(Dated: June 11, 2021)

QED in multipolar form and its relation to the Poincaré-gauge has been a recent topic of controversy and debate. It was claimed by Rousseau and Felbacq in the article Scientific Reports 7, 11115 (2017) that Hamiltonian multipolar QED is not the same as Poincaré-gauge QED and that it is not generally equivalent to Coulomb-gauge QED. This claim has subsequently been refuted, but since both sides of the debate appear technically sound, a clear reconciliation remains to be given. This task is of paramount importance due to the widespread use of multipolar QED in quantum optics and atomic physics. Here, unlike in other responses, we adopt the same method as Rousseau and Felbacq of using Dirac’s constrained quantisation procedure. However, our treatment shows that Poincaré-gauge and multipolar QED are identical. We identify the precise source of the apparent incompatibility of previous results as nothing more than a semantic mismatch. In fact there are no inconsistencies. Our results firmly and rigorously solidify the multipolar theory.

I. INTRODUCTION

Quantum electrodynamics (QED) is the prototypical quantum gauge-field theory. Therein, the non-dynamical constraint called Gauss’ law: \( \nabla \cdot \mathbf{E} = \rho \) where \( \mathbf{E} \) is the electric field and \( \rho \) the density of charges, implies gauge redundancy. When electromagnetic potentials are used as generalised coordinates the Lagrangian of the theory is degenerate implying that there will be fewer canonical momenta than canonical coordinates when passing to the Hamiltonian formalism. Dirac laid out a systematic procedure by which a suitable Lie algebra of classical observables, known as Dirac brackets, can be constructed, which respect both the equations of motion and the non-dynamical constraints. This enables passage to the quantum theory via the replacement of Dirac brackets with commutators.

Applied to QED, Dirac’s procedure requires invoking a gauge-fixing constraint to eliminate gauge redundancy. Refs. [1, 2] apply this method in the case of nonrelativistic material charges to derive the Poincaré-gauge canonical theory. They claim that textbook multipolar QED is not the same as the Poincaré-gauge theory and will not produce the same results as the well-known Coulomb-gauge theory. Refs. [3] and [4] dispute this claim, concluding that criticisms of the multipolar framework in Ref. [1] are not valid. In turn Ref. [2] disputes the conclusions of Ref. [3] maintaining that the conclusion of Ref. [1] is valid.

Although the responses [3] and [4] to Ref. [1] contain valuable insights, the situation has not been clearly and decisively resolved. This is because it is not clear where, if anywhere, either side of the debate is technically flawed, and if both sides are technically sound, it is unclear how the apparent disagreement comes to be. Here, unlike in the responses [3, 4], we adopt the same method of Dirac’s constrained quantisation as is used in Refs. [1, 2] (these being the original articles that claim there is disparity between multipolar and Poincaré-gauge QED). We show precisely why this claim is in fact not valid, despite the technical validity of the Poincaré-gauge theory obtained in Refs. [1, 2]. We demonstrate how the theory derived in this way is in fact identical to textbook multipolar theory. The key to the resolution we provide is the construction of the canonical operators that are commonly used in multipolar QED from the canonical operators of the Poincaré-gauge that are found using Dirac’s method. Attempting to equate these distinct canonical operator sets results in the incorrect conclusion that the two theories are disparate. In fact the two sets of operators are not identical, but they can be easily related. Expressing the Poincaré-gauge theory in terms of the multipolar canonical operators reveals that the two theories are identical. We show moreover, that all fixed-gauge theories of QED are equivalent by explicitly constructing the necessary unitary gauge-fixing transformations that act within the physical state space. The Power-Zienau-Woolley transformation between Coulomb-gauge and multipolar QED is an example of such a transformation.

This article is divided into four sections. In Sec. II we provide a pedagogical overview of gauge-freedom, which facilitates a straightforward understanding of our results in Sec. III. This includes understanding both electromagnetic and material auxiliary potentials. In Sec. III we provide our main results, which resolve all controversy surrounding multipolar QED and its relation to the Poincaré-gauge, rigorously solidifying the multipolar theory. We summarise our findings briefly in Sec. V.

