^l_{\alpha,c} + \beta^l, \\
\hat{z}^l_{\alpha,c} &= \phi(\hat{y}^l_{\alpha,c}),
\end{align}

with the convention that, if $P_x(z^{l-1}) = 0$, then $\forall \alpha, c$: $\hat{z}^{l-1}_{\alpha,c} = 0$, $\hat{x}^l_{\alpha,c} = 0$ and if $P(z^{l-1}) = 0$, then $\forall \alpha, c$: $\hat{y}^l_{\alpha,c} = 0$.

Moments. We introduce the notation $\varrho$ for the ratio of the traces of the covariance matrix and Gram matrix of the activation vectors $(y^l_{\alpha,1}, \ldots, y^l_{\alpha,C_l})^T$ with respect to the randomness from $(x, \alpha)$, i.e.

$$
\varrho(y^l) \equiv \frac{\mathcal{P}(y^l) - \mathcal{P}^{(1)}(y^l)}{\mathcal{P}(y^l)} \leq 1,
$$

with the convention $\varrho(y^l) = 0$ if $\mathcal{P}(y^l) = 0$.

Note that with this definition, it holds that

$$
\varrho(y^l) = 0 \implies \left( \mathcal{P}(y^l) - \mathcal{P}^{(1)}(y^l) = 0 \right) \lor \left( \mathcal{P}(y^l) = 0 \right)
\implies \mathcal{P}(y^l) - \mathcal{P}^{(1)}(y^l) = 0,
$$

(20)

with $\lor$ the logical “or”.

We extend the definition of the terms $\mathcal{P}_x^{(1)}(y^l)$, $\mathcal{P}_x^{(2)}(y^l)$, $\mathcal{P}_x^{(3)}(y^l)$, $\mathcal{P}_x^{(4)}(y^l)$ and $\mathcal{P}^{(1)}(y^l)$, $\mathcal{P}^{(2)}(y^l)$, $\mathcal{P}^{(3)}(y^l)$, $\mathcal{P}^{(4)}(y^l)$, $\varrho(y^l)$ to all other tensors of layer $l$, with the implication of Eq. (20) equally holding for all other tensors.

D.2 Required Lemmas

Lemma 1. Fix a layer $l \geq 1$, $\nu_\omega$, $\nu_\beta$, $\nu_\gamma$, $\mathcal{D}$ in Definition 1 and model parameters $\Theta^{l-1}$ up to layer $l-1$ such that $\mathcal{P}_x(z^{l-1}) > 0$, $\forall x$. Further suppose $\text{Norm} = \text{LN}$ and suppose that the convolution of Eq. (2) uses periodic boundary conditions.

Then for any $\eta > 0$ and $\delta > 0$, there exists $N'(\eta, \delta) \in \mathbb{N}^*$ independent of $\Theta^{l-1}$, $l$ such that if $C_l \geq N'(\eta, \delta)$, it holds for random nets of Definition 1 that

$$
\mathbb{P}_{\theta^l} \left[ |\varrho(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
$$

$$
\mathbb{P}_{\theta^l} \left[ |\varrho(\hat{z}^l) - \rho \chi(\hat{z}^{l-1})\varrho(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
$$

with $\hat{z}^{l-1}, \hat{y}^l, \hat{z}^l$ defined in Eq. (15), (17), (19), and with $\rho = \gamma^2 / (\gamma^2 + \beta^2) < 1$ and $\chi(\hat{z}^{l-1}) \in \mathbb{R}^+$ dependent on $\Theta^{l-1}$ but independent of $\theta^l$ such that $\chi(\hat{z}^{l-1}) \leq 1$ in general and $\chi(\hat{z}^{l-1}) = 1$ if $\phi = \text{identity}$.
Proof. Let us first note that $\tilde{x}^l = \omega^l + \tilde{z}^{l-1}$. Let us then define $\hat{r}^{l-1}_{\alpha,c} \in \mathbb{R}^{H \times W \times K_l^2 C_l-1}$ the “receptive field” tensor containing at each spatial position $\alpha \in \{1, \ldots, H\} \times \{1, \ldots, W\}$ the $K_l^2 C_l-1$ elements of $\tilde{z}^{l-1}$ belonging to the receptive field of $(\tilde{x}^l_{\alpha,1}, \ldots, \tilde{x}^l_{\alpha,C_l})^T$.

For fixed fan-in element $c'$ originating from channel $c$, the assumption of periodic boundary conditions implies that $\hat{r}^{l-1}_{\alpha,c'}$ has the same distribution as $z^{l-1}_{\alpha,c}$ with respect to $(x, \alpha)$ such that

$$\mathcal{P}_{c'}(\hat{r}^{l-1}) = \mathcal{P}(z^{l-1}), \quad \mathcal{P}^{(1)}_{c'}(\hat{r}^{l-1}) = \mathcal{P}^{(1)}(z^{l-1}).$$

Since the number of fan-in elements $c'$ originating from channel $c$ is equal to $K_l^2$ for any choice of $c$, it follows that

$$\mathcal{P}(\hat{r}^{l-1}) = \mathcal{P}(z^{l-1}), \quad \mathcal{P}^{(1)}(\hat{r}^{l-1}) = \mathcal{P}^{(1)}(z^{l-1}). \quad (21)$$

Now if we denote $W^l \in \mathbb{R}^{C_l \times K_l^2 C_l-1}$ the reshaped matricial form of $\omega^l$, we may then write $\forall \alpha : (\tilde{x}^l_{\alpha,1}, \ldots, \tilde{x}^l_{\alpha,C_l})^T = W^l (\hat{r}^{l-1}_{\alpha,1}, \ldots, \hat{r}^{l-1}_{\alpha,K_l^2 C_l-1})^T$, such that $\forall c$:

$$\mu_c(\tilde{x}^l) = \mathbb{E}_{x,\alpha} \left[ \tilde{x}^l_{\alpha,c} \right] = \mathbb{E}_{x,\alpha} \left[ \sum_{c'} W^l_{cc'} \hat{r}^{l-1}_{\alpha,c'} \right], \quad (22)$$

$$\mathcal{P}_c(\tilde{x}^l) = \mathbb{E}_{x,\alpha} \left[ (\tilde{x}^l_{\alpha,c})^2 \right] = \mathbb{E}_{x,\alpha} \left[ \left( \sum_{c'} W^l_{cc'} \hat{r}^{l-1}_{\alpha,c'} \right)^2 \right], \quad (23)$$

$$\mathcal{P}^{(1)}_c(\tilde{x}^l) = \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c} \right]^2 = \mathbb{E}_{x,\alpha} \left[ \sum_{c'} W^l_{cc'} \hat{r}^{l-1}_{\alpha,c'} \right]^2. \quad (24)$$

Further expanding Eq. (22), (23) and (24), we get $\forall c$:

$$\mu_c(\tilde{x}^l) = \sum_{c'} W^l_{cc'} \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c'} \right],$$

$$\mathcal{P}_c(\tilde{x}^l) = \sum_{c',c''} W^l_{cc'} W^l_{cc''} \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c'} \hat{r}^{l-1}_{\alpha,c''} \right],$$

$$\mathcal{P}^{(1)}_c(\tilde{x}^l) = \sum_{c',c''} W^l_{cc'} W^l_{cc''} \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c'} \right] \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c''} \right].$$

$$\mathcal{P}_c(\tilde{x}^l) - \mathcal{P}^{(1)}_c(\tilde{x}^l) = \sum_{c',c''} W^l_{cc'} W^l_{cc''} \left( \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c'} \hat{r}^{l-1}_{\alpha,c''} \right] - \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c'} \right] \mathbb{E}_{x,\alpha} \left[ \hat{r}^{l-1}_{\alpha,c''} \right] \right).$$

Since the components of $\sqrt{K_l^2 C_l-1} W^l$ are sampled iid from the fixed distribution $\nu_\omega$ which is assumed symmetric around zero, we get $\forall c$:

$$\mathbb{E}_{\omega} \left[ \mu_c(\tilde{x}^l) \right] = 0, \quad (25)$$

$$\mathbb{E}_{\omega} \left[ \mathcal{P}_c(\tilde{x}^l) \right] = \sum_{c'} \mathbb{E}_{\omega} \left[ (W^l_{cc'})^2 \right] \mathbb{E}_{x,\alpha} \left[ (\hat{r}^{l-1}_{\alpha,c'})^2 \right] = \sum_{c'} \frac{\omega^2}{K_l^2 C_l-1} \mathcal{P}_{c'}(\hat{r}^{l-1}) = \omega^2 \mathcal{P}(\tilde{z}^{l-1}), \quad (26)$$

$$\mathbb{E}_{\omega} \left[ \mathcal{P}_c(\tilde{x}^l) - \mathcal{P}^{(1)}_c(\tilde{x}^l) \right] = \sum_{c',c''} \mathbb{E}_{\omega} \left[ (W^l_{cc'})^2 \right] \left( \mathbb{E}_{x,\alpha} \left[ (\hat{r}^{l-1}_{\alpha,c'})^2 \right] - \mathbb{E}_{x,\alpha} \left[ (\hat{r}^{l-1}_{\alpha,c'})^2 \right] \right) = \sum_{c'} \frac{\omega^2}{K_l^2 C_l-1} \left( \mathcal{P}_{c'}(\hat{r}^{l-1}) - \mathcal{P}^{(1)}_{c'}(\hat{r}^{l-1}) \right) = \omega^2 \left( \mathcal{P}(\tilde{z}^{l-1}) - \mathcal{P}^{(1)}(\tilde{z}^{l-1}) \right), \quad (27)$$

27
where we recall that $\omega \equiv E_{\theta l} \left[ \left( \sqrt{K_l^2 C_{l-1}} W_{cc}^l \right)^2 \right]^{1/2} > 0$ is the $L^2$ norm (i.e. the root mean square) of $\sqrt{K_l^2 C_{l-1}} W_{cc}^l \sim \nu_\omega$, and where we used Eq. (21) in Eq. (26) and Eq. (27).

Let us now bound $E_{\theta l} \left[ \mu_c(\hat{\chi}^l)^2 \right]$ and $E_{\theta l} \left[ P_c(\hat{\chi}^l)^2 \right]$, with the aim of bounding $\text{Var}_{\theta l} \left[ \mu_c(\hat{\chi}^l) \right]$ and $\text{Var}_{\theta l} \left[ P_c(\hat{\chi}^l) \right]$. We start by expanding $\mu_c(\hat{\chi}^l)^2$ and $P_c(\hat{\chi}^l)^2$ as

$$
\mu_c(\hat{\chi}^l)^2 = \sum_{c', c''} W_{cc'}^l W_{cc''}^l E_{X, \alpha} \left[ \hat{r}_{\alpha, c'}^{l-1} \right] E_{X, \alpha} \left[ \hat{r}_{\alpha, c''}^{l-1} \right],
$$

$$
P_c(\hat{\chi}^l)^2 = \left( \sum_{c'} (W_{cc'}^l)^2 E_{X, \alpha} \left[ (\hat{r}_{\alpha, c'}^{l-1})^2 \right] + \sum_{c', c'' \neq c'} W_{cc'}^l W_{cc''}^l E_{X, \alpha} \left[ \hat{r}_{\alpha, c'}^{l-1} \hat{r}_{\alpha, c''}^{l-1} \right] \right)^2
$$

$$
= \left( \sum_{c'} (W_{cc'}^l)^2 E_{X, \alpha} \left[ (\hat{r}_{\alpha, c'}^{l-1})^2 \right] + 2 \sum_{c', c''} W_{cc'}^l W_{cc''}^l E_{X, \alpha} \left[ \hat{r}_{\alpha, c'}^{l-1} \hat{r}_{\alpha, c''}^{l-1} \right] \right)^2.
$$

When taking the expectation over $\theta^l$, only terms in $(W_{cc'}^l)^4$, $(W_{cc'}^l)^2 (W_{cc''}^l)^2$ and $(W_{cc'}^l)^2$ remain. For $E_{\theta l} \left[ \mu_c(\hat{\chi}^l)^2 \right]$, we then get

$$
E_{\theta l} \left[ \mu_c(\hat{\chi}^l)^2 \right] = \sum_{c'} E_{\theta l} \left[ (W_{cc'}^l)^2 \right] E_{X, \alpha} \left[ \hat{r}_{\alpha, c'}^{l-1} \right]^2
$$

$$
= \sum_{c'} \frac{\omega^2}{K_l^2 C_{l-1}} \mu_c(\hat{r}_{\alpha, c'}^{l-1})^2
$$

$$
= \sum_{c'} \frac{\omega^2}{K_l^2 C_{l-1}} P_{c'}(\hat{r}_{\alpha, c'}^{l-1})
$$

$$
= \omega^2 P^{(1)}(\hat{r}_{\alpha, c'}^{l-1})
$$

$$
\leq \omega^2 P(\hat{r}_{\alpha, c'}^{l-1})
$$

$$
\leq \omega^2 P(\hat{r}_{\alpha, c'}^{l-1}),
$$

(28)

where Eq. (28) is obtained using Eq. (21).

