Abstract

Convolutional neural networks perform a local and translationally-invariant treatment of the data: quantifying which of these two aspects is central to their success remains a challenge. We study this problem within a teacher-student framework for kernel regression, using ‘convolutional’ kernels inspired by the neural tangent kernel of simple convolutional architectures of given filter size. Using heuristic methods from physics, we find in the ridgeless case that locality is key in determining the learning curve exponent $\beta$ (that relates the test error $\epsilon_t \sim P^{-\beta}$ to the size of the training set $P$), whereas translational invariance is not. In particular, if the filter size of the teacher $t$ is smaller than that of the student $s$, $\beta$ is a function of $s$ only and does not depend on the input dimension. We confirm our predictions on $\beta$ empirically. Theoretically, in some cases (including when teacher and student are equal) it can be shown that this prediction is an upper bound on performance. We conclude by proving, using a natural universality assumption, that performing kernel regression with a ridge that decreases with the size of the training set leads to similar learning curve exponents to those we obtain in the ridgeless case.

1 Introduction

Deep Convolutional Neural Networks (CNNs) are widely recognised as the engine of the latest successes of deep learning methods, yet such a success is surprising. Indeed, any supervised learning model suffers in principle from the curse of dimensionality: under minimal assumptions on the function to be learnt, achieving a fixed target generalisation error $\epsilon$ requires a number of training samples $P$ which grows exponentially with the dimensionality $d$ of input signals [1], i.e. $\epsilon(P) \sim P^{-1/d}$. Nonetheless, empirical evidence shows that the curse of dimensionality is beaten in practice [2, 3, 4], with $\epsilon(P) \sim P^{-\beta}$, $\beta \gg 1/d$. (1)

CNNs, in particular, achieve excellent performances on high-dimensional tasks such as image classification on ImageNet with state-of-the-art architectures, for which $\beta \approx [0.3, 0.5]$ [2]. Natural data must then possess additional structures that make them learnable. A classical idea [5] ascribes the success of recognition systems to the compositionality of data, i.e. the fact that objects are made of features, themselves made of sub-features [6, 7, 8]. In this view, the locality of CNNs plays a

∗Equal contribution.
key role for their performance, as supported by empirical observations [9]. Yet, there is no clear
analytical understanding of the relationship between compositionality of the data and learning curves.

We study this relationship in a teacher-student setting, where the true function to be learnt takes one
of the following two forms:

\[ f_{LC}(x) = \sum_{i \in P} g_i(x_i), \quad f_{CN}(x) = \sum_{i \in P} g(x_i). \]  

(2)

Here, \( x \) is a \( d \)-dimensional input and \( x_i \) denotes the \( i \)-th patch of \( x \), \( x_i = (x_{i_1}, \ldots, x_{i_{t-1}}) \) where \( t < d \) is the filter size of the network and \( i \) ranges in a subset \( P \) of \( \{1, \ldots, d\} \). \( g_i \) and \( g \) are random
functions, whose smoothness is controlled by some exponent \( \alpha_t \). Such functions can be generated
for example by randomly-initialised one-hidden-layer neural networks. \( f_{LC} \) corresponds then to a
locally connected network (LCN) [10, 11], in which the input is split into lower-dimensional patches
before being processed, whereas a network enforcing invariance with respect to shifts of the input
via weight sharing can be described by \( f_{CN} \), for a suitable choice of \( P \). Our goal is to compute the
learning curve exponent \( \beta \) of a student kernel performing regression on such data. The student kernel
corresponds to a prior on the true function of the form described by Eq. (2), except that the filter size
of the student \( s \) and its prior \( \alpha_s \) on the smoothness of the functions \( g \)'s can differ from those of the
teacher. Such students include one-hidden-layer neural networks of diverging width operating in the
lazy training regime [12, 13, 14, 15, 16].

1.1 Our contributions

We consider a teacher-student framework where the teacher is a Gaussian random field of covariance
\( K_T(x, y) \) characterised by a filter size \( t \) and leading to local functions of the forms in Eq. (2),
whose smoothness is characterised by an exponent \( \alpha_t > 0 \). Kernel regression is performed by a student
kernel with ‘smoothness’ \( \alpha_s > 0 \) and filter size \( s \). Our main contributions are the following:

- We use recent results based on the replica method of statistical physics on the generalisation
  error of kernel methods [17, 18, 19] to estimate the training curve exponent. We find that
  \( \beta = \alpha_t / s \) if \( t \leq s \) and \( \alpha_t \leq 2(\alpha_s + s) \). This approach is non-rigorous, but it can be proven
  for Gaussian fields if data are sampled on a lattice [4]. It also corresponds to a provable
  lower bound on the error when teacher and student are equal [20].
- We confirm systematically our predictions by performing ridgeless regression numerically
  for various \( t, s \) and embedding dimension \( d \).
- We use the recent framework of [21] and a natural Gaussian universality assumption to
  prove an estimate of \( \beta \) for ridge regression with a ridge which decreases with the size of
  the training set. The exponent depends on \( s \) and not on \( d \), demonstrating that the curse of
  dimensionality can indeed be beaten using local filters on compositional data.

Overall, our results on the learning curve exponent \( \beta \) show that a locality prior allows the student to
beat the curse of dimensionality on data displaying a compositional structure. By contrast, invariance
for shifts can affect the prefactor entering the learning curve, but not \( \beta \).

1.2 Related work

Several recent works study the role of the compositional structure of data. When such structure is
hierarchical, deep convolutional networks can be much more expressive than shallow ones [6, 22, 7].
Concerning training, [23] shows that both convolutional and locally-connected networks can achieve
a target generalisation error in polynomial time, whereas fully-connected networks cannot, for a class
of functions which depend only on \( s \) consecutive bits of the \( d \)-dimensional input, with \( s = O(\log d) \).
In [8] the effects of the architecture’s locality are studied from a kernel perspective, using a class of
depth convolutional kernels introduced in [24, 25] and characterising their Reproducing Kernel
Hilbert Space (RKHS). Belonging to the RKHS ensures favourable bounds on performance and, for
isotropic kernels, is a constraint on the function smoothness that becomes stringent in large \( d \). For
local functions, the corresponding constraint on smoothness is governed by the filter size \( s \) and not
\( d \) [8]. Lastly, a recent work shows that weight sharing, in the absence of locality, leads to a mild
improvement of the generalisation error of shift-invariant kernels [26].
By contrast, our work focuses on computing non-trivial training curve exponents in a setup where the locality and shift-invariance priors of the kernel can differ from those of the class of functions being learnt. In our setup, the latter are in general not in the RKHS of the kernel. Technically, our result that the size of the student filter $s$ controls the learning curve (and not that of the teacher $t$) relates to the fact that kernels are not able to detect data anisotropy (the fact that the function depends only on a subset of the coordinates) in worst case settings $^{28}$ nor in the typical case for Gaussian fields $^{29}$.