II. BACKGROUND

A. Gauge-freedom and electromagnetic potentials

Throughout this article we use natural Lorentz-Heaviside units. For simplicity we restrict our attention
to a single-electron atom with fixed nucleus at the origin within the surrounding electromagnetic field. The classical charge and current densities are
\[ \rho(x) = q\delta(x - r) - q\delta(x) \]  
\[ J(x) = q\vec{r}\delta(x - r) \]  
where \( q \) is the electron’s charge, and \( r \) is its position.

Electric and magnetic fields \( E \) and \( B \) are defined in terms of the scalar and vector potentials \( A_0 \) and \( A \) as
\[ E = -\nabla A_0 - \dot{A}, \]  
\[ B = \nabla \times A. \]  
These definitions imply that the homogeneous Maxwell equations, \( \nabla \cdot B = 0 \) and \( \vec{B} = -\nabla \times \vec{E} \), are automatically satisfied. To see this note that \( \nabla \cdot \nabla \times \vec{V} = 0 \) for any twice differentiable \( \vec{V} \) and that \( \nabla \times \nabla \nabla \vec{V} = 0 \) for any twice differentiable \( \vec{V} \). The inhomogeneous constraint \( \nabla \cdot \vec{E} = -\rho = 0 \) (Gauss’ law) must be imposed within the theory while the remaining inhomogeneous equation is dynamical \( \vec{E} = \nabla \times \vec{B} - \vec{J} \) (Maxwell-Ampère law). This is an equation of motion that must be produced by any satisfactory Lagrangian or Hamiltonian description.

The electric and magnetic fields are invariant under the gauge transformation
\[ A' = A + \nabla \chi, \]  
\[ A'_0 = A_0 - \partial_t \chi \]  
where \( \chi \) is an arbitrary function over spacetime. Recall that the Helmholtz decomposition of a vector-field \( \vec{V} \) into transverse and longitudinal fields, \( \vec{V} = \vec{V}_T + \vec{V}_L \), is unique. The transverse and longitudinal components satisfy \( \nabla \cdot \vec{V}_T = 0 \) and \( \nabla \times \vec{V}_L = 0 \). We see therefore that the transverse vector potential \( A_T \) is gauge-invariant and unique, that is, if \( \vec{A} \) and \( \vec{A}' \) are related as in Eq. (5) then \( A'_T = A_T \). Gauge-freedom is therefore the freedom to choose the longitudinal vector potential \( A_L = \nabla \chi \) where \( \vec{A} = A_T + \nabla \chi \). Perhaps the most straightforward choice is \( A_L = 0 \), which is called the Coulomb-gauge. If we denote the corresponding Coulomb-gauge scalar potential by \( \phi \) then we have from Eq. (3) that \( \vec{E} = -\nabla \phi - \vec{A}_T \) from which it follows that \( \nabla \cdot \vec{E} = -\nabla^2 \phi \) (noting that partial derivatives commute). If we invoke Gauss’ law, \( \nabla \cdot \vec{E} = \rho \), then we obtain
\[ \phi(x) = -\frac{1}{\sqrt{4\pi}}\rho(x) = \int d^3x' \frac{\rho(x')}{4\pi|x - x'|}, \]  
which is called the Coulomb potential of the charge distribution \( \rho \).

The Coulomb-gauge potentials \( (\phi, A_T) \) provide a convenient reference set in terms of which any other gauge may be specified as
\[ \vec{A} = \vec{A}_T + \nabla \chi, \]  
\[ A_0 = \phi - \partial_t \chi. \]  

We emphasise however, that it is incorrect to identify \( A_T \) and \( \phi \) as belonging to the Coulomb-gauge, because they are well-defined fields that are identifiable and the same in every gauge. What defines the Coulomb-gauge is the (gauge-fixing) condition that \( \chi \) in Eqs. (8) and (9) vanishes. This condition has nothing to do with \( \phi \) and \( A_T \). Its effect is to fix \( \vec{A} \) as equal to \( \vec{A}_T \) and to fix \( A_0 \) as equal to \( \phi \), but whether or not these equalities happen to hold, the quantities \( A_T \) and \( \phi \) are always well-defined and identifiable.

