Abstract

For a graph $G = (V, E)$, a restrained double Roman dominating function is a function $f : V \to \{0, 1, 2, 3\}$ having the property that if $f(v) = 0$, then the vertex $v$ must have at least two neighbors assigned 2 under $f$ or one neighbor $w$ with $f(w) = 3$, and if $f(v) = 1$, then the vertex $v$ must have at least one neighbor $w$ with $f(w) \geq 2$, and at the same time, the subgraph $G[V_0]$ which includes vertices with zero labels has no isolated vertex. The weight of a restrained double Roman dominating function $f$ is the sum $f(V) = \sum_{v \in V} f(v)$, and the minimum weight of a restrained double Roman dominating function on $G$ is the restrained double Roman domination number of $G$. We initiate the study of restrained double Roman domination with proving that the problem of computing this parameter is $NP$-hard. Then we present an upper bound on the restrained double Roman domination number of a connected graph $G$ in terms of the order of $G$ and characterize the graphs attaining this bound. We study the restrained double Roman domination versus the restrained Roman domination. Finally, we characterized all trees $T$ attaining the exhibited bound.

2010 Mathematical Subject Classification: 05C69

Keywords: Domination, restrained Roman domination, restrained double Roman domination.

1 Introduction

Throughout this paper, we consider $G$ as a finite simple graph with vertex set $V = V(G)$ and edge set $E = E(G)$. We use [15] as a reference for terminology and notation which are not explicitly

*Corresponding author
defined here. The open neighborhood of a vertex \( v \) is denoted by \( N(v) \), and its closed neighborhood is \( N[v] = N(v) \cup \{v\} \). The minimum and maximum degrees of \( G \) are denoted by \( \delta(G) \) and \( \Delta(G) \), respectively. Given subsets \( A, B \subseteq V(G) \), by \( [A, B] \) we mean the set of all edges with one end point in \( A \) and the other in \( B \). For a given subset \( S \subseteq V(G) \), by \( G[S] \) we represent the subgraph induced by \( S \) in \( G \). A tree \( T \) is a double star if it contains exactly two vertices that are not leaves. A double star with \( p \) and \( q \) leaves attached to each support vertex, respectively, is denoted by \( S_{p,q} \). A wounded spider is a tree obtained from subdividing at most \( n-1 \) edges of a star \( K_{1,n} \). A wounded spider obtained by subdividing \( t \leq n-1 \) edges of \( K_{1,n} \), is denoted by \( ws(1,n,t) \).

A set \( S \subseteq V(G) \) is called a dominating set if every vertex not in \( S \) has a neighbor in \( S \). The domination number \( \gamma(G) \) of \( G \) is the minimum cardinality among all dominating sets of \( G \). A restrained dominating set (RD set) in a graph \( G \) is a dominating set \( S \) in \( G \) for which every vertex in \( V(G) - S \) is adjacent to another vertex in \( V(G) - S \). The restrained domination number (RD number) of \( G \), denoted by \( \gamma_r(G) \), is the smallest cardinality of an RD set of \( G \). This concept was formally introduced in [4] (albeit, it was indirectly introduced in [5, 6]).

The variants of restrained domination have been already worked. For instance, a total restrained domination of a graph \( G \) is an RD set of \( G \) for which the subgraph induced by the dominating set of \( G \) has no isolated vertex, which can be referred to the [3]. Secure restrained dominating set (SRDS) which is a set \( S \subseteq V(G) \) for which \( S \) is restrained dominating and for all \( u \in V \setminus S \) there exists \( v \in S \cap N(u) \) such that \( (S \setminus \{v\}) \cup \{u\} \) is restrained dominating set [12].

The restrained Roman dominating function is a Roman dominating function \( f : V(G) \rightarrow \{0, 1, 2, 3\} \) such that the subgraph induced by the set \( \{v \in V(G) : f(v) = 0\} \) has no isolated vertex, [13]. The restrained Italian dominating function (RIDF) is an Italian dominating function \( f : V(G) \rightarrow \{0, 1, 2\} \) such that the subgraph induced by the set \( \{v \in V(G) : f(v) = 0\} \) has no isolated vertex, [14].

These results motivates us to consider a double Roman dominating function \( f \) for which the subgraph induced by \( V_0^f \) has no isolated vertex, which is the concept that we stand on it as new parameter namely restrained double Roman domination and will be investigated in this paper.

Beeler et al. (2016) [2] introduced the concept of double Roman domination of a graph. If \( f : V(G) \rightarrow \{0, 1, 2, 3\} \) is a function, then let \( \{V_0, V_1, V_2, V_3\} \) be the ordered partition of \( V(G) \) induced by \( f \), where \( V_i = \{v \in V(G) : f(v) = i\} \) for \( i = 0, 1, 2, 3 \). There is a 1-1 correspondence between the function \( f \) and the ordered partition \( \{V_0, V_1, V_2, V_3\} \). So we will write \( f = (V_0, V_1, V_2, V_3) \). A double Roman dominating function (DRD function for short) of a graph \( G \) is a function \( f : V(G) \rightarrow \{0, 1, 2, 3\} \) for which the following conditions are satisfied.

(a) If \( f(v) = 0 \), then the vertex \( v \) must have at least two neighbors in \( V_1 \) or one neighbor in \( V_3 \).

(b) If \( f(v) = 1 \), then the vertex \( v \) must have at least one neighbor in \( V_2 \cup V_3 \).

This parameter was also studied in [1], [9], [11] and [16].

Accordingly, a restrained double Roman dominating function (RDRD function for short) is a double Roman dominating function \( f : V \rightarrow \{0, 1, 2, 3\} \) having the property that: the subgraph induced by \( V_0 \) (the vertices with zero labels under \( f \)) \( G[V_0] \) has no isolated vertex. The restrained double Roman domination number (RDRD number) \( \gamma_{rRDRD}(G) \) is the minimum weight of an RDRD function \( f \) of \( G \). For the sake of convenience, an RDRD function \( f \) of a graph \( G \) with weight \( \gamma_{rRDRD}(G) \) is called a \( \gamma_{rRDRD}(G) \)-function.
This paper is organized as follows. We prove that the restrained double Roman domination problem is \(NP\)-hard even for general graphs. Then, we present an upper bound on the restrained double Roman domination number of a connected graph \(G\) in terms of the order of \(G\) and characterize the graphs attaining this bound. We study the restrained double Roman domination versus the restrained Roman domination. Finally, we characterize trees \(T\) by the given restrained double Roman domination number of \(T\).