2 Setup

**Kernel ridge regression** Kernel ridge regression is a method to learn a target function $f^*$ from $P$ observations $\{(x^\mu, f^*_\mu)\}_{\mu=1}^P$, where the inputs $x^\mu \in \mathbb{R}^d$ are i.i.d. random variables distributed according to the measure $p(\text{d}^d x)$ on $\mathbb{R}^d$, and $f^*_\mu = f^*(x^\mu)$. Let $K$ be a positive-definite kernel and $\mathcal{H}$ the corresponding Reproducing Kernel Hilbert Space (RKHS). The kernel ridge regression estimator $f$ of the target function $f^*$ is defined as

$$f = \arg\min_{f \in \mathcal{H}} \left\{ \frac{1}{P} \sum_{\mu=1}^P (f(x_\mu) - f^*_\mu)^2 + \lambda \| f \|^2_\mathcal{H} \right\}, \tag{3}$$

where $\| \cdot \|_\mathcal{H}$ denotes the RKHS norm and $\lambda$ is the ridge parameter. The limit $\lambda \to 0^+$ is known as the ridgeless case and corresponds to the solution with minimum RKHS norm that interpolates the $P$ observations. Eq. (3) is a convex optimisation problem, having the unique solution

$$f(x) = \frac{1}{P} \sum_{\mu, \nu=1}^P K(x, x^\nu) \left( \frac{1}{P} \mathbb{K}_P + \lambda \mathbb{I}_P \right)^{-1} f^*_\mu, \tag{4}$$

where $\mathbb{K}_P$ is the Gram matrix defined as $(\mathbb{K}_P)_{\mu\nu} = K(x^\mu, x^\nu)$, and $\mathbb{I}_P$ denotes the $P$-dimensional identity matrix. Our goal is to compute the generalisation error, which we define as the expectation of the mean squared error over the data distribution $p(\text{d}^d x)$ and the target $f^*$, i.e:

$$\epsilon = \mathbb{E}_{x, f^*} \left[ (f(x) - f^*(x))^2 \right]. \tag{5}$$

**Statistical mechanics of generalisation in kernel regression** The theoretical estimation of the generalisation error is still an open problem. In $^{17,18}$, the authors derived an approximation of $\epsilon$ by decomposing the target function in the eigenbasis of the kernel $K$. A positive-definite kernel $K$ can indeed be written, by Mercer’s theorem, in terms of its eigenvalues $\{\lambda_\rho\}$ and eigenfunctions $\{\phi_\rho\}$:

$$K(x, y) = \sum_{\rho=1}^{\infty} \lambda_\rho \phi_\rho(x) \overline{\phi_\rho(y)}, \quad \int p(\text{d}^d y) K(x, y) \phi_\rho(y) = \lambda_\rho \phi_\rho(x). \tag{6}$$

Let us define the kernel’s features as $\psi_\rho(x) = \sqrt{\lambda_\rho} \phi_\rho(x)$. Since the kernel’s eigenfunctions form a complete basis, we can decompose the target function and estimator in terms of the features

$$f^*(x) = \sum_{\rho} w^*_\rho \psi_\rho(x), \quad f(x) = \sum_{\rho} w_\rho \psi_\rho(x). \tag{7}$$

Using the replica method—a heuristic technique from statistical physics $^{30}$—the following set of equations is obtained in the ridgeless limit $\lambda \to 0^+$ $^{17,18}$:

$$\epsilon(P) = \sum_{\rho} \mathbb{E}||w^*_\rho||^2 \lambda_\rho \left( \frac{1}{\lambda_\rho} + \frac{P}{t(P)} \right)^{-2} \left( 1 - \frac{P}{t(P)} \right)^{-1}, \tag{8}$$

$$t(P) = \sum_{\rho} \left( \frac{1}{\lambda_\rho} + \frac{P}{t(P)} \right)^{-1}, \quad \gamma(P) = \sum_{\rho} \left( \frac{1}{\lambda_\rho} + \frac{P}{t(P)} \right)^{-2}. \tag{9}$$

The learning curve exponent $\beta$ can be extracted from the asymptotic behaviour of these expressions. In the following, we assume that the kernel and the target function have a power-law spectrum. In $^{27,29}$

2 A Gaussian field of covariance $K$ is never in the RKHS of the kernel $K$, see e.g. $^{27}$. 

particular, if \( i) \lambda_p = \rho^{-a} \) and \( ii) \) \( \mathbb{E}[|c_p|^2] = \lambda_p \mathbb{E}[|w_p^*|^2] = \rho^{-b} \), with \( 2a > b - 1 \), then \( \mathbb{E} \) and \( \text{Eq. (9)} \) yield \[ 4 \] \[ 17 \]
\[ \epsilon(P) \sim \sum_{\rho > P} \mathbb{E}[|c_p|^2] = \mathcal{B}(P). \] \[ (10) \]

\[ \text{Eq. (10)} \] indicates that, given \( P \) examples, the expected generalisation error can be approximated by the tail sum of the power in the target function past the first \( P \) modes of the kernel, which we denote as \( \mathcal{B}(P) \). Note that in teacher-student settings for kernel ridgeless regression \[ 31 \] \[ 32 \] \[ 4 \] \[ 29 \] additional rigorous results are available:

- if teacher and student are isotropic kernels and data are sampled on a lattice \[ \text{Eq. (10)} \] can be proven rigorously \[ 4 \];
- if teacher and student coincide, \( \epsilon(P) \leq \mathcal{B}(P) \), i.e. this estimate is a lower bound on performance \[ 20 \].

### 3 Kernels for convolutional and local teacher-student scenarios

In this section we introduce convolutional and local kernels and motivate our choice by considering one-hidden-layer architectures. Because of the relationship between our kernels and the Neural Tangent Kernel of one-hidden-layer convolutional neural networks, our framework encompasses regression with simple neural networks trained in the lazy training regime. For the sake of clarity we limit the discussion to inputs which are sequences in \( \mathbb{R}^d \), i.e. \( x = (x_1, \ldots, x_d) \). Extension to higher-order tensorial inputs such as images \( X \in \mathbb{R}^{d\times d} \) is straightforward. To avoid dealing with the boundaries of the sequence we identify \( x_{i+d} \) with \( x_i \) for all \( i = 1, \ldots, d \).

**Definition 3.1 (one-hidden-layer CNN).** A one-hidden-layer convolutional network with \( H \) hidden neurons and average pooling is defined as follows,

\[
f^{\text{CNN}}(x) = \frac{1}{\sqrt{H}} \sum_{h=1}^{H} \sum_{|P|} a_{h,i} \sum_{i \in P} \sigma(w_{h,i} \cdot x_{i}),
\]

where \( x \in \mathbb{R}^d \) is the input, \( H \) is the width, \( \sigma \) a nonlinear activation function, \( P \subseteq \{1, \ldots, d\} \) is a set of patch indices and \( |P| \) its cardinality. For all \( i \in P \), \( x_{i} \) is an \( s \)-dimensional patch of \( x \). For all \( h = 1, \ldots, H \), \( w_{h,i} \in \mathbb{R}^s \) is a filter with filter size \( s \), \( a_{h,i} \in \mathbb{R} \) is a scalar weight. The dot \( \cdot \) denotes the standard Euclidean scalar product.