Since the transverse potential \( A_T \) is gauge-invariant, in any gauge it can be used as an elementary physical coordinate for the electromagnetic field. The standard Coulomb and Poincaré gauges of nonrelativistic QED can be generalised by specifying the freely choosable gauge-function \( \chi \) as a functional of \( A_T \). This can be achieved by defining the gauge-fixing constraint [5]
\[ C_2 := \int d^3x' \vec{g}(x', x) \cdot \vec{A}(x') \]  
in which \( \vec{g} \) is the Green’s function for the divergence operator;
\[ \nabla \cdot \vec{g}(x, x') = \delta(x - x'). \]  
The longitudinal part \( \vec{g}_L(x, x') \) is uniquely defined by this equation as the gradient of the Green’s function for the Laplacian [cf. Eq. 12]:
\[ \vec{g}_L(x, x') = -\frac{1}{4\pi|x - x'|} \]  
whereas the transverse part \( \vec{g}_T(x, x') \) is a completely arbitrary function of \( x' \) and an arbitrary transverse function of \( x \). Given the constraint \( C_2 \), choosing a concrete \( \vec{g}_T \) specifies the gauge, because imposing \( C_2 = 0 \) implies that \( \vec{A} \) can be written [5]
\[ \vec{A}(x) = \vec{A}_T(x) + \nabla \int d^3x' \vec{g}(x', x) \cdot \vec{A}_T(x'), \]  
which defines the gauge-function \( \chi_g \) such that \( \nabla \chi_g = \vec{A}_L \) as
\[ \chi_g(x) = \int d^3x' \vec{g}(x', x) \cdot \vec{A}_T(x') \]  
\[ = \int d^3x' \vec{g}_T(x', x) \cdot \vec{A}_T(x'). \]  
The Coulomb-gauge is defined by \( \vec{g}_T = 0 \). The Poincaré-gauge is defined by the condition \( x \cdot \vec{A}(x) = 0 \) and it is easily verified that by letting
\[ \vec{g}_T(x, x') = -\int_0^1 d\lambda \vec{x}' \cdot \delta^T(x - \lambda x') \]  
in Eq. (13) we obtain a potential for which \( x \cdot \vec{A}(x) = 0 \). Thus, the gauge-fixing constraint \( C_2 \) in Eq. (10) is sufficiently general to accommodate the Coulomb and Poincaré gauges as special cases. In Sec. III we will use Dirac’s constrained quantisation procedure in conjunction with the constraints \( C_1 \) and \( C_2 \), to obtain an arbitrary-gauge Hamiltonian QED.
B. Gauge-freedom and material potentials

Before providing our main results we briefly discuss the lesser known gauge-freedom that is inherent in material auxiliary potentials. Doing so already allows us to identify the connection between the Poincaré-gauge and the well-known multipolar formalism. Auxiliary material potentials $\mathbf{P}$ and $\mathbf{M}$ can be defined using the inhomogenous Maxwell equations:

$$\begin{align*}
\rho &= -\nabla \cdot \mathbf{P}, \\
\mathbf{J} &= \mathbf{P} + \nabla \times \mathbf{M}.
\end{align*}$$

(16) (17)

In the absence of any accompanying homogenous Maxwell equations the fields $\mathbf{P}$ and $\mathbf{M}$ are not unique. Specifically, the physical charge and current densities are invariant under a transformation by pseudo-magnetic and pseudo-electric fields as

$$\begin{align*}
\mathbf{P} &\rightarrow \mathbf{P} + \nabla \times \mathbf{U}, \\
\mathbf{M} &\rightarrow \mathbf{M} - \nabla U_0 - \mathbf{U},
\end{align*}$$

(18) (19)

where $(U_\mu) = (U_0, -\mathbf{U})$ are the components of an arbitrary pseudo-four-potential. The polarisation $\mathbf{P}$ and magnetisation $\mathbf{M}$ are in turn invariant under a gauge transformation $U_\mu \rightarrow U_\mu - \partial_\mu \chi$ where $\mu = 0, 1, 2, 3$ and $\chi$ is arbitrary.