And for $E_{\theta l} \left[ P_c(\hat{\chi}^l)^2 \right]$, we get

$$
E_{\theta l} \left[ P_c(\hat{\chi}^l)^2 \right]
$$

$$
= E_{\theta l} \left[ \left( \sum_{c'} (W_{cc'}^l)^2 E_{X, \alpha} \left[ (\hat{r}_{\alpha, c'}^{l-1})^2 \right] \right)^2 + 4 \sum_{c'} \sum_{c'' \neq c'} (W_{cc'}^l)^2 (W_{cc''}^l)^2 E_{X, \alpha} \left[ \hat{r}_{\alpha, c'}^{l-1} \hat{r}_{\alpha, c''}^{l-1} \right]^2 \right]
$$

$$
\leq E_{\theta l} \left[ \left( \sum_{c'} (W_{cc'}^l)^2 P_c(\hat{r}_{\alpha, c'}^{l-1}) \right)^2 + 4 \sum_{c'} \sum_{c'' \neq c'} (W_{cc'}^l)^2 (W_{cc''}^l)^2 P_c(\hat{r}_{\alpha, c'}^{l-1}) P_c(\hat{r}_{\alpha, c''}^{l-1}) \right]
$$

(29)

$$
\leq E_{\theta l} \left[ \left( \sum_{c'} (W_{cc'}^l)^4 P_c(\hat{r}_{\alpha, c'}^{l-1}) \right)^2 + 6 \sum_{c', c''} (W_{cc'}^l)^2 (W_{cc''}^l)^2 P_c(\hat{r}_{\alpha, c'}^{l-1}) P_c(\hat{r}_{\alpha, c''}^{l-1}) \right]
$$

$$
\leq \sum_{c'} E_{\theta l} \left[ (W_{cc'}^l)^4 P_c(\hat{r}_{\alpha, c'}^{l-1})^2 + 2 \sum_{c', c''} E_{\theta l} \left[ (W_{cc'}^l)^2 (W_{cc''}^l)^2 P_c(\hat{r}_{\alpha, c'}^{l-1}) P_c(\hat{r}_{\alpha, c''}^{l-1}) \right] \right]
$$

$$
\leq \sum_{c'} E_{\theta l} \left[ (W_{cc'}^l)^4 \right] P_c(\hat{r}_{\alpha, c'}^{l-1})^2 + 3 \sum_{c', c'' \neq c'} E_{\theta l} \left[ (W_{cc'}^l)^4 P_c(\hat{r}_{\alpha, c'}^{l-1}) P_c(\hat{r}_{\alpha, c''}^{l-1}) \right]
$$

(30)

where Eq. (29) and Eq. (30) are obtained using Cauchy-Schwarz inequality combined with $E_{X, \alpha} \left[ (\hat{r}_{\alpha, c'}^{l-1})^2 \right] = P_c(\hat{r}_{\alpha, c'}^{l-1})$ and $E_{X, \alpha} \left[ (\hat{r}_{\alpha, c''}^{l-1})^2 \right] = P_c(\hat{r}_{\alpha, c''}^{l-1})$. 28
Returning to Eq. (30), we get
\[
\mathbb{E}_{\psi} \left[ \mathcal{P}_{c}(\hat{x}_l^2) \right] \leq 3 \sum_{c'} \mathbb{E}_{\psi} \left[ (W_{c,c}')^4 \right] \mathcal{P}_{c'}(\hat{r}_l^2) + 3 \sum_{c''} \sum_{c'''} \mathbb{E}_{\psi} \left[ (W_{c,c''})^4 \right] \mathcal{P}_{c'''}(\hat{r}_l^2)
\]
\[
\leq 3 \sum_{c',c''} \mathbb{E}_{\psi} \left[ (W_{c,c'})^4 \right] \mathcal{P}_{c'}(\hat{r}_l^2) \mathcal{P}_{c''}(\hat{r}_l^2)
\]
\[
\leq 3 \mathbb{E}_{\psi} \left[ (W_{c,c})^4 \right] (K^2_{c,c})^2 \mathcal{P}(\hat{r}_l^2)^2
\]
\[
\leq 3 \mathbb{E}_{\psi} \left[ \left( \sqrt{K^2_{c,c}1} W_{c,c} \right)^4 \right] \mathcal{P}(\hat{r}_l^2)^2
\]
\[
\leq 3 \bar{\omega}^4 \mathcal{P}(\hat{r}_l^2)^2,
\]
with \( \bar{\omega} \equiv \mathbb{E}_{\psi} \left[ \left( \sqrt{K^2_{c,c}1} W_{c,c} \right)^4 \right]^{1/4} \geq \omega > 0 \) the \( L^4 \) norm of \( \sqrt{K^2_{c,c}1} W_{c,c} \sim \nu_{\omega} \).

Now we turn to \( \hat{y}_l^i \) and \( \hat{y}_l^i \) defined in Eq. (17) and Eq. (18).

Due to \( \mu_c(\hat{y}_l^i) = \frac{1}{w}\mathbb{P}(\hat{y}_l^i) \) \( \mathcal{P}_c(\hat{y}_l^i) = \frac{1}{w}\mathbb{P}(\hat{y}_l^i) \) \( \mathcal{P}_c(\hat{y}_l^i) = \frac{1}{w}\mathbb{P}(\hat{y}_l^i) \) \( \mathcal{P}_c(\hat{y}_l^i) = \frac{1}{w}\mathbb{P}(\hat{y}_l^i) \) \( \mathcal{P}_c(\hat{y}_l^i) = \frac{1}{w}\mathbb{P}(\hat{y}_l^i) \), Eq. (25), (26) and (27) imply
\[
\mathbb{E}_{\psi} \left[ \mu_c(\hat{y}_l^i) \right] = 0,
\]
\[
\mathbb{E}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i) \right] = 1,
\]
\[
\mathbb{E}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i) - \mathcal{P}_c^{(1)}(\hat{y}_l^i) \right] = \frac{\mathcal{P}(\hat{y}_l^i) - \mathcal{P}(\hat{y}_l^i)}{\mathcal{P}(\hat{y}_l^i)} = \varrho(\hat{y}_l^i).
\]

Using Eq. (28) and Eq. (31), we further get
\[
\text{Var}_{\psi} \left[ \mu_c(\hat{y}_l^i) \right] = \mathbb{E}_{\psi} \left[ \mu_c(\hat{y}_l^i)^2 \right] \leq 1,
\]
\[
\text{Var}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i) \right] \leq \mathbb{E}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i)^2 \right] \leq 3 \bar{\omega}^4 \omega^{-4},
\]
\[
\text{Var}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i) - \mathcal{P}_c^{(1)}(\hat{y}_l^i) \right] \leq \mathbb{E}_{\psi} \left[ \left( \mathcal{P}_c(\hat{y}_l^i) - \mathcal{P}_c^{(1)}(\hat{y}_l^i) \right)^2 \right] \leq \mathbb{E}_{\psi} \left[ \mathcal{P}_c(\hat{y}_l^i)^2 \right] \leq 3 \bar{\omega}^4 \omega^{-4}.
\]

The terms \( \mu_c(\hat{y}_l^i), \mathcal{P}_c(\hat{y}_l^i) \) and \( \mathcal{P}_c(\hat{y}_l^i) - \mathcal{P}_c^{(1)}(\hat{y}_l^i) \) being \( iid \) with respect to \( \theta_l^i \) in the different channels \( c \), we get
\[
\mathbb{E}_{\psi} \left[ \mu(\hat{y}_l^i) \right] = 0,
\]
\[
\text{Var}_{\psi} \left[ \mu(\hat{y}_l^i) \right] \leq \frac{1}{C_l},
\]
\[
\mathbb{E}_{\psi} \left[ \mathcal{P}(\hat{y}_l^i) \right] = 1,
\]
\[
\text{Var}_{\psi} \left[ \mathcal{P}(\hat{y}_l^i) \right] \leq \frac{3 \bar{\omega}^4 \omega^{-4}}{C_l},
\]
\[
\mathbb{E}_{\psi} \left[ \mathcal{P}(\hat{y}_l^i) - \mathcal{P}(\hat{y}_l^i) \right] = \varrho(\hat{y}_l^i),
\]
\[
\text{Var}_{\psi} \left[ \mathcal{P}(\hat{y}_l^i) - \mathcal{P}(\hat{y}_l^i) \right] \leq \frac{3 \bar{\omega}^4 \omega^{-4}}{C_l}.
\]

Combining Eq. (36) and Eq. (37) with Chebyshev’s inequality, we get for any \( 1 \geq \eta > 0 \) that
\[
\mathbb{P}_{\psi} \left[ \left| \mathcal{P}(\hat{y}_l^i) - 1 \right| > \eta \frac{1}{1 + \eta} \right] \leq \left( \frac{1 + \eta}{\eta} \right)^2 \frac{3 \bar{\omega}^4 \omega^{-4}}{C_l},
\]
\[
\mathbb{P}_{\psi} \left[ \left| \mathcal{P}(\hat{y}_l^i) - 1 \right| > \eta \frac{1}{1 - \eta} \right] \leq \left( \frac{1 - \eta}{\eta} \right)^2 \frac{3 \bar{\omega}^4 \omega^{-4}}{C_l},
\]
\[
\mathbb{P}_{\psi} \left[ \left| \mathcal{P}(\hat{y}_l^i) - \mathcal{P}(\hat{y}_l^i) - \varrho(\hat{y}_l^i) \right| > \eta \right] \leq \left( \frac{1}{\eta} \right)^2 \frac{3 \bar{\omega}^4 \omega^{-4}}{C_l}.
\]
Thus, for any $1 \geq \eta > 0$ and $\delta > 0$, there exists $N_1(\eta, \delta) \in \mathbb{N}^*$ independent of $\Theta^{l-1}$, $l$, such that if $C_l \geq N_1(\eta, \delta)$, it holds that

\[
\mathbb{P}_{\theta_l} \left[ \mathcal{P}(\hat{y}^l) \geq \frac{1}{1 + \eta} \right] \geq \mathbb{P}_{\theta_l} \left[ |\mathcal{P}(\hat{y}^l) - 1| \leq \frac{\eta}{1 + \eta} \right] \geq 1 - \delta, \\
\mathbb{P}_{\theta_l} \left[ \mathcal{P}(\hat{y}^l) \leq \frac{1}{1 - \eta} \right] \geq \mathbb{P}_{\theta_l} \left[ |\mathcal{P}(\hat{y}^l) - 1| \leq \frac{\eta}{1 - \eta} \right] \geq 1 - \delta, \\
\mathbb{P}_{\theta_l} \left[ |\mathcal{P}(\hat{y}^l) - \mathcal{P}^{(1)}(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta.
\]

Thus, if $C_l \geq N_1(\eta, \delta)$, it holds with probability greater than $1 - 3\delta$ with respect to $\theta^l$ that (i) $(1 + \eta)\mathcal{P}(\hat{y}^l) \geq 1$, (ii) $(1 - \eta)\mathcal{P}(\hat{y}^l) \leq 1$, (iii) $|\mathcal{P}(\hat{y}^l) - \mathcal{P}^{(1)}(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq \eta$, implying

\[
\mathcal{P}(\hat{y}^l) - \mathcal{P}^{(1)}(\hat{y}^l) \leq \varrho(\hat{z}^{l-1}) + \eta \\
\leq (\varrho(\hat{z}^{l-1}) + \eta)(1 + \eta)\mathcal{P}(\hat{y}^l) \\
\leq (\varrho(\hat{z}^{l-1}) + \varrho(\hat{z}^{l-1})\eta + \eta^2)\mathcal{P}(\hat{y}^l) \\
\leq (\varrho(\hat{z}^{l-1}) + 3\eta)\mathcal{P}(\hat{y}^l), \\
\mathcal{P}(\hat{y}^l) - \mathcal{P}^{(1)}(\hat{y}^l) \geq \varrho(\hat{z}^{l-1}) - \eta \\
\geq \max \left( 0, \varrho(\hat{z}^{l-1}) - \eta \right) \\
\geq \max \left( 0, \varrho(\hat{z}^{l-1}) - \eta \right)(1 - \eta)\mathcal{P}(\hat{y}^l) \\
\geq \varrho(\hat{z}^{l-1}) - \eta) \frac{1 - \eta}{1 - \eta}\mathcal{P}(\hat{y}^l) \\
\geq (\varrho(\hat{z}^{l-1}) - \varrho(\hat{z}^{l-1})\eta - \eta^2)\mathcal{P}(\hat{y}^l) \\
\geq (\varrho(\hat{z}^{l-1}) - 2\eta)\mathcal{P}(\hat{y}^l)
\]

where we used $\varrho(\hat{z}^{l-1}) \leq 1$ and $\eta^2 \leq \eta$ due to $\eta \leq 1$, as well as $\mathcal{P}(\hat{y}^l) - \mathcal{P}^{(1)}(\hat{y}^l) \geq 0$.

