ONE NOTE ON VEECH GROUPS OF INFINITE HYPERELLIPTIC CURVES

CAMILO RAMÍREZ MALUENDAS

ABSTRACT. An infinite hyperelliptic curve is the set conformed by all couples \((z, w)\) satisfying the formula \(w^m = f(z)\), where \(m \geq 2\) and the map of Weierstrass \(f : \mathbb{C} \to \mathbb{C}\) is an entire function having infinitely many zeros and, each of them is a simple zero. Such infinite hyperelliptic curve is a connected Riemann surface topologically equivalent to the Loch Ness monster. In this paper we endowed each infinite hyperelliptic curve with a tame translation structure and, study the possible subgroups of \(\text{GL}_+(2, \mathbb{R})\), which could be realised as Veech group of an infinite hyperelliptic curve.

INTRODUCTION

A translation surface is a (connected) two manifold with a translation atlas. These objects have been studied in different contexts of the mathematics such as Dynamical system \[2,15\], Riemann surface \[12,14\], Teichmüller theory \[17,23\] among others. In 1989 W. A. Veech \[25\] associated to each translate surface \(S\) a group of affine matrices \(\Gamma(S)\), which is well known as the Veech group, and proved that if such group of a compact translate surface \(S\) is a lattice, then the geodesic flow on \(S\) obeys a dichotomy. Such Veech group of a tame translation surface is either a countable subgroup of \(\text{GL}_+(2, \mathbb{R})\) without contracting elements or a suitable uncountable subgroup of \(\text{GL}_+(2, \mathbb{R})\) (see \[19, \text{Theorem 1.1}\]). The realisation problem of suitable group as Veech group of tame translation surfaces has been studied widely by several authors as e.g., G. Weitze-Schmithüsen \[28\] developed a nice algorithm that determine the Veech group of a translate surface called tiled-square surface or origami. In \[19\] P. Przytycki, G. Weitze-Schmithüsen and F. Valdez introduced the operation gluing marks and realised all possible subgroups of \(\text{GL}_+(2, \mathbb{R})\) as Veech group of the Loch Ness monster, which is the unique, up homeomorphisms, surface of infinite genus and one only end \[24, \text{Definition 2}\]. Subsequently, this work was generalized by F. Valdez and the author \[21\] and, we obtained a diversity of (non-compact) tame translate surfaces with certain Veech group. R. Chamanara \[4\] introduced infinite translate surface and proved that some of them have as Veech group a non-elementary Fuchsian group of the second kind which is generated by two parabolic elements; in \[20\] the author built tame translate surfaces having certain subgroups of \(\text{GL}_+(2, \mathbb{R})\) as Veech group such that the topology (ends) of these surfaces is related to the ends of the group.

The work of several authors on the hyperelliptic curves has contributed to the development of the theory of compact Riemann surfaces as complex algebraic curves e.g., W. Harvey in \[7\] studied the automorphisms group of compact Riemann surfaces. In \[22\] S. Rose introduced a generating function for the number of hyperelliptic curves on suitable Abelian surface, among others. In the classical theory, a hyperelliptic curve is the collection of couples \((z, w)\) conformed by complex numbers satisfying the formula \(w^2 = f(z)\),

\[\text{2000 Mathematics Subject Classification.} \quad 20F65; 53A99; 37F10; 20H10; 57N05; 57N16.\]
\[\text{Key words and phrases.} \quad \text{Infinite hyperelliptic curve, Loch Ness monster, Veech group, tame translate surface, Veech group, saddle connection, holonomy vectors.} \]
\[\text{Partially supported by Project HERMES 47019.}\]
where \( f(z) \) is a suitable polynomial (see e.g. [5, 6]). In a recent work [3], this concept was extended to the case of infinite hyperelliptic curve. More precisely, for a sequence of different complex numbers \((z_k)_{k \in \mathbb{N}}\) such that \( \lim_{k \to \infty} \|z_k\| = \infty \), there exists an entire map \( f : \mathbb{C} \to \mathbb{C} \) whose only zeros are the points of this sequence and, each one of them is a simple zero. Thus, the infinite hyperelliptic curve \( S(f, m) \) is the affine plane curve determined by all couples \((z, w)\) satisfying the relation \( w^m = f(z) \), for any positive integer \( m \geq 2 \). In this case, the object \( S(f, m) \) is a connected Riemann surface topologically equivalent to the Loch Ness monster [3, Theorem 6.2].

The goal of this paper is to focus on the realisation of certain subgroups of \( \text{GL}_+(2, \mathbb{R}) \) as Veech group of an infinite hyperelliptic curve, which is other proposal to understand the realisation problem and, the study of the tame translation structures on the infinite hyperelliptic curves.