2 Complexity and computational issues

We consider the problem of deciding whether a graph \(G\) has an \(RDRD\) function of weight at most a given integer. That is stated in the following decision problem. We shall prove the \(NP\)-completeness by reducing the following vertex cover decision problem, which is known to be \(NP\)-complete.

**VERTEX COVER DECISION PROBLEM**

**INSTANCE:** A graph \(G = (V,E)\) and a positive integer \(p \leq |V(G)|\).

**QUESTION:** Does there exist a subset \(C \subseteq V(G)\) of size at most \(p\) such that for each edge \(xy \in E(G)\) we have \(x \in C\) or \(y \in C\)?

**Theorem 1.** (Karp [10]) Vertex cover decision problem is \(NP\)-complete for general graphs.

**RISTRAINED DOUBLE ROMAN DOMINATION problem (RDRD problem)**

**INSTANCE:** A graph \(G\) and an integer \(p \leq |V(G)|\).

**QUESTION:** Is there an \(RDRD\) function \(f\) for \(G\) of weight at most \(p\)?

**Theorem 2.** The restrained double Roman domination problem is \(NP\)-complete for general graphs.

**Proof.** We transform the vertex cover decision problem for general graphs to the restrained double Roman domination decision problem for general graphs. For a given graph \(G = (V(G), E(G))\), let \(m = 3|V(G)| + 4\) and construct a graph \(H = (V(H), E(H))\) as follows. Let \(V(H) = \{x_i : 1 \leq i \leq m\} \cup \{y\} \cup V(G) \cup \{u_{ji} : 1 \leq i \leq m\}\) for each \(e_j \in E(G)\), and let

\[
E(H) = \{x_ix_{i+1} \mod m : 1 \leq i \leq m\} \\
\cup \{x_iy : 1 \leq i \leq m\} \cup \{vy : v \in V(G)\} \\
\cup \{vu_{ji} : v \text{ is the vertex of edge } e_j \in E(G) \text{ and } 1 \leq i \leq m\} \\
\cup \{u_{ji}u_{(i+1) \mod m} : 1 \leq i \leq m\}.
\]

Figure 1 shows the graph \(H\) obtained from \(G = P_4 = a_1a_2a_3a_4\) by the above procedure. Note that, since \(m = 3|V(G)| + 4 = 16\) for this example and \(G\) has three edges \(e_1, e_2, e_3\),

\[
H[\{x_i : 1 \leq i \leq 16\}] \cong H[\{u_1 : 1 \leq i \leq 16\}] \cong H[\{u_2 : 1 \leq i \leq 16\}] \cong H[\{u_3 : 1 \leq i \leq 16\}] \cong C_{16}
\]
Figure 1: The graph $G = P_4$ and $H$.

$y$ is adjacent to $x_i$ for $1 \leq i \leq 16$ and $a_l$ for $1 \leq l \leq 4$; $u_j$ is adjacent to both $a_j$ and $a_{j+1}$ for $1 \leq j \leq 3$ and $1 \leq i \leq 16$.

We claim that $G$ has a vertex cover of size at most $k$ if and only if $H$ has an RDRDF with weight at most $3k + 3$. Hence the NP-completeness of the restrained double Roman domination problem in general graphs will be equivalent to the NP-completeness of vertex cover problem. First, if $G$ has a vertex cover $C$ of size at most $k$, then the function $f$ defined on $V(G)$ by $f(v) = 3$ for $v \in C \cup \{y\}$ and $f(v) = 0$ otherwise, is an RDRDF with weight at most $3k + 3$. On the other hand, suppose that $g$ is an RDRDF on $H$ with weight at most $3k + 3$. If $g(y) \neq 3$, then there exist two cases.

Case 1. Let $g(y) \in \{0, 1\}$. Then

$$
\sum_{i=1}^{m} g(x_i) \geq \gamma_{rdR}(C_m) \geq \gamma_{dR}(C_m) \geq m > 3|V(G)| + 3 \geq 3k + 3
$$

that is a contradiction.

Case 2. Let $g(y) = 2$ and $C_m = \{x_i, x_{i+1} \mod m \mid 1 \leq i \leq m\}$. Then $g(C_m) \geq 2m/3 + 2k + 2 = 2(3|V(G)| + 4)/3 + 2k + 2 \geq 4k + 14/3 > 3k + 3$ which is a contradiction. Thus $g(y) = 3$. Similarly, we have $g(u) = 3$ or $g(v) = 3$ for any $e = uv \in E(G)$. Therefore $C = \{v \in V : g(v) = 3\}$ is a vertex cover of $G$ and $3|C| + 3 \leq w(g) \leq 3k + 3$. Consequently, $|C| \leq k$.

3 RDRD number of some graphs

In this section we investigate the exact value of the restrained double Roman domination number of some graphs.
Observation 3. For complete graph $K_n$ and complete bipartite graph $K_{m,n}$,

(i) $\gamma_{rdR}(K_n) = 3$ for $n \geq 2$.

(ii) $\gamma_{rdR}(K_{n,m}) = 6$ for $m, n \geq 2$.

(iii) $\gamma_{rdR}(K_{1,m}) = m + 2$.

(iv) $\gamma_{rdR}(K_{n_1,n_2,\ldots,n_m}) = \begin{cases} 3, & \text{if } \min\{n_1, n_2, \ldots, n_m\} = 1, \\ 6, & \text{otherwise.} \end{cases}$

Theorem 4. For a path $P_n$ ($n \geq 4$), $\gamma_{rdR}(P_n) = n + 2$.

Proof. Assume that $n \geq 4$ and $P_n = v_1v_2 \cdots v_n$. Define $h : V(P_n) \to \{0, 1, 2, 3\}$ by $h(v_{3i+2}) = 3$ for $0 \leq i \leq n/3 - 1$, $h(v_1) = h(v_n) = 1$ and $h(v) = 0$ otherwise, whenever $n \equiv 0 \pmod{3}$.

Define $h : V(P_n) \to \{0, 1, 2, 3\}$ by $h(v_{3i+1}) = 3$ for $0 \leq i \leq (n - 1)/3$ and $h(v) = 0$ otherwise, whenever $n \equiv 1 \pmod{3}$.

Define $h : V(P_n) \to \{0, 1, 2, 3\}$ by $h(v_{3i+2}) = 3$ for $0 \leq i \leq (n - 2)/3$, $h(v_1) = 1$ and $h(v) = 0$ otherwise, whenever $n \equiv 2 \pmod{3}$. Therefore $\gamma_{rdR}(P_n) \leq n + 2$ for $n \geq 4$.