The field $\mathbf{M}_0$ is completely arbitrary because it does not contribute to either $\rho$ or $\mathbf{J}$. Only the transverse freedom in $\mathbf{P}$ and $\mathbf{M}$ is non-trivial. By specifying $\mathbf{P}_T$ both $\mathbf{P}$ and $\nabla \times \mathbf{M} = \mathbf{J}_T - \mathbf{P}_T = \mathbf{J} - \mathbf{P}$ are fully specified. If we define the polarisation $\mathbf{P}$ as

$$\mathbf{P}(\mathbf{x}) = -\int d^3x' \mathbf{g}(\mathbf{x}, \mathbf{x}') \rho(\mathbf{x}')$$

(20)

then we see that $-\nabla \cdot \mathbf{P} = \rho$ is satisfied identically and $\mathbf{P}_L = \nabla \phi$ (the gradient of the Coulomb-potential) is obtained from the expression for $\mathbf{g}_L$ given in Eq. (12). Noting that

$$\delta_{ij}^L(x) = -\nabla_i \nabla_j \frac{1}{4\pi|x|} = \int \frac{d^3k}{(2\pi)^3} \hat{k}_i \hat{k}_j e^{i\mathbf{k} \cdot \mathbf{x}},$$

(21)

it is easy to show using the gradient theorem or by Fourier transformation, that for $\rho$ specified by Eq. (1), $\mathbf{P}_L$ can also be written as a line-integral between the two charges as

$$\mathbf{P}_L(\mathbf{x}) = \int_0^1 d\lambda q \mathbf{r} \cdot \delta_{ij}(\mathbf{x} - \lambda \mathbf{r}).$$

(22)

The transverse polarisation $\mathbf{P}_T = \mathbf{P} - \mathbf{P}_L$ is freely choosable and is fully specified by choosing $\mathbf{g}_T(\mathbf{x}, \mathbf{x}')$, which, under the constraint $C_2 = 0$, is also what specifies the gauge of the electromagnetic potentials. If, in particular, we choose the Poincaré-gauge, then $\mathbf{g}_T$ is given by Eq. (15) and upon using Eq. (22) we see that $\mathbf{P}$ is nothing but the well-known multipolar polarisation field:

$$\mathbf{P}(\mathbf{x}) = \int_0^1 d\lambda q r \delta(\mathbf{x} - \lambda \mathbf{r}).$$

(23)

In the following section, our proof that Poincaré-gauge and multipolar QED are identical uses the transverse polarisation field $\mathbf{P}_T$ to express the Poincaré-gauge theory in terms of the same canonical degrees of freedom that are typically used within textbook expressions of multipolar QED.

III. RESULTS

We now derive an arbitrary-gauge Hamiltonian quantum theory of the atom-field system via the construction of Dirac brackets. We begin with the standard QED Lagrangian for the nonrelativistic atom within the field $[6]$

$$L = L_{KE} + \int d^3x \mathcal{L}$$

$$= \frac{1}{2} m \dot{\mathbf{r}}^2 - \int d^3x \left[ J^\mu(\mathbf{x}) A_\mu(\mathbf{x}) + \frac{1}{4} F_{\mu\nu}(\mathbf{x}) F^{\mu\nu}(\mathbf{x}) \right],$$

$$= \frac{1}{2} m \dot{\mathbf{r}}^2 - \int d^3x \left[ \rho(\mathbf{x}) A_0(\mathbf{x}) - \mathbf{J}(\mathbf{x}) \cdot \mathbf{A}(\mathbf{x}) \right]$$

$$+ \frac{1}{2} \int d^3x \left[ \mathbf{E}(\mathbf{x})^2 - \mathbf{B}(\mathbf{x})^2 \right],$$

(24)

where $m$ is the mass of the dynamical charge $+q$, $(J^\mu) = (\rho, \mathbf{J})$, $(A_\mu) = (A_0, -\mathbf{A})$ and $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$. Here greek indices take values 0, 1, 2, 3 and repeated indices are summed. $L_{KE}$ is the kinetic energy of the atomic electron while $\mathcal{L}$ is the sum of the interaction and pure electromagnetic Lagrangian densities. Using $\mathbf{r}$ and $A^\mu = (A_0, \mathbf{A})$ as generalised coordinates, the Lagrangian yields the expected Newton-Lorentz and Maxwell-Ampere dynamical equations. The naive canonical momenta $\mathbf{p}$, $\mathbf{P}_0$, $\mathbf{P}$ and $\mathbf{P}_0$ conjugate to $\mathbf{r}$, $\mathbf{A}$ and $A_0$, respectively, are obtained from the Lagrangian in the usual way as

$$\mathbf{p} = \frac{\partial L}{\partial \dot{\mathbf{r}}} = m \dot{\mathbf{r}} + q \mathbf{A}(\mathbf{r}),$$

(25)

$$\mathbf{P}_0 = \frac{\partial L}{\partial \dot{A}_0} = \dot{\mathbf{A}} + \nabla A_0,$$

(26)

$$\mathbf{P} = \frac{\partial L}{\partial \dot{\mathbf{A}}} = 0.$$
Thus, our second constraint $C_1 = 0$ (Gauss’ law) ensures that if $C_0 = 0$ at a fixed time, then $C_1 = 0$ for all times.

