Cosmology of a polynomial model for de Sitter gauge theory sourced by a fluid

Jia-An Lu

School of Physics, Sun Yat-sen University, Guangzhou 510275, China

Abstract

In the de Sitter gauge theory (DGT), the fundamental variables are the de Sitter (dS) connection and the gravitational Higgs/Goldstone field $\xi^A$. Previously, a model for DGT was analyzed, which generalizes the MacDowell–Mansouri gravity to have a variable cosmological constant $\Lambda = 3/l^2$, where $l$ is related to $\xi^A$ by $\xi^A \xi_A = l^2$. It was shown that the model sourced by a perfect fluid does not support a radiation epoch and the accelerated expansion of the parity invariant universe. In this work, I consider a similar model, namely, the Stelle–West gravity, and couple it to a modified perfect fluid, such that the total Lagrangian 4-form is polynomial in the gravitational variables. The Lagrangian of the modified fluid has a nontrivial variational derivative with respect to $l$, and as a result, the problems encountered in the previous work no longer appear. Moreover, to explore the elegance of the general theory, as well as to write down the basic framework, I perform the Lagrange–Noether analysis for DGT sourced by a matter field, yielding the field equations and the identities with respect to the symmetries of the system. The resulted formula are dS covariant and do not rely on the existence of the metric field.

1 Introduction

The gauge theories of gravity (GTG) aim at treating gravity as a gauge field, in particular, constructing a Yang–Mills-type Lagrangian which reduces to GR in some limiting case, while providing some novel falsifiable predictions. A well-founded subclass of GTG is the Poincaré gauge theory (PGT) [1–5], in which the gravitational field consists of the Lorentz connection and the co-tetrad field. Moreover, the PGT can be reformulated as de Sitter gauge theory (DGT), in which the Lorentz connection and the co-tetrad field are united into a de Sitter (dS) connection [6,7]. In fact, before the idea of DGT is realized, a related Yang–Mills-type Lagrangian for gravity was proposed by MacDowell and Mansouri [8], and reformulated into a dS-invariant form by West [9], which reads

$$L_{MM} = \epsilon_{ABCDE} \xi^E F^{AB} \wedge F^{CD}$$

$$= \epsilon_{\alpha\beta\gamma\delta} \left( I R^{\alpha\beta} \wedge R^{\gamma\delta} - 2 l^{-1} R^{\alpha\beta} \wedge e^\gamma \wedge e^\delta + l^{-3} e^\alpha \wedge e^\beta \wedge e^\gamma \wedge e^\delta \right),$$

where $\epsilon_{ABCDE}$ and $\epsilon_{\alpha\beta\gamma\delta}$ are the 5d and 4d Levi-Civita symbols, $\xi^A$ is a dS vector constrained by $\xi^A \xi_A = l^2$, $l$ is a positive constant, $F^{AB}$ is the dS curvature, $R^{\alpha\beta}$ is the

1Email: ljagdgz@163.com
Lorentz curvature, and $e^\alpha$ is the orthonormal co-tetrad field. This theory is equivalent to the Einstein–Cartan (EC) theory with a cosmological constant $\Lambda = 3/l^2$ and a Gauss–Bonnet (GB) topological term, as seen in Eq. (1).

Note that some special gauges with the residual Lorentz symmetry can be defined by $\xi^A = \delta^A_d l$. Henceforth, $\xi^A$ is akin to an unphysical Goldstone field. To make $\xi^A$ physical, and so become the gravitational Higgs field, one may replace the constant $l$ by a dynamical $l$, resulting in the Stelle–West (SW) theory \cite{7}. The theory is further explored by Refs. \cite{10,11} (see also the review \cite{12}), in which the constraint $\xi^A\xi_A = l^2$ is completely removed, in other words, $\xi^A\xi_A$ needs not to be positive. Suppose that $\xi^A\xi_A = \sigma l^2$, where $\sigma = \pm 1$. When $l \neq 0$, the metric field can be defined by $g_{\mu\nu} = (\tilde{D}_\mu \xi^A)(\tilde{D}_\nu \xi_A)$, where $\tilde{D}_\mu \xi^A = \tilde{\delta}^A_B D_\mu \xi^B$, $\tilde{\delta}^A_B = \delta^A_B - \xi^A\xi_B/\sigma l^2$, $D_\mu \xi^A = d_\mu \xi^A + \Omega^A_{B\mu} \xi^B$, and $\Omega^A_{B\mu}$ is the dS connection. It was shown that $\sigma = \pm 1$ corresponds to the Lorentz/Euclidean signature of the metric field, and the signature changes when $\xi^A\xi_A$ changes its sign \cite{11}.

On the other hand, it remains to check whether the SW gravity is viable. Although the SW lagrangian reduces to the MM Lagrangian when $l$ is a constant, the field equations do not. In the SW theory, there is an additional field equation coming from the variation with respect to $l$, which is nontrivial even when $l$ is a constant. Actually, a recent work \cite{13} presents some negative results for a related model, whose Lagrangian is equal to the SW one times $(-l/2)$. For a homogeneous and isotropic universe with parity-invariant torsion, it is found that $l$ being a constant implies the energy density of the material fluid being a constant, and so $l$ should not be a constant in the general case. Moreover, in the radiation epoch, the $l$ equation forces the energy density equal to zero; while in the matter epoch, a dynamical $l$ only works to renormalize the gravitational constant by some constant factor, and hence the cosmic expansion decelerates as in GR.