Given $(1 + \eta)\mathcal{P}(\hat{y}^l) \geq 1 \implies \mathcal{P}(\hat{y}^l) > 0$, if $C_l \geq N_1(\eta, \delta)$, it holds with probability greater than $1 - 3\delta$ with respect to $\theta^l$ that

\[
\varrho(\hat{z}^{l-1}) - 2\eta \leq \varrho(\hat{y}^l) \leq \varrho(\hat{z}^{l-1}) + 3\eta \implies |\varrho(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq 3\eta.
\]

Now, let $N_2$ be defined independently of $\Theta^{l-1}$, $l$ by $N_2(\eta, \delta) = N_1 \left( \min \left( \frac{\eta}{3}, 1 \right), \frac{\delta}{3} \right)$, $\forall \eta > 0$, $\forall \delta > 0$. Then for any $\eta > 0$ and $\delta > 0$, if $C_l \geq N_2(\eta, \delta)$, it holds that

\[
\mathbb{P}_{\theta_l} \left[ |\varrho(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq \eta \right] \geq \mathbb{P}_{\theta_l} \left[ |\varrho(\hat{y}^l) - \varrho(\hat{z}^{l-1})| \leq 3 \min \left( \frac{\eta}{3}, 1 \right) \right] \\
\geq 1 - \frac{3\delta}{3} = 1 - \delta. \tag{38}
\]

Let us apply a similar approach with respect to $\hat{z}^l$, first noting that $\forall \alpha, c$:

\[
(\gamma^l_{\alpha,c})^2 = (\gamma^l_{\alpha,c} + \beta^l_c)^2 = (\gamma^l_{\alpha,c})^2 + (\beta^l_c)^2 + 2\gamma^l_{\alpha,c}\beta^l_c, \\
\mathcal{P}_c(\hat{y}^l) = (\gamma^l_{\alpha,c})^2 \mathcal{P}_c(\hat{y}^l) + (\beta^l_c)^2 + 2\gamma^l_{\alpha,c}\beta^l_c \mathcal{P}_c(\hat{y}^l), \\
\mathbb{E}_{\theta_l} \left[ \mathcal{P}_c(\hat{y}^l) \right] = \mathbb{E}_{\theta_l} \left[ (\gamma^l_{\alpha,c})^2 \mathcal{P}_c(\hat{y}^l) + (\beta^l_c)^2 \right] = \gamma^2 \mathbb{E}_{\theta_l} \left[ \mathcal{P}_c(\hat{y}^l) \right] + \beta^2, \tag{39}
\]

where we recall that $\gamma^l$, $\beta^l$ are the $L^2$ norms (i.e., the root mean squares) of $\gamma^l_c \sim \nu_\gamma$ and $\beta^l_c \sim \nu_\beta$, and where we used the fact that $\gamma^l_{\alpha,c}$ is independent of $\mathcal{P}_c(\hat{y}^l)$ with respect to $\theta^l$, while $\beta^l_c$ is independent of $\gamma^l_{\alpha,c}(\hat{y}^l)$ with respect to $\theta^l$, with the distribution of $\beta^l_c$ symmetric around zero.
At the same time, \( \forall \alpha, c:\)
\[
\left( \tilde{y}'_{\alpha,c} - \mu_c(\tilde{y}') \right)^2 = \left( \gamma'_c \tilde{y}'_{\alpha,c} + \beta'_c - (\gamma'_c \mu_c(\tilde{y}') + \beta'_c) \right)^2 = (\gamma'_c)^2 \left( \tilde{y}'_{\alpha,c} - \mu_c(\tilde{y}') \right)^2,
\]
\[
\mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') = (\gamma'_c)^2 \left( \mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') \right),
\]
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') \right] = \gamma^2 \mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') \right],
\]
where we used the fact that \( \gamma'_c \) is independent of \( \mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') \) with respect to \( \theta' \).

Using Eq. (32) and Eq. (33), Eq. (39) and Eq. (40) imply that \( \forall c:\)
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}') \right] = \gamma^2 + \beta^2,
\]
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}') - \mathcal{P}_c^{(1)}(\tilde{y}') \right] = \gamma^2 \varrho(\tilde{z}'^{l-1}).
\]

We then get
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}(\tilde{y}') \right] = \gamma^2 + \beta^2,
\]
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}(\tilde{y}') - \mathcal{P}^{(1)}(\tilde{y}') \right] = \gamma^2 \varrho(\tilde{z}'^{l-1}).
\]

Now, we may bound \( \mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}')^2 \right] \) using \( \forall \alpha, c:\)
\[
(\tilde{y}'_{\alpha,c})^2 = \left( \gamma'_c \tilde{y}'_{\alpha,c} + \beta'_c \right)^2 \leq 2 \left( (\gamma'_c)^2 (\tilde{y}'_{\alpha,c})^2 + (\beta'_c)^2 \right),
\]
\[
\mathcal{P}_c(\tilde{y}') \leq 2 \left( (\gamma'_c)^2 \mathcal{P}_c(\tilde{y}') + (\beta'_c)^2 \right),
\]
\[
\mathcal{P}_c(\tilde{y}')^2 \leq 8 \left( (\gamma'_c)^4 \mathcal{P}_c(\tilde{y}')^2 + (\beta'_c)^4 \right),
\]
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}')^2 \right] \leq 8 \frac{1}{\tilde{\beta}^4} \mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}')^2 \right] + \beta^4,
\]
where we defined \( \tilde{\gamma} \equiv \mathbb{E}_{\theta'} \left[ (\gamma'_c)^4 \right]^{1/4} > \gamma > 0 \) and \( \tilde{\beta} \equiv \mathbb{E}_{\theta'} \left[ (\beta'_c)^4 \right]^{1/4} > \beta > 0 \) the \( L^4 \) norms of \( \gamma'_c \sim \nu'_\gamma \) and \( \beta'_c \sim \nu'_\beta \), and we used twice \( (a + b)^2 \leq 2(a^2 + b^2) \), \( \forall a, b \).

Using Eq. (34), we then get \( \forall c:\)
\[
\mathbb{E}_{\theta'} \left[ \mathcal{P}_c(\tilde{y}')^2 \right] \leq 24 \tilde{\gamma}^4 \omega^4 \omega^{-4} + 8 \tilde{\beta}^4.
\]

Next, we consider \( \tilde{z}' \). We adopt the notations \( \tilde{y}'^{l+}, \tilde{y}'^{l-} \) for the positive and negative parts of \( \tilde{y}' \) such that \( \forall \alpha, c:\)
\[
\tilde{y}'^{l+}_{\alpha,c} = \max(\tilde{y}'_{\alpha,c}, 0), \quad \tilde{y}'^{l-}_{\alpha,c} = \max(-\tilde{y}'_{\alpha,c}, 0).
\]

The positive homogeneity of \( \phi \) implies that \( \forall \alpha, c:\)
\[
\tilde{z}'_{\alpha,c} = \phi(\tilde{y}'_{\alpha,c}) = \phi(1) \cdot \tilde{y}'^{l+}_{\alpha,c} + \phi(-1) \cdot \tilde{y}'^{l-}_{\alpha,c}, \quad (\tilde{z}'_{\alpha,c})^2 = \phi(1)^2 \cdot (\tilde{y}'^{l+}_{\alpha,c})^2 + \phi(-1)^2 \cdot (\tilde{y}'^{l-}_{\alpha,c})^2.
\]

For any \( c \), this implies for \( \mu_c(\tilde{z}') \) and \( \mathcal{P}_c(\tilde{z}') \) that
\[
\mu_c(\tilde{z}')^2 = \phi(1) \mathbb{E}_{\alpha,c} \left[ (\tilde{y}'^{l+}_{\alpha,c})^2 \right] + \phi(-1) \mathbb{E}_{\alpha,c} \left[ (\tilde{y}'^{l-}_{\alpha,c})^2 \right]
\]
\[
= \left( \phi(1)^2 \mu_c(\tilde{y}'^{l+}) + \phi(-1)^2 \mu_c(\tilde{y}'^{l-}) \right)^2
\]
\[
= \phi(1)^2 \mu_c(\tilde{y}'^{l+})^2 + \phi(-1)^2 \mu_c(\tilde{y}'^{l-})^2 + 2 \phi(1) \phi(-1) \mu_c(\tilde{y}'^{l+}) \mu_c(\tilde{y}'^{l-})
\]
\[
\mathcal{P}_c(\tilde{z}') = \mathbb{E}_{\alpha,c} \left[ \phi(1)^2 (\tilde{y}'^{l+}_{\alpha,c})^2 + \phi(-1)^2 (\tilde{y}'^{l-}_{\alpha,c})^2 \right]
\]
\[
= \phi(1)^2 \mathcal{P}_c(\tilde{y}'^{l+}) + \phi(-1)^2 \mathcal{P}_c(\tilde{y}'^{l-}).
\]
As for \( \hat{y}^l \), we have \( \forall \alpha, c 
abla \)
\[
\hat{y}^l_{\alpha,c} = \hat{y}^{l,+}_{\alpha,c} - \hat{y}^{l,-}_{\alpha,c},
\]
\[
(\hat{y}^l_{\alpha,c})^2 = (\hat{y}^{l,+}_{\alpha,c})^2 + (\hat{y}^{l,-}_{\alpha,c})^2.
\]

For any \( c \), this implies for \( \mu_c(\hat{y}^l)^2 \) and \( \mathcal{P}_c(\hat{y}^l) \) that
\[
\mu_c(\hat{y}^l)^2 = \left( \mathbb{E}_{x,\alpha} \left[ \hat{y}^{l,+}_{\alpha,c} \right] - \mathbb{E}_{x,\alpha} \left[ \hat{y}^{l,-}_{\alpha,c} \right] \right)^2
= \left( \mu_c(\hat{y}^{l,+}) - \mu_c(\hat{y}^{l,-}) \right)^2
= \mu_c(\hat{y}^{l,+})^2 + \mu_c(\hat{y}^{l,-})^2 - 2\mu_c(\hat{y}^{l,+})\mu_c(\hat{y}^{l,-})
\]
\[
\mathcal{P}_c(\hat{y}^l) = \mathbb{E}_{x,\alpha} \left[ (\hat{y}^{l,+}_{\alpha,c})^2 + (\hat{y}^{l,-}_{\alpha,c})^2 \right]
= \mathcal{P}_c(\hat{y}^{l,+}) + \mathcal{P}_c(\hat{y}^{l,-}).
\]

At this point, we note that \( \hat{y}^l \) and \(-\hat{y}^l\) have the same distribution with respect to \( \theta^l \) by symmetry around zero of \( \mu_\theta \). From this and the symmetry around zero of \( \nu_\mu \), we deduce that \( \hat{y}^l \) and \(-\hat{y}^l\) have the same distribution with respect to \( \theta^l \). In turn, this implies that \( \hat{y}^{l,+} \) and \( \hat{y}^{l,-} \) have the same distribution with respect to \( \theta^l \).