The construction of an unconstrained quantum theory proceeds by positing Poisson brackets for the naive Hamiltonian theory as

$$\{ r_i, p_j \} = \delta_{ij}, \quad \{ A_\mu(x), \tilde{\Pi}_\nu(x') \} = \delta_{\mu\nu} \delta(x - x').$$

(29) (30)

The infinitesimal generator of gauge transformations $G[\chi]$ is defined using the constraints by

$$G[\chi] = \int d^3x \left[ C_0 \dot{\chi} + C_1 \chi \right]$$

(31)

in which $\chi$ is arbitrary. Specifically, a gauge transformation of the potentials is given by $A + \{ G[\chi], A \} = A + \nabla \chi$ and $A_0 + \{ G[\chi], A_0 \} = A_0 - \dot{\chi}$. The naive Hamiltonian is the sum of material-kinetic and electromagnetic energies, plus the generator of gauge transformations,

$$H = \mathbf{r} \cdot \mathbf{p} + \int d^3x \left[ \dot{A}_0(x) \tilde{\Pi}_0(x) + \dot{A}(x) \cdot \tilde{\Pi}(x) \right] - L$$

$$= \frac{1}{2m} \mathbf{r}^2 + \frac{1}{2} \int d^3x \left[ E(x)^2 + B(x)^2 \right] + G[A_0]$$

$$= \frac{1}{2m} (\mathbf{p} - qA(x))^2 + \frac{1}{2} \int d^3x \left[ \tilde{\Pi}(x)^2 + B(x)^2 \right]$$

$$+ G[A_0],$$

(32)

where repeated indices are summed. Like the Poisson bracket the Dirac bracket is a Lie bracket, but unlike the Poisson bracket, it will yield the correct equations of motion when used in conjunction with the Hamiltonian, even once the constraints $C_i = 0$ have been imposed.

Hereafter we denote contravariant indices with subscripts. The nonzero Dirac brackets between the remaining canonical variables are easily computed to be [5]

$$\{ r_i, p_j \}_D = \delta_{ij},$$

(35)

$$\{ A_i(x), \tilde{\Pi}_j(x') \}_D = \delta_{ij} \delta(x - x') + \nabla_i^T \delta_j(x', x),$$

(36)

$$\{ p_i, \tilde{\Pi}_j(x) \}_D = q \nabla_i^T \delta_j(x, r) = -\nabla_i^T P_j(x),$$

(37)

where $\mathbf{P}$ is defined in Eq. (20). These Dirac brackets are consistent with those given in Ref. [1]. Quantisation of the theory may now be carried out via the replacement $\{ \cdot, \cdot \}_D \rightarrow -i [\cdot, \cdot]$. The construction of the quantum theory is complete. However, so far only the Dirac brackets of the fields $\mathbf{A}$ and $\tilde{\Pi}$ have been determined and as operators these fields provide an inconvenient expression of the quantum theory, due to Eq. (37). This feature is noted in Ref. [3] and its response Ref. [2]. The ensuing lack of commutativity between $\mathbf{p}$ and $\tilde{\Pi}$ within the final quantum theory, implies that the canonical pairs $(\mathbf{r}, \mathbf{p})$ and $(\mathbf{A}, \tilde{\Pi})$ do not define separate (“matter” and “light”) quantum subsystems. In order to understand the light-matter quantum state space as a tensor-product of a material Hilbert space $[L^2(\mathbb{R}^3)]$ and a photonic Fock space $[\mathcal{F}(L^2(\mathbb{R}^3; \mathbb{C}^2))]$, we must identify material and photonic canonical degrees of freedom that are in involution with respect to the Dirac Bracket.