**Reader's guide.** In the Section 1 we explore each infinite hyperelliptic curve as a tame translation surfaces. In addition, we study the concept of isomorphism between two hyperelliptic curve and propose a moduli space of infinite hyperelliptic curve as tame translation surfaces. In Section 2 we collect the concepts of the Veech group, saddles connection and holonomy vectors associated a translate surface. Then, we give a precise description of all saddles connection and holonomy vectors of an infinite hyperelliptic curve. Moreover, we discuss the sufficient and necessary conditions to guarantee that the Veech of an infinite hyperelliptic curve is an uncountable proper subgroup of \( \text{GL}_+(2, \mathbb{R}) \). We show some examples of hyperelliptic curves having uncountable Veech group and, determine a subset of the moduli space of infinite hyperelliptic curve, which corresponds to those infinite hyperelliptic curve with uncountable Veech group. Finally, we introduce each countable Veech group of a infinite hyperelliptic curve as an finite sequences of groups. For a fix countable subgroup \( G \) of \( \text{GL}_+(2, \mathbb{R}) \) without contracting elements we build an infinite hyperelliptic curve having \( G \) as subgroup of its Veech group and, we construct an infinite hyperelliptic curve as a tiled-square surfaces with Veech group \( \text{SL}_+(2, \mathbb{Z}) \).

1. **INFINITE HYPERELLIPTIC CURVE AS TAME TRANSLATION SURFACE**

We begin this section introducing the concept of tame translation surface and infinite hyperelliptic curve.

We shall identify throughout the whole manuscript \( \mathbb{C} \) with \( \mathbb{R}^2 \) by sending \( \{1, i\} \) to the standard basis of \( \mathbb{R}^2 \). The term surface means a connected 2-dimensional topological real manifold with empty boundary, and it will be denoted as \( S \).

1.1. **Tame translation surface.** A surface \( S \) is called translate, if \( S \) except a set of points \( X(S) \) can be endowed with a translation atlas, i.e., an atlas whose transition maps are locally the restriction of a translations of \( \mathbb{C} \). In this paper we suppose that each point in \( X(S) \) is not removable, it means, the translation atlas can not be extended to any of these points \( X(S) \). Let us remark that the only surfaces admitting a translate structure such that \( X(S) = \emptyset \) are: the complex plane \( \mathbb{C} \), the flat torus and the flat cylinder (see [1, p: 580], [5, p. 193]).

On a translate surface \( S \) we can pull back the complex metric of \( \mathbb{C} \), thus we define a flat Riemannian metric on \( S \). Let \( \overline{S} \) denote the metric completion of \( S \) with respect to this flat Riemannian metric.

**Definition 1.1** ([19, Definition 2.2]). *A translation surface \( S \) is said to be tame if for every point \( x \in \overline{S} \) there exists a neighborhood \( U_x \subset \overline{S} \) isometric to either:

1. Some open of the complex plane,*
2. An open of the ramification point of a (finite or infinite) cyclic branched covering of the unit disk in the complex plane.

In the later case, the point $x$ is called finite cone angle singularity of angle $2n\pi$, if the cyclic covering has finite order $n \in \mathbb{N}$. Contrary, if the cyclic covering is infinite, then the point is called infinite cone angle singularity.

Let $X(S)$ denote the set conformed by all finite cone angle singularities of the translation surface $S$ and let $X_\infty(S)$ denote the set conformed by all infinite cone angle singularities of $S$. A point in the union set $X(S) \cup X_\infty(S)$ is called cone angle singularity of $S$ or just cone point. Let us remark that the space $\overline{S} \setminus X_\infty(S)$ is topologically equivalent to the surface $S$.

1.2. Infinite hyperelliptic curve. A sequence conformed by different complex numbers $Z := (z_k)_{k \in \mathbb{N}}$ is said to be converge to infinity, if the limit of the norms $\lim_{k \to \infty} ||z_k|| = \infty$.

Throughout this paper, we will consider sequences of complex numbers described as above and we will assume that, unless otherwise noted, the terms of each one of these sequences $Z = (z_k)_{k \in \mathbb{N}}$ are ordered as follows: $||z_k|| < ||z_{k+1}||$ and, in the case $||z_k|| = ||z_{k+1}||$, then $0 \leq \arg(z_k) < \arg(z_{k+1}) < 2\pi$. From the Weierstrass’s theorem (see e.g., [16] p. 498), for a sequences of complex numbers $Z$, we can find an entire function $f : \mathbb{C} \to \mathbb{C}$ such that its zeros are the points conforming such sequence $Z$ and, each one of those zeros is simple. Moreover, the map $f$ is uniquely determined up multiplication by a zero-free entire map, and it can be written as

$$f(z) = g(z) \prod_{k=1, z_k \neq 0}^{\infty} \left(1 - \frac{z}{z_k}\right) E_k(z),$$

where $g$ is a zero-free entire function ($m = 0$, if $z_k \neq 0$ for every $k \in \mathbb{N}$; in the other case, $m = 1$, if $z_k = 0$ for any $k \in \mathbb{N}$), and $E_k(z)$ is a function of the form

$$E_n(z) = \exp \left[ \sum_{k=1}^{d(n)} \frac{1}{k} \left( \frac{z}{z_k} \right)^k \right],$$

for a suitably large non-negative integer $d(n)$. The holomorphic map $f$ will be called a function of Weierstrass associated to the sequence $Z$.