We deduce that \( \forall c \):
\[
\mathbb{E}_{\phi^l} \left[ \mu_c(\hat{z}^l)^2 \right]
= (\phi(1)^2 + \phi(-1)^2)\mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^{l,+})^2 \right] + 2\phi(1)\phi(-1)\mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^{l,+})\mu_c(\hat{y}^{l,-}) \right]
= F_\phi \mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^{l,+})^2 + \mu_c(\hat{y}^{l,-})^2 \right] + 2\phi(1)\phi(-1)\mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^{l,+})\mu_c(\hat{y}^{l,-}) \right],
\]
\[
\mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{z}^l) \right]
= (\phi(1)^2 + \phi(-1)^2)\mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{y}^{l,+}) \right]
= F_\phi \mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{y}^{l,+}) + \mathcal{P}_c(\hat{y}^{l,-}) \right],
\]
where we defined \( F_\phi \equiv \left( \frac{\phi(1)^2 + \phi(-1)^2}{2} \right) \), with \( F_\phi > 0 \) given the assumption that \( \phi \) is nonzero.

Given \( |\phi(1)| \phi(-1)| \leq \left( \frac{\phi(1)^2 + \phi(-1)^2}{2} \right) \implies \phi(1)\phi(-1) \geq -F_\phi \), and given \( \mu_c(\hat{y}^{l,+})\mu_c(\hat{y}^{l,-}) \geq 0 \), we deduce that \( \forall c \):
\[
\mathbb{E}_{\phi^l} \left[ \mu_c(\hat{z}^l)^2 \right] \geq F_\phi \mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^{l,+})^2 + \mu_c(\hat{y}^{l,-})^2 - 2\mu_c(\hat{y}^{l,+})\mu_c(\hat{y}^{l,-}) \right],
\]
\[
\geq F_\phi \mathbb{E}_{\phi^l} \left[ \mu_c(\hat{y}^l)^2 \right],
\]
\[
\mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{z}^l) \right] = F_\phi \mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{y}^l) \right]
= F_\phi (\gamma^2 + \beta^2),
\]
\[
\mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right] \leq F_\phi \mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{y}^l) - \mathcal{P}_c^{(1)}(\hat{y}^l) \right]
\leq F_\phi \gamma^2 g(\hat{z}^{l,-1}).
\]
where we used Eq. (49), (50) and Eq. (43), (44).

Let us now define \( \chi(\hat{z}^{l,-1}) \in \mathbb{R}^+ \) independently of \( c \) as
\[
\chi(\hat{z}^{l,-1}) \equiv \begin{cases} \frac{\mathbb{E}_{\phi^l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right]}{F_\phi \gamma^2 g(\hat{z}^{l,-1})} & \text{if } g(\hat{z}^{l,-1}) > 0, \\ 1 & \text{otherwise.} \end{cases}
\]

We note that \( \chi(\hat{z}^{l,-1}) \) is independent of \( \theta^l \) and that \( \chi(\hat{z}^{l,-1}) \leq 1 \) in general, and \( \chi(\hat{z}^{l,-1}) = 1 \) if \( \phi = \text{identity} \) since the inequalities of Eq. (51) and Eq. (53) become equalities if \( \phi = \text{identity} \).
Using this definition of \( \chi(\hat{z}^{l-1}) \), we may rewrite \( \mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right] \) for any \( c \) as
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right] = \chi(\hat{z}^{l-1}) F_\phi \gamma^2 \varrho(\hat{z}^{l-1}). \tag{54}
\]
Now let us bound \( \text{Var}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) \right] \) and \( \text{Var}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right] \). We get from Eq. (48) that \( \forall c: \)
\[
\mathcal{P}_c(\hat{z}^l) \leq \left( \phi(1)^2 + \phi(-1)^2 \right) \left( \mathcal{P}_c(\hat{y}^{l-1}) + \mathcal{P}_c(\hat{y}^{l-1}) \right) \leq 2F_\phi \mathcal{P}_c(\hat{y}^l),
\]
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l)^2 \right] \leq 4F_\phi^2 \mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{y}^l)^2 \right] \leq 4F_\phi^2 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right),
\]
\[
\text{Var}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) \right] \leq \mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l)^2 \right] \leq 4F_\phi^2 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right),
\]
\[
\text{Var}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right] \leq \mathbb{E}_{\omega_l} \left[ \left( \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \right)^2 \right] \leq \mathbb{E}_{\omega_l} \left[ \mathcal{P}_c(\hat{z}^l)^2 \right] \leq 4F_\phi^2 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right),
\]
where we used Eq. (46).

Using Eq. (52), (54),(55), (56) and the fact that the terms \( \mathcal{P}_c(\hat{z}^l) \) and \( \mathcal{P}_c(\hat{z}^l) - \mathcal{P}_c^{(1)}(\hat{z}^l) \) are \( iid \) in the different channels \( c \), we get
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) \right] = F_\phi \left( \gamma^2 + \beta^2 \right), \quad \text{Var}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) \right] \leq \frac{4F_\phi^2 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right)}{C_l}, \tag{57}
\]
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) - \mathcal{P}^{(1)}(\hat{z}^l) \right] = \chi(\hat{z}^{l-1}) F_\phi \gamma^2 \varrho(\hat{z}^{l-1}), \quad \text{Var}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) - \mathcal{P}^{(1)}(\hat{z}^l) \right] \leq \frac{4F_\phi^2 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right)}{C_l},
\]

Now if we define \( \hat{z}^l \) such that \( \forall \alpha, c: \hat{z}^l_{\alpha, c} = \frac{\hat{z}^l_{\alpha, c}}{\sqrt{F_\phi(\gamma^2 + \beta^2)}} \), we get
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) \right] = 1, \quad \text{Var}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) \right] \leq \frac{1}{C_l} \frac{4 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right)}{(\gamma^2 + \beta^2)^2},
\]
\[
\mathbb{E}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) - \mathcal{P}^{(1)}(\hat{z}^l) \right] = \rho \chi(\hat{z}^{l-1}) \varrho(\hat{z}^{l-1}), \quad \text{Var}_{\omega_l} \left[ \mathcal{P}(\hat{z}^l) - \mathcal{P}^{(1)}(\hat{z}^l) \right] \leq \frac{1}{C_l} \frac{4 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right)}{(\gamma^2 + \beta^2)^2},
\]
with \( \rho = \gamma^2/(\gamma^2 + \beta^2) \).

The reasoning that yielded Eq. (38) from Eq. (36) and Eq. (37) can be immediately transposed by replacing \( \hat{y}^l \) by \( \hat{z}^l \), \( \varrho(\hat{z}^{l-1}) \) by \( \rho \chi(\hat{z}^{l-1}) \varrho(\hat{z}^{l-1}) \) and \( 3\omega^4 \omega^{-4} \) by \( \frac{4 \left( 24\gamma^4 \omega^4 \omega^{-4} + 8\beta^4 \right)}{(\gamma^2 + \beta^2)^2} \).

Consequently, for any \( \eta > 0 \) and \( \delta > 0 \), there exists \( N_3(\eta, \delta) \in \mathbb{N}^* \) independent of \( \Theta^{l-1}, l \), such that if \( C_l \geq N_3(\eta, \delta) \), it holds that
\[
\mathbb{P}_{\eta_l} \left[ |\varrho(\hat{z}^l) - \rho \chi(\hat{z}^{l-1}) \varrho(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
\]
\[
\mathbb{P}_{\eta_l} \left[ |\varrho(\hat{z}^l) - \rho \chi(\hat{z}^{l-1}) \varrho(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
\]
where we used the fact that \( \phi(z') = \phi(\hat{z}') \).

Thus, if we define \( N' \) independently of \( \Theta_l \), as \( N'(\eta, \delta) = \max(N_2(\eta, \delta), N_3(\eta, \delta)) \), \( \forall \eta > 0, \forall \delta > 0 \), then for any \( \eta > 0 \) and \( \delta > 0 \), if \( C_l \geq N'(\eta, \delta) \), it holds that

\[
\mathbb{P}_{\theta_l} \left[ |\phi(\hat{y}^l) - \phi(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
\]

\[
\mathbb{P}_{\theta_l} \left[ |\phi(\hat{z}^l) - \rho(\hat{z}^{l-1})\phi(\hat{z}^{l-1})| \leq \eta \right] \geq 1 - \delta,
\]

where we recall that \( \chi(\hat{z}^{l-1}) = 1 \) in general, and that \( \chi(\hat{z}^{l-1}) = 1 \) if \( \phi = \text{identity} \).

**Lemma 2.** Fix a layer \( l \geq 1 \), \( \nu_\omega, \nu_\gamma, \nu_\nu, D \) in Definition 1 and model parameters \( \Theta^{l-1} \) up to layer \( l - 1 \) such that \( \mathbb{P}_x(\hat{z}^{l-1}) > 0, \forall x \). Further suppose \( \text{Norm} = LN \) and suppose that the convolution of Eq. (2) uses periodic boundary conditions.

Then for any \( \eta > 0 \) and \( \delta > 0 \), there exists \( N''(\eta, \delta) \in \mathbb{N}^+ \) independent of \( \Theta^{l-1} \), \( l \) such that if \( C_l \geq N''(\eta, \delta) \), it holds for random nets of Definition 1 with probability greater than \( 1 - \delta \) with respect to \( \theta^l \) that

\[
|\mathcal{P}(\hat{y}^l) - \mathcal{P}(\hat{y}^l)| \leq \eta, \quad |\mathcal{P}(\hat{z}^l) - \mathcal{P}(\hat{z}^l)| \leq \eta,
\]

\[
|\mathcal{P}_x(\hat{y}^l) - 1| \leq \eta, \quad \forall x \in D, \quad |\mathcal{P}_x(\hat{z}^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta, \quad \forall x \in D,
\]

with \( F_\phi \equiv \left( \frac{\gamma^2 + \beta^2}{2} \right) > 0 \) and \( \tilde{y}^l, \tilde{z}^l \) defined in Eq. (17) and Eq. (19).

**Proof.** Let us start by noting that \( \forall \alpha, \gamma, \tilde{x}^l_{\alpha, \gamma} = \sqrt{\mathcal{P}(\hat{z}^{l-1})} \tilde{x}^l_{\alpha, \gamma}, \tilde{y}^l_{\alpha, \gamma} = \frac{1}{\omega \sqrt{\mathcal{P}(\hat{z}^{l-1})}} \tilde{y}^l_{\alpha, \gamma} = \frac{1}{\omega \sqrt{\mathcal{P}_x(\hat{z}^{l-1})}} \tilde{x}^l_{\alpha, \gamma} \).

This implies that \( \tilde{y}^l \) only depends on \( \xi \) and not on other inputs in the dataset.