It is straightforward to construct canonical operator pairs that define quantum subsystems by imposing the constraints. The constraint $C_1 = \nabla \cdot \mathbf{P} + \rho = 0$ uniquely fixes $\tilde{\Pi}_L$ as a function of $\mathbf{r}$ through the charge density $\rho(x)$ given in Eq. (1) as

$$\tilde{\Pi}_L(x) = - \int d^3x' g_L(x, x') \rho(x') = \mathbf{P}_L(x) = -\mathbf{E}_L(x)$$

(38)

where $g_L$ is defined in Eq. (12). The constraint $C_2 = 0$ implies that $\mathbf{A}$ can be written as in Eq. (13) and so it is fully determined by $\mathbf{A}_T$ and $\mathbf{g}_T$. We now define the momentum $\Pi$ by

$$\Pi = \tilde{\Pi} - \mathbf{P} = \tilde{\Pi}_T - \mathbf{P}_T = -\mathbf{E} - \mathbf{P} = -\mathbf{E}_T - \mathbf{P}_T,$$

(39)

where the second, third, and fourth equalities hold for $C_1 = 0$. Since immediately we have that $\{ p_i, P_j(x) \}_D = -\nabla_i^T P_j(x)$, it follows from Eq. (37) that

$$\{ p_i, \tilde{\Pi}_j(x) \}_D = \{ p_i, \tilde{\Pi}_j(x) \}_D - \{ p_i, P_j(x) \}_D = 0.$$

(40)

Thus, the only non-zero Dirac Brackets of the variables within the set $\{ \mathbf{r}, \mathbf{p}, \mathbf{A}_T, \Pi \}$ are

$$\{ r_i, p_j \}_D = \delta_{ij},$$

(41)

$$\{ A_{T,i}(x), \tilde{\Pi}_j(x') \}_D = \delta_{ij}(x - x'),$$

(42)
where the second bracket follows immediately from Eq. (36) and \{A_T(x), P_L(x)\}_D = 0. We see therefore that the theory can be expressed entirely in terms of these canonical variables, which respectively define matter and light quantum subsystems upon quantisation. If we choose the Poincaré-gauge, that is, if we let \( g_T(x, x') = -\int_0^1 d\lambda \lambda' \delta^3(\mathbf{x} - \lambda \mathbf{x}') \) as in Eq. (15), then the momentum \( \Pi = -E_T - P_T \) where \( P_T \) is the multipolar transverse displacement field. In this case \( -\Pi = D_T \) is nothing but the standard multipolar transverse polarisation. Note that the new variables \( \{r, p, A_T, \Pi\} \) are not obtained by a canonical transformation, since this would leave the Dirac brackets unchanged. We emphasise that we have not transformed the theory, rather, we have simply re-expressed it in terms of new variables that have been defined in terms of our original variables.

The Poincaré-gauge Hamiltonian is given by Eq. (32) in which \( A(x) \) is the Poincaré-gauge potential and \(-\Pi = E_{\Pi} \) is the total electric field. This result coincides with the final result of Ref. [2] (Eq. (12) therein). As in Ref. [2], all algebraic relations between objects appearing in the Poincaré-gauge Hamiltonian are fully specified by the Dirac Brackets in Eqs. (35)-(37). The authors of Ref. [2] remark that when expressed in terms of the transverse vector potential \( A_T \) and the longitudinal part \( A_L = \nabla \chi g[A_T] \) [in which \( g_T \) is given by Eq. (15)], the Poincaré-gauge Hamiltonian is not the multipolar Hamiltonian. However, when expressed in terms of \( A_T \) and \( \Pi \) the Poincaré-gauge Hamiltonian is given by

\[
H = \frac{1}{2m} [p - qA(r)]^2 + \frac{1}{2} \int d^3x \rho(x) \rho(x') \delta(\mathbf{x} - \mathbf{x}') = V_{\text{Coul}}
\]

and the fields \( P_T \) and \( \Pi = -D_T \) are the multipolar transverse polarisation and transverse displacement field respectively. The contribution

\[
\frac{1}{2} \int d^3x \rho(x) \rho(x') \delta(\mathbf{x} - \mathbf{x}') = \frac{1}{2} \int d^3x \rho(x) \rho(x') \delta(\mathbf{x} - \mathbf{x}') = \frac{1}{2} \int d^3x \rho(x) \rho(x') \delta(\mathbf{x} - \mathbf{x}') = V_{\text{Coul}}
\]

is the energy of the longitudinal electric field which by Gauss’ law \( C = 0 \) is the Coulomb energy of the charge distribution. It includes the nuclear binding energy \(-q^2/(4\pi\epsilon_0|\mathbf{r}|)\) as well as the infinite Coulomb self-energies of the constituent charges. Eq. (43), which is nothing but the Poincaré-gauge Hamiltonian expressed in terms of a convenient set of variables and on the physical subspace, is identical to the well-known multipolar Hamiltonian of textbook nonrelativistic QED [6, 7]. The non-zero Dirac brackets [Eqs. (41) and (42)] for the canonical degrees of freedom \( \{r, p, A, \Pi\} \) appearing in Eq. (43) are determined from the the Dirac brackets for the Poincaré-gauge fields \( A \) and \( \Pi \). They are identical to those encountered in textbook multipolar QED. Thus, the two theories are identical.