**Definition 1.2 (3 Subsection 6.3.1).** Given $f$ a function of Weierstrass associated to a sequence $Z$, then for each integer $m \geq 2$ the affine plane curve

$$(1) \quad S(f, m) = \{ (z, w) \in \mathbb{C}^2 : w^m = f(z) \},$$

is called an infinite hyperelliptic curve.

As 0 is a regular value of the map $F : \mathbb{C}^2 \to \mathbb{C}$ defined by $F(z, w) = w^m - f(z)$, then from the Implicit Function Theorem (see e.g., [11], [13] p. 10, Theorem 2.1) it follows that infinite hyperelliptic curve $S(f, m)$ is a Riemann surface. The following result describes the topological type of $S(f, m)$.

**Theorem 1.1 (3 Theorem 6.2).** The infinite hyperelliptic curve $S(f, m)$ is a Riemann surface topologically equivalent to the Loch Ness monster.

The Loch Ness monster $S(f, m)$ together with the projection map $p_z : S(f, m) \to \mathbb{C}$ given by

$$(2) \quad (z, w) \mapsto z,$$
define a branched covering of the complex plane $\mathbb{C}$, whose branch points are the complex numbers of the sequence $Z$. In addition, for each complex number $z \neq z_k$ for each $n \in \mathbb{N}$, the fiber $p^{-1}(z)$ is conformed by exactly $m$ elements (see [3] Remark 6.5)).

Now, using the projection map $p_z$ we can lift the translation structure of the translation surface $\mathbb{C} \setminus \{z_k : k \in \mathbb{N}\}$ on $S(f, m)$ except the couples $(z_k, 0)$ for each $k \in \mathbb{N}$. As the subset $\{z_k, 0) : k \in \mathbb{N}\} \subset S(f, m)$ is discrete, then the metric completion of $S$ with respect to the flat Riemannian metric, which comes from the translate structure, is itself. From the above short comment about of the branched points, it follows that for each $k \in \mathbb{N}$ the couple $(z_k, 0)$ in $S(f, m)$ is a finite cone angle singularity of angle $2\pi m$. It implies the following fact.

**Theorem 1.2.** The infinite hyperelliptic curve $S(f, m)$ admits a tame translate structure, such that $\text{Sing}(S(f, m)) = \{(z_k, 0) : \text{for each } k \in \mathbb{N}\}$.

1.3. **Isomorphism.** Let $S_1$ and $S_2$ be translate surfaces with translate atlas $\mathcal{A} = \{U_i, \phi_i\}$ and $\mathcal{B} = \{V_j, \psi_j\}$, respectively. A homeomorphism $f : S_1 \to S_2$ is called translate isomorphism from the structure $\mathcal{A}$ to the structure $\mathcal{B}$ if $h$ sends the cone points onto cone points and $\mathcal{B} = \{f(U_i), \phi_i \circ f^{-1} : f(U_i) \to \mathbb{C}\}$. The tame translation surfaces $S_1$ and $S_2$ are translate isomorphic, if there is a translate isomorphism $f : S_1 \to S_2$ (for more details see e.g., [8] Subsection 2.1).

A necessary and sufficient condition for two infinite hyperelliptic curves $S(f, m)$ and $S(g, m)$ to be a translate isomorphic is given by

**Theorem 1.3.** Let $f$ and $g$ be functions of Weierstrass associated to the sequences $Z = (z_k)_{k \in \mathbb{N}}$ and $\tilde{Z} = (\tilde{z}_k)_{k \in \mathbb{N}}$, respectively. Let $S(f, m)$ and $S(g, m)$ be infinite hyperelliptic curves. There exists a fiber-preserving translate isomorphism $\tilde{T} : S(f, m) \to S(g, m)$ if and only if there exists a translate map $T : \mathbb{C} \to \mathbb{C}$ sending the zeros of $f$ onto the zeros of $g$.

**Proof.** We assume that there exists a fiber-preserving translate isomorphisms $\tilde{T} : S(f, m) \to S(g, m)$. As the translation structure on $S(f, m)$ is defined by the projection map $\pi_z$, then it is immediate that the map $T = \pi_z \circ \tilde{T} \circ \pi_z^{-1}$ is a well defined translate isomorphism from $C$ onto itself, which sends the complex numbers of the sequence $Z$ onto the complex numbers of the sequence $\tilde{Z}$. This proves the sufficient condition.