In the network defined above, a \( d \)-dimensional input sequence \( x \) is first mapped to \( s \)-dimensional patches \( x_i \), which are ordered subsequences of the input. Comparing each patch to a filter \( w_{h,i} \) and applying the activation function \( \sigma \) leads to a \( |P| \)-dimensional hidden representation which is equivariant for shifts of the input. The summation over the patch index \( i \) promotes this equivariance to full invariance, leading to a model which is both local and shift-invariant in \( f^{\text{CNN}} \) in \( \text{Eq. (2)} \). A model which is only local (as \( f^{\text{LCN}} \) in \( \text{Eq. (2)} \)) can be obtained by lifting the constraint of weight-sharing, which forces, for each \( h = 1, \ldots, H \), the same filter \( w_h \) to apply to all patches \( x_i \).

**Definition 3.2 (one-hidden-layer LCN).** In the notation of \( \text{3.1} \), a one-hidden-layer locally-connected network with \( H \) hidden neurons is defined as follows,

\[
f^{\text{LCN}}(x) = \frac{1}{\sqrt{H}} \sum_{h=1}^{H} \sum_{|P|} a_{h,i} \sigma(w_{h,i} \cdot x_{i}),
\]

For all \( i \in P \) and \( h = 1, \ldots, H \): \( x_i \) is an \( s \)-dimensional patch of \( x \), \( w_{h,i} \in \mathbb{R}^s \) is a filter with filter size \( s \), \( a_{h,i} \in \mathbb{R} \) is a scalar weight.

Notice that the definition above reduces to that of a fully-connected network, when the filter size is set to the input dimension, \( s = d \), and \( P = \{1\} \). With the target functions taking one of the two forms in \( \text{Eq. (2)} \) our framework contains the case where the observations are generated by neural networks such as \( \text{3.1} \) and \( \text{3.2} \). Let us now introduce the neural tangent kernels of such architectures.

**Definition 3.3 (Neural Tangent Kernel).** Given a neural network function \( f(x; \theta) \), where \( \theta = (\theta_1, \ldots, \theta_N) \) denotes the complete set of parameters and \( N \) the total number of parameters, the
Neural Tangent Kernel (NTK) is defined as \[\Theta_N(x, y; \theta) = \sum_{n=1}^{N} \partial_{\theta_n} f(x, \theta) \partial_{\theta_n} f(y, \theta), \] (13) where \(\partial_{\theta_n}\) denotes partial derivation w.r.t. the \(n\)-th parameter \(\theta_n\).

For one-hidden-layer networks with random, \(O(1)\)-variance Gaussian initialisation of all the weights, and normalisation by \(\sqrt{H}\) as in (3.1) and (3.2), the NTK converges to a deterministic limit \(\Theta(x, y)\) as \(N \to \infty\) \[\Theta(x, y)\] \[\Theta(x, y)\] \[\Theta(x, y)\]. Furthermore, training \(f(x, \theta) - f(x, \theta_0)\) with \(\theta_0\) denoting the network parameters at initialisation, under gradient descent on the mean squared error is equivalent to performing ridgeless regression with kernel \(\Theta(x, y)\). The following lemmas relate the NTK of convolutional and local architectures acting on \(d\)-dimensional inputs to those of a fully-connected architecture acting on \(s\)-dimensional inputs. Both lemmas are proved in Appendix A.

**Lemma 3.1.** Call \(\Theta^{FC}\) the NTK of a fully-connected network function acting on \(s\)-dimensional inputs and \(\Theta^{CN}\) the NTK of a convolutional network function \(3.1\) with filter size \(s\) acting on \(d\)-dimensional inputs. Then
\[
\Theta^{CN}(x, y) = \frac{1}{|P|^2} \sum_{i,j \in P} \Theta^{FC}(x_i, y_j) \tag{14}
\]
As the functions in Eq. (2) \(\Theta^{CN}\) is written as a combination of a lower-dimensional constituent kernel \(\Theta^{FC}\) acting on patches, and the dimensionality of the constituent kernel coincides with the filter size of the corresponding network. For inputs \(x\) of fixed norm, the constituent \(\Theta^{FC}(x, y)\) of network with ReLU activations displays a cusp-like nonanalyticity at the origin \[33\], i.e. \(\Theta^{FC}(x, y) \approx \|x_i - y_j\|\) plus analytic (or smaller nonanalytic) contributions. This observation extends to local kernels, via

**Lemma 3.2.** Call \(\Theta^{LC}\) the NTK of a locally-connected network function \(3.2\) with filter size \(s\) acting on \(d\)-dimensional inputs. Then
\[
\Theta^{LC}(x, y) = \frac{1}{|P|} \sum_{i \in P} \Theta^{FC}(x_i, y_i) \tag{15}
\]
Following the general structure of Eq. (14) and Eq. (15) we introduce local \((K^{LC})\) and convolutional \((K^{CN})\) student and teacher kernels, defined as sums of lower-dimensional constituent kernels \(C\),
\[
K^{CN}(x, y) = |P|^{-2} \sum_{i,j \in P} C(x_i, y_j), \tag{16a}
\]
\[
K^{LC}(x, y) = |P|^{-1} \sum_{i \in P} C(x_i, y_i). \tag{16b}
\]
The kernels in Eq. (16) are characterised by the dimensionality of the constituent kernel \(C\), or filter size \(s\) (for the student, or \(t\) for the teacher) and the nonanalytic behaviour of \(C\) when the two arguments approach, \(C(x_i, y_j) \approx \|x_i - y_j\|^\alpha\) (for the student, or \(\alpha_t\) for the teacher) plus analytic contributions, with \(\alpha_s \neq 2m\) for \(m \in \mathbb{N}\). The corresponding target function \(f^*\) and estimator \(f\) have the form displayed in Eq. (2). The \(\alpha\)’s control the smoothness of these functions, in the sense that, if \(\alpha > n \in \mathbb{N}\), then the constituent kernel \(C\) is at least \(n\) times differentiable \[34\].

A notable example is the NTK of ReLU networks \(\Theta^{FC}\), which presents a cusp at the origin corresponding to \(\alpha_s = 1\). In addition, in the \(H \to \infty\) limit, a network initialised with random weights converges to a Gaussian process \[35\] \[36\] \[37\] \[38\] \[39\]. For networks with ReLU activations, the covariance kernel of the process has nonanalytic behaviour with \(\alpha_t = 3\) \[40\].

### 3.1 Mercer’s decomposition of convolutional and local kernels

We now turn to describing how the eigendecomposition of the constituent kernel \(C\) induces an eigendecomposition of convolutional and local kernels. We work under the following assumptions,

i) The constituent kernel \(C(x, y)\) on \(\mathbb{R}^s \times \mathbb{R}^s\) admits the following Mercer’s decomposition,
\[
C(x, y) = \sum_{\rho=1}^{\infty} \lambda_\rho \phi_\rho(x) \phi_\rho(y), \tag{17}
\]
with (ordered) eigenvalues $\lambda_\rho$ and eigenfunctions $\phi_\rho$, such that, with $p^{(s)}(d^sx)$ denoting the $s$-dimensional patch measure, $\phi_1(x) = 1 \forall x$ and $\int p^{(s)}(d^sx)\phi_\rho(x) = 0$ for all $\rho > 1$;

ii) Convolutional and local kernels from Eq. (16) have nonoverlapping patches, i.e. $d$ is an integer multiple of $s$ and $\mathcal{P} = \{1 + n \times s | n = 1, \ldots, d/s \}$ with $|\mathcal{P}| = d/s$;

iii) The $s$-dimensional marginals on patches of the $d$-dimensional input measure $p^{(d)}(d^d x)$ are all identical and equal to $p^{(s)}(d^sx)$.