Ref. [1, 2] conclude that when written in terms of \( A_T \) and \( \Pi = -E_T - E_L \), the Poincaré-gauge Hamiltonian is not the multipolar Hamiltonian, because \( \Pi_T \) equals \(-E_T \) rather than \(-D_T \) and so the momentum \( \Pi_T \) is not the well-known canonical momentum encountered in textbook multipolar theory. However, what is required in order that the two theories coincide is that \( \Pi_T = -D_T \), and this is the case. Indeed, as we have shown, this equality is implied by the equality \( \Pi_T = -E_T \), which therefore proves that the two theories are identical rather than disparate.

### IV. DISCUSSION AND GENERALISATION

Misunderstanding stems from a one-to-two usage of the name “canonical momentum”. Apparent disagreement between results occurs because different authors use this label for different fields. In multipolar QED we call \( \Pi = -D_T \) the canonical momentum, because in the final unconstrained theory it is conjugate to \( A_T \) in the sense of Eq. (42) and it commutes with \( r \) and \( p \). On the other hand, when we follow Dirac’s method of quantisation (as above and as in Refs. [1, 2]) the object termed “canonical momentum” is \( \tilde{\Pi} = -E \), because in the starting naive (constrained) theory this momentum is conjugate to \( A \) in the sense of Eq. (30) and it commutes with \( r \) and \( p \). Thus, the same name “canonical momentum” has been used for distinct fields that are not equal but that are instead related by Eq. (39). Both of these nomenclatures are reasonable, but adopting them both simultaneously will inevitably cause confusion. We must recognise that neither \( \tilde{\Pi} \) nor \( \Pi_T \) equals \( \Pi \) in general. This fact does not imply that Poincaré-gauge and multipolar QED are not the same, and in fact, by taking into account the relationship between \( \Pi \) and \( \Pi_T \) one can prove that the two theories are identical, as we have done.

More generally, the arbitrary-gauge Hamiltonian in Eq. (32) expressed on the physical subspace in terms of the set \( \{r, p, A, \Pi\} \) is found from Eqs. (32) and (39) to be

\[
H[g_T] = \frac{1}{2m} [p - qA_T(r)]^2 + \frac{1}{2} \int d^3x [\Pi(x) + \rho(x)]^2 + B(x)^2
\]
respectively as

$$A_g(x) = A_T(x) + \nabla \int d^3x' g(x',x) \cdot A_T(x'),$$  \hfill (47)$$

$$P_g(x) = -\int d^3x' g(x,x') \rho(x').$$  \hfill (48)$$

The gauge is fully determined via a choice of $g_T$, which uniquely determines $g$. Upon quantisation the Hamiltonians of different gauges $g_T$ and $g'_T$ are unitarily related as

$$H[g'_T] = U_{gg'} H[g_T] U_{gg'}^\dagger$$  \hfill (49)$$

where the gauge-fixing transformation $U_{gg'}$ is defined over the physical Hilbert space by

$$U_{gg'} := \exp \left( -i \int d^3x \left[ \chi_g(x) - \chi_{g'}(x) \right] \rho(x) \right),$$  \hfill (50)$$

$$= \exp \left( i \int d^3x \left[ P_g(x) - P_{g'}(x) \right] \cdot A_T(x) \right).$$  \hfill (51)$$

Equation (49) can be obtained immediately from

$$U_{gg'}[p - qA_g(r)]U_{gg'}^\dagger = p - qA_{g'}(r),$$  \hfill (52)$$

$$U_{gg'}[\Pi + P_{g'T}]U_{gg'}^\dagger = \Pi + P_{g'T},$$  \hfill (53)$$

showing that $U_{gg'}$ implements the gauge-change $g_T \rightarrow g'_T$ within the Hamiltonian via transformation of the momenta $p$ and $\Pi$. The Coulomb and Poincaré (multipolar)-gauge Hamiltonians are special cases obtained by making the Coulomb and Poincaré-gauge choices of $g_T$ respectively. The unitary gauge-fixing transformation between these particular gauges is called the Power-Zienau-Woolley (PZW) transformation. It is given according to Eq. (50) by

$$U = \exp \left( -i \int d^3x P(x) \cdot A_T(x) \right),$$  \hfill (54)$$

where $P$ is the multipolar polarisation. This is the textbook expression for the PZW transformation [6, 7].