We shall show the necessary condition. By hypothesis, there is a translate map $T : \mathbb{C} \to \mathbb{C}$ sending the sequence $Z$ onto the sequence $\tilde{Z}$, the map $\tilde{T} : S(f, m) \to S(g, m)$ will be defined as a lifting of the map $T$. For each $k \in \mathbb{N}$, the image of the cone angle singularity $(z_k, 0)$ under $\tilde{T}$ is given by

$$\tilde{T}(z_k, 0) = (T(z_k), 0).$$

Now, we choose a basepoint $(z_0, w_0) \in S(f, m) \setminus \text{Sing}(S(f, m))$ and fix an element $(u, v)$ in the fiber $\pi_z^{-1}(f(z_0))$. Thus, we define the image of $(z_0, w_0)$ under $\tilde{T}$ as

$$\tilde{T}(z_0, w_0) = (u, v).$$

For each couple $(s, t) \in S(f, m) \setminus \text{Sing}(S(f, m))$, we consider a path $\gamma$ in $\mathbb{C}$ joining the complex numbers $z_0$ and $s$, and not having points of the sequence $(z_k)_{k \in \mathbb{N}}$ in its interior. For the composition map $T \circ \gamma$ there is a lifting path $\tilde{\gamma}$ in $S(g, m)$ joining the pairs $T(z_0, w_0)$ and $(\tilde{s}, \tilde{t})$, for any point $(\tilde{s}, \tilde{t})$ in the fiber $\pi_z^{-1}(f(s))$. Thus, the image of $(s, t)$ under $\tilde{T}$ is defined as

$$\tilde{T}(s, t) = (\tilde{s}, \tilde{t}).$$

By construction the map $\tilde{T} : S(f, m) \to S(g, m)$ is a fiber-preserving homeomorphism. Given that $T$ is a translate isomorphism of the complex plane onto itself, then $\tilde{T}$ is also a translate isomorphisms.
1.4. The set-theoretic moduli space. Recall that each sequence of different complex numbers $Z = (z_k)_{k \in \mathbb{N}}$ determines an infinite hyperelliptic curve $S(f, m)$, where $f$ is the function of Weierstrass associated to the sequence $Z$. Such infinite hyperelliptic curve $S(f, m)$ admits a tame translation structure. Let us note that each complex number $b \in \mathbb{C}$ defines the sequence of different complex numbers $Z + b =: (z_k + b)_{k \in \mathbb{N}}$, which converges to infinity and differs from $Z$ by $b$. Using the Theorem 1.3 it follows that the infinite hyperelliptic curve $S(g, m)$ is translate isomorphic to $S(f, m)$, where $g$ is the map of Weierstrass associated to the sequence $Z + b$.

On the other hand, let $C_\infty$ denote the set conformed by all sequence of different complex numbers such that each one of them converge to infinity, then it can be thought as the set of all infinite hyperelliptic curves having tame translation structure. Further, the group of complex translations maps $\mathcal{T} = \{T_b(z) = z + b : b \in \mathbb{C}\}$ acts on $C_\infty$ as follows

$$(T_b, Z) \mapsto Z + b.$$ 

Let $\ell_\infty$ denote the Banach space conformed by all bounded sequence of complex numbers $(z_k)_{k \in \mathbb{N}}$ equipped with the norm given by the formula

$$\| (z_k)_{k \in \mathbb{N}} \|_\infty = \sup_{k \in \mathbb{N}} \| z_k \| < \infty.$$ 

Let $C_0$ be the subspace of $\ell_\infty$ conformed by all sequences of different complex numbers $(w_k)_{k \in \mathbb{N}}$ such that each one of them converge to zero and, $w_k \neq 0$, for each $k \in \mathbb{N}$. Using the involution map $w \mapsto \frac{1}{w}$, we identify each sequence $(w_k)_{k \in \mathbb{N}}$ of $C_0$ with the sequence $(\frac{1}{w_k})_{k \in \mathbb{N}}$ of $C_\infty$. Then the group $\mathcal{T}$ acts on the space $C_0$ by

$$(T_b, (w_k)_{k \in \mathbb{N}}) \mapsto \left( \frac{w_k}{1 + bw_k} \right)_{k \in \mathbb{N}}.$$ 

As a consequence of above action, we obtain the following result.

**Theorem 1.4.** The moduli space of infinite hyperelliptic curves with tame translation structure is given by the quotient space $C_0/\mathcal{T}$.

2. VEECH GROUP OF AN INFINITE HYPERELLIPTIC CURVE

An affine diffeomorphism of a tame translation surface $S$ is a homeomorphism $f : \widehat{S} \rightarrow \widehat{S}$, which maps cone points to cone points, and it is an affine map in the local coordinates of the translation atlas on $S$. We denote by $\text{Aff}_+(S)$ the group conformed by all affine orientation preserving diffeomorphism of the tame translation surface $S$. For the case of infinite hyperelliptic curves $S(f, m)$, we can find some elements of $\text{Aff}_+(S(f, m))$. More precisely, if we develop the same ideas about of the theory of covering space described in the proof of the Theorem 1.3 then it follows the following result:

**Theorem 2.1.** Let $S(f, m)$ be the infinite hyperelliptic curves, where $f$ is a function of Weierstrass associated to the sequence $Z$. There exists a fiber-preserving affine orientation preserving diffeomorphism of $S(f, m)$ if and only if there exists an affine orientation preserving diffeomorphism of $\mathbb{C}$ permuting the zeros of $f$.

Now, if we fix a translate surface $S$ and choose an element $f \in \text{Aff}_+(S)$, then using the translation structure on $S$, we hold that $df(p)$ the differential of $f$ at any point $p \in S$ is a constant matrix $A$ belongs to $\text{GL}_n(2, \mathbb{R})$. Hence, we have the well defined group homomorphism

$$\rho : \text{Aff}_+(S) \rightarrow \text{GL}_n(2, \mathbb{R}),$$

where $\rho(f)$ is the differential matrix of $f$. 