The part of assumption i) regarding the eigenfunctions properties is satisfied, for instance, when the constituent kernel $C$ is isotropic and data are distributed uniformly on a $d$-dimensional torus. The request of nonoverlapping patches in assumption ii) can be relaxed at the price of further assumptions, i.e. $C(x, y) = C(x - y)$ and data distributed uniformly on the torus, so that $C$ is diagonalised in Fourier space (details in Appendix B).

**Lemma 3.3** (Spectra of convolutional kernels). Let $K^{CN}$ be a convolutional kernel defined as in Eq. (16a) with a constituent kernel $C$ satisfying assumptions i), ii) and iii) above. Then $K^{CN}$ admits the following Mercer’s decomposition,

$$K^{CN}(x, y) = \sum_{\rho=1}^{\infty} \Lambda_\rho \Phi_\rho(x) \Phi_\rho(y),$$

with eigenvalues and eigenfunctions

$$\Lambda_1 = \lambda_1, \quad \Phi_1(x) = 1; \quad \Lambda_\rho = \frac{s}{d} \lambda_\rho, \quad \Phi_\rho(x) = \sqrt{\frac{s}{d}} \sum_{i \in \mathcal{P}} \phi_\rho(x_i) \text{ for } \rho > 1.$$  

**Lemma 3.4** (Spectra of local kernels). Let $K^{LC}$ be a local kernel defined as in Eq. (16b) with a constituent kernel $C$ satisfying assumptions i), ii) and iii) above. Then $K^{LC}$ admits the following Mercer’s decomposition,

$$K^{LC}(x, y) = \Lambda_1 \Phi_1(x) \Phi_1(y) + \sum_{\rho>1} \sum_{i \in \mathcal{P}} \Lambda_{\rho,i} \Phi_{\rho,i}(x) \Phi_{\rho,i}(y),$$

with eigenvalues and eigenfunctions ($\forall i \in \mathcal{P}$)

$$\Lambda_1 = \lambda_1, \quad \Phi_1(x) = 1; \quad \Lambda_{\rho,i} = \frac{s}{d} \lambda_\rho, \quad \Phi_{\rho,i}(x) = \phi_\rho(x_i) \text{ for } \rho > 1.$$

Under assumptions i), ii) and iii) above, lemmas 3.3 and 3.4 follow from the definitions of convolutional and local kernels and the eigendecompositions of the constituents (see Appendix B for a proof of the lemmas and generalisation to kernels with overlapping patches). In the next section we explore the consequences of these results on the asymptotics of learning curves.

## 4 Asymptotic learning curves for ridgeless regression

In what follows, we consider explicitly translationally-invariant constituent kernels $C(x_i, x_i) = C(x_i - x_j)$ and a $d$-dimensional data distribution $p(d^d x)$ which is uniform on the torus, so that all lower-dimensional marginals are also uniform on lower-dimensional tori. Under these conditions, Mercer’s decomposition Eq. (17) can be written in Fourier space [41], with $s$-dimensional plane waves $\phi^{(s)}_n(x) = e^{i k \cdot x}$ as eigenfunctions and the eigenvalues coinciding with the Fourier transform of $C$. All the assumptions required by lemmas 3.3 and 3.4 in the previous section are satisfied in this setting. Furthermore, for kernels with filter size $s$ (or $t$) and positive smoothness exponent $\alpha_s$ (or $\alpha_t$), the eigenvalues decay with a power $-(s + \alpha_s)$ (or $-(t + \alpha_t)$) of the modulus of the wavevector $k = \sqrt{\mathbf{k}\cdot\mathbf{k}}$ [42]. In this setting, we obtain our main result:

**Theorem 4.1.** Let $K_T$ be a $d$-dimensional convolutional kernel with a translationally-invariant $t$-dimensional constituent and leading nonanalyticity at the origin controlled by the exponent $\alpha_t > 0$. Let $K_S$ be a $d$-dimensional convolutional or local student kernel with a translationally-invariant $s$-dimensional constituent, and with a nonanalyticity at the origin controlled by the exponent $\alpha_s > 0$. If all the $t$-dimensional patches of the teacher are contained in at least one of the $s$-dimensional
patches of the student and data are uniformly distributed on a d-dimensional torus, the following asymptotic equivalence holds in the limit \( P \to \infty \),
\[
B(P) \sim P^{-\beta}, \quad \beta = \alpha_t/s.
\] (22)

Theorem 4.1 together with Eq. (10) and the additional assumption \( \alpha_t \leq 2(\alpha_s + s) \), yields the following expression for the learning curves asymptotics,
\[
\epsilon(P) \sim P^{-\beta}, \quad \beta = \alpha_t/s.
\] (23)

As \( \beta \) is independent of the embedding dimension \( d \), we conclude that the curse of dimensionality is beaten when a convolutional target is learnt with a convolutional or local kernel. In fact, Eq. (23) indicates that there is no asymptotic advantage in using a convolutional rather than local student when learning a convolutional task, confirming the picture that locality, not weight sharing, is the main source of the convolutional architecture’s performances. The prediction in Eq. (23) is confirmed empirically, as discussed in Section 5.

Theorem 4.1 is proven in Appendix C and extended to the case of a local teacher and local student in Appendix D. Here we sketch the proof for the nonoverlapping case, which begins with the calculation of the variance of the coefficients of the target function in the student basis. By indexing the coefficients with the \( s \)-dimensional wavevectors \( \mathbf{k} \),
\[
E[|c_k|^2] = \int_{[0,1]^d} d^d x \Phi_k(x) \int_{[0,1]^d} d^d y \Phi_k(y) E[f^*(x)f^*(y)]
\]
\[
= \int_{[0,1]^d} d^d x \Phi_k(x) \int_{[0,1]^d} d^d y \Phi_k(y) E[f^*(x)f^*(y)]
\] (24)

If the size of teacher and student coincide, \( s = t \), teacher and student have the same eigenfunctions. Thus, using the eigenvalue equation \[ Eq. (6) \] of the teacher yields \( E[|c_k|^2] \sim k^{-(\alpha_t+s)} \) after ranking eigenvalues by \( k \), with multiplicity \( k^{s-1} \) from all the wavevectors having the same modulus \( k \), one has
\[
B(P) = \sum_{\{k | k > P^{1/s} \}} k^{-(\alpha_t+s)} \sim \int_{P^{1/s}}^{\infty} dk k^{-1} k^{-(\alpha_t+s)} \sim P^{-\frac{\alpha_t}{s}}.
\] (25)

When the filter size of the teacher \( t \) is lowered, some of the coefficients \( E[|c_k|^2] \) vanish. As the target function becomes a composition of \( t \)-dimensional constituents, the only non-zero coefficients are found for \( k \)'s which lie in some \( t \)-dimensional subspaces of the \( s \)-dimensional Fourier space. These subspaces correspond to the \( k \) having at most a patch of \( t \) consecutive non-vanishing components. In other words, \( E[|c_k|^2] \) is finite only if \( k \) is effectively \( t \)-dimensional and the integral on the right-hand side of Eq. (25) becomes \( t \)-dimensional, thus
\[
B(P) \sim \int_{P^{1/s}}^{\infty} dk k^{t-1} k^{-(\alpha_t+t)} \sim P^{-\frac{\alpha_t}{t}}.
\] (26)

If the teacher patches are not contained in the student ones, the target cannot be represented with a combination of student eigenfunctions, hence the error asymptotes to a finite value when \( P \to \infty \).