We remark that previous authors have concluded that the PZW transformation is not a gauge-transformation [4], but this conclusion is not at odds with our findings. The PZW transformation is not a gauge-symmetry transformation, which is defined as a transformation that acts directly on the potential $A$ to implement a gauge transformation $A \rightarrow A - d\chi$ within the starting constrained theory. That the PZW is not a gauge-symmetry transformation is the statement that has been previously made [4]. The PZW transformation is however, an example of a gauge-fixing transformation $U_{gg'}$, which is defined as a unitary transformation acting within the final unconstrained theory to transform from one fixed-gauge realisation of the physical state space to a different fixed-gauge realisation. There is clearly a distinction between gauge-symmetry and gauge-fixing transformations in Hamiltonian QED, and the distinction provides unambiguous clarification of the relation between the PZW transformation and gauge-freedom.

V. CONCLUSIONS

Refs. [1, 2] express the Poincaré-gauge theory in terms of the Poincaré-gauge potential $A$ and the momentum $\Pi$ (see for example Eq. (12) of Ref. [2]). The multipolar framework is the same theory expressed in terms of different fields $A_T$ and $\Pi$, which are more convenient for use within the quantum theory. We have verified this via the explicit construction of Dirac Brackets as are also derived in Refs. [1, 2]. Before now such a demonstration had not been clearly provided within the literature. Indeed, as well as being unrecognised in Refs. [1, 2], the distinction between $\Pi$ and $\Pi$ is perhaps also obfuscated elsewhere. For example, the constraint $C_2$ used in this article was first employed by Woolley in Ref. [5], who then also constructs the Dirac brackets for the theory, but chooses the notation $E^\perp$ for $-\Pi$, despite that $-\Pi$ does not represent the transverse electric field except when $g_T = 0$ (Coulomb-gauge). We emphasise that the distinction between Coulomb-gauge and multipolar QED is no more or less than a distinction between gauge choices. As we have shown, all gauges of this type are related by unitary gauge-fixing transformations and they are all equivalent to each other. Multipolar QED in particular, is strictly equivalent to Coulomb-gauge QED and is identical to the Poincaré-gauge theory.

More generally, we have shown that the conventional Hamiltonians of nonrelativistic QED used in light-matter physics and quantum optics, are fixed-gauge cases of the general Hamiltonian $H$ in Eq. (32) once it has been restricted to the physical subspace and written in terms of convenient canonical variables that possess the algebraic properties in Eqs. (41) and (42). This writing of $H$ is nothing but $H[g_T]$ given in Eq. (46). All instances of this Hamiltonian are unitarily equivalent, being related by unitary transformations confined to the physical subspace. They are therefore all physically equivalent. This is nothing but canonical QED’s expression of gauge-invariance.

The Hamiltonian $H[g_T]$ is consistent with all of the required physical constraints and yields all of the required dynamical equations of motion for any choice of gauge $g_T$. This fact alone justifies the use of $H[g_T]$ for any choice of $g_T$ and in particular it justifies the use of the multipolar theory. While it is satisfying to connect a Hamiltonian to a Lagrangian description, there is no further justification for the latter than that it produces the correct equations of motion. Thus, $H[g_T]$ is no less fundamental than the Lagrangian $L$ from which it happened to be derived. In this sense, any criticism of Hamiltonian multipolar QED as less physical than another description is immediately unfounded because whether or not one can derive it from some other description, one can certainly verify that it produces the required equations of motion. The pertinent question therefore, is whether or not the Hamiltonians commonly used in practice, all of which produce the correct equations of motion, are physically equivalent in the general sense. Fortunately,
one can show (as we have) that they are, because the quantum-theoretic definition of physical equivalence is unitary equivalence.