Definition 2.1 ([25, p. 556]). The image of ρ, that we denote by Γ(S), is called the Veech group of S.

From the Theorems 1.3 and 2.1, we can conclude that if the translate surfaces S_1 and S_2 are translate isomorphic, then their respective Veech group Γ(S_1) and Γ(S_2) also are isomorphic. Thus, if we consider the infinite hyperelliptic curves S(f, m) and S(g, m), where f and g are function of Weierstrass associated to the sequences Z and Z - z_1, respectively, then they have isomorphic Veech group. Throughout this section we shall assume that the first term of any sequence Z is zero i.e., z_1 = 0.

The result described the Veech group of a tame translation surface. In particular, the Veech group any infinite hyperelliptic curve. We shall abuse of language and we will use the terminology A · w to refer to matrix product given by A ∈ GL_s(2, R) and the complex number z.

Theorem 2.2 ([19, Theorem 1.1]). Let Γ(S) < GL_s(2, R) be the Veech group of a tame translation surface S. Then one of the following holds:

1. The group Γ(S) is countable and without contracting elements, it means, Γ(S) is disjoint from the set \{ A ∈ GL_s(2, R) : ||A · z|| < ||z|| for all z ∈ C \ {0}\}, or
2. The group Γ(S) is conjugated to \( \Gamma := \left\{ \begin{pmatrix} 1 & t \\ 0 & s \end{pmatrix} : t ∈ R \text{ and } s ∈ R^+ \right\} \), or
3. The group Γ(S) is conjugated to \( \Gamma' < \text{GL}_s(2, R) \), the subgroup generated by \( P \text{ and } -1\text{d} \), or
4. The group Γ(S) is equal to GL_s(2, R).

2.1. Saddles connection and holonomy vectors of an infinite hyperelliptic curve. It is well-known that the Veech group of a compact translate surface is a Fuchsian group (see e.g., [25, Proposition 2.7], [26, Proposition 3.3]). In original proof of this statement, which is due to W. Veech, are used some geometric objects called saddles connection and holonomy vectors. So, we dedicate this subsection to the study of these objects on the infinite hyperelliptic curve.

In general, a saddle connection γ of a tame translation surface S is a geodesic interval joining two cone points and not having cone points in its interior. From the translation structure, a saddle connection γ is locally a straight line in the direction [θ], for any \([θ] ∈ R / 2π\mathbb{Z}\). So, we can associate to each saddle connection γ two holonomy vectors \([v, -v] ∈ C\), which are in the direction [θ] and [−θ], respectively, and their norm are equal to the length of γ with respect to the flat Riemannian metric μ on S. Two saddle connection of S are called to be parallel if their respective holonomy vectors are parallel. The set formed by those holonomy vectors of each one saddle connection of the translation surface S is denoted by Hol(S). Given that each affine orientation preserving diffeomorphism f of the tame translate surface S sends each saddle connection to a saddle connection, then the Veech group Γ(S) associated to the (tame) translate surface S acts on its set of holonomy vectors Hol(S) by matrix multiplication.

Now, we take a sequence of different complex numbers Z = (z_k)_{k ∈ N} and the infinite hyperelliptic curve S(f, m), where f is the function of Weierstrass associated to the sequence Z. As the tame translation structure on S(f, m) is defined from the projection map p_c (see equation (2)), then the function p_c sends each saddle connection γ of S(f, m) to a straight line segment L in the complex plane C joining two different points z_r and z_l of the sequence Z, such that L does not have points of Z in its interior. Likewise, if L is a straight line segment in the complex plane C such that its endpoints are z_r and z_l for any r, l ∈ N and, L does not has points of the sequence Z in its interior, then L is lifted to a m saddle
connection of \( S(f,m) \) with endpoints \((z_r, 0)\) and \((z_l, 0)\). This fact describes sufficient and necessary conditions to build saddles connection of \( S(f,m) \).

**Theorem 2.3.** Given the curve \( \gamma \) of \( S(f,m) \) with endpoints \((z_r, 0)\) and \((z_l, 0)\) for any \( r, l \in \mathbb{N} \). Then \( \gamma \) is a saddle connected if and only if the projection curve \( p_r \circ \gamma \) is a straight line segment in the complex plane \( \mathbb{C} \) such that its endpoints are \( z_r \) and \( z_l \). It does not have points of the sequence \( \mathbb{Z} \) in its interior.

If the curve \( \gamma \) of the infinite hyperelliptic curve \( S(f,m) \) is a saddle connection having endpoints \((z_r, 0)\) and \((z_l, 0)\), then the straight line segment \( p_r \circ \gamma \) have associated the same holonomy vectors that \( \gamma \). Hence, the two holonomy vectors associated to \( \gamma \) are the complex vectors \( z_r - z_l \) and \( z_l - z_r \). As consequence of this fact and the Theorem 2.3, we hold the following description of the set of holonomy vectors of the infinite hyperelliptic curve \( S(f,m) \).