5 Empirical learning curves for ridgeless regression

This section investigates numerically the asymptotic behaviour of the learning curves for our teacher-student framework. We consider different combinations of convolutional and local teachers and students with overlapping patches and Laplacian constituent kernels, i.e. \( C(x_i - x_j) = e^{-\|x_i - x_j\|} \). In order to test the robustness of our results to the data distribution, data are uniformly generated in the hypercube \([0,1]^d\) (results in Fig. 1) or on a \( d \)-hypersphere (results in Appendix F, together with further details on the experiments). Fig. 1 shows learning curves for both convolutional (left panels) and local (right panels) students learning a convolutional target function. The results in the case of a local teacher are presented in Appendix F and display no qualitative differences.

\[^{3}\text{This condition is satisfied when } s \geq t \text{ in the full overlapping-patches case, while requires that } s \text{ is an integer multiple of } t \text{ in the nonoverlapping-patches case.}\]
Figure 1: Learning curves for different combinations of convolutional teachers with convolutional (left panels) and local (right panels) students. The teacher and student filter sizes are denoted with \( t \) and \( s \) respectively. Data are sampled uniformly in the hypercube \([0, 1]^d\), with \( d = 9 \) if not specified otherwise. Solid lines are the results of numerical experiments averaged over 128 realizations and the shaded areas represent the empirical standard deviations. The predicted scaling are shown by dashed lines. All the panels are discussed in Section 5, while additional details on experiments are reported in Appendix F, together with additional experiments.

In the following, we always refer to Fig. 1. Panels A and B show that, under the assumptions of Theorem 4.1, with \( \alpha_t = \alpha_s = 1 \), our prediction \( \beta = 1/s \) holds independently of the embedding dimension \( d \). Furthermore, notice that fixing the dimension \( d \) and the teacher filter size \( t \), the generalisation errors of a convolutional and a local student with the same filter size differ only by a multiplicative constant independent of \( P \). Indeed, the shift-invariant nature of the convolutional student only results in a pre-asymptotic corrections to our estimate of the generalisation error \( B(P) \).

Panels C and D show learning curves for several values of \( s \) and fixed \( t \). The curse of dimensionality is recovered when the size of the student filters coincide with the input dimension, both for local and convolutional students. Finally, panels E and F show learning curves for fixed \( t \) and \( s \) being smaller than, equal to or larger than \( t \). We stress that, when \( s < t \) the student kernel cannot reproduce the target function, hence the error does not decrease by increasing \( P \). All experiments are in excellent agreement with our predictions.
6 Asymptotics of learning curves with decreasing ridge

We now prove an upper bound for the exponent $\beta$ implying that the curse of dimensionality is beaten by a local or convolutional kernel learning a convolutional target (as in Eq. (2)), using the framework developed in \cite{21} and a natural assumption. We stress that this framework does not require the target function to be generated by a teacher kernel. Proofs are presented in Appendix E. Let $D(\Lambda)$ denote the density of eigenvalues of the student kernel, $D(\Lambda) = \sum_p \delta(\Lambda - \Lambda_p)$, with $\delta(x)$ denoting Dirac delta function. Having a random target function with coefficients $c_p$ in the kernel eigenbasis having variance $\mathbb{E}[|c_p|^2]$, one can define the following reduced density (with respect to the teacher):

$$D_T(\Lambda) = \sum\nolimits_{\{p : |c_p|^2 > 0\}} \delta(\Lambda - \Lambda_p)$$

$D_T(\Lambda)$ counts eigenvalues for which the target has a non-zero variance, such that:

$$\sum\nolimits_{\rho} \mathbb{E}[|c_\rho|^2] = \int d\Lambda D_T(\Lambda)c^2(\Lambda),$$

where the function $c(\Lambda)$ is defined by $c^2(\Lambda_p) = \mathbb{E}[|c_p|^2]$ for all $\rho$ such that $\mathbb{E}[|c_p|^2] > 0$. The following theorem then follows from the results of \cite{21}.

**Theorem 6.1.** Let us consider a positive-definite kernel $K$ with eigenvalues $\Lambda_p$, $\sum_p \Lambda_p < \infty$, and eigenfunctions $\Phi_\rho$ learning a (random) target function $f^*$ in kernel ridge regression (Eq. (3)) with ridge $\lambda$ from $P$ observations $f^*_\mu = f^*(x^\mu)$, with $x^\mu \in \mathbb{R}^d$ drawn from a certain probability distribution. Let us denote with $D_T(\Lambda)$ the reduced density of kernel eigenvalues with respect to the target and $c(\Lambda, P)$ the generalisation error and also assume that

i) For any $P$-tuple of indices $\rho_1, \ldots, \rho_P$, the vector $(\Phi_{\rho_1}(x^1), \ldots, \Phi_{\rho_P}(x^P))$ is a Gaussian random vector;

ii) The target function can be written in the kernel eigenbasis with coefficients $c_\rho$ and $c^2(\Lambda_p) = \mathbb{E}[|c_p|^2]$, with $D_T(\Lambda) \sim \Lambda^{-1(1+r)}$, $c^2(\Lambda) \sim \Lambda^r$ asymptotically for small $\Lambda$ and $r > 0$, $r < q < r + 2$;

Then the following equivalence holds in the joint $P \to \infty$ and $\lambda \to 0$ limit with $1/(\lambda \sqrt{P}) \to 0$:

$$\epsilon(\lambda, P) \sim \sum\nolimits_{\{\rho : \Lambda_\rho < \lambda\}} \mathbb{E}[|c_\rho|^2] = \int_0^\lambda d\Lambda D_T(\Lambda)c^2(\Lambda).$$

Note that the assumption i) of the theorem on the Gaussianity of the eigenbasis does not hold in our setup where the $\Phi_\rho$’s are plane waves. However, the random variables $\Phi_\rho(x^\mu)$ have a probability density with compact support. It is thus natural to assume that a Gaussian universality assumption holds, i.e. that \textbf{[Theorem 6.1] applies to our problem. With this assumption, we obtain the following}

**Corollary 6.1.** Performing kernel ridge regression in a teacher-student scenario with smoothness exponents $\alpha_t$ (teacher) and $\alpha_s$ (student), with ridge $\lambda \sim P^{-\gamma}$ and $0 < \gamma < 1/2$, under the joint hypotheses of \textbf{Theorem 4.1} and \textbf{Theorem 6.1}, the exponent governing the asymptotic scaling of the generalisation error with $P$ is given by:

$$\beta = \gamma \frac{\alpha_t}{\alpha_s + s},$$

which does not vanish in the limit $d \to \infty$. Furthermore, Eq. (30) depends on $s$ and not on $t$ as the prediction of Eq. (23)

7 Conclusions and future work

Our work shows that, even in large dimension $d$, a function can be learnt efficiently if it can be expressed as a sum of constituent functions each depending on a smaller number of variables $t$, by performing regression with a kernel that entails such a compositional structure with $s$-dimensional
constituents. The learning curve exponent is then independent of \(d\) and governed by \(s\) if \(s \geq t\), optimal for \(s = t\) and null if \(s < t\).