In this work, it is shown that the SW gravity suffers from similar problems encountered in the model considered by Ref. \cite{13}. Also, I try to solve these problems by using a new fluid with the Lagrangian being polynomial in the gravitational variables. The merits of a Lagrangian polynomial in some variables are that it is simple and nonsingular with respect to those variables. In Refs. \cite{14,15}, the polynomial Lagrangian for gravitation and other fundamental fields were proposed, while in this paper, the polynomial Lagrangian for an perfect fluid is proposed, which reduces to the Lagrangian of a usual perfect fluid when $l$ is a constant. It turns out that, in contrast to the case with an ordinary fluid, the SW gravity coupled with the new fluid supports the radiation epoch and naturally drives the cosmic acceleration. In addition, when writing down the basic framework of DGT, a Lagrangian–Noether analysis is performed, which generalizes the results of Ref. \cite{16} to the cases with arbitrary matter field and arbitrary $\xi^A$.

The article is organized as follows. In Sec. 2.1 a Lagrangian–Noether analysis is done for the general DGT sourced by a matter field. In Sec. 2.2 I reduce the analysis in Sec. 2.1 in the Lorentz gauges, and show how the two Noether identities in PGT can be elegantly unified into one identity in DGT. In Sec. 3.1 the SW model of DGT is introduced, with the field equations derived both in the general gauge and the Lorentz gauges. Further, the matter source is discussed in Sec. 3.2 where a modified perfect fluid with the Lagrangian polynomial in the gravitational variables is constructed, and a general class of perfect fluids is defined, which contains both the usual and the modified perfect fluids. Then I couple the SW gravity with the class of fluids and study the coupling system in the homogeneous, isotropic and parity-invariant universe. The field equations are deduced in Sec. 4.1 and solved in Sec. 4.2 and the results are compared with observations in Sec. 4.
2 de Sitter gauge theory

2.1 Lagrangian–Noether machinery

The DGT sourced by a matter field is described by the Lagrangian 4-form

\[ \mathcal{L} = \mathcal{L}(\psi, D\psi, \xi^A, D\xi^A, F^{AB}), \tag{2} \]

where \( \psi \) is a \( p \)-form valued at some representation space of the dS group \( SO(1,4) \), \( D\psi = d\psi + \Omega^{AB}T_{AB} \wedge \psi \) is the covariant exterior derivative, \( T_{AB} \) are representations of the dS generators, \( \xi^A \) is a dS vector, \( D\xi^A = d\xi^A + \Omega^{AB}\xi^B \), \( \Omega^{AB} \) is the dS connection 1-form, and \( F^{AB} = d\Omega^{AB} + \Omega^A_C \wedge \Omega^C_B \) is the dS curvature 2-form. The variation of \( \mathcal{L} \) resulted from the variations of the explicit variables reads

\[ \delta \mathcal{L} = \delta \psi \wedge \partial \mathcal{L} / \partial \psi + \delta D\psi \wedge \partial \mathcal{L} / \partial D\psi + \delta \xi^A \cdot \partial \mathcal{L} / \partial \xi^A + \delta D\xi^A \wedge \partial \mathcal{L} / \partial D\xi^A + \delta F^{AB} \wedge \partial \mathcal{L} / \partial F^{AB}, \tag{3} \]

where \( \partial \mathcal{L} / \partial \psi \) similar defined. The variations of \( D\psi, D\xi^A \) and \( F^{AB} \) can be transformed into the variations of the fundamental variables \( \psi, \xi^A \), and \( \Omega^{AB} \), leading to

\[ \delta \mathcal{L} = \delta \psi \wedge V_\psi + \delta \xi^A \cdot V_A + \delta \Omega^{AB} \wedge V_{AB} + d(\delta \psi \wedge \partial \mathcal{L} / \partial D\psi + \delta \xi^A \cdot \partial \mathcal{L} / \partial D\xi^A + \delta \Omega^{AB} \wedge \partial \mathcal{L} / \partial F^{AB}), \tag{4} \]

where

\[ V_\psi \equiv \delta \mathcal{L} / \delta \psi = \partial \mathcal{L} / \partial \psi - (-1)^p D \partial \mathcal{L} / \partial D\psi, \tag{5} \]

\[ V_A \equiv \delta \mathcal{L} / \delta \xi^A = \partial \mathcal{L} / \partial \xi^A - D \partial \mathcal{L} / \partial D\xi^A, \tag{6} \]

\[ V_{AB} \equiv \delta \mathcal{L} / \delta \Omega^{AB} = T_{AB} \psi \wedge \partial \mathcal{L} / \partial D\psi + \partial \mathcal{L} / \partial D\xi^A \cdot \xi_B + D \partial \mathcal{L} / \partial F^{AB}. \tag{7} \]

The symmetry transformations in DGT consist of the diffeomorphism transformations and the dS transformations. For the diffeomorphism transformations, they can be promoted to a gauge-invariant version \[ \text{[16, 17]}, \] namely, the parallel transports in the fiber bundle with the gauge group as the structure group. The action of an infinitesimal parallel transport on a variable is a gauge-covariant Lie derivative \( L_v \equiv \{ v \} D + Dv \}, \) where \( v \) is the vector field which generates the infinitesimal parallel transport, and \( \{ \} \) denotes a contraction, for example, \( \{ v \} \psi_{\mu_2 \cdots \mu_p} = v^{\mu_2} \psi_{\mu_1 \mu_2 \cdots \mu_p} \). Put \( \delta = L_v \) in Eq. (3), utilize the arbitrariness of \( v \), then one obtains the chain rule

\[ v \{ \mathcal{L} \} = (v \{ \psi \} \wedge \partial \mathcal{L} / \partial \psi + (v \{ D\psi \} \wedge \partial \mathcal{L} / \partial D\psi + (v \{ D\xi^A \} \cdot \partial \mathcal{L} / \partial D\xi^A + (v \{ F^{AB} \} \wedge \partial \mathcal{L} / \partial F^{AB}, \tag{8} \]