**Theorem 2.4.** The set of holonomy vectors \( \text{Hol}(S(f,m)) \) of the infinite hyperelliptic curve \( S(f,m) \) is a countable non-empty discrete subset of \( \mathbb{C} \) conformed by the complex vectors \( z_r - z_l \), such that the \( z_r \) and \( z_l \) are different elements of the sequence \( \mathbb{Z} \), and the straight line segment with endpoints \( z_r \) and \( z_l \) does not have points of the sequence \( \mathbb{Z} \) in its interior.

Let us remark that the formula \( \text{Hol}(S(f,m)) \subset \mathbb{Z} \) is not true in general, because if we consider the sequence \( \mathbb{Z} \) conformed by the complex zero and all positive integers, then the set of holonomy vectors of \( S(f,m) \) is conformed by the vectors \( \pm 1 \). Thus, the difference \( \text{Hol}(S(f,m)) \setminus \mathbb{Z} \neq \emptyset \). However, if all elements of the sequence \( \mathbb{Z} \) define an additive discrete subgroup of \( \mathbb{C} \), then we hold that \( \text{Hol}(S(f,m)) \subset \mathbb{Z} \). In this case the subgroup must be isomorphic to either: \( \{0\}, \mathbb{Z} \) or \( \mathbb{Z} \times \mathbb{Z} \). (see [10, Theorem 3.1.3]). In addition, it is not generally true that \( \mathbb{Z} \subset \text{Hol}(S(f,m)) \), because we can consider the sequences \( \mathbb{Z} \) conformed by all integers, then the set of holonomy vector of \( S(f,m) \) are the vectors \( \pm 1 \). Hence, the difference \( \mathbb{Z} \setminus \text{Hol}(S(f,m)) \neq \emptyset \).

On the other hand, if \( S \) is a compact translate surface, it is known that the directions of the vectors in \( \text{Hol}(S) \) are everywhere dense on the unit circle (see [26, Proposition 3.1]). In the case of Infinite hyperelliptic curve, this is not true, because if we consider the sequence \( \mathbb{Z} \) given by the integers numbers join with \( -i \), then the set of holonomy vectors of \( S(f,m) \) is \( \text{Hol}(S(f,m)) = \{ \pm (l + i) : l \in \mathbb{Z} \} \). Consequently, the set of directions of the vectors in \( \text{Hol}(S(f,m)) \) is topologically equivalent to two disjoint copies of the ordinal number \( \omega + 1 \). Clearly, this set is not dense on the unit circle.

**2.2. Uncountable Veech group of infinite hyperelliptic curves.** Let us remark that the only tame translate surfaces with Veech group \( \text{GL}_+(2, \mathbb{R}) \) are the cyclic branched coverings of the Euclidean plane [19, Lemma 3.2]. It implies that if the Veech group \( \Gamma(S(f,m)) \) of the hyperelliptic curve \( S(f,m) \) is uncountable, then \( \Gamma(S(f,m)) \) is either: conjugated to the group \( P \) or conjugated to the group \( P' \) (see Theorem 2.2). We shall give sufficient and necessary conditions to guarantee that the Veech of an infinite hyperelliptic curve \( S(f,m) \) is an uncountable proper subgroup of \( \text{GL}_+(2, \mathbb{R}) \).

**Theorem 2.5.** Let \( \mathbb{Z} = (z_k)_{k \in \mathbb{N}} \) be a sequence of complex numbers and let \( S(f,m) \) be the infinite hyperelliptic curve such that \( f \) is a Weierstrass function associated to the sequence \( \mathbb{Z} \). The Veech group of the tame translation surface \( S(f,m) \) is an uncountable proper subgroup of \( \text{GL}_+(2, \mathbb{R}) \) if and only if the all points conforming the sequence \( \mathbb{Z} \) are collinear.

**Proof.** We suppose that all points conforming the sequence \( \mathbb{Z} \) are collinear, then there exists a straight line \( L \) passing through the origin \( 0 \) such that \( z_k \in L \), for each \( k \in \mathbb{N} \).
We denote by $R_\theta$ the rotation complex map given by $z \mapsto e^{i\theta}z$, for any $\theta \in \mathbb{R}$, such that $R_\theta$ sends the straight line $L$ onto the real axis. Now, for each matrix $A \in P$, we take the linear transformation $T_A$ defined by the matrix $A$. Then, the straight line $L$ is a fixed set of the orientation preserving linear transformation $R_\theta^{-1} \circ T_A \circ R_\theta$. In particular, the complex numbers of the sequence $Z$ are fixpoints of the linear map $R_\theta^{-1} \circ T_A \circ R_\theta$. From Theorem 2.1, it follows that there exists an affine orientation preserving diffeomorphism $f$ from $S(f, m)$ to itself such that its differential $Df = D(R_\theta^{-1} \circ T_A \circ R_\theta)$. Given that the matrix $A \in P$ is arbitrary, then the Veech group $\Gamma(S(f, m))$ contains a subgroup conjugated to the group $P$ by a rotation matrix. As the group $P$ has uncountable cardinality, then the Veech group $\Gamma(S(f, m))$ must be uncountable.