Now we prove the inverse inequality. It is straightforward to verify that $\gamma_{rdR}(P_n) = n + 2$ for $4 \leq n \leq 6$. For $n \geq 7$ we proceed by induction on $n$. Let $n \geq 7$ and let the inverse inequality be true for every path of order less than $n$. Assume that $f = (V_0, V_1, V_2, V_3)$ is a $\gamma_{rdR}$-function of $P_n$.

It is well known that $f(v_n) \neq 0$. If $f(v_n) = 1$, then $f(v_{n-1}) \geq 2$. Define $g : P_{n-1} \to \{0, 1, 2, 3\}$, $g(v_i) = f(v_i)$ for $1 \leq i \leq n - 1$. Clearly, $g$ is an RDRD-function of $P_{n-1}$. It follows from the induction hypothesis that

$$\gamma_{rdR}(P_n) = w(f) = w(g) + 1 \geq \gamma_{rdR}(P_{n-1}) + 1 \geq (n - 1) + 2 + 1 \geq n + 2.$$ 

If $f(v_n) = 2$, then $f(v_{n-1}) = 1$ and $f(v_{n-2}) \geq 1$. Define $g : P_{n-2} \to \{0, 1, 2, 3\}$, $g(v_i) = f(v_i)$ for $1 \leq i \leq n - 2$. Clearly, $g$ is a RDRD-function of $P_{n-2}$. As above we obtain,

$$\gamma_{rdR}(P_n) = w(f) = w(g) + 3 \geq \gamma_{rdR}(P_{n-2}) + 3 \geq (n - 2) + 2 + 3 = n + 3.$$ 

If $f(v_n) = 3$, then $f(v_{n-1}) = 0$, $f(v_{n-2}) = 0$ and $f(v_{n-3}) = 3$. Define $g : P_{n-3} \to \{0, 1, 2, 3\}$, $g(v_i) = f(v_i)$ for $1 \leq i \leq n - 3$. Clearly, $g$ is a RDRD-function of $P_{n-3}$. It also follows from the induction hypothesis that

$$\gamma_{rdR}(P_n) = w(f) = w(g) + 3 \geq \gamma_{rdR}(P_{n-3}) + 3 \geq (n - 3) + 2 + 3 = n + 2.$$ 

Thus the proof is complete.

\[ \square \]

Theorem 5. For a cycle $C_n$, $(n \geq 3)$, $\gamma_{rdR}(C_n) = \begin{cases} n, & \text{if } n \equiv 0 \pmod{3}, \\ n + 2, & \text{otherwise.} \end{cases}$
Proof. Assume that \( n \geq 3 \) and \( C_n = v_1v_2 \cdots v_nv_1 \). Define \( h : V(C_n) \to \{0, 1, 2, 3\} \) by \( h(v_3i) = 3 \) for \( 1 \leq i \leq n/3 \) and \( h(v) = 0 \) otherwise, whenever \( n \equiv 0 \pmod{3} \).

Define \( h : V(C_n) \to \{0, 1, 2, 3\} \) by \( h(v_{3i+1}) = 3 \) for \( 0 \leq i \leq (n-1)/3 \) and \( h(v) = 0 \) otherwise, whenever \( n \equiv 1 \pmod{3} \).

Define \( h : V(C_n) \to \{0, 1, 2, 3\} \) by \( h(v_{3i+2}) = 3 \) for \( 0 \leq i \leq (n-2)/3 \), \( h(v_1) = 1 \) and \( h(v) = 0 \) otherwise, whenever \( n \equiv 2 \pmod{3} \). Therefore

\[
\gamma_{rdR}(C_n) \leq \begin{cases} 
  n, & \text{if } n \equiv 0 \pmod{3}, \\
  n+2, & \text{otherwise}.
\end{cases}
\]

Now we prove the inverse inequality. For \( n \equiv 0 \pmod{3} \), since \( \gamma_{rdR}(C_n) \geq \gamma_{dR}(C_n) = n \), (see [1, 2]), clearly the result holds. Let \( n \equiv 0 \pmod{3} \) and let \( f = (V_0, V_1, V_2, V_3) \) be a \( \gamma_{rdR} \)-function of \( C_n \). Since the neighbor of vertex of weight 0 is a vertex of weight 3 and a vertex of weight 0, if \( n \neq 0 \pmod{3} \), there are two adjacent vertices \( v_i, v_{i+1} \) in \( C_n \) such that their weights are positive. Now, if \( f(v_i) \geq 2 \) and \( f(v_{i+1}) \geq 2 \), then by removing the edge \( v_iv_{i+1} \), the resulted graph is \( P_n \).

Define \( g : P_n \to \{0, 1, 2, 3\} \), \( g(v_i) = f(v_i) \) for \( 1 \leq i \leq n \). Clearly, \( g \) is an RDRD-function of \( P_n \) with \( w(g) = w(f) \). Since \( w(g) \geq n+2 \) then \( w(f) \geq n+2 \).

Let \( f(v_i) \geq 2 \) and \( f(v_{i+1}) = 1 \). Then \( f(v_{i+2}) = 1 \). Now remove the edge \( v_{i+1}v_{i+2} \) and obtain a \( P_n \). Define \( g : P_n \to \{0, 1, 2, 3\} \), \( g(v_i) = f(v_i) \) for \( 1 \leq i \leq n \). Clearly, \( g \) is an RDRD-function of \( P_n \) with \( w(g) = w(f) \). Thus \( w(f) \geq n+2 \).

Let \( f(v_i) = f(v_{i+1}) = 1 \). As above, we remove the edge \( v_iv_{i+1} \) and the resulted graph \( P_n \) has an RDRD-function \( g \) of weight at least \( w(f) \). That is \( w(f) \geq n+2 \). Therefore the proof is complete.

\[\square\]

4 Upper bounds on the RDRD number

In this section we obtain sharp upper bounds on the restrained double Roman domination number of a graph.

**Proposition 6.** Let \( G \) be a connected graph of order \( n \geq 2 \). Then \( \gamma_{rdR}(G) \leq 2n-1 \), with equality if and only if \( n = 2 \).

*Proof.* If \( w \) is a vertex of \( G \), then define the function \( f \) by \( f(w) = 1 \) and \( f(x) = 2 \) for \( x \in V(G) \setminus \{w\} \).