Thus, Eq. (35) and Eq. (36) still hold when considering the moments conditioned on \( \xi \), such that \( \forall \xi \):

\[
\mathbb{E}_{\theta^l} \left[ \mu_x(\tilde{y}^l) \right] = 0, \quad \text{Var}_{\theta^l} \left[ \mu_x(\tilde{y}^l) \right] \leq \frac{1}{C_l^l}, \quad \text{Eq. (58)}
\]

\[
\mathbb{E}_{\theta^l} \left[ \mathcal{P}_x(\tilde{y}^l) \right] = 1, \quad \text{Var}_{\theta^l} \left[ \mathcal{P}_x(\tilde{y}^l) \right] \leq \frac{3\gamma^4 \omega^{-4}}{C_l}, \quad \text{Eq. (59)}
\]

Similarly, Eq. (57) still holds when considering the moments conditioned on \( \xi \), such that \( \forall \xi, c \):

\[
\mathbb{E}_{\theta^l} \left[ \mathcal{P}_x(\tilde{z}^l) \right] = F_\phi(\gamma^2 + \beta^2), \quad \text{Var}_{\theta^l} \left[ \mathcal{P}_x(\tilde{z}^l) \right] \leq \frac{4F_\phi^2 (24\gamma^4 \omega^{-4} + 8\beta^4)}{C_l}. \quad \text{Eq. (60)}
\]

Combining Eq. (58), (59), (60) we deduce for any \( \eta > 0 \) and \( \delta > 0 \) that there exists \( N_5(\eta, \delta) \in \mathbb{N}^+ \) independent of \( \Theta^{l-1}, l, \xi \) such that, if \( C_l \geq N_5(\eta, \delta) \), it holds for any \( \xi \) that

\[
\mathbb{P}_{\theta^l} \left[ |\mu_\xi(\tilde{y}^l)| \leq \eta \right] \geq 1 - \delta, \quad \text{Eq. (61)}
\]

\[
\mathbb{P}_{\theta^l} \left[ |\mathcal{P}_\xi(\tilde{y}^l) - 1| \leq \eta \right] \geq 1 - \delta, \quad \text{Eq. (62)}
\]

\[
\mathbb{P}_{\theta^l} \left[ \mathcal{P}_\xi(\tilde{z}^l) - F_\phi(\gamma^2 + \beta^2) \right] \leq \eta \quad \geq 1 - \delta. \quad \text{Eq. (63)}
\]

Now let us bound \( |\mathcal{P}(\tilde{y}^l) - \mathcal{P}(\tilde{y}^l)| \) and \( |\mathcal{P}(\tilde{z}^l) - \mathcal{P}(\tilde{z}^l)| \).

We start by noting that \( \tilde{y}^l_{\alpha, \gamma} = \frac{\tilde{x}^l_{\alpha, \gamma} - \mu_\xi(\tilde{y}^l)}{\sigma_\xi(\tilde{y}^l)} = \frac{\tilde{x}^l_{\alpha, \gamma} - \mu_\xi(\tilde{y}^l)}{\sigma_\xi(\tilde{y}^l)}, \forall \xi, \alpha, \gamma \). Thus, \( \forall \xi, \alpha, \gamma, \tilde{y}^l_{\alpha, \gamma} = \sigma_\xi(\tilde{y}^l) \tilde{y}^l_{\alpha, \gamma} + \mu_\xi(\tilde{y}^l) = \gamma_\xi \gamma_{\alpha, \gamma} + \beta_\gamma + \gamma_{\alpha, \gamma} (\sigma_\xi(\tilde{y}^l) - 1) \tilde{y}^l_{\alpha, \gamma} + \gamma_{\alpha, \gamma} \mu_\xi(\tilde{y}^l) = \tilde{y}^l_{\alpha, \gamma} + \gamma_{\alpha, \gamma} (\sigma_\xi(\tilde{y}^l) - 1) \tilde{y}^l_{\alpha, \gamma} + \gamma_{\alpha, \gamma} \mu_\xi(\tilde{y}^l) \).
Now let us fix \( x \) and bound \( \mathcal{P}_x(\hat{y}^l - y^l) \) and \( \mathcal{P}_x(\hat{z}^l - z^l) \). We start by noting that

\[
(\hat{y}^l_{a,c} - y^l_{a,c})^2 \leq 2(\sigma_x(\hat{y}^l) - 1)^2(\gamma^c_{a,c}y^l_{a,c})^2 + 2\mu_x(\hat{y}^l)^2,
\]

\[
(\hat{y}^l_{a,c} - \hat{y}^l_{a,c})^2 \leq 2(\sigma_x(\hat{y}^l) - 1)^2(\gamma^c_{a,c}y^l_{a,c})^2 + 2\mu_x(\hat{y}^l)^2(\gamma^c_{a,c})^2,
\]

\[
(\hat{z}^l_{a,c} - z^l_{a,c})^2 = (\phi(\hat{y}^l_{a,c}) - \phi(\hat{y}^l_{a,c}))^2 
\leq 2F_\phi(\hat{y}^l_{a,c} - y^l_{a,c})^2 
\leq 4F_\phi(\sigma_x(\hat{y}^l) - 1)^2(\gamma^c_{a,c}y^l_{a,c})^2 + 4F_\phi\mu_x(\hat{y}^l)^2(\gamma^c_{a,c})^2,
\]

where we used \((a + b)^2 \leq 2a^2 + 2b^2, \forall a, b \) and \((\phi(a) - \phi(b))^2 \leq (F_\phi')^2(a - b)^2 \leq 2F_\phi(a - b)^2, \forall a, b, \) by \( F_\phi \)-Lipschitzness of \( \phi \) with \( F_\phi = \max(|\phi(1)|, |\phi(-1)|) \leq \sqrt{2F_\phi} \).

We deduce for \( \mathcal{P}_x(\hat{y}^l - y^l) \) and \( \mathcal{P}_x(\hat{z}^l - z^l) \) that

\[
\mathcal{P}_x(\hat{y}^l - y^l) \leq 2(\sigma_x(\hat{y}^l) - 1)^2\mathcal{P}_x(y^l) + 2\mu_x(\hat{y}^l)^2 
\leq 2\left((\sigma_x(\hat{y}^l) - 1)^2 + \mu_x(\hat{y}^l)^2\right),
\]

\[
\mathcal{P}_x(\hat{z}^l - z^l) \leq 4F_\phi(\sigma_x(\hat{y}^l) - 1)^2\mathcal{E}_c[\gamma^c_{a,c}^2\mathcal{P}_x,c(y^l)] + 4F_\phi\mu_x(\hat{y}^l)^2\mathcal{E}_c[\gamma^c_{a,c}^2] 
\leq 4F_\phi\left((\sigma_x(\hat{y}^l) - 1)^2 + \mu_x(\hat{y}^l)^2\right)\mathcal{E}_c[\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)],
\]

where we used \( \mathcal{P}_x(y^l) \leq 1 \).

Next, let us bound the expectation over \( \theta^l \) of \( \mathcal{E}_c[\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)] \):

\[
\mathbb{E}_{\theta^l}[\mathcal{E}_c[\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)]] = \mathbb{E}_c[\mathbb{E}_\theta[\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)]] 
= \gamma^c_{a,c}^2\mathbb{E}_c[\mathcal{P}_x,c(y^l) + 1] 
\leq 2\gamma^c_{a,c}^2,
\]

where we used the independence of \( \gamma^c_{a,c} \) and \( \mathcal{P}_x,c(y^l) \) w.r.t. \( \theta^l \) for any \( c \), and again \( \mathcal{P}_x(y^l) \leq 1 \).

Markov’s inequality then gives for any \( \delta > 0 \) that

\[
\mathbb{E}_\theta[\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)] \geq \frac{2\gamma^c_{a,c}^2}{\delta} \leq 2\gamma^c_{a,c}^2 \frac{\delta}{2\gamma^c_{a,c}^2} = \delta.
\]

Thus, for any \( 1 \geq \eta > 0 \) and \( \delta > 0 \), if \( C_l \geq N_5(\eta, \delta) \), it holds for any \( x \) with probability greater than \( 1 - 4\delta \) that

\[
|\mu_x(\hat{y}^l)| \leq \eta, \quad (66)
\]

\[
|\mathcal{P}_x(\hat{y}^l) - 1| \leq \eta, \quad (67)
\]

\[
|\mathcal{P}_x(\hat{z}^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta, \quad (68)
\]

\[
\mathbb{E}_c[(\gamma^c_{a,c}^2(\mathcal{P}_x,c(y^l) + 1)] \leq \frac{2\gamma^2}{\delta}. \quad (69)
\]

If both inequalities of Eq. (66) and Eq. (67) hold, then

\[
|\sigma_x(\hat{y}^l) - 1| \leq |\sigma_x(\hat{y}^l) - 1||\sigma_x(\hat{y}^l) + 1| \leq |\sigma_x(\hat{y}^l)^2 - 1| \leq |\mathcal{P}(\hat{y}^l) - 1| + \mu_x(\hat{y}^l)^2 \leq \eta + \eta^2 \leq 2\eta,
\]

\[
(\sigma_x(\hat{y}^l) - 1)^2 \leq 4\eta^2 \leq 4\eta \leq \eta \leq \eta,
\]

\[
\mu_x(\hat{y}^l)^2 \leq \eta^2 \leq \eta.
\]
where we used $\eta^2 \leq \eta$ due to $\eta \leq 1$.

 Injecting this into Eq. (64) and Eq. (65), we get that, if $C_l \geq N_5(\eta, \delta)$, it holds with probability greater than $1 - 4\delta$ that

$$
\mathcal{P}_x(\hat{y}^l - y^l) \leq 10\eta, \quad \mathcal{P}_x(\hat{z}^l - z^l) \leq 20 F_0 \eta \frac{2\gamma^2}{\delta},
$$

Defining $N_0(\eta, \delta)$ independently of $\Theta^l$, $l$ as $N_0(\eta, \delta) = N_5 \left( \min \left( \frac{n}{n_0^m}, \frac{\eta}{20F_0 \delta}, 1, \frac{\delta}{2\gamma/n_0^m} \right) \right)$, $\forall \eta > 0$, $\forall \delta > 0$, if $C_l \geq N_0(\eta, \delta)$, it holds with probability greater than $1 - \delta$ that

$$
\forall x \in D \implies |\mathcal{P}_x(\hat{y}^l) - 1| \leq \eta, \quad |\mathcal{P}_x(\hat{z}^l) - 1| \leq \eta, \quad (70)
$$

$$
|\mathcal{P}_x(\hat{z}^l) - F_0(\gamma^2 + \beta^2)| \leq \eta, \quad \forall x \in D \implies |\mathcal{P}_x(\hat{z}^l) - F_0(\gamma^2 + \beta^2)| \leq \eta, \quad (72)
$$

$$
\mathcal{P}_x(\hat{z}^l - z^l) \leq \eta, \quad \forall x \in D \implies \mathcal{P}_x(\hat{z}^l - z^l) \leq \eta. \quad (73)
$$

If all inequalities of Eq. (70), (71), (72), (73) hold, then

$$
|\mathcal{P}^{(1)}(\hat{y}^l) - \mathcal{P}^{(1)}(y^l)| \leq \mathcal{P}(\hat{y}^l - y^l) + 2\mathbb{E}_c \left[ \mu_c(\hat{y}^l) \mu_c(y^l) \right] \\
\leq \mathcal{P}(\hat{y}^l - y^l) + 2\mathbb{E}_c \left[ \mu_c(\hat{y}^l) \mu_c(y^l) \right] \\
\leq \mathcal{P}(\hat{y}^l - y^l) + 2\sqrt{\mathbb{E}_c \mu_c(\hat{y}^l)^2 \mathbb{E}_c \mu_c(y^l)^2} \\
\leq \mathcal{P}(\hat{y}^l - y^l) + 2\sqrt{\mathcal{P}(\hat{y}^l - y^l)} \\
\leq \eta + 2\sqrt{(1 + \eta)\eta},
$$

where we used $\mathbb{E}_c \left[ \mu_c(\hat{y}^l)^2 \right] = \mathcal{P}^{(1)}(\hat{y}^l) \leq \mathcal{P}(\hat{y}^l), \mathbb{E}_c \left[ \mu_c(y^l)^2 \right] = \mathcal{P}^{(1)}(y^l) \leq \mathcal{P}(y^l)$, as well as Jensen’s inequality and Cauchy-Schwartz inequality.