and the first Noether identity

\[ (v \{ D\psi \} \wedge V_\psi + (-1)^p (v \{ \psi \} \wedge DV_\psi + (v \{ D\xi^A \} \cdot V_A + (v \{ F^{AB} \} \wedge V_{AB} = 0. \tag{9} \]

\[ \text{[2] The gauge-covariant Lie derivative has been used in the metric-affine gauge theory of gravity [15].} \]
On the other hand, the dS transformations are defined as vertical isomorphisms on the fiber bundle. The actions of an infinitesimal dS transformation on the fundamental variables are as follows:

\[ \delta \psi = B^{AB} T_{AB} \psi, \quad \delta \xi^A = B^{AB} \xi_B, \quad \delta \Omega^{AB} = - DB^{AB}, \]

where \( B^{AB} \) is a dS algebra-valued function which generates the infinitesimal dS transformation. Substitute Eq. (10) and \( \delta \mathcal{L} = 0 \) into Eq. (4), and make use of Eq. (7) and the arbitrariness of \( B^{AB} \), one arrives at the second Noether identity

\[ DV_{AB} = - T_{AB} \psi \wedge V_\psi - V_{[A} \cdot \xi_{B]} . \]

The above analyses are so general that they do not require the existence of a metric field. In the special case with a metric field being defined, \( \xi^A \xi_A \) equating to a positive constant, and \( p = 0 \), the above analyses coincide with those in Ref. [16].

### 2.2 Reduction in the Lorentz gauges

Consider the case with \( \xi^A \xi_A = l^2 \), where \( l \) is a positive function. Then we may define the projector \( \tilde{\delta}^A_B = \delta^A_B - \xi^A \xi_B / l^2 \), the generalized tetrad \( \tilde{\xi}^A = \tilde{\delta}^A_B D \xi^B \), and a symmetric rank-2 tensor

\[ g_{\mu \nu} = \eta_{AB} (\tilde{D}_\mu \xi^A)(\tilde{D}_\nu \xi^B), \]

which is a localization of the dS metric \( \hat{g}_{\mu \nu} = \eta_{AB}(d \mu \hat{\xi}^A)(d \nu \hat{\xi}^B) \), where \( \hat{\xi}^A \) are the 5d Minkowski coordinates on the 4d dS space. Though Eq. (12) seems less natural than the choice \( g^*_{\mu \nu} = \eta_{AB}(D_\nu \xi^A)(D_\mu \xi^B) \), it coincides with another natural identification (13) (the relation between Eqs. (12) and (13) will be discussed later). If \( g_{\mu \nu} \) is non-degenerate, it is a metric field with Lorentz signature, and one may define \( \tilde{\xi}^\mu_A \equiv g^{\mu \nu} \tilde{D}_\nu \xi_A \). Put \( v^\mu = \tilde{D}_\mu \xi_A \) in Eq. (9) and utilize \( (\tilde{D}_\mu \xi^A)(\tilde{D}_\mu \xi_B) = \tilde{\delta}^A_B \), we get

\[
\tilde{V}_A = -(\tilde{D}_\mu \xi_A) D \psi \wedge V_\psi - (-1)^p (\tilde{D}_\mu \xi_A) V_\psi \wedge (\tilde{D}_\mu \xi_A) d \ln l \cdot V_C \xi^C \\
- (\tilde{D}_\mu \xi_A) \mathcal{F}^{CD} \wedge V_{CD}.
\]

where \( \tilde{V}_A = \tilde{\delta}^B_A V^B \). When \( l \) is a constant, Eq. (13) implies that the \( \xi^A \) equation (\( \tilde{V}_A = 0 \) for this case) can be deduced from the other field equations (\( V_\psi = 0 \) and \( V_{CD} = 0 \)), as pointed out by Ref. [19]. Substitute Eq. (13) into Eq. (11), and make use of \( \tilde{V}_{[A} \cdot \xi_{B]} = V_{[A} \cdot \xi_{B]} \) and \( \tilde{D}_\mu \xi_{[A} \cdot \xi_{B]} = D_\mu \xi_{[A} \cdot \xi_{B]} \), one attains

\[
DV_{AB} = - T_{AB} \psi \wedge V_\psi + (D_\xi_{[A} \cdot \xi_{B]} D \psi) \wedge V_\psi + (-1)^p (D_\xi_{[A} \cdot \xi_{B]} \psi) \wedge V_\psi \\
+ (D_\xi_{[A} \cdot \xi_{B]} d \ln l) \cdot V_C \xi^C + (D_\xi_{[A} \cdot \xi_{B]}) \mathcal{F}^{CD} \wedge V_{CD}.
\]

When \( l \) is a constant, Eq. (14) coincides with the corresponding result in Ref. [16]. As will be shown later, Eq. (14) unifies the two Noether identities in PGT.