Since \( G \) is connected of order \( n \geq 2 \), we observe that \( f \) is an RDRD function of \( G \) of weight \( 2n-1 \) and thus \( \gamma_{rdR}(G) \leq 2n-1 \). If \( n \geq 3 \), then \( G \) contains a vertex \( w \) with at least two neighbors \( u \) and \( v \). Now define the function \( g \) by \( g(u) = g(v) = 1 \) and \( g(x) = 2 \) for \( x \in V(G) \setminus \{u, v\} \).

Then \( g \) is an RDRD function of \( G \) of weight \( 2n-2 \) and so \( \gamma_{rdR}(G) \leq 2n-2 \) in this case. Since \( \gamma_{rdR}(K_2) = 3 = 2 \cdot 2 - 1 \), the proof is complete.

\[\square\]

**Proposition 7.** Let \( G \) be a connected graph of order \( n \geq 2 \). Then \( \gamma_{rdR}(G) \leq 2n + 1 - \text{diam}(G) \) and this bound is sharp for the path \( P_n \) \((n \geq 4)\).

*Proof.* By Theorem 4, \( \gamma_{rdR}(P_n) \leq n+2 \). Let \( P = v_1v_2 \cdots v_{\text{diam}(G)+1} \) be a diametrical path in \( G \). Let \( g \) be a \( \gamma_{rdR} \)-function of \( P \). Then \( w(g) \leq \text{diam}(G) + 3 \). Now we define an RDRD-function \( f \) as:

\[
f(x) = \begin{cases} 
  2, & x \notin V(P), \\
  g(x), & \text{otherwise}.
\end{cases}
\]
It is clear that \( f \) is an RDRD-function of \( G \) of weight \( w(f) \leq 2(n - (\text{diam}(G) + 1)) + \text{diam}(G) + 3 \). Therefore \( \gamma_{rdr}(G) \leq 2n + 1 - \text{diam}(G) \).

Theorem 4 shows the sharpness of this bound.

**Proposition 8.** Let \( G \) be a connected graph of order \( n \) and circumference \( c(G) < \infty \). Then \( \gamma_{rdr}(G) \leq 2n + 2 - c(G) \), and this bound is sharp for each cycle \( C_n \) with \( 3 \mid n \).

**Proof.** Let \( C \) be a longest cycle of \( G \), that means \( |V(C)| = c(G) \). By Theorem 5, \( \gamma_{rdr}(C) \leq c(G) + 2 \). Let \( h \) be a \( \gamma_{rdr} \)-function on \( C \). Then \( w(h) \leq c(G) + 2 \). Now we define an RDRD-function \( f \) as:

\[
  f(x) = \begin{cases} 
    2, & x \notin V(C), \\
    h(x), & \text{otherwise}.
  \end{cases}
\]

It is clear that \( f \) is an RDRD-function of \( G \) of weight \( w(f) \leq 2(n - c(G)) + c(G) + 2 \). Therefore \( \gamma_{rdr}(G) \leq 2n + 2 - c(G) \).

For sharpness, if \( G = C_n \) and \( 3 \mid n \), then \( \gamma_{rdr}(C_n) = n + 2 = 2n + 2 - n = 2n + 2 - c(G) \).

**Observation 9.** Let \( G \) be a graph and \( f = (V_0, V_1, V_2) \) a \( \gamma_r \)-function of \( G \). Then \( \gamma_{rdr}(G) \leq 2|V_1| + 3|V_2| \).

**Proof.** Let \( G \) be a graph and \( f = (V_0, V_1, V_2) \) a \( \gamma_r \)-function of \( G \). We define a function \( g = (V'_0, V'_2, V'_3) \) as follows: \( V'_0 = V_0, V'_2 = V_1, V'_3 = V_2 \). Note that under \( g \), every vertex with a label 0 has a neighbor assigned 3 and each vertex with label 1 becomes a vertex with label 2 and also \( G[V'_0] \) has no isolated vertex. Hence, \( g \) is a restrained double Roman dominating function. Thus, \( \gamma_{rdr}(G) \leq 2|V'_2| + 3|V'_3| = 2|V_1| + 3|V_2| \).

Clearly, the bound of observation 9 is sharp, as can be seen with the path \( G = P_4 \), where \( \gamma_r(G) = 4 \) and \( \gamma_{rdr}(G) = 6 \). We also note that strict inequality in the bound can be achieved by the subdivided star \( G = S(K_{1,k}) \) which formed by subdividing each edge of the star \( K_{1,k} \), for \( k \geq 3 \), exactly once. Then it is simple to check that \( \gamma_{rdr}(G) = 2k + 1 \) and \( \gamma_{rdr}(G) = 3k \). Hence, \( |V_1| = 1 \) and \( |V_2| = k \), and so, \( 3k = \gamma_{rdr}(G) < 2|V_1| + 3|V_2| = 2 + 3k \).

**Lemma 10.** If a graph \( G \) has a non-pendant edge, then there is a \( \gamma_{rdr}(G) \)-function \( f = (V_0, V_1, V_2, V_3) \) such that \( V_0 \cup V_1 \neq \emptyset \).

**Proof.** If \( \gamma_{rdr}(G) < 2n \), then obviously \( V_0 \cup V_1 \neq \emptyset \). Now we show that \( \gamma_{rdr}(G) < 2n \). Let \( uw \) be a non-pendant edge with \( \text{deg}(u) \) and \( \text{deg}(w) \) be at least 2.

Assume that \( N_G(u) \cap N_G(w) \neq \emptyset \), and let \( v \) be a vertex in \( N_G(u) \cap N_G(w) \). Then the function \( f = (V_0 = \{u, w\}, V_1 = \emptyset, V_2 = V(G) \setminus \{u, w, v\}, V_3 = \{v\}) \) is an RDRD-function of \( G \) with \( w(f) \leq 2n - 3 \).

Assume that \( N_G(u) \cap N_G(w) = \emptyset \), and let \( a \in N_G(u) \setminus \{w\} \) and \( b \in N_G(w) \setminus \{u\} \). Then the function \( f = (V_0 = \{u, w\}, V_1 = \emptyset, V_2 = V(G) \setminus \{u, w, a, b\}, V_3 = \{a, b\}) \) is an RDRD-function of \( G \) with \( w(f) \leq 2n - 2 \). This completes the proof. All in all the proof is complete.
For any integer \( n \geq 3 \), let \( H_n \) be the graph obtained from \( (n-2)/2 \) copies of \( K_2 \) and a copy of \( K_1 \) by adding a new vertex and joining it to both leaves of each \( K_2 \) and the given \( K_1 \), and let \( F_n \) be the graph obtained from \( (n-2)/2 \) copies of \( K_2 \) by adding a new vertex and joining it to both leaves of each \( K_2 \). Thus for \( n \geq 4 \), \( H_n \) have a vertex of degree \( n-1 \), a vertex of degree 1 and other vertices of degree two and for \( n \geq 3 \), \( F_n \) have a vertex of degree \( n-1 \) and other vertices of degree two. Figure 2 shows the graph \( H_{10} \) and \( F_9 \). Let \( \mathcal{H} = \{ H_n : n \geq 4 \text{ is even} \} \) and \( \mathcal{F} = \{ F_n : n \geq 3 \text{ is odd} \} \).