In the context of image classification, this result relates to the “Bag of Words” viewpoint. Consider for example two-dimensional images consisting of \(M\) features of \(t\) adjacent pixels, and that different classes correspond to distinct subsets of (possibly shared) features. If features can be located anywhere in the image, then data lie on a \(2M\)-dimensional manifold. On the one hand, we expect a one-hidden-layer convolutional network with filter size \(s \geq t\) to learn well with a learning curve exponent governed by \(s\) and independent of \(M\). On the other hand, a fully-connected network operating in the lazy training regime would suffer from the curse of dimensionality for large \(M\).

Our work does not consider that the compositional structure of real data is hierarchical, with large features that consist of smaller sub-features. It is intuitively clear that depth and locality taken together are well-suited for such data structure [8, 6]. Extending the present teacher-student framework to this case would offer valuable quantitative insights into the question of how many data are required to learn such tasks.

References

A NTKs of convolutional and locally-connected networks

We begin this section by reviewing the computation of the NTK of a one-hidden-layer fully-connected network \[16\].

**Definition A.1 (one-hidden-layer FCN).** A one-hidden-layer fully-connected network with \(H\) hidden neurons is defined as follows,

\[
f_{\text{FCN}}(x) = \frac{1}{\sqrt{H}} \sum_{h=1}^{H} a_h \sigma(w_h \cdot x), \quad (S1)
\]

where \(x \in \mathbb{R}^d\) is the input, \(H\) is the width, \(\sigma\) is a nonlinear activation function, \(\{w_h \in \mathbb{R}^d\}_{h=1}^{H}\) and \(\{a_h \in \mathbb{R}\}_{h=1}^{H}\) are the network’s parameters. The dot \(\cdot\) denotes the standard Euclidean scalar product.

Inserting Eq. (S1) into Eq. (13), one obtains

\[
\Theta_{\text{FCN}}(x, y; \theta) = \frac{1}{H} \sum_{h=1}^{H} \left( \sigma(w_h \cdot x)\sigma(w_h \cdot y) + a_h^2 \sigma'(w_h \cdot x)\sigma'(w_h \cdot y)x \cdot y \right), \quad (S2)
\]

where \(\sigma'\) denotes the derivative of \(\sigma\) with respect to its argument. If all the parameters are initialised independently from a standard Normal distribution, \(\Theta_{\text{FCN}}(x, y; \theta)\) is a random-feature kernel that in the \(H \to \infty\) limit converges to

\[
\Theta_{\text{FCN}}(x, y) = \mathbb{E}_{w}[\sigma(w \cdot x)\sigma(w \cdot y)] + \mathbb{E}_{a}[a^2]\mathbb{E}_{w}[\sigma'(w \cdot x)\sigma'(w \cdot y)]x \cdot y. \quad (S3)
\]

When \(\sigma\) is the ReLU activation function, the expectations can be computed exactly using techniques from the literature of arc-cosine kernels \[40\]

\[
\Theta_{\text{FCN}}(x, y) = \frac{1}{2\pi} ||x|| ||y|| (\sin \varphi + (\pi - \varphi) \cos \varphi) + \frac{1}{2\pi} x^\top y(\pi - \varphi), \quad (S4)
\]

with \(\varphi\) denoting the angle between \(x\) and \(y\).

\[
\varphi = \arccos \left( \frac{x^\top y}{||x|| ||y||} \right). \quad (S5)
\]

Notice that, as commented in Section 3 for ReLU networks \(\Theta_{\text{FCN}}(x, y)\) displays a cusp at \(x = y\).

**Proof of Lemma 3.1**

**Proof.** Inserting Eq. (11) into Eq. (13)

\[
\Theta_N(x, y; \theta) = \frac{1}{|P|^2} \sum_{i,j \in P} \left( \frac{1}{H} \sum_{h=1}^{H} \left( \sigma(w_h \cdot x_i)\sigma(w_h \cdot y_j) + a_h^2 \sigma'(w_h \cdot x_i)\sigma'(w_h \cdot y_j)v \cdot x_i \right) \right) \quad (S6)
\]

In the previous line, the single terms of the summation over patches are the random-feature kernels \(\Theta_{\text{FCN}}^{(FC)}\) obtained in Eq. (S2) acting on \(s\)-dimensional inputs, i.e. the patches of \(x\) and \(y\). Therefore,

\[
\Theta_N(x, y; \theta) = \frac{1}{|P|^2} \sum_{i,j \in P} \Theta_N^{(FC)}(x, y). \quad (S7)
\]
If all the parameters are initialised independently from a standard Normal distribution, the $H \to \infty$ limit of Eq. (S7) yields Eq. (14).

Proof of Lemma 3.2

Proof. Inserting Eq. (12) into Eq. (13),

$$
\Theta_{L^C}^N(x, y; \theta) = \frac{1}{|P|} \sum_{i \in P} \left( \frac{1}{H} \sum_{h=1}^{H} \left( \sigma(w_{h,i} \cdot x_i) \sigma(w_{h,i} \cdot y_i) + a_{h,i}^2 \sigma'(w_{h,i} \cdot x_i) \sigma'(w_{h,i} \cdot y_i) x_i \cdot y_i \right) \right). 
$$

(S8)

In the previous line, the single terms of the summation over patches are the random-feature kernels $\Theta_{F^C}^N$ obtained in Eq. (S2) acting on $s$-dimensional inputs, i.e. the patches of $x$ and $y$. Therefore,

$$
\Theta_{L^C}^N(x, y; \theta) = \frac{1}{|P|} \sum_{i \in P} \Theta_{F^C}^N(x_i, y_i). 
$$

(S9)

If all the parameters are initialised independently from a standard Normal distribution, Eq. (15) is recovered in the $H \to \infty$ limit.