Now, we assume that the Veech group $\Gamma(S(f, m))$ of the infinite hyperelliptic curve $S(f, m)$ is an uncountable proper subgroup of $\text{GL}_+(2, \mathbb{R})$. Let us observe that the following assert are equivalent:

1. All points of the sequence $Z$ are collinear,
2. The saddles connection of $S(f, m)$ are parallel,
3. The holonomy vectors of $S(f, m)$ are parallel.

So, we shall proceed by contradiction, and suppose that there are two linearly independent holonomy vectors $v, u \in \text{Hol}(S(f, m))$ over $\mathbb{R}$. Given that the vectors $z$ and $w$ form a basis for $\mathbb{C}$, then the map $\rho$ from $G$ to the product $\text{Hol}(S(f, m)) \times \text{Hol}(S(f, m))$ given by

$$g \mapsto (g \cdot z, g \cdot w),$$

it is an injective function. This implies that the product $\text{Hol}(S(f, m)) \times \text{Hol}(S(f, m))$ must be an uncountable set. Clearly, this fact is a contradiction because such product is countable (see Theorem 2.4). Hence, we conclude that the holonomy vectors of $S(f, m)$ are parallel.

\[\square\]

The following corollary is immediate from the above Theorem.

**Corollary 2.1.** Let $T_{-\text{Id}}$ be the linear transformation defined by the matrix $-\text{Id}$. If the set conformed by all terms of the sequence $Z$ are invariant under the linear transformation $R_\theta^{-1} \circ T_{-\text{Id}} \circ R_\theta$, then the Veech group $\Gamma(S(f, m))$ of the infinite hyperelliptic curve is conjugated to the group $P'$.

Now, we shall introduce some examples of infinite hyperelliptic curve with uncountable Veech group.

**Example 2.1.** If we consider the sequences $Z$ of complex numbers conformed by all positive integers numbers, then the Veech group of the infinite hyperelliptic curve $S(f, m)$ is the group $P$.

Given the sequence $Z$ of complex numbers conformed by the real numbers $4n + 1$ and $4n + 3$ for $n \geq 1$, then the Veech group of the tame translation surface $S(f, m)$ is the group $P$. In the case $m = 2$, the Loch Ness monster $S(f, 2)$ is biholomorphically equivalent to the tame translate surface appearing in [19] Lemma 3.7.

For the sequence $Z$ of complex numbers conformed by all integer numbers, we define the infinite hyperelliptic curve $S(f, m)$ with Veech group the group $P$.

If $Z$ is the sequence of complex numbers conformed by the real numbers $4n + 1$ and $4n + 3$ for $n \in \mathbb{Z}$, then the tame translation surface $S(f, m)$ has as Veech group the group $P'$. In the case $m = 2$, the Loch Ness monster $S(f, 2)$ is biholomorphically equivalent to the tame translate surface appearing in [19] Lemma 3.8.
2.2.1. **The set-theoretic moduli space of the infinite hyperelliptic curves with uncountable Veech group.** Recall that the involution complex map \( w \mapsto \frac{1}{w} \) send any straight line onto a straight line, then from the Theorem [1.4] we can state the following result, which described the space conformed by the infinite hyperelliptic curves with uncountable Veech group.

**Theorem 2.6.** If \( \mathcal{U} \) denotes the subspace of the quotient space \( C_0/\mathcal{T} \) conformed by all equivalent classes \( \{(y_k)_{k \in \mathbb{N}}\} \) such that all terms of the sequence \( (y_k)_{k \in \mathbb{N}} \) are collinear, then \( \mathcal{U} \) is the space of all the infinite hyperelliptic curves with tame translation structure and uncountable Veech group. Moreover, the complement \( (C_0/\mathcal{T}) \setminus \mathcal{U} \) is the space of all the infinite hyperelliptic curves with tame translation structure and countable Veech group.

2.3. **Countable Veech groups of infinite hyperelliptic curves.** Given a sequence of different complex numbers \( Z = (z_k)_{k \in \mathbb{N}} \) and the infinite hyperelliptic curve \( S(f,m) \), where \( f \) is the map of Weierstrass associated to the sequence \( Z \). Then from the Theorem [2.5] it follows that the Veech group of the infinite hyperelliptic curve \( S(f,m) \) is a countable subgroup of \( \text{GL}_+(2,\mathbb{R}) \) without contracting elements if and only if the points of the sequence \( Z \) are not collinear. Our goal is to study the countable Veech groups appearing in the hyperelliptic curves, then in this subsection we shall consider sequence of different complex numbers such that their terms are not collinear.