**Theorem 11.** For every connected graph \( G \) of order \( n \geq 3 \) with \( m \) edges, \( \gamma_{rdR}(G) \geq 2n + 1 - [(4m - 1)/3] \), with equality if and only if \( G \in \mathcal{H} \cup \mathcal{F} \) or \( G \in \{ K_{1,2}, K_{1,3}, K_{1,4} \} \).

**Proof.** If \( G = K_{1,n-1} \) is a star, then \( \gamma_{rdR}(G) = n+1 \) and \( m = n-1 \). Now it is easy to see that \( \gamma_{rdR}(K_{1,n-1}) = 2n + 1 - [(4m - 1)/3] \) for \( 3 \leq n \leq 5 \) and \( \gamma_{rdR}(K_{1,n-1}) > 2n + 1 - [(4m - 1)/3] \) for \( n \geq 6 \). Next assume that \( G \) is not a star. By Lemma 10 there is a \( \gamma_{rdR}(G) \)-function of \( f = (V_0, V_1, V_2, V_3) \) such that \( V_0 \cup V_1 \neq \emptyset \). It is well known that, the induced subgraph \( G[V_0] \) has no isolated vertex. Therefore, \( |E(G[V_0])| \geq |V_0|/2 \). Let \( V'_0 = \{ v \in V_0 : N(v) \subseteq V_2 \} \) and \( V''_0 = \{ v \in V_0 : v \text{ has a neighbor in } V_3 \} \). Then \( |E(V_0, V_2)| \geq 2|V'_0|, |E(V_0, V_3)| \geq |V''_0| \) and \( |E(V_1, V_2 \cup V_3)| \geq |V_1| \). Therefore

\[
|E(G)| = m \geq |V_0|/2 + 2|V'_0| + |V''_0| + |V_1|.
\]

Since \( |V_0| = |V'_0| + |V''_0| \), we deduce that

\[
(4m - 1)/3 \geq 2|V'_0| + 4/3|V''_0| + 4/3|V_1| - 1/3 \tag{1}
\]

and thus

\[
2n + 1 - [(4m - 1)/3] \leq 2n + 1 - (4m - 1)/3 \leq 2n + 1 - 2|V_0| - 4/3|V''_0| - 4/3|V_1| + 1/3. \tag{2}
\]

Since \( \gamma_{rdR}(G) = |V_1| + 2|V_2| + 3|V_3|, |V_0| + |V_1| + |V_2| + |V_3| = n \) and \( 2n + 1 = 2|V_0| + 2|V_1| + 2|V_2| + 2|V_3| + 1 \), we obtain

\[
2n + 1 - 2|V_0| - 4/3|V'_0| - 4/3|V_1| + 1/3 = -4/3|V'_0| + 2/3|V_1| + 2|V_2| + 2|V_3| + 4/3 = \gamma_{rdR}(G) - 4/3|V'_0| - 1/3|V_1| - |V_3| + 4/3. \tag{3}
\]

Next we will show that

\[
\gamma_{rdR}(G) - 4/3|V'_0| - 1/3|V_1| - |V_3| + 4/3 \leq \gamma_{rdR}(G) \]

Figure 2: The graph \( H_{10}, F_9 \).
or $\gamma_{rdR}(G) \geq 2n + 1 - \left[(4m - 1)/3\right]$. If $|V_0''| \geq 1$, then $-4/3|V_0''| - 1/3|V_1| - |V_3| + 4/3 \leq 0$ and so $\gamma_{rdR}(G) - 4/3|V_0''| - 1/3|V_1| - |V_3| + 4/3 \leq \gamma_{rdR}(G)$. Let now $|V_0''| = 0$. Note that the condition $V_0 \cup V_1 \neq \emptyset$ implies $V_0'' \cup V_1 \neq \emptyset$.

Assume next that $V_1 = \emptyset$. We deduce that $|V_0''| \geq 1$ and therefore $|V_3| \geq 1$. If there are at least two vertices of weight 3, then $\gamma_{rdR}(G) - 4/3|V_0''| - 1/3|V_1| - |V_3| + 4/3 \leq \gamma_{rdR}(G)$. If there is only one vertex of weight 3, then $\gamma_{rdR}(G) - 4/3|V_0''| - 1/3|V_1| - |V_3| + 4/3 \leq \gamma_{rdR}(G)$. Now assume that $|V_3| = 0$. This implies that all vertices have weight 1 or 2. If $3 \leq n \leq 5$, then it is easy to see that $\gamma_{rdR}(G) > 2n + 1 - \left\lceil \frac{4m - 1}{3} \right\rceil$. Let now $n \geq 6$. If $|V_1| \geq 5$, then $\gamma_{rdR}(G) - 4/3|V_0''| - 1/3|V_1| - |V_3| + 4/3 \leq \gamma_{rdR}(G)$. Otherwise $|V_1| \leq 4$, $|V_2| \geq n - 4$ and $m \geq n - 1$. This implies

$$\gamma_{rdR}(G) \geq 2(n - 4) + 4 = 2n - 4 > 2n + 1 - \left\lceil \frac{4(n - 1) - 1}{3} \right\rceil \geq 2n + 1 - \left\lceil \frac{4m - 1}{3} \right\rceil.$$ 

Thus $\gamma_{rdR}(G) \geq 2n + 1 - (4m - 1)/3 \geq 2n + 1 - (4m - 1)/3$. For equality: If $G \in \mathcal{H}$, then $G = H_n$ for $n \geq 4$ even and $|E(H_n)| = (3n - 2)/2 + 1$. Thus $2n + 1 - [(4(3(n - 2)/2 + 1) - 1)/3] = 2n + 1 - [(4(3(n - 2)/2 + 1) - 1)/3] = 2n + 1 - (2n - 2) - 1 = 4 = \gamma_{rdR}(H_n)$. If $G \in \mathcal{F}$, then $G = F_n$ for $n \geq 3$ odd and $|E(F_n)| = (3n - 1)/2$. Thus $2n + 1 - [(4(3(n - 1)/2)) - 1/3] = 2n + 1 - (2n - 1) = 3 = \gamma_{rdR}(F_n)$.