B Mercer’s decomposition of convolutional and local kernels

In this section we prove the eigendecompositions introduced in Lemma 3.3 and Lemma 3.4, then extend them to overlapping-patches kernel (cf. B.1). We define the scalar product in input space between two (complex) functions $f$ and $g$ as

$$
\langle f, g \rangle = \int p(d^d x) f(x) g(x). 
$$

(S10)

Proof of Lemma 3.3

Proof. We start by proving orthonormality of the eigenfunctions. By writing the $d$-dimensional eigenfunctions $\Phi_\rho$ in terms of the $s$-dimensional eigenfunctions $\phi_\rho$ of the constituent kernel as in Eq. (19) for $\rho, \sigma \neq 1$,

$$
\langle \Phi_\rho, \Phi_\sigma \rangle = \frac{s}{d} \sum_{i,j \in P} \int p(d^d x) \phi_\rho(x_i) \phi_\sigma(x_j). 
$$

(S11)

Separating the term in the sum over patches in which $i$ and $j$ coincide from the others, and since the patches are not overlapping, the RHS can be written as

$$
\frac{s}{d} \sum_{i \in P} \int p(d^d x_i) \phi_\rho(x_i) \phi_\sigma(x_i) + \sum_{i,j \in P, i \neq j} \int p(d^d x_i) \phi_\rho(x_i) \int p(d^d x_j) \phi_\sigma(x_j). 
$$

(S12)

From the orthonormality of the eigenfunctions $\phi_\rho$, the first integral is non-zero and equal to one only when $\rho = \sigma$, while, from assumption i), $\int p^{(s)}(d^d x) \phi_\rho(x) = 0$ for all $\rho > 1$, so that the second integral is always zero. Therefore,

$$
\langle \Phi_\rho, \Phi_\sigma \rangle = \delta_{\rho,\sigma}, \text{ for } \rho, \sigma > 1. 
$$

(S13)
When \( \rho = 1 \) and \( \sigma \neq 1 \), \( \int p(d^d x) \Phi_1(x) \Phi_\sigma(x) = 0 \) from assumption \( i \), i.e. \( \Phi_1 = 1 \) and \( \int p(s)(d^d x) \phi_\rho(x) = 0 \) for all \( \rho > 1 \). Finally, if \( \rho = \sigma = 1 \), \( \int p(d^d x) \Phi_1(x) \Phi_1(x) = 1 \) trivially.

Then, we prove that the eigenfunctions and the eigenvalues defined in \( \text{Eq. (19)} \) satisfy the kernel eigenproblem. For \( \rho = 1 \),

\[
\int p(d^d y) K^{CN}(x, y) = \int p(d^d y) \frac{s^2}{d^2} \sum_{i,j \in P} C(x_i, y_j) = \frac{s^2}{d^2} \sum_{i,j \in P} \lambda_1 = \Lambda_1, \tag{S14}
\]

where we used \( \int p(s)(d^d y) C(x, y) = \lambda_1 \) from assumption \( i \). For \( \rho > 1 \),

\[
\int p(d^d y) K^{CN}(x, y) \Phi_\rho(y) = \int p(d^d y) \frac{s^2}{d^2} \sum_{i,j \in P} C(x_i, y_j) \sqrt{\frac{s}{d}} \sum_{l \in \mathbb{P}} \phi_\rho(y_l). \tag{S15}
\]

Splitting the sum over \( l \) into the term with \( l = j \) and the remaining ones, the RHS can be written as

\[
\frac{s^2}{d^2} \sum_{i,j \in P} \left( \int p(d^d y_j) C(x_i, y_j) \sqrt{\frac{s}{d}} \phi_\rho(y_j) \right)
+ \int p(d^d y_j) C(x_i, y_j) \sqrt{\frac{s}{d}} \sum_{l \neq j \in \mathbb{P}} \int p(d^d y_l) \phi_\rho(y_l) = \int p(d^d y) K^{CN}(x, y) \Phi_\rho(y).
\]

Using assumption \( i \), the third integral is always zero, therefore

\[
\int p(d^d y) K^{CN}(x, y) \Phi_\rho(y) = \frac{s^2}{d^2} \sum_{i,j \in P} \lambda_\rho \sqrt{\frac{s}{d}} \phi_\rho(x_i) = \Lambda_\rho \Phi_\rho(x). \tag{S17}
\]

Finally, we prove the expansion of \( \text{Eq. (18)} \) from the definition of \( K^{CN} \),

\[
K^{CN}(x, y) = \frac{s^2}{d^2} \sum_{i,j \in P} C(x_i, y_j) \tag{S18}
\]

\[
= \frac{s^2}{d^2} \sum_{i,j \in P} \sum_{\rho} \lambda_\rho \phi_\rho(x_i) \phi_\rho(y_j)
= \lambda_1 \frac{s^2}{d^2} \sum_{i,j \in P} \phi_1(x_i) \phi_1(y_j) + \sum_{\rho > 1} \left( \sqrt{\frac{s}{d}} \lambda_\rho \right) \left( \sqrt{\frac{s}{d}} \sum_{l \in \mathbb{P}} \phi_\rho(x_l) \right) \left( \sqrt{\frac{s}{d}} \sum_{l \in \mathbb{P}} \phi_\rho(y_l) \right)
= \sum_{\rho} \Lambda_\rho \Phi_\rho(x) \Phi_\rho(y).
\]

**Proof of Lemma 3.4**

**Proof.** We start again by proving the orthonormality of the eigenfunctions. By writing the \( d \)-dimensional eigenfunctions \( \Phi_{\rho,i} \) in terms of the \( s \)-dimensional eigenfunctions \( \phi_\rho \) of the constituent kernel as in \( \text{Eq. (21)} \) for \( \rho, \sigma \neq 1 \),

\[
\langle \Phi_{\rho,i}, \Phi_{\sigma,j} \rangle = \int p(d^d x) \phi_\rho(x_i) \phi_\sigma(x_j) = \delta_{\rho,\sigma} \delta_{i,j}, \tag{S19}
\]
from the orthonormality of the eigenfunctions \( \phi_\rho \) when \( i = j \), and assumption \( i \), \( \int \rho^{(s)}(d^d x) \phi_\rho(x) = 0 \) for all \( \rho > 1 \), when \( i \neq j \). Moreover, as \( \Phi_1(x) = 1 \), 
\( \int \rho^{(d)} x) \Phi_1(x) \Phi_\rho(x) = 0 \) and \( \int \rho^{(d)} x) \Phi_1(x) = 1 \).

Then, we prove that the eigenfunctions and the eigenvalues defined in Eq. (21) satisfy the kernel eigenproblem. For \( \rho = 1 \),

\[
\int \rho^{(d)} y) K_{LC}^{(d)}(x, y) = \int \rho^{(d)} y) \frac{s}{d} \sum_{i \in P} C(x_i, y_i) = \frac{s}{d} \sum_{i \in P} \lambda_1 = \Lambda_1, \tag{S20}
\]

where we used \( \int \rho^{(s)}(d^d y) C(x, y) = \lambda_1 \) from assumption \( i \). For \( \rho > 1 \),

\[
\int \rho^{(d)} y) K_{LC}^{(d)}(x, y) \Phi_\rho(y) = \int \rho^{(d)} y) \frac{s}{d} \sum_{j \in P} C(x_j, y_j) \Phi_\rho(y_j). \tag{S21}
\]

Splitting the sum over \( j \) in the term for which \( j = i \) and the remaining ones, the RHS can be written as

\[
\frac{s}{d} \int \rho^{(d)} y_i) C(x_i, y_i) \Phi_\rho(y_i) + \frac{s}{d} \sum_{j \neq i \in P} \int \rho^{(d)} y_j) C(x_j, y_j) \int \rho^{(d)} y_i) \Phi_\rho(y_i). \tag{S22}
\]

Using assumption \( i \), the third integral is always zero, therefore

\[
\int \rho^{(d)} y) K^{CN}(x, y) \Phi_\rho(y) = \frac{s}{d} \lambda_\rho \Phi_\rho(x) = \Lambda_\rho \Phi_\rho(x). \tag{S23}
\]