Similarly,

$$
|\mathcal{P}(\hat{y}^l) - \mathcal{P}(y^l)| \leq \mathcal{P}(\hat{y}^l - y^l) + 2\mu(|\hat{y}^l||y^l - y^l|) \\
\leq \mathcal{P}(\hat{y}^l - y^l) + 2\sqrt{\mathcal{P}(\hat{y}^l - y^l)} \\
\leq \eta + 2\sqrt{(1 + \eta)\eta},
$$

A similar calculation with $\hat{z}^l$, $z^l$ shows that if all inequalities of Eq. (70), (71), (72), (73) hold, then

$$
|\mathcal{P}^{(1)}(\hat{z}^l) - \mathcal{P}^{(1)}(z^l)| \leq \eta + 2\sqrt{\eta} \sqrt{F_0(\gamma^2 + \beta^2)} + \eta, \\
|\mathcal{P}(\hat{z}^l) - \mathcal{P}(z^l)| \leq \eta + 2\sqrt{\eta} \sqrt{F_0(\gamma^2 + \beta^2)} + \eta.
$$

Given that the three terms $\eta, \eta + 2\sqrt{(1 + \eta)\eta}$ and $\eta + 2\sqrt{\eta} \sqrt{F_0(\gamma^2 + \beta^2)} + \eta$ converge to 0 as $\eta \to 0$, it follows that there exists a mapping $h$ such that for any $\eta > 0$, $h(\eta) > 0$ and

$$
h(\eta) \leq \eta, \quad h(\eta) + 2\sqrt{(1 + h(\eta))h(\eta)} \leq \eta, \quad h(\eta) + 2\sqrt{h(\eta)} \sqrt{F_0(\gamma^2 + \beta^2)} + h(\eta) \leq \eta.
$$

Thus, if we define $N_0'$ independently of $\Theta^l$, as $N_0'(\eta, \delta) = N_0(h(\eta), \delta), \forall \eta > 0$, $\forall \delta > 0$, then for any $\eta > 0$ and $\delta > 0$, if $C_l \geq N_0'(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
|\mathcal{P}^{(1)}(\hat{y}^l) - \mathcal{P}^{(1)}(y^l)| \leq \eta, \quad |\mathcal{P}^{(1)}(\hat{z}^l) - \mathcal{P}^{(1)}(z^l)| \leq \eta, \\
|\mathcal{P}(\hat{y}^l) - \mathcal{P}(y^l)| \leq \eta, \quad |\mathcal{P}(\hat{z}^l) - \mathcal{P}(z^l)| \leq \eta, \\
|\mathcal{P}_x(\hat{y}^l) - 1| \leq \eta, \quad \forall x \in D, \quad |\mathcal{P}_x(\hat{z}^l) - F_0(\gamma^2 + \beta^2)| \leq \eta, \quad \forall x \in D. \quad \Box
$$
Lemma 3. Fix a layer \( l \geq 1, \nu, \nu_\beta, \nu_\gamma, D \) in Definition 1 and model parameters \( \Theta^{l-1} \) up to layer \( l - 1 \) such that \( P(x|z^{l-1}) > 0, \forall x \). Further suppose Norm = LN and suppose that the convolution of Eq. (2) uses periodic boundary conditions.

Then for any \( \eta > 0 \) and \( \delta > 0 \), there exists \( N''(\eta, \delta) \in \mathbb{N}^+ \) independent of \( \Theta^{l-1}, l \) such that if \( C_1 \geq N''(\eta, \delta) \), it holds for random nets of Definition 1 with probability greater than \( 1 - \delta \) with respect to \( \theta^l \) that

\[
|\phi(y^l) - \phi(z^{l-1})| \leq \eta, \\
|P_x(y^l) - 1| \leq \eta, \ \forall x \in D, \\
|\phi(y^l) - \rho \chi(z^{l-1})\phi(z^{l-1})| \leq \eta, \\
|P_x(z^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta, \ \forall x \in D,
\]

with \( F_\phi \equiv \frac{\phi(1)^2 + \phi(-1)^2}{2} > 0 \), and with \( \rho = \gamma^2 / (\gamma^2 + \beta^2) < 1 \) and \( \chi(z^{l-1}) \in \mathbb{R}^+ \) dependent on \( \Theta^{l-1} \) but independent of \( \theta^l \) such that \( \chi(z^{l-1}) \leq 1 \) in general and \( \chi(z^{l-1}) = 1 \) if \( \phi \) = identity.

Proof. First let us note that

\[
|P_x(\bar{y}^l) - 1| \leq \eta, \ \forall x \in D \quad \implies \quad |P(\bar{y}^l) - 1| \leq \eta, \\
|P_x(z^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta, \ \forall x \in D \quad \implies \quad |P(z^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta.
\]

Combined with Lemma 2, we deduce for any \( \eta > 0 \) and \( \delta > 0 \) that there exists \( N''(\eta, \delta) \in \mathbb{N}^+ \) independent of \( \Theta^{l-1}, l \) such that if \( C_1 \geq N''(\eta, \delta) \), it holds for random nets of Definition 1 with probability greater than \( 1 - \delta \) with respect to \( \theta^l \) that

\[
|P(1)(\bar{y}^l) - P(1)(y^l)| \leq \eta, \\
|P(\bar{y}^l) - P(y^l)| \leq \eta, \\
|P(\bar{y}^l) - 1| \leq \eta, \\
|P(z^l) - F_\phi(\gamma^2 + \beta^2)| \leq \eta,
\]

with \( F_\phi \equiv \frac{\phi(1)^2 + \phi(-1)^2}{2} > 0 \).

If all inequalities of Eq. (74), (75), (76) hold with \( \eta \leq \frac{1}{4} F_\phi(\gamma^2 + \beta^2) \), then \( \phi(z^l) - \phi(\bar{z}^l) \) may be upper-bounded using

\[
\begin{align*}
\mathcal{P}(z^l) - \mathcal{P}(1)(z^l) & \leq \mathcal{P}(\bar{z}^l) - \mathcal{P}(1)(\bar{z}^l) + |\mathcal{P}(1)(\bar{z}^l) - \mathcal{P}(1)(z^l)| + |\mathcal{P}(z^l) - \mathcal{P}(\bar{z}^l)| \\
& \leq \mathcal{P}(\bar{z}^l) - \mathcal{P}(1)(\bar{z}^l) + 2\eta \\
& \leq \mathcal{P}(\bar{z}^l) + F_\phi(\gamma^2 + \beta^2) + 2\eta \\
& \leq \mathcal{P}(\bar{z}^l) F_\phi(\gamma^2 + \beta^2) + 3\eta, \\
\mathcal{P}(z^l) \geq \mathcal{P}(\bar{z}^l) & - \eta \geq F_\phi(\gamma^2 + \beta^2) - 2\eta, \\
\phi(z^l) \leq & \frac{\mathcal{P}(\bar{z}^l) F_\phi(\gamma^2 + \beta^2) + 3\eta}{F_\phi(\gamma^2 + \beta^2) - 2\eta} \\
& \leq \frac{\phi(\bar{z}^l) + \frac{3\eta}{F_\phi(\gamma^2 + \beta^2)}}{1 - \frac{2\eta}{F_\phi(\gamma^2 + \beta^2)}} \\
& \leq \left( \phi(\bar{z}^l) + \frac{3\eta}{F_\phi(\gamma^2 + \beta^2)} \right) \left( 1 + \frac{8\eta}{F_\phi(\gamma^2 + \beta^2)} \right) \\
& \leq \phi(\bar{z}^l) + \frac{35\eta}{F_\phi(\gamma^2 + \beta^2)},
\end{align*}
\]

where we used \( \phi(\bar{z}^l) \leq 1 \), as well as \( \frac{1}{1-x} \leq 1 + 4x \) for \( x \leq \frac{1}{2} \) and \( \left( \frac{\eta}{F_\phi(\gamma^2 + \beta^2)} \right)^2 \leq \left( \frac{\eta}{F_\phi(\gamma^2 + \beta^2)} \right) \) for \( \left( \frac{\eta}{F_\phi(\gamma^2 + \beta^2)} \right) \leq 1. \)
Similarly, if all inequalities of Eq. (74), (75), (76) hold with \( \eta \leq \frac{1}{4} F_\phi(\gamma^2 + \beta^2) \), then \( \varrho(z') - \varrho(\hat{z}') \) may be lower-bounded using

\[
\mathcal{P}(z') - \mathcal{P}^{(1)}(z') \geq \mathcal{P}(\hat{z}') - \mathcal{P}^{(1)}(\hat{z}') - |\mathcal{P}^{(1)}(\hat{z}') - \mathcal{P}^{(1)}(z')| - |\mathcal{P}(z') - \mathcal{P}(\hat{z}')|
\]

\[
\geq \mathcal{P}(\hat{z}') - \mathcal{P}^{(1)}(\hat{z}') - 2\eta
\]

\[
\geq \varrho(\hat{z}') \mathcal{P}(\hat{z}') - 2\eta
\]

\[
\geq \varrho(\hat{z}')(F_\phi(\gamma^2 + \beta^2) - \eta) - 2\eta
\]

\[
\geq \varrho(\hat{z}')(F_\phi(\gamma^2 + \beta^2) - 3\eta,
\]

\[
\mathcal{P}(z') \leq \mathcal{P}(\hat{z}') + \eta \leq F_\phi(\gamma^2 + \beta^2) + 2\eta,
\]

\[
\varrho(z') \geq \max \left( \frac{\varrho(\hat{z}')(F_\phi(\gamma^2 + \beta^2) - 3\eta, 0) }{F_\phi(\gamma^2 + \beta^2) + 2\eta} \right)
\]

\[
\geq \max \left( \frac{\varrho(\hat{z}') - \frac{3\eta}{F_\phi(\gamma^2 + \beta^2)} , 0} {1 + \frac{2\eta}{F_\phi(\gamma^2 + \beta^2)}} \right)
\]

\[
\geq \max \left( \frac{\varrho(\hat{z}') - \frac{3\eta}{F_\phi(\gamma^2 + \beta^2)} (1 - \frac{2\eta}{F_\phi(\gamma^2 + \beta^2)}) , 0} {1 + \frac{2\eta}{F_\phi(\gamma^2 + \beta^2)}} \right)
\]

\[
\geq \varrho(\hat{z}') - \frac{5\eta}{F_\phi(\gamma^2 + \beta^2)}
\]

where we used \( \varrho(\hat{z}') \leq 1 \), as well as \( \frac{1}{1+x} \geq 1 - x \geq 0 \) for \( 0 \leq x \leq 1 \).

We deduce that if all inequalities of Eq. (74), (75), (76) hold with \( \eta \leq \frac{1}{4} F_\phi(\gamma^2 + \beta^2) \), then

\[
|\varrho(z') - \varrho(\hat{z}')| \leq \frac{35\eta}{F_\phi(\gamma^2 + \beta^2)}, \tag{77}
\]

The reasoning that yielded Eq. (77) from Eq. (74), (75), (76) can be immediately transposed by replacing \( z' \) by \( y' \), \( \hat{z}' \) by \( y' \) and \( F_\phi(\gamma^2 + \beta^2) \) by \( 1 \).

Consequently, if all inequalities of Eq. (74), (75), (76) hold with \( \eta \leq \frac{1}{4} \), then

\[
|\varrho(y') - \varrho(\hat{y}')| \leq 35\eta.
\]

Lemma 1 also tells us that for any \( \eta > 0 \) and \( \delta > 0 \), there exists \( N'(\eta, \delta) \in \mathbb{N}^* \) independent of \( \Theta^{-1} \), \( l \) such that if \( C_l \geq N'(\eta, \delta) \), it holds with probability greater than \( 1 - 2\delta \) with respect to \( \theta^l \) that

\[
|\varrho(y') - \varrho(\hat{y}')| \leq \eta,
\]

\[
|\varrho(z') - \rho \chi(\hat{z}'^{(-1)}) \varrho(\hat{z}'^{(-1)})| \leq \eta,
\]

with \( \rho = \gamma^2 / (\gamma^2 + \beta^2) < 1 \) and \( \chi(\hat{z}'^{(-1)}) \in \mathbb{R}^+ \) dependent on \( \Theta^{-1} \) but independent of \( \theta^l \) such that \( \chi(\hat{z}'^{(-1)}) \leq 1 \) in general and \( \chi(\hat{z}'^{(-1)}) = 1 \) if \( \phi = \text{identity} \).