Conversely, assume that $\gamma_{rdR}(G) = 2n + 1 - [(4m - 1)/3]$. Then all inequalities occurring in the proof become equalities. In the case $|V_1| = 0$, we have seen above that we have equality if and only if $G \in \mathcal{F}$. In the case $|V_1| \geq 1$, we have seen above that $|V_3| \geq 1$. Therefore the equality in Inequality (3) leads to $|V_3| = |V_1| = 1$ and $|V_0''| = 0$. Hence $V_0 = V_0''$. Thus equality in Inequality (1) or equivalently, in the inequality $|E(G)| = m \geq |V_0|/2 + 2|V_0''| + |V_0''| + |V_1|$ leads to $m = 3/2|V_0''| + 1$. Now let the vertices $v, u$ be of weight 3, 1 respectively. Then $m = |E(G)| \geq |E(v, V_0'')| + G[V_0''] + 1 \geq |V_0''| + 1/2|V_0''| + 1 = 3/2|V_0''| + 1$. If $|V_2| \neq 0$, then the connectivity of $G$ leads to the contradiction $m \geq 3/2|V_0''| + 2$. Consequently, $|V_2| = 0$, $|V_0| = (2m - 2)/3$ and $u$ and $v$ are adjacent. Since $G$ is connected, $G \in \mathcal{H}$.

\[\Box\]

5 \textbf{RDRD-set versus RRD-set}

One of the aim of studying these parameters is that to see the related between them and compare each together.

**Proposition 12.** For any graph $G$, $\gamma_{rdR}(G) \leq 2\gamma_{R}(G)$ with equality if and only if $G = K_n$. 

9
Proof. Let \( f = (V_0, V_1, V_2) \) be a \( \gamma_{rR} \)-function of \( G \). Since \( \gamma_{rR}(G) = |V_1| + 2|V_2| \), by Observation 9, we have that \( \gamma_{rdR}(G) \leq 2|V_1| + 3|V_2| = \gamma_{rR}(G) + |V_1| + |V_2| \leq 2\gamma_{rR}(G) \). If \( \gamma_{rdR}(G) = 2\gamma_{rR}(G) = 2|V_1| + 4|V_2| \), then since \( \gamma_{rdR}(G) \leq 2|V_1| + 3|V_2| \), we must have \( V_2 = \emptyset \). Hence, \( V_0 = \emptyset \) must hold, and so \( V = V_1 \). By definition of \( \gamma_{rR} \)-function, we deduce that no two vertices in \( G \) are adjacent, for otherwise, if \( u \) and \( v \) are adjacent, then only one of them in every \( \gamma_{rdR} \)-function on \( G \) has a label of 2 which contradicts with \( \gamma_{rdR}(G) = 2\gamma_{rR}(G) \).

The proof of Lemma 10 shows the next proposition.

**Proposition 13.** If \( G \) contains a triangle, then \( \gamma_{rdR}(G) \leq 2n - 3 \).

**Theorem 14.** For every graph \( G \), \( \gamma_{rR}(G) < \gamma_{rdR}(G) \).

**Proof.** Let \( f = (V_0, V_1, V_2, V_3) \) be a \( \gamma_{rdR}(G) \)-function. If \( V_3 \neq \emptyset \), then \( (V'_0 = V_0, V'_1 = V_1, V'_2 = V_2 \cup V_3) \) is an RRD-function \( g \) such that \( w(g) < w(f) \). Let \( V_3 = \emptyset \). If \( V_0 = \emptyset \), then, since \( V_2 \neq \emptyset \), \( g = (\emptyset, V'_1 = V_1 \cup V_2, \emptyset) \) is an RRD-function such that \( w(g) < w(f) \). If \( V_0 \neq \emptyset \), then \( |V_2| \geq 2 \). Let \( f(v) = 2 \) for a vertex \( v \). Then \( g = (V'_0 = V_0, V'_1 = V_1 \cup \{v\}, V'_2 = V_2 - \{v\}) \) is an RRD-function \( g \) for which \( w(g) < w(f) \). Therefore \( \gamma_{rR}(G) < \gamma_{rdR}(G) \).

As an immediate consequence of Proposition 12, we have.

**Corollary 15.** For any nontrivial connected graph \( G \), \( \gamma_{rdR}(G) < 2\gamma_{rR}(G) \).

**Theorem 16.** Let \( G \) be a graph of order \( n \). Then \( \gamma_{rdR}(G) = \gamma_{rR}(G) + 1 \) if and only if \( G \) is one of the following graphs.

1. \( G \) has a vertex of degree \( n - 1 \).
2. There exists a subset \( S \) of \( V(G) \) such that:\n   1. every vertex of \( V - S \) is adjacent to a vertex in \( S \),
   2. there are two subsets \( A_0 \) and \( A_1 \) of \( V - S \) with \( A_0 \cup A_1 = V - S \) such that \( A_0 \) is the set of non-isolated vertices in \( N(S) \) and each vertex in \( A_0 \) has at least two neighbors in \( S \),
   3. for any 2-subset \( \{a, b\} \) of \( S \), \( N(\{a, b\}) \cup A_0 \neq \emptyset \) and for a 3-subset \( \{x, y, z\} \) of \( S \), if \( \{x, y, z\} \cap A_0 \neq \emptyset \), then there are three vertices \( u, v, w \) in \( A_0 \) such that \( N(u) \cup S = \{x, y\}, N(v) \cup S = \{x, z\} \) and \( N(w) \cup S = \{y, z\} \).

**Proof.** Let \( \gamma_{rdR}(G) = \gamma_{rR}(G) + 1 \) with a \( \gamma_{rdR}(G) \)-function \( f = (V_0, V_1, V_2, V_3) \) and a \( \gamma_{rR}(G) \)-function \( g = (U_0, U_1, U_2) \). If \( V_3 \neq \emptyset \), then \( |V_3| = 1 \). Because if \( |V_3| \geq 2 \) then by changing 3 to 2 we obtain a RRD-function \( h \) with \( w(h) < w(g) \), a contradiction. Let \( V_3 = \{v\} \). In addition, we note that \( |V_2| = 0 \). If we suppose that \( |V_2| \geq 1 \), then let \( u \in V_2 \). Then \( h = (V'_0 = V_0, V'_1 = V_1 \cup \{u\}, V'_2 = V_2 \cup \{v\}) \) is an RRD-function \( g \) for which \( w(h) < w(g) \), a contradiction. Thus all vertices different from \( v \) are adjacent to the vertex \( v \) such that the non-isolated vertices in \( N(v) \) are assigned with 0 and the isolated vertices in \( N(v) \) are assigned with 1. In this case \( U_0 = V_0, U_1 = V_1 \) and \( U_2 = V_3 \).