We take a sequences \( Z = (z_k)_{k \in \mathbb{N}} \), an non-contracting matrix \( A \) of \( \text{GL}_+(2,\mathbb{R}) \) and denote by \( T_A \) the linear transformation defined by the matrix \( A \). If the transformation \( T_A \) permutes the complex numbers of the sequence \( Z \), from the Theorem [2.1] it follows that the matrix \( A \) is an element of the Veech group \( \Gamma(S(f,m)) \) of the infinite hyperelliptic curve \( S(f,m) \). This fact naturally induces to introduce the subgroup \( \text{Aff}_+(Z) < \text{GL}_+(2,\mathbb{R}) \), which is conformed by all non-contracting matrix \( A \) of \( \text{GL}_+(2,\mathbb{R}) \) such that the linear transformation \( T_A \) permutes the complex numbers of the sequence \( Z \).

**Theorem 2.7.** The group \( \text{Aff}_+(Z) \) is a subgroup of the Veech group \( \Gamma(S(f,m)) \).

Recall that he Veech group \( \Gamma(S(f,m)) \) acts on its set of holonomy vectors \( \text{Hol}(S(f,m)) \) by matrix multiplication. Let \( \text{Aff}_+(\text{Hol}(S(f,m))) \) denote the subgroup of \( \text{GL}_+(2,\mathbb{R}) \) conformed by all non-contracting matrix \( A \) of \( \text{GL}_+(2,\mathbb{R}) \) such that the linear transformation \( T_A \) permutes the holonomy vectors of \( S(f,m) \). Consequently, it follows that

**Theorem 2.8.** The Veech group of the hyperelliptic curve \( S(f,m) \) satisfies

\[
\text{Aff}_+(Z) < \Gamma(S(f,m)) < \text{Aff}_+(\text{Hol}(S(f,m))).
\]

In the following example we shall introduce a construction to get infinite hyperelliptic curve such that its respective Veech group has as subgroup a fix subgroup \( G < \text{GL}_+(2,\mathbb{R}) \), without contracting elements.

**Example 2.2.** We fix a subgroup \( G \) of \( \text{GL}_+(2,\mathbb{R}) \) without contracting elements and consider the countable discrete subset \( K = \{p,qi : p,q \in \mathbb{N}_0\} \) of the complex plane \( \mathbb{C} \). Then, we define the countable discrete subset

\[
K_G := \{A \cdot w : A \in G \text{ and } w \in K\} \subset \mathbb{C}.
\]

As the subset \( K_G \) is countable, then it can be thought as a sequence of different complex numbers \( Z = (z_k)_{k \in \mathbb{N}} \). Let us remark that by construction the sequence \( Z \) converges to infinity. In addition, the group \( G \) acts on the set \( K_G \) by matrix multiplication. Thus, the subset \( K_G \subset \mathbb{C} \) is invariant under the linear transformation \( T_A \), for each matrix \( A \) in \( G \).

Now, we take the infinite hyperelliptic curve \( S(f,m) \), where \( f \) is a Weierstrass of map associated to the sequence \( Z \). Given the set \( K_G \) is invariant under the linear transformation
$T_A$, for each matrix $A$ in $G$, for each matrix $A \in G$, then from the Theorem 2.1 it follows that $G < \Gamma(S(f,m))$.

A translate surface $S$ is called origami or square-tiled surface if $S$ is a branched cover of the standard square torus $T := \mathbb{C}/\mathbb{Z} \times \mathbb{Z}$ with branching cover exactly one point (for more details see e.g. [27 Section 2], [29 Section 1]). In the following example we shall show an infinite hyperelliptic curve as square-tiled surface such that it Veech group if $SL(2, \mathbb{Z})$.

**Example 2.3.** Let $\pi$ denote the natural projection map from the complex plane $\mathbb{C}$ to the standard square torus $T$. We consider the sequence of complex numbers $\mathbb{Z}$ conformed by all elements in additive group $\mathbb{Z} \times \mathbb{Z}$ and define the infinite hyperelliptic curve $S(f,m)$, where $f$ is the map of Weierstrass associated to the sequence $\mathbb{Z}$. Then the composition $p_z \circ \pi : S(f,m) \to \mathbb{T}$ (see equation (2)) is a branched covering of the standard square torus $T$, whose only branch point is the class $[0]$. We shall prove that the Veech group of the infinite hyperelliptic curve $S(f,m)$ is $SL(2, \mathbb{Z})$.

**Proof.** Given that the linear map $T_A$ preserves the elements of the additive group $\mathbb{Z} \times \mathbb{Z}$, for each each matrix $A$ of $SL(2, \mathbb{Z})$ (see [10 Theorem 3.4.2]), then by the Theorem 2.1 it follows that $SL(2, \mathbb{Z}) < \Gamma(S(f,m))$. Now, we take a matrix $A$ in the Veech group $\Gamma(S(f,m))$ and we shall prove that $A \in SL(2, \mathbb{Z})$. We remark that $\text{Hol}(S(f,m)) \subset \mathbb{Z} \times \mathbb{Z}$ and the complex numbers 1 and $i$ are holonomy vectors of $S(f,m)$. As $A \cdot 1$ and $A \cdot i$ are also holonomy vectors, then the coefficients of the matrix $A$ must be integers numbers.

In addition, the determinant of $A$ is equal to one because the infinite hyperelliptic curve $S(f,m)$ is a covering space of the torus $\mathbb{T}$. □