Let us then define \( N_\tau \) independently of \( \Theta^{-1} \), \( l \) as

\[
N_\tau(\eta, \delta) = \max \left( N'(\eta, \delta), \min \left( \eta, \frac{5}{4}, \frac{1}{4} F_\phi(\gamma^2 + \beta^2), \delta \right) \right), \quad \forall \eta > 0, \quad \forall \delta > 0.
\]

Then for any \( \eta > 0 \) and \( \delta > 0 \), if \( C_l \geq N_\tau(\eta, \delta) \), it holds with probability greater than \( 1 - 3\delta \) with respect to \( \theta^l \) that

\[
|\varrho(y') - \varrho(\hat{y}')| \leq |\varrho(y') - \varrho(\hat{y}')| + |\varrho(\hat{y}') - \varrho(\hat{z}')|
\]

\[
\leq 35\eta + \eta
\]

\[
\leq 36\eta.
\]

\[
|\varrho(z') - \rho \chi(\hat{z}'^{(-1)}) \varrho(\hat{z}'^{(-1)})| \leq |\varrho(z') - \varrho(\hat{z}')| + |\varrho(\hat{z}') - \rho \chi(\hat{z}'^{(-1)}) \varrho(\hat{z}'^{(-1)})|
\]

\[
\leq \frac{35\eta}{F_\phi(\gamma^2 + \beta^2)} + \eta
\]

\[
\leq \left( \frac{35 + F_\phi(\gamma^2 + \beta^2)}{F_\phi(\gamma^2 + \beta^2)} \right) \eta,
\]

38
Let us define $N_8$ independently of $\Theta^{l-1}, l$ as

$$N_8(\eta, \delta) = N_7\left(\min\left(\eta, \frac{F_{\phi}(\gamma^2 + \beta^2)}{15 + F_{\phi}(\gamma^2 + \beta^2)} \right), \forall \eta > 0, \forall \delta > 0.\right)$$

Then for any $\eta > 0$ and $\delta > 0$, if $C_l \geq N_8(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\theta^l$ that

$$|\phi(y^l) - \phi(z^l)| \leq \eta, \quad |\phi(z^l) - \rho(x^n)\phi(z^l)| \leq \eta.$$

Next, let us note that for any $\eta > 0$ and $\delta > 0$, if $C_l \geq N''(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\theta^l$ that

$$\forall x \in D : \quad |\mathcal{P}_x(y^l) - 1| \leq |\mathcal{P}_x(y^l) - \mathcal{P}_x(y^l')| + |\mathcal{P}_x(y^l') - 1| \leq |\mathcal{D}|(\mathcal{P}(y^l) - \mathcal{P}(y^l') + \eta) \leq (|\mathcal{D}| + 1)\eta.$$

Let us finally define $N'''$ independently of $\Theta^{l-1}, l$ as $N'''(\eta, \delta) = \max\left(N_8(\eta, \frac{\delta}{2}), N''(\frac{1}{|\mathcal{D}| + 1} \eta, \frac{\delta}{2})\right)$, $\forall \eta > 0, \forall \delta > 0$. Then, for any $\eta > 0$ and $\delta > 0$, if $C_l \geq N'''(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\theta^l$ that

$$|\phi(y^l) - \phi(z^l)| \leq \eta, \quad |\phi(z^l) - \rho(x^n)\phi(z^l)| \leq \eta, \quad |\mathcal{P}_x(y^l) - 1| \leq \eta, \quad \forall x \in D,$$

and

$$\mathcal{P}_x(y^l) - \mathcal{P}^{(1)}(y^l) \leq \rho^{l-1} + \eta, \quad \mathcal{P}(y^l) = 1,$$

with $\rho \equiv \gamma^2/(\gamma^2 + \beta^2) < 1$.

**Proof.** For fixed $\Theta^{l-1}$ such that $\mathcal{P}_x(z^l) > 0, \forall x \in D$, Lemma 3 tells us that for any $\delta > 0$, if $C_l \geq N''\left(\min\left(\frac{1}{2}, \frac{F_{\phi}(\gamma^2 + \beta^2)}{2}\right), \delta\right)$ with $F_{\phi} \equiv \left(\frac{\phi(1)^2 + \phi(-1)^2}{2}\right) > 0$, then it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\theta^l$ that

$$|\mathcal{P}_x(y^l) - 1| \leq \frac{1}{2} \implies \mathcal{P}_x(y^l) \geq 1 - \frac{1}{2} > 0,$$

$$|\mathcal{P}_x(y^l) - \mathcal{P}_x(y^l')| \leq \frac{F_{\phi}(\gamma^2 + \beta^2)}{2} \implies \mathcal{P}_x(y^l') \geq \mathcal{P}_x(y^l) - \frac{F_{\phi}(\gamma^2 + \beta^2)}{2} > 0.$$

If we define the event $A^{l-1} \equiv (\mathcal{P}_x(y^l) > 0, \forall x \in D) \land (\mathcal{P}_x(z^l) > 0, \forall x \in D)$, given that $N'''$ is independent of $\Theta^{l-1}, l$, this implies for $C_l \geq N'''\left(\min\left(\frac{1}{2}, \frac{F_{\phi}(\gamma^2 + \beta^2)}{2}\right), \delta\right)$ that

$$\mathbb{P}_\theta\left[\left(\mathcal{P}_x(y^l) > 0, \forall x \in D\right) \land \left(\mathcal{P}_x(z^l) > 0, \forall x \in D\right)\right] \geq 1 - \delta.$$
Using the fact that $P(x) > 0$, $\forall x \in D$ by Definition 1, this implies for $\min_{1 \leq k \leq l} C_k \geq N'' \left( \min \left( \frac{1}{2}, \frac{F_\phi(\gamma^2 + \beta^2)}{2} \right), \delta \right)$ that

$$P_{\Theta^l} \left( (P_x(y^l) > 0, \forall x \in D) \wedge (P_x(z^l) > 0, \forall x \in D) \right) \geq (1 - \delta)^l.$$  

Thus, for any $\delta > 0$ there exists $N_9(\delta) \in \mathbb{N}^*$ such that, if $\min_{1 \leq k \leq l} C_k \geq N_9(\delta)$, it holds with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$\left( P_x(y^l) > 0, \forall x \in D \right) \wedge \left( P_x(z^l) > 0, \forall x \in D \right) \implies P_x(y^l) = 1, \forall x \in D \implies P(y^l) = 1.$$  

Lemma 3 also tells us that for any $1 > \eta > 0$ and $\delta > 0$, if $C_l \geq N'' \left( \min \left( \eta, F_\phi(\gamma^2 + \beta^2) \right), \delta \right)$, it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$F_\phi(\gamma^2 + \beta^2)(1 - \eta) \leq P_x(z^l) \leq F_\phi(\gamma^2 + \beta^2)(1 + \eta) \quad \forall x \in D,$$

$$F_\phi(\gamma^2 + \beta^2)(1 - \eta) \leq P(z^l) \leq F_\phi(\gamma^2 + \beta^2)(1 + \eta),$$

$$\sqrt{\frac{1 - \eta}{1 + \eta}} \leq \sqrt{\frac{P(z^l)}{P_x(z^l)}} \leq \sqrt{\frac{1 + \eta}{1 - \eta}} \quad \forall x \in D,$$

$$\left( \sqrt{\frac{P(z^l)}{P_x(z^l)}} - 1 \right)^2 \leq g(\eta) \equiv \max \left( \left( \sqrt{\frac{1 - \eta}{1 + \eta}} - 1 \right)^2, \left( \sqrt{\frac{1 + \eta}{1 - \eta}} - 1 \right)^2 \right) \quad \forall x \in D. \quad (80)$$

If Eq. (80) holds, then

$$\hat{z}_{\alpha, c}^l - z_{\alpha, c}^l = \left( \sqrt{\frac{P(z^l)}{P_x(z^l)}} - 1 \right)z_{\alpha, c}^l,$$

$$P_x(\hat{z}^l - z^l) = \left( \sqrt{\frac{P(z^l)}{P_x(z^l)}} - 1 \right)^2 \leq g(\eta) \leq g(\eta) P(z^l),$$

$$P(\hat{z}^l - z^l) \leq g(\eta) \leq g(\eta) P(z^l).$$

In turn, this implies that if both Eq. (79) and Eq. (80) hold, then

$$|P(\hat{z}^l) - P(z^l)| \leq P(\hat{z}^l - z^l) + 2\mu((\hat{z}^l - z^l)||z^l))$$

$$\leq P(\hat{z}^l - z^l) + 2 \sqrt{P(\hat{z}^l - z^l)P(z^l)}$$

$$\leq \left( g(\eta) + 2\sqrt{g(\eta)} \right) P(z^l)$$

$$\leq \left( g(\eta) + 2\sqrt{g(\eta)} \right) F_\phi(\gamma^2 + \beta^2)(1 + \eta),$$

$$|P^{(1)}(\hat{z}^l) - P^{(1)}(z^l)| \leq P^{(1)}(\hat{z}^l - z^l) + 2 \mathbb{E}_{\mu_c}(z^l) \mu_c(\hat{z}^l)$$

$$\leq P(\hat{z}^l - z^l) + 2 \mathbb{E}_{\mu_c}(z^l) \mu_c(\hat{z}^l)$$

$$\leq P(\hat{z}^l - z^l) + 2 \mathbb{E}_{\mu_c}(\mu_c(\hat{z}^l) - z^l)^2) \mathbb{E}_{\mu_c}(z^l)$$

$$\leq P(\hat{z}^l - z^l) + 2 \sqrt{P(\hat{z}^l - z^l)P(z^l)}$$

$$\leq \left( g(\eta) + 2\sqrt{g(\eta)} \right) F_\phi(\gamma^2 + \beta^2)(1 + \eta).$$

Since $\left( g(\eta) + 2\sqrt{g(\eta)} \right) F_\phi(\gamma^2 + \beta^2)(1 + \eta) \to 0$ as $\eta \to 0$, we deduce for any $\eta > 0$ and $\delta > 0$ that there exists $N_{10}(\eta, \delta) \in \mathbb{N}^*$, such that, if $C_l \geq N_{10}(\eta, \delta)$, it holds with probability greater than $1 - \delta$
with respect to $\theta^l$ that

$$\|P_\theta(z^l) - F_\phi(\gamma^2 + \beta^2)\| \leq \eta \quad \forall x \in D \implies \|P(z^l) - F_\phi(\gamma^2 + \beta^2)\| \leq \eta,$$

$$\|P(z^l) - P(z^l')\| \leq \eta,$$

$$\|P^{(1)}(z^l) - P^{(1)}(z^l')\| \leq \eta.$$

Defining $N_{11}$ independently of $\Theta^{l-1}$, $l$ as $N_{11}(\eta, \delta) = \max \left( N^{\eta}(\eta, \frac{\delta}{2}), N_{10}(\eta, \frac{\delta}{2}) \right)$, $\forall \eta > 0$, $\forall \delta > 0$, we deduce for any $\eta > 0$ and $\delta > 0$ that, if $C_l \geq N_{11}(\eta, \delta)$, it holds that

$$\|\phi(y^l) - \phi(z^l\!\backslash\!1)\| \leq \eta,$$

$$\|\phi(z^l) - \rho \chi (z^l\!\backslash\!1)\| \leq \eta,$$

$$\|P(z^l) - F_\phi(\gamma^2 + \beta^2)\| \leq \eta,$$

$$\|P(z^l) - P(z^l)\| \leq \eta,$$

$$\|P^{(1)}(z^l) - P^{(1)}(z^l)\| \leq \eta.$$

The reasoning that yielded Eq. (77) from Eq. (74), (75), (76) can be immediately transposed by replacing $z^l$ by $y^l$ and $z^l$ by $z^l$.