If \( V_3 = \emptyset \), then \( V_2 \neq \emptyset \) and \( |V_2| \geq 2 \). In this case, there must exist a vertex \( v \in V_2 \) such that \( U_0 = V_0, U_1 = V_1 \cup \{v\} \) and \( U_2 = V_2 - \{v\} \). There is such a function \( f \) if we guarantee a subset \( S \) of \( V(G) \) with each vertex of weight 2 for which every other vertex in \( V - S \) has to adjacent to
a vertex of $S$, that is the condition 2.1 holds.
Since we can only change one of vertices of weight 2 in $f$ to a vertex of weight 1 in $g$, there must be existed two subsets $A_0$ and $A_1$ in $V - S$ such that the conditions 2.2 and 2.3 hold.

Conversely, if the condition 1 holds, then $f = (V_0, V_1, \emptyset, V_3 = \{v\})$ and $g = (U_0 = V_0, U_1 = V_1, U_2 = \{v\})$ are $\gamma_{rdR}(G)$-function and $\gamma_{R}(G)$-function respectively where $V_0$ is the set of non-isolated vertices in $N(v)$ and $V_1$ is the set of isolated vertices in $N(v)$. Thus $\gamma_{rdR}(G) = \gamma_{R}(G) + 1$.
If the condition 2 holds, then we can have only one vertex of weight 2 in $G$ under $f$ such that it changes to the weight 1 in $G$ under $g$. Thus $\gamma_{rdR}(G) = \gamma_{R}(G) + 1$.

We showed that for any graph $G$, $\gamma_{rdR}(G) \leq 2\gamma_{R}(G)$ and the equality holds if and on if $G$ is a trivial graph $\overline{K_n}$. Hence, for any nontrivial graph $G$, $\gamma_{rdR}(G) \leq 2\gamma_{R}(G) - 1$. Now we characterise graph $G$ with this property $\gamma_{rdR}(G) = 2\gamma_{R}(G) - 1$.

**Theorem 17.** If $G$ is a nontrivial graph, then $\gamma_{rdR}(G) \leq 2\gamma_{R}(G) - 1$. If $\gamma_{rdR}(G) = 2\gamma_{R}(G) - 1$, then $G$ consists of a $K_2$ and $n - 2$ isolated vertices or $G$ consists of a vertex $h$ and two disjoint vertex sets $H$ and $R$ such that $H = N(h)$, $G[H]$ does not have isolated vertices, $G[R]$ is trivial, there is no edge between $h$ and $R$ and $N(h) \cap N(R) \neq \emptyset$.

**Proof.** Since $G$ is a nontrivial graph, Proposition 12 implies $\gamma_{rdR}(G) \leq 2\gamma_{R}(G) - 1$. Now we investigate the equality.
Let $U_1, U_2$ is a $\gamma_{rdR}(G)$-function. Then $U_1 = U_2 = 1$, and therefore $V[1] = 2|U_1| + 2|U_2| + 3|V_3|$. On the other hand, since $2|U_1| + 4|U_2| - 1 = |V_1| + 2|V_2| + 3|V_3| = \gamma_{rdR}(G) \leq 2|U_1| + 3|U_2|$, it follows that $|U_2| \leq 1$.

If $U_2 = \emptyset$, then $|U_0| = 0$ and therefore $|U_1| = n$. Using the inequality above, we obtain

$$2n - 1 = 2|U_1| - 1 \leq \gamma_{rdR}(G) \leq 2|U_1| = 2n.$$ 

If $\gamma_{rdR}(G) + 2 = 2n$, then $G$ is trivial, a contradiction. If $\gamma_{rdR}(G) = 2n - 1$, then Proposition 6 shows that $G$ consists of a $K_2$ and $n - 2$ isolated vertices.

Let now $|U_2| = 1$ such that $U_2 = \{h\}$, $H = N(h)$, $R = V(G) \setminus N[h] = \{u_1, u_2, \ldots, u_p\}$. Clearly, $U_0 \subseteq H$ and $R \subseteq U_1$.

If $H$ contains exactly $s \geq 1$ isolated vertices, then $\gamma_{R}(G) = 2 + s + p$ and therefore $\gamma_{rdR}(G) \leq 3 + s + 2p \leq 2\gamma_{R}(G) - 2$, a contradiction. Hence $H = N(h)$ does not contain isolated vertices and thus $\gamma_{R}(G) = p + 2$.

If $G[R]$ contains an edge, then we obtain the contradiction $\gamma_{rdR}(G) \leq 3 + 2p - 1 = 2p + 2 \leq 2\gamma_{R}(G) - 2$. Thus $G[R]$ is trivial.

If there is an edge between $h$ and $R$, then we also obtain the contradiction $\gamma_{rdR}(G) \leq 3 + 2p - 1 = 2p + 2 \leq 2\gamma_{R}(G) - 2$.

If $N(h) \cap N(R) = N(h)$, then $f = (H, \emptyset, \{h\} \cup R, \emptyset)$ is an RDRD function of $G$, and hence $\gamma_{rdR}(G) \leq 2p + 2 \leq 2\gamma_{R}(G) - 2$, a contradiction.

6 Trees

In this section we study the restrained double Roman domination of trees.
Theorem 18. If $T$ is a tree of order $n \geq 2$, then $\gamma_{rdR}(T) \leq \lceil \frac{3n-1}{2} \rceil$. The equality holds if $T \in \{P_2, P_3, P_4, P_5, S_{1,2}, ws(1,n,n-1), ws(1,n,n-2)\}$.