To see this, let us define the Lorentz gauges by the condition \( \xi^A = \delta^A_4 l \) [7]. If \( h^{AB} \in SO(1,4) \) preserves these gauges, then \( h^{AB} = \text{diag}(h^\alpha_\beta,1) \), where \( h^\alpha_\beta \) belongs to the Lorentz group \( SO(1,3) \). In the Lorentz gauges, \( \Omega^\alpha_\beta \) transforms as a Lorentz connection,

\(^3\)This formula has been given by Refs. [11,19], and is different from that originally proposed by Stelle and West [2] by a factor \((l_0/l)^2\), where \( l_0 \) is the vacuum expectation value of \( l \).
and \( \Omega^\alpha_4 \) transforms as a co-tetrad field. Therefore, one may identify \( \Omega^\alpha_\beta \) as the spacetime connection \( \Gamma^\alpha_\beta \), and \( \Omega^\alpha_4 \) as the co-tetrad field \( e^\alpha \) divided by some quantity with the dimension of length, a natural choice for which is \( l \). Resultantly, \( \Omega^{AB} \) is identified with a combination of geometric quantities as follows:

\[
\Omega^{AB} = \begin{pmatrix}
\Gamma^\alpha_\beta & l^{-1} e^\alpha \\
-l^{-1} e^\beta & 0
\end{pmatrix}
\]  

(15)

In the case with constant \( l \), this formula has been given by Refs. [7,20], and, in the case with varying \( l \), it has been given by Refs. [10,19]. In the Lorentz gauges, \( \tilde{D}\xi^4 = 0 \), \( \tilde{D}\xi^4 = \Omega^\alpha_4 l = e^\alpha \) (where Eq. (15) is used), and so \( g_{\mu\nu} \) defined by Eq. (12) satisfies \( g_{\mu\nu} = \eta_{\alpha\beta} e^\alpha \mu e^\beta_\nu \), implying that Eq. (12) coincides with Eq. (15). Moreover, according to Eq. (15), one finds the expression for \( F^{AB} \) in the Lorentz gauges as follows [19]:

\[
F^{AB} = \begin{pmatrix}
R^\alpha_\beta - l^{-2} e^\alpha \wedge e^\beta & l^{-1}[S^\alpha - d\ln l \wedge e^\alpha] \\
-l^{-1}[S^\beta - d\ln l \wedge e^\beta] & 0
\end{pmatrix}
\]  

(16)

where \( R^\alpha_\beta = d\Gamma^\alpha_\beta + \Gamma^\alpha_\gamma \wedge \Gamma^\gamma_\beta \) is the spacetime curvature, and \( S^\alpha = de^\alpha + \Gamma^\alpha_\beta \wedge e^\beta \) is the spacetime torsion.

Now it is ready to interpret the results in Sec. 2.1 in the Lorentz gauges. In those gauges, \( D\psi = D^\Gamma \psi + 2l^{-1} e^\alpha T_{\alpha 4} \wedge \psi, D\xi^4 = e^\alpha, D\xi^4 = dl \), and so Eq. (2) becomes

\[
\mathcal{L} = \mathcal{L}^L(\psi, D^\Gamma \psi, l, dl, e^\alpha, R^\alpha_\beta, S^\alpha),
\]

(17)

where \( D^\Gamma \psi = d\psi + \Gamma^\alpha_\beta T_{\alpha \beta} \wedge \psi \). It is the same as a Lagrangian 4-form in PGT [21], with the fundamental variables being \( \psi, l, \Gamma^\alpha_\beta \) and \( e^\alpha \). The relations between the variational derivatives with respect to the PGT variables and those with respect to the DGT variables can be deduced from the following equality:

\[
\delta \xi^A \cdot V_A + 2\delta \Omega^\alpha_4 \wedge V_{\alpha 4} = \delta l \cdot \Sigma_l + \delta e^\alpha \wedge \Sigma^\alpha,
\]

(18)

where \( \Sigma_l \equiv \delta \mathcal{L}^L / \delta l \) and \( \Sigma^\alpha \equiv \delta \mathcal{L}^L / \delta e^\alpha \). Explicitly, the relations are:

\[
\Sigma_\psi \equiv \delta \mathcal{L}^L / \delta \psi = V_\psi,
\]

(19)

\[
\Sigma_l = V_4 - 2l^{-2} e^\alpha \wedge V_{\alpha 4},
\]

(20)

\[
\Sigma_{\alpha \beta} \equiv \delta \mathcal{L}^L / \delta \Gamma^\alpha_\beta = V_{\alpha \beta},
\]

(21)

\[
\Sigma^\alpha = 2l^{-1} V_{\alpha 4}.
\]

(22)

It is remarkable that the DGT variational derivative \( V_{AB} \) unifies the two PGT variational derivatives \( \Sigma_{\alpha \beta} \) and \( \Sigma^\alpha \). With the help of Eqs. (19)–(22), the \( \alpha \beta \) components and \( \alpha 4 \) components of Eq. (14) are found to be

\[
D^\Gamma \Sigma_{\alpha \beta} = -T_{\alpha \beta} \psi \wedge \Sigma_\psi + e_{[\alpha} \wedge \Sigma_{\beta]},
\]

(23)

\[
D^\Gamma \Sigma^\alpha = D^\Gamma_\alpha \psi \wedge \Sigma_\psi + (-1)^p e_{[\alpha} \psi \wedge D^\Gamma \Sigma_\psi + \partial_\alpha l \cdot \Sigma_l + (e_{\alpha} R^{\beta \gamma}) \wedge \Sigma_{\beta \gamma} + (e_{\alpha} S^3) \wedge \Sigma_{\beta},
\]

(24)

which are just the two Noether identities in PGT [21], with both \( \psi \) and \( l \) as the matter fields. This completes our proof for the earlier statement that the DGT identity (14) unifies the two Noether identities in PGT.
3 Polynomial models for DGT