Thus, if $C_l \geq N_{11}(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\theta^l$ that

$$\|\phi(y^l) - \phi(z^l\!\backslash\!1)\| \leq \eta,$$

$$\|\phi(z^l) - \rho \chi (z^l\!\backslash\!1)\| \leq \eta,$$

$$\|\phi(z^l) - \rho \chi (z^l\!\backslash\!1)\| \leq \eta + \frac{35 \eta}{F_\phi(\gamma^2 + \beta^2)} = \left( \frac{F_\phi(\gamma^2 + \beta^2) + 35}{F_\phi(\gamma^2 + \beta^2)} \right) \eta.$$

Defining $N_{12}$ independently of $\Theta^{l-1}$, $l$ as $N_{12}(\eta, \delta) = N_{11}\left( \frac{F_\phi(\gamma^2 + \beta^2)}{F_\phi(\gamma^2 + \beta^2) + 35} \eta, \delta \right)$, $\forall \eta > 0$, $\forall \delta > 0$, we deduce for any $\eta > 0$ and $\delta > 0$ that, if $C_l \geq N_{12}(\eta, \delta)$, it holds that

$$\mathbb{P}_{\theta^l}\left[ |\phi(y^l) - \phi(z^l\!\backslash\!1)\| \leq \eta \right] \geq \mathbb{P}_{\theta^l}\left[ |\phi(y^l) - \phi(z^l\!\backslash\!1)\| \leq \frac{F_\phi(\gamma^2 + \beta^2)}{F_\phi(\gamma^2 + \beta^2) + 35} \eta \right] \geq 1 - \delta,$$

$$\mathbb{P}_{\theta^l}\left[ |\phi(z^l) - \rho \chi (z^l\!\backslash\!1)\| \leq \eta \right] \geq 1 - \delta.$$

Consequently, for any layer $k$ and any $\eta > 0$ and $\delta > 0$, if $C_k \geq N_{12}(\eta, \delta)$, it holds for random nets of Definition 1 that

$$\mathbb{P}_{\Theta^k}\left[ |\phi(y^k) - \phi(z^k\!\backslash\!1)\| \leq \eta \right] \geq 1 - \delta,$$

$$\mathbb{P}_{\Theta^k}\left[ |\phi(z^k) - \rho \chi (z^k\!\backslash\!1)\| \leq \eta \right] \geq 1 - \delta.$$

Thus, for any $\eta > 0$ and $\delta > 0$, if $\min_{1 \leq k \leq l} C_k \geq N_{12}(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - l\delta$ with respect to $\Theta^l$ that

$$|\phi(z^k) - \rho \chi (z^k\!\backslash\!1)\| \leq \eta, \quad \forall k \leq l - 1,$$

$$|\phi(y^l) - \phi(z^l)\| \leq \eta. \quad \text{(81)}$$
Given $\chi(\hat{z}^{k-1}) \leq 1$, $\forall k$ and given $\varrho(\hat{x}^0) = \varrho(x) \leq 1$, we note that if Eq. (81) and Eq. (82) hold, then

$$
\varrho(\hat{z}) \leq \rho(\hat{x}^0)\varrho(\hat{x}^0) + \eta \leq \rho + \eta,
$$

$$
\varrho(\hat{z}^2) \leq \rho(\hat{x}^1)\varrho(\hat{x}^1) + \eta \leq \rho^2 + \rho\eta + \eta,
$$

and so on.

$$
\varrho(\hat{z}^{l-1}) \leq \rho(\hat{x}^{l-2})\varrho(\hat{x}^{l-2}) + \eta \leq \rho^{l-1} + \left(\sum_{k=0}^{l-2} \rho^k\right)\eta \leq \rho^{l-1} + \frac{1}{1-\rho}\eta,
$$

$$
\varrho(y^{l-1}) \leq \varrho(\hat{z}^{l-1}) + \eta \leq \rho^{l-1} + \frac{1}{1-\rho}\eta + \eta \leq \rho^{l-1} + \left(\frac{2-\rho}{1-\rho}\right)\eta.
$$

(83)

Defining $N_{13}$ such that $N_{13}(\eta, \delta) = N_{12}\left(\frac{1-\rho}{2}, \frac{1}{\rho}, \frac{1}{\rho}\right), \forall \eta > 0, \forall \delta > 0$, we deduce for any $\eta > 0$ and $\delta > 0$ that, if $\min_{1 \leq k \leq l} C_k \geq N_{13}(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
\varrho(y^{l-1}) \leq \rho^{l-1} + \eta.
$$

Finally, let us define $N$ such that $N(\eta, \delta) = \max\left(\left\{N_{0}, N_{13}(\eta, \delta)\right\}\right)$, $\forall \eta > 0, \forall \delta > 0$. Then for any $\eta > 0$ and $\delta > 0$, if $\min_{1 \leq k \leq l} C_k \geq N(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
\varrho(y^{l-1}) = \mathcal{P}(y^{l-1}) - \mathcal{P}^{(1)}(y^{l-1}) \leq \rho^{l-1} + \eta, \quad \mathcal{P}(y^{l-1}) = 1.
$$

D.4 Case $\phi = \text{identity}$

**Proposition 4.** Fix a layer $l \geq 1$ and $\nu_{\omega}, \nu_{\beta}, \nu_{\gamma}, D$ in Definition 1, with $D$ “centered” such that $\mathcal{P}^{(1)}(x) = 0$. Further suppose $\text{Norm} = LN$ and $\phi = \text{identity}$, and suppose that the convolution of Eq. (2) uses periodic boundary conditions.

Then for any $\eta > 0$ and $\delta > 0$, there exists $N(\eta, \delta) \in \mathbb{N}^*$ such that if $\min_{1 \leq k \leq l} C_k \geq N(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
|\mathcal{P}(y^{l-1}) - \mathcal{P}^{(1)}(y^{l-1}) - \rho^{l-1}| \leq \eta, \quad \mathcal{P}(y^{l-1}) = 1,
$$

with $\rho \equiv \gamma^2/(\gamma^2 + \beta^2) < 1$.

**Proof.** Since $\phi = \text{identity}$ is a particular case of positive homogeneous activation function, the whole proof of Theorem 1 still applies. Let us then define $N_{0}, N_{12}$ as in the proof of Theorem 1.

Then for any $\delta > 0$, if $\min_{1 \leq k \leq l} C_k \geq N_{0}(\delta)$, it holds with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
\mathcal{P}(y^{l-1}) = 1.
$$

In addition, for any $\eta > 0$ and $\delta > 0$, if $\min_{1 \leq k \leq l} C_k \geq N_{12}(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
|\varrho(\hat{z}^k) - \rho(\hat{z}^{k-1})\varrho(\hat{z}^{k-1})| = |\varrho(\hat{z}^k) - \rho\varrho(\hat{z}^{k-1})| \leq \eta, \quad \forall k \leq l - 1,
$$

$$
|\varrho(y^{l-1}) - \varrho(\hat{z}^{l-1})| \leq \eta,
$$

where we used the fact that $\chi(\hat{z}^{k-1}) = 1$, $\forall k$ in the case $\phi = \text{identity}$.

Next we note that: (i) the assumptions that $\mathcal{P}^{(1)}(x) = 0$ and that $\mathcal{P}_{\nu}(x) > 0$, $\forall x$ (cf Definition 1) together imply $\varrho(\hat{z}^0) = \varrho(x) = 1$; (ii) the reasoning yielding Eq. (83) from Eq. (81), (82) still applies.
Therefore, if $\min_{1 \leq k \leq l} C_k \geq N_{12}(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - l\delta$ with respect to $\Theta^l$ that

$$
\begin{align*}
\ell \varrho(\tilde{z}^1) &\geq \rho \varrho(x) - \eta = \rho - \eta, \\
\ell \varrho(\tilde{z}^2) &\geq \rho \varrho(\tilde{z}^1) - \eta \geq \rho^2 - \rho \eta - \eta, \\
&\vdots \\
\ell \varrho(\tilde{z}^{l-1}) &\geq \rho \varrho(\tilde{z}^{l-2}) - \eta \geq \rho^{l-1} - \left( \sum_{k=0}^{l-2} \rho^k \right) \eta \geq \rho^{l-1} - \frac{1}{1 - \rho} \eta, \\
\ell \varrho(y^l) &\geq \rho \varrho(\tilde{z}^{l-1}) - \eta \geq \rho^{l-1} - \frac{1}{1 - \rho} \eta - \eta \geq \rho^{l-1} - \left( \frac{2 - \rho}{1 - \rho} \right) \eta, \\
\ell \varrho(y^l) &\leq \rho^{l-1} + \left( \frac{2 - \rho}{1 - \rho} \right) \eta, \\
\end{align*}
$$

(84)

where Eq. (84) follows from Eq. (83).

As in the proof of Theorem 1, defining $N_{13}$ such that $N_{13}(\eta, \delta) = N_{12} \left( \frac{1 - \rho}{2 - \rho} \eta, \frac{1}{2} \delta \right)$, we deduce for any $\eta > 0$ and $\delta > 0$ that, if $\min_{1 \leq k \leq l} C_k \geq N_{13}(\eta, \delta)$, it holds for random nets of Definition 1 with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
|\ell \varrho(y^l) - \rho^{l-1}| \leq \eta.
$$

As in the proof of Theorem 1, defining $N$ such that $N(\eta, \delta) = \max \left( N_{\eta} \left( \frac{1}{2} \right), N_{13}(\eta, \delta) \right)$, \forall $\eta > 0$, \forall $\delta > 0$, we deduce for any $\eta > 0$ and $\delta > 0$ that, if $\min_{1 \leq k \leq l} C_k \geq N(\eta, \delta)$, it holds with probability greater than $1 - \delta$ with respect to $\Theta^l$ that

$$
|\ell \varrho(y^l) - \rho^{l-1}| = |\varrho(y^l) - \varrho^{(1)}(y^l) - \rho^{l-1}| \leq \eta, \quad \varrho(y^l) = 1. \quad \square
$$

### E Proof of Theorem 2

**Theorem 2.** Fix a layer $l \in \{1, \ldots, L\}$. Further suppose Norm = IN and suppose that model parameters are chosen such that the denominator of Eq. (3) at layer $l$ is nonzero for all inputs $x$ and channels $c$.

Then it holds that

- $y^l$ is normalized in each channel $c$ with $p_c^{(1)}(y^l) = 0, \quad p_c(y^l) = 1$;
- $y^l$ lacks variability in instance statistics in each channel $c$ with $p_c^{(2)}(y^l) = 0, \quad p_c^{(3)}(y^l) = 1, \quad p_c^{(4)}(y^l) = 0$.

**Proof.** With Norm = IN, if $\sigma_{x,c}(x') > 0, \forall x, c$, the instance-level statistics are given by

$$
\begin{align*}
\mu_{x,c}(y^l) &= \mathbb{E}_{\alpha} \left[ y_{\alpha,c}^l \right] = \left( \mathbb{E}_{\alpha} \left[ x_{\alpha,c}^l \right] - \mu_{x,c}(x') \right) / \sigma_{x,c}(x') = \left( \mu_{x,c}(x^l) - \mu_{x,c}(x') \right) / \sigma_{x,c}(x') = 0, \\
p_{x,c}(y^l) &= \mathbb{E}_{\alpha} \left[ \left( y_{\alpha,c}^l - \mu_{x,c}(x') \right)^2 \right] / \sigma_{x,c}(x') = \left( \sigma_{x,c}(x^l)^2 / \sigma_{x,c}(x')^2 \right) = 1, \\
\sigma_{x,c}(y^l) &= \left( p_{x,c}(y^l) - \mu_{x,c}(y^l)^2 \right)^{1/2} = 1.
\end{align*}
$$

43
In turn, this implies that the different power terms are given by

\[ P_c(y^l) = \mathbb{E}_x[P_{x,c}(y^l)] = \mathbb{E}_x[1] = 1, \]
\[ P_c^{(1)}(y^l) = \mathbb{E}_x[\mu_{x,c}(y^l)]^2 = \mathbb{E}_x[0]^2 = 0, \]
\[ P_c^{(2)}(y^l) = \text{Var}_x[\mu_{x,c}(y^l)] = \text{Var}_x[0] = 0, \]
\[ P_c^{(3)}(y^l) = \mathbb{E}_x[\sigma_{x,c}(y^l)]^2 = \mathbb{E}_x[1]^2 = 1, \]
\[ P_c^{(4)}(y^l) = \text{Var}_x[\sigma_{x,c}(y^l)] = \text{Var}_x[1] = 0. \]