Proof. Let $T$ be a tree of order $n \geq 2$. We will proceed by induction on $n$. If $n = 2$, then $\gamma_{rdR}(T) = 3 = \lceil \frac{3n-1}{2} \rceil$. If $n \geq 3$ and $\gamma_{rdR}(T) = n + 1 \leq \lceil \frac{3n-1}{2} \rceil$. If $\gamma_{rdR}(T) = 3$, then $T$ is a double star $S_{r,s}$ for $1 \leq r \leq s$. Hence, $n = r + s + 2 \geq 3$. If $r = 1$, $s = 4$, then $T = P_4$ and $\gamma_{rdR}(T) = 6 \leq \lceil \frac{12}{2} \rceil$. If $r = 1, s \geq 2$, then $n = s + 3$ and $\gamma_{rdR}(T) = s + 5 \leq \lceil \frac{3(s+3)-1}{2} \rceil$. If $r \geq 2, s \geq 2$, then $n = r + s + 2$ and $\gamma_{rdR}(T) = r + s + 4 \leq \lceil \frac{3(r+s+2)-1}{2} \rceil$.

Hence, we may assume that $diam(T) \geq 4$. This implies that $n \geq 5$. Assume that any tree $T'$ with order $2 \leq n' < n$ has $\gamma_{rdR}(T') \leq \lceil \frac{3n' - 1}{2} \rceil$. Among all longest paths in $T$, choose $P$ to be one that maximizes the degree of its next-to-last vertex $v$, and let $w$ be a leaf neighbor of $v$. Note that by our choice of $v$, every child of $v$ is a leaf. Since $\deg(v) \geq 2$, the vertex $v$ has at least one leaf as a child. Now we put $T' = T - T_v$ where the order of the substar $T_v$ is $k + 1$ with $k \geq 1$. Note that since $diam(T) \geq 4$, $T'$ has at least three vertices, that is, $n' \geq 3$. Let $f'$ be a $\gamma_{rdR}$-function of $T'$. Form $f'$ from $f$ by letting $f(x) = f'(x)$ for all $x \in V(T')$, $f(v) = 2$, and $f(z) = 1$ for all leaf neighbors of $v$. Thus $f$ is a restrained double Roman dominating function of $T$, implying that $\gamma_{rdR}(T) \leq \gamma_{rdR}(T') + k + 2 \leq \lceil \frac{3(n - k - 1) - 1}{2} \rceil + k + 2 = \lceil \frac{3n - k}{2} \rceil \leq \lceil \frac{3n - 1}{2} \rceil$.

If $T \in \{P_2, P_3, P_4, P_5, S_{1,2}, ws(1,n,n-1), ws(1,n,n-2)\}$, then clearly $\gamma_{rdR}(T) = \lceil \frac{3n - 1}{2} \rceil$. \hfill $\square$

Theorem 19. For every tree $T$ of order $n \geq 3$, with $l$ leaves and $s$ support vertices, we have $\gamma_{rdR}(T) \leq \frac{4n + 2s - l}{3}$, and this bound is sharp for the family of stars $(K_{1,n-1} n \geq 3)$, double stars, caterpillars for which each vertex is a leaf or a support vertex and all support vertices have even degree $2m$ or at most two end support vertices has degree $2m - 1$ and the other support vertices has degree $2m$, wounded spiders in which the central vertex is adjacent with at least two leaves.

Proof. Let $T$ be a tree with order $n \geq 3$. Since $n \geq 3$, $diam(T) \geq 2$. If $\gamma_{rdR}(T) = 3$, then $T$ is the star $K_{1,n-1}$ for $n \geq 3$ and $\gamma_{rdR}(T) = n + 1 \leq \frac{4n + 2 - (n - 1)}{3} = \frac{3n + 3}{3} = n + 1$. If $\gamma_{rdR}(T) = 3$, then $T$ is a double star $S_{r,t}$ for $1 \leq r \leq t$. We have $\gamma_{rdR}(T) = n + 2 = \frac{4n + 2s - l}{3}$. Hence, we may assume $diam(T) \geq 4$. Thus, $n \geq 5$. Assume that any tree $T'$ with order $3 \leq n' < n$, $l'$ leaves and $s'$ support vertices has $\gamma_{rdR}(T') \leq \frac{4n' + 2s' - l'}{3}$. Among all longest paths in $T$, choose $P$ to be one that maximizes the degree of its next-to-last vertex $u$, and let $x$ be a leaf neighbor of $u$, $w$ be a parent vertex of $v$ and $v$ be a parent vertex of $u$. Note that by our choice of $u$, every child of $u$ is a leaf. Since $t = \deg(u) \geq 2$, the vertex $u$ has at least one leaf children. We now consider the two cases as follows:

Case 1. $\deg(v) \geq 3$. In this case, we put $T' = T - T_u$, where the order of the star $T_u$ is $t$ with $t \geq 2$. Note that since $diam(T) \geq 4$, $T'$ has at least three vertices, that is, $n' \geq 3$. Let
Proposition 21. Let $G$ be a connected graph $G$ of order $n \geq 2$ with $m$ edges. Then $\gamma_{rdR}(G) \leq 4m - 2n + 3$, with equality if and only if $G$ is a tree with $\gamma_{rdR}(G) = 2n - 1$.

Proof. For the given connected graph, $m \geq n - 1$ and according to Proposition 7 $\gamma_{rdR}(G) \leq 2n - 1 = 4n - 4 - 2n + 3 \leq 4m - 2n + 3$.

If $\gamma_{rdR}(G) = 4m - 2n + 3$, then $m = n - 1$ and $G$ is a tree with $\gamma_{rdR}(G) = 2n - 1$. Conversely, assume that $G$ is a tree with $\gamma_{rdR}(G) = 2n - 1$. Hence $\gamma_{rdR}(G) = 4m - 2n + 3$.

7 Conclusions and problems

The concept of restrained double Roman domination in graphs was initially investigated in this paper. We studied the computational complexity of this concept and proved some bounds on the $RDRD$ number of graphs. In the case of trees, we characterized all trees attaining the exhibited bound. We now conclude the paper with some problems suggested by this research.

• For any graph $G$, provided the characterizations of graphs with small or large $RDRD$ numbers.
• It is also worthwhile proving some other nontrivial sharp bounds on $\gamma_{rdR}(G)$ for general graphs $G$ or some well-known families such as, chordal, planar, triangle-free, or claw-free graphs.

• The decision problem RESTRAINED DOUBLE ROMAN DOMINATION is NP-complete for general graphs, as proved in Theorem 2. By the way, there might be some families of graphs such that $RDRD$ is NP-complete for them or there might be some polynomial-time algorithms for computing the $RDRD$ number of some well-known families of graphs, for instance, trees. Can you provide these families?

• In Theorems 18 and 19 we showed upper bounds for $\gamma_{rdR}(T)$. The sufficient and necessity conditions for equality may be problems.