3.1 Stelle–West gravity

It is natural to require that the Lagrangian for DGT is regular with respect to the fundamental variables. The simplest regular Lagrangian are polynomial in the variables, and, in order to recover the EC theory, the polynomial Lagrangian should be at least quadratic in the gauge curvature. Moreover, to ensure $F^{AB} = 0$ is naturally a vacuum solution, the polynomial Lagrangian should be at least quadratic in $F^{AB}$\(^4\). The general Lagrangian quadratic in $F^{AB}$ reads:

$$
\mathcal{L}^G = (\kappa_1 \epsilon_{ABCD} \xi^E + \kappa_2 \eta_{AC} \xi_B \xi_D + \kappa_3 \eta_{AC} \eta_{BD}) F^{AB} \wedge F^{CD} = \kappa_1 L^{SW} + \kappa_2 \left( S^a \wedge S_a - 2 S^a \wedge d \ln l \wedge e_a \right) + \kappa_3 \left[ R^\alpha \beta \wedge R_{\alpha \beta} + d (2 l^{-2} S^a \wedge e_a) \right],
$$

(25)

where the $\kappa_1$ term is the SW Lagrangian, the $\kappa_2$ and $\kappa_3$ terms are parity odd, and the $\kappa_3$ term is a sum of the Pontryagin and modified Nieh–Yan topological terms. This quadratic Lagrangian is a special case of the at most quadratic Lagrangian proposed in Refs. [10,22], and one should note that the quadratic Lagrangian satisfies the requirement mentioned above about the vacuum solution, while the at most quadratic Lagrangian does not always satisfy that requirement.

Among the three terms in Eq. (25), the SW term is the only one that can be reduced to the EC Lagrangian in the case with positive and constant $\xi^A \xi_A$. Thus the SW Lagrangian is the simplest choice for the gravitational Lagrangian which (i) is regular with respect to the fundamental variables; (ii) can be reduced to the EC Lagrangian; (iii) ensures $F^{AB} = 0$ is naturally a vacuum solution.

The SW Lagrangian 4-form $L^{SW}$ takes the same form as $L^{MM}$ in the first line of Eq. (11), while $\xi^A$ is not constrained by any condition. Substitute Eq. (11) into Eqs. (6)–(7), make use of $\partial L^{SW} / \partial F^{AB} = \epsilon_{ABCD} \xi^E F^{CD}$ and the Bianchi identity $D F^{AB} = 0$, one immediately gets the gravitational field equations

$$
- \kappa \epsilon_{ABCD} F^{AB} \wedge F^{CD} = \delta L^m / \delta \xi^E,
$$

(26)

$$
- \kappa \epsilon_{ABCD} D \xi^E \wedge F^{CD} = \delta L^m / \delta \Omega^{AB},
$$

(27)

where $L^m$ is the Lagrangian of the matter field coupled to the SW gravity, with $\kappa$ as the coupling constant. In the vacuum case, Eq. (27) has been given by Ref. [22] by direct computation, while here, Eq. (27) is obtained from the general formula (17).

In the Lorentz gauges, $L^{SW}$ takes the same form as $L^{MM}$ in the second line of Eq. (11), while $l$ becomes a dynamical field. The gravitational field equations read

$$
- \left( \kappa / 4 \right) \epsilon_{\alpha \beta \gamma \delta} \epsilon_{\mu \nu \rho} e^{-1} R^\beta_{\mu \nu} R^\gamma_{\rho} - 4 \kappa l^{-2} R + 72 \kappa l^{-4} = \delta S_m / \delta l,
$$

(28)

$$
- \kappa \epsilon_{\alpha \beta \gamma \delta} \epsilon_{\mu \nu \rho} e^{-1} \partial_\mu l \cdot R^\gamma_{\rho \sigma} + 8 \kappa \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \partial_\nu l^{-1} + 4 \kappa l^{-1} T^\alpha_{\alpha \beta} = \delta S_m / \delta \Gamma^\alpha_{\beta \mu},
$$

(29)

$$
- 8 \kappa l^{-1} \left( G^\mu_{\alpha +} + \Lambda e^\mu_{\alpha} \right) = \delta S_m / \delta e^\alpha_{\mu},
$$

(30)

where $e = \det (e^a_{\mu})$, $R$ is the scalar curvature, $G^\mu_{\alpha}$ is the Einstein tensor, $T^\nu_{\alpha \beta} = S^\nu_{\alpha \beta} + 2 e_{[\alpha} S_{\beta \mu]}$, and $S_m$ is the action of the matter field.

\(^4\)When the Lagrangian is linear in $F^{AB}$, we may add some ‘constant term’ (independent of $F^{AB}$) to ensure $F^{AB} = 0$ is a vacuum solution, but this way is not so natural.
3.2 Polynomial dS fluid

For the same reason of choosing a polynomial Lagrangian for DGT, we intend to use those matter sources with polynomial Lagrangian. It has been shown that the Lagrangian of fundamental fields can be reformulated into polynomial forms \[14,15\]. However, when describing the universe, it is more adequate to use a fluid as the matter source. The Lagrangian of an ordinary perfect fluid \[23\] can be written in a Lorentz-invariant form:

\[ L_{\mu
u} = -\epsilon_{\alpha\beta\gamma\delta} e^{\alpha}_\mu e^{\beta}_\nu e^{\gamma}_\rho e^{\delta}_\sigma \rho + \epsilon_{\alpha\beta\gamma\delta} J^\alpha \epsilon^{\beta}_\nu e^{\gamma}_\rho e^{\delta}_\sigma \partial_\mu \phi, \]  
(31)

where \( \phi \) is a scalar field, \( J^\alpha \) is the particle number current which is Lorentz covariant and satisfies \( J^\alpha J_\alpha < 0 \), \( \rho = \rho(n) \) is the energy density, and \( n \equiv \sqrt{-J^\alpha J_\alpha} \) is the particle number density. The Lagrangian (31) is polynomial in the PGT variable \( e^{\alpha}_\mu \), but it is not polynomial in the DGT variables when it is reformulated into a dS-invariant form, in which case the Lagrangian reads

\[ L_{\mu
u}^{\text{DF}} = -\epsilon_{ABCDE}(D_\mu \xi^A)(D_\nu \xi^B)(D_\rho \xi^C)(D_\sigma \xi^D)(\xi^E/l) \rho + \epsilon_{ABCDE} J^A (D_\mu \xi^B)(D_\rho \xi^C)(D_\sigma \xi^D) \wedge (\xi^E/l) \partial_\mu \phi, \]  
(32)

where \( J^A \) is a dS-covariant particle number current, which satisfies \( J^A J_A < 0 \) and \( J^A \xi_A = 0 \), \( \rho = \rho(n) \) and \( n \equiv \sqrt{-J^A J_A} \). Because \( l^{-1} \) appears in Eq. (32), the Lagrangian is not polynomial in \( \xi^A \).

A straightforward way to modify Eq. (32) into a polynomial Lagrangian is to multiply it by \( l \). In the Lorentz gauges, \( J^4 = 0 \), and we may define the invariant \( J^\mu \equiv J^\alpha e^{\alpha}_\mu \). Then the modified Lagrangian \( L_{\mu
u}^{\text{DF}} = -\epsilon e_{\mu\nu\rho \sigma} \rho l + \epsilon e_{\mu\nu\rho \sigma} J^\mu \wedge l \cdot \partial_\mu \phi \). It can be verified that this Lagrangian violates the particle number conservation law \( \nabla_\mu J^\mu = 0 \), where \( \nabla_\mu \) is the linearly covariant, metric-compatible and torsion-free derivative. To preserve the particle number conservation, we may replace \( l \cdot \partial_\mu \phi \) by \( \partial_\mu (l \phi) \), and the corresponding dS-invariant Lagrangian is

\[ L_{\mu
u}^{\text{DF}} = -\epsilon_{ABCDE}(D_\mu \xi^A)(D_\nu \xi^B)(D_\rho \xi^C)(D_\sigma \xi^D) \xi^E \rho(n) + \epsilon_{ABCDE} J^A (D_\mu \xi^B)(D_\rho \xi^C)(D_\sigma \xi^D) \wedge \left( \frac{1}{4} D_\mu \xi^E \cdot \phi + \xi^E \partial_\mu \phi \right). \]  
(33)

The perfect fluid depicted by the above Lagrangian is called the polynomial dS fluid, or dS fluid for short. In the Lorentz gauges,

\[ L_{\mu
u}^{\text{DF}} = -\epsilon e_{\mu\nu\rho \sigma} \rho l + \epsilon e_{\mu\nu\rho \sigma} J^\mu \wedge l \partial_\mu (l \phi) = -\epsilon e_{\mu\nu\rho \sigma} \rho l + \epsilon e_{\mu\nu\rho \sigma} J^\mu \wedge l \partial_\mu (l \phi), \]  
(34)

which is equivalent to Eq. (31) when \( l \) is a constant.

Define the Lagrangian function \( L_\text{DF} \) by \( L_{\mu
u}^{\text{DF}} = L_{DF} e_{\mu\nu\rho \sigma} \), then \( L_{DF} = -\rho l + J^\mu \partial_\mu (l \phi) \). To compare the polynomial dS fluid with the ordinary perfect fluid, let us consider a general model with the Lagrangian function

\[ L_m = -\rho l^k + J^\mu \partial_\mu (l^k \phi), \]  
(35)

where \( k \in \mathbb{R} \). When \( k = 0 \), it describes the ordinary perfect fluid; when \( k = 1 \), it describes the polynomial dS fluid. The variation of \( S_m \equiv \int dx^4 e L_m \) with respect to \( \phi \) gives the
particle number conservation law $\nabla_\mu J^\mu = 0$. The variation with respect to $J^\alpha$ yields 
$\partial_\mu (l^k \phi) = -\mu U^k l^k$, where $\mu \equiv dp/dn = (p + p)/n$ is the chemical potential, $p = p(n)$ is the pressure, and $U^\mu \equiv J^\mu/n$ is the 4-velocity of the fluid particle. Making use of these results, one may check that the on-shell Lagrangian function is equal to $pl^k$, and the variational derivatives

$$
\delta S_m/\delta l = -kpl^{k-1},
$$
$$
\delta S_m/\delta \Gamma^\alpha\beta\mu = 0,
$$
$$
\delta S_m/\delta e^\alpha_\mu = (p + p)l^k U_\alpha + pl^k e^\alpha_\mu.
$$

It is seen that $\delta S_m/\delta l = 0$ for the ordinary perfect fluid, while $\delta S_m/\delta l = -\rho$ for the polynomial dS fluid.

Finally, it should be noted that the polynomial dS fluid does not support a signature change corresponding to $\xi^A \xi_A$ varying from negative to positive. The reason is that when $\xi^A \xi_A < 0$, there exists no $J^A$ which satisfies $J^A J_A < 0$ and $J^A \xi_A = 0$.

## 4 Cosmological solutions

### 4.1 Field equations for the universe

In this section, the coupling system of the SW gravity and the fluid model (35) will be analyzed in the homogenous, isotropic, parity-invariant and spatially flat universe characterized by the following ansatz [13]:

$$
e^\mu_0 = d_\mu t, \quad e^i_\mu = a d_\mu e^i,
$$

$$
S^0_\mu = 0, \quad S^i_\mu = b e^0_\mu \land e^i_\nu, \tag{40}
$$

where $a$ and $b$ are functions of the cosmic time $t$, and $i = 1, 2, 3$. On account of Eqs. (39)–(40), the Lorentz connection $\Gamma^\alpha\beta\mu$ and curvature $R^{\alpha\beta}_\mu\nu$ can be calculated [13]. Further, assume that $U^\mu = e^0_\mu$, then $U_\mu = -e^0_\mu$, and so $U_\alpha = -\delta^0_\alpha$. Now the reduced form of each term of Eqs. (28)–(30) can be attained. In particular,

$$
\epsilon_{\alpha\beta\gamma\delta} \epsilon^\mu\nu\rho\sigma e^{-1} R^{\alpha\beta}_\mu R^{\gamma\delta}_\sigma = 96(ha)^{-1} h^2, \tag{41}
$$

$$
R = 6[(ha)^{-1} + h^2], \tag{42}
$$

$$
\epsilon_{0i}\gamma\delta \epsilon^\mu\nu\rho e^{-1} \partial_\mu l \cdot R^{\gamma\delta}_\rho = -4h^2 \partial_i e^\mu_\mu, \tag{43}
$$

$$
\epsilon_{ij}\gamma\delta \epsilon^\mu\nu\rho e^{-1} \partial_\mu l \cdot R^{\gamma\delta}_\rho = 0, \tag{44}
$$

$$
T^\mu_{0i} = -2b e^\mu_i, \quad T^\mu_{ij} = 0, \tag{45}
$$

$$
G^\mu_0 = -3h e^\mu_0, \tag{46}
$$

$$
G^\mu_i = -[2(ha)^{-1} + h^2] e^\mu_i, \tag{47}
$$

$$
\delta S_m/\delta e^0_\mu = -pl^k e^\mu_0, \tag{48}
$$

$$
\delta S_m/\delta e^i_\mu = pl^k e^\mu_i, \tag{49}
$$

where $\cdot$ on top of a quantity or being a superscript denotes the differentiation with respect to $t$, and $h = \dot{a}/a - b$. Substitution of the above equations into Eqs. (28)–(30) leads to

$$
(ha)^{-1}(h^2 + l^2) + l^{-2}(h^2 - \Lambda) = kpl^{k-1}/24\kappa, \tag{50}
$$
\[(h^2 + l^{-2})\dot{h} - 2bl^{-1} = 0, \]  
\[8\kappa l^{-1}(-3h^2 + \Lambda) = \rho l^k, \]  
\[8\kappa l^{-1}[-2(ha)^{-1} - h^2 + \Lambda] = -\rho l^k, \] which constitute the field equations for the universe.

### 4.2 Solutions for the field equations

Before solving the field equations (50)–(53), let us first derive the continuity equation from the field equations. Rewrite Eq. (52) as

\[h^2 = l^{-2} - \rho l^{k+1}/24\kappa. \] (54)

Substituting Eq. (54) into Eq. (53) yields

\[(ha)^{-1} = l^{-2} + (\rho + 3p)t^{k+1}/48\kappa. \] (55)

Multiply Eq. (55) by 2\(h\), making use of Eq. (54) and \(h = \dot{a}/a - b\), one gets

\[2h\dot{h} = (\rho + p)t^{k+1}a^{-1}/8\kappa - 2b(ha)^{-1}, \] (56)

in which, according to Eqs. (50), (51) and (54),

\[2b(ha)^{-1} = \dot{l}[(k + 1)\rho l^k/24\kappa + 2l^{-3}]. \] (57)

Differentiate Eq. (54) with respect to \(t\), and compare it with Eqs. (56)–(57), one arrives at the continuity equation

\[\dot{\rho} + 3(\rho + p)a^{-1} = 0, \] (58)

which is, unexpectedly, the same as the usual one. Suppose that \(p = w\rho\), where \(w\) is a constant. Then Eq. (58) has the solution

\[\rho = \rho_0(a/a_0)^{-3(1+w)}, \] (59)

where \(a_0\) and \(\rho_0\) are the values of \(a\) and \(\rho\) at some moment \(t_0\).

Now it is ready to solve Eqs. (50)–(52), while Eq. (53) is replaced by Eq. (58) with the solution (59). Firstly, substitute Eqs. (54)–(55) into Eq. (50), one finds

\[\rho l^{k+3} = 48\kappa (3w - k - 1)/(3w + 1). \] (60)

Assume that \(\kappa < 0\), then according to the above relation, \(\rho l^{k+3} > 0\) implies \((3w - k - 1)/(3w + 1) < 0\). We only concern the cases with \(k = 0, 1\), and so assume that \(k + 1 > -1\), then \(\rho l^{k+3} > 0\) constrains \(w\) by

\[-\frac{1}{3} < w < \frac{k + 1}{3}. \] (61)

For the ordinary fluid \((k = 0)\), the pure radiation \((w = 1/3)\) cannot exist. In fact, on account of Eq. (60), \(\rho l^3 = 0\) in this case, which is unreasonable. This problem is similar to that appeared in Ref. [13]. On the other hand, for the dS fluid \((k = 1)\), Eq. 61
becomes $-1/3 < w < 2/3$, which contains both the cases with pure matter ($w = 0$) and pure radiation ($w = 1/3$). Generally, the combination of Eqs. (59) and (60) yields

$$l = l_0 (a/a_0)^{3(w + 1)/(k + 3)}$$  \hfill (62)

where $l_0$ is the value of $l$ when $t = t_0$, and is related to $\rho_0$ by Eq. (60).

Secondly, substitute Eq. (54) into Eq. (51), and utilize Eqs. (60) and (62), one gets

$$b = \frac{3(w + 1)(k + 2)}{(3w + 1)(k + 3)} \dot{a}^{-1} a$$ \hfill (63)

and hence

$$h = \frac{3w - 2k - 3}{(3w + 1)(k + 3)} \dot{a}^{-1}.$$ \hfill (64)

Thirdly, substitution of Eqs. (60) and (64) into Eq. (52) leads to

$$\dot{a}^{-1} = H_0 (l_0 / l),$$ \hfill (65)

where $H_0 \equiv (\dot{a}^{-1})_{t = t_0}$ is the Hubble constant, being related to $l_0$ by

$$H_0 = \sqrt{\frac{3w + 1}{-3w + 2k + 3}} \cdot (k + 3) l_0^{-1}.$$ \hfill (66)

Here note that Eq. (61) implies that $3w + 1 > 0$, $-3w + k + 1 > 0$, $k + 1 > -1$, and so $-3w + 2k + 3 > 0$. In virtue of Eqs. (63), (65) and (62), one has

$$b = b_0 (a_0/a)^{3(w + 1)/(k + 3)},$$ \hfill (67)

where $b_0$ is related to $H_0$ by Eq. (63). Moreover, substitute Eq. (62) into Eq. (65) and solve the resulting equation, one attains

$$(a/a_0)^{3(w + 1)/(k + 3)} - 1 = \frac{3(w + 1)}{k + 3} \cdot H_0 (t - t_0).$$ \hfill (68)

In conclusion, the solutions for the field equations (50)–(53) are given by Eqs. (59), (62), (67) and (68), with the independent constants $a_0$, $H_0$ and $t_0$.

4.3 Comparison with observations

If $k$ is specified, we can determine the value of the coupling constant $\kappa$ from the observed values of $H_0 = 67.4 \text{ km} \cdot \text{s}^{-1} \cdot \text{Mpc}^{-1}$ and $\Omega_0 \equiv 8\pi \rho_0 / 3H_0^2 = 0.315$ [24]. For example, put $k = 1$, then according to Eq. (66) (with $w = 0$), one has

$$l_0 = 4/\sqrt{5} H_0 = 8.19 \times 10^{17} \text{ s}.$$ \hfill (69)

Substitution of Eq. (69) and $\rho_0 = 3H_0^2\Omega_0 / 8\pi = 1.79 \times 10^{-37} \text{s}^{-2}$ into Eq. (60) yields

$$\kappa = -\rho_0 l_0^2 / 96 = -8.41 \times 10^{32} \text{s}^2.$$ \hfill (70)

This value is an important reference for the future work which will explore the viability of the model in the solar system scale.
Also, we can compare the deceleration parameter \( q \equiv -\ddot{a}/\dot{a}^2 \) derived from the above models with the observed one. With the help of Eqs. (65) and (62), one finds \( \dot{a} \sim a^{(k-3w)/(k+3)} \), then \( \ddot{a} = \frac{k-3w}{k+3} \cdot \dot{a}^2 a^{-1} \), and so
\[
q = \frac{3w - k}{k + 3}.
\]

Put \( w = 0 \), it is seen that the universe accelerates \( (q < 0) \) if \( k > 0 \), linearly expands \( (q = 0) \) if \( k = 0 \), and decelerates \( (q > 0) \) if \( k < 0 \). In particular, for the model with an ordinary fluid \( (k = 0) \), the universe expands linearly\(^5\); while for the model with a dS fluid \( (k = 1) \), the universe accelerates with \( q = -1/4 \), which is consistent with the observational result \(-1 \leq q_0 < 0\) \(^{25,27} \), where \( q_0 \) is the present-day value of \( q \). It should be noted that Eq. (71) implies that \( q \) is a constant when \( w \) is a constant, and so the models cannot describe the transition from deceleration to acceleration when \( w \) is a constant.

### 5 Remarks

It is shown that the requirement of regular Lagrangian may be crucial for DGT, as it is shown that the SW gravity coupled with an ordinary perfect fluid (whose Lagrangian is not regular with respect to \( \xi^A \) when \( \xi^A \xi_A = 0 \)) does not permit a radiation epoch and the acceleration of the universe, while the SW gravity coupled with a polynomial dS fluid (whose Lagrangian is regular with respect to \( \xi^A \)) is out of these problems. Yet, the latter model is still not a realistic model, because it cannot describe the transition from deceleration to acceleration in the matter epoch.

There are two possible ways to find a more reasonable model. The first is to modify the gravitational part to be the general quadratic model \(^{23} \), which is a special case of the at most quadratic model proposed in Refs. \(^{10,22} \), but the coupling of which with the polynomial dS fluid is unexplored. It is unknown whether the effect of the \( \kappa_2 \) term could solve the problem encountered in the SW gravity.

The second way is to modify the matter part. Although the Lagrangian of the polynomial dS fluid is regular with respect to \( \xi^A \), it is not regular with respect to \( J^A \) when \( \xi^A \xi_A = 0 \), in which case there should be \( J^A J_A \geq 0 \), and so the number density \( n \equiv \sqrt{-J^A J_A} \) is not regular. Maybe one could find a new fluid model whose Lagrangian is regular with respect to all the variables, based on the polynomial models for fundamental fields proposed in Refs. \(^{14,15} \).

### Acknowledgments

I thank Profs. S.-D. Liang and Z.-B. Li for their abiding help. Also, I would to thank my parents and my wife. This research is supported by the National Natural Science Foundation for Young Scientists of China under Grant No. 12005307.

---

\(^5\)This result is different from that in Ref. \(^{13} \), where the cosmological solution describes a decelerating universe. It shows that the SW model is not equivalent to the model considered in Ref. \(^{13} \).