Finally, we prove the expansion of Eq. (18) from the definition of \( K_{LC}^{(d)} \),

\[
K_{LC}^{(d)}(x, y) = \frac{s}{d} \sum_{i \in P} C(x_i, y_i) \tag{S24}
\]

\[
= \frac{s^2}{d^2} \sum_{i \in P} \sum_{\rho \in P} \lambda_\rho \phi_\rho(x_i) \phi_\rho(y_i) \tag{S25}
\]

\[
= \lambda_1 \frac{s}{d} \sum_{i \in P} \phi_1(x_i) \phi_1(y_i) + \sum_{\rho > 1} \sum_{i \in P} \left( \frac{s}{d} \lambda_\rho \right) \phi_\rho(x_i) \phi_\rho(y_i) \tag{S26}
\]

\[
= \Lambda_1 \phi_1(x) \phi_1(y) + \sum_{\rho > 1} \sum_{i \in P} \Lambda_\rho \phi_\rho(x) \phi_\rho(y). \tag{S27}
\]

\[\blacksquare\]

### B.1 Spectra of convolutional kernels with overlapping patches

In this section Lemma 3.3 and Lemma 3.4 are extended to kernels with overlapping patches, having \( P = \{ 1, \ldots, d \} \) and \( |P| = d \). Such extension requires additional assumptions, which are stated below:

1. The \( d \)-dimensional input measure \( \rho^{(d)}(d^d x) \) is uniform on the \( d \)-torus \([0, 1]^d\);
2. The constituent kernel \( C(x, y) \) is translationally-invariant, isotropic and periodic,

\[
C(x, y) = C(||x - y||), \quad C(||x - y + n||) = C(||x - y||) \quad \forall n \in \mathbb{Z}^d. \tag{S28}
\]

Assumptions 1) and 2) above imply that \( C(x, y) \) can be diagonalised in Fourier space, i.e. (with \( k \) denoting the \( s \)-dimensional wavevector)
We also use the following notation for denoting subspaces of the \( k \)-space and that inputs are 'wrapped', i.e. we identify \( \mathbb{Z} \) and eigenvalues \( K \) above. Then,

\[
  s \text{ with eigenfunctions } \Phi_k, \quad \Phi_0 = 1, \quad \Phi_k(x) = \frac{1}{\sqrt{d}} \sum_{i=1}^{d} \phi_k(x_i) \quad \forall k \neq 0, \quad \Lambda_0 = \lambda_0, \quad \Lambda_k = \frac{s - u + 1}{d} \lambda_k \quad \forall k \in \mathcal{F}^u \text{ with } u \leq s.
\]

**Proof.** We start by proving the orthonormality of the eigenfunctions. In general, by orthonormality of the \( s \)-dimensional plane waves \( \phi_k(x) \), we have

\[
  \langle \phi_k(x), \phi_{k'}(y) \rangle = \begin{cases} 1 & \text{if } k = k' \text{ and } x = y, \\ 0 & \text{otherwise}. \end{cases}
\]

We denote with \( \mathcal{P} \) the set of patch indices associated with a given kernel/architecture.

Let us introduce the following definitions, after recalling that a patch \( x_i \) is formed by first considering only wavevectors having the last \( u \) components \( u \)-dimensional overlap, the union \( x_{i \cup j} \equiv x_i \cup x_j \) and differences \( x_{i \setminus j} \equiv x_i \setminus x_j \) are all patches of \( x \), with dimensions \( 2s - o, s - o \) and \( s - o \), respectively.

We also use the following notation for denoting subspaces of the \( k \)-space \( \mathbb{Z}^s \).

\[
  \mathcal{F}^u = \{ k = 2\pi n \mid n \in \mathbb{Z}^s; \ n_1, n_u \neq 0; \ n_v = 0 \forall v \text{ s. t. } u < v \leq s \}. \quad (S31)
\]

\( \mathcal{F}^s \) is the set of all wavevectors \( k \) having nonvanishing extremal components \( k_1 \) and \( k_s \). For \( u < s \), \( \mathcal{F}^u \) is formed by first considering only wavevectors having the last \( s - u \) components equal to zero, then asking the resulting \( u \)-dimensional wavevectors to have nonvanishing extremal components. Practically, \( \mathcal{F}^u \) contains wavevectors which can be entirely specified by the first \( u \)-dimensional patch \( k^{(u)}_1 = (k_1, \ldots, k_u) \) but not by the first \( (u - 1) \)-dimensional one. Notice that, in order to safely compare \( k \)'s in different \( \mathcal{F} \)'s, we have introduced an apex \( u \) denoting the dimensionality of the patch.

**Lemma B.1** (Spectra of overlapping convolutional kernels). Let \( K^{CN} \) be a convolutional kernel defined as in Eq. (16a) with \( \mathcal{P} = \{1, \ldots, d\} \) and constituent kernel \( C \) satisfying assumptions i), ii) above. Then, \( K^{CN} \) admits the following Mercer’s decomposition,

\[
  K^{CN}(x, y) = \Lambda_0 + \sum_{u=1}^{s} \left( \sum_{k \in \mathcal{F}^u} \Lambda_k \Phi_k(x) \Phi_k(y) \right), \quad (S32)
\]

with eigenfunctions

\[
  \Phi_0(x) = 1, \quad \Phi_k(x) = \frac{1}{\sqrt{d}} \sum_{i=1}^{d} \phi_k(x_i) \quad \forall k \neq 0, \quad (S33)
\]

and eigenvalues

\[
  \Lambda_0 = \lambda_0, \quad \Lambda_k = \frac{s - u + 1}{d} \lambda_k \quad \forall k \in \mathcal{F}^u \text{ with } u \leq s. \quad (S34)
\]
\[ \langle \Phi_k, \Phi_q \rangle = \frac{1}{d} \int_{[0,1]^d} d^d x \left( \sum_{i=1}^d \phi_k(x_i) \right) \left( \sum_{j=1}^d \phi_q(x_j) \right) \]

\[ = \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \not\in \mathcal{P}} \int d^d x_i e^{ik \cdot x_i} \int d^d x_j e^{-iq \cdot x_j} + \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \in \mathcal{P}} \int d^d x_i e^{i(k-q) \cdot x_i} \]

\[ + \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \in \mathcal{P}, i \neq j} \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \int (d^d x_{i,j}) \]

\[ + \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \in \mathcal{P}, i \neq j} \sum_{k \not\in \mathcal{P}} \delta(k, 0) \delta(q, 0) + \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \not\in \mathcal{P}} \delta(k, q) \]

\[ + \frac{1}{d} \sum_{i \in \mathcal{P}} \sum_{j \in \mathcal{P}, i \neq j} \left( \sum_{k \not\in \mathcal{P}} \delta(k_1^{(s-o)}, 0) \delta(k_1^{(s-o)}, q_1^{(o)}) \delta(q_1^{(s-o)}, 0) \right) \]

\[ + \sum_{j \in \mathcal{P}, i} \delta(q_1^{(s-o)}, 0) \delta(k_1^{(o)}, q_1^{(s-o)}) \delta(k_1^{(s-o)}, 0) \right) \]

(S35)

with \( \delta(k, q) \) denoting the multi-dimensional Kronecker delta. For fixed \( i \), the three terms on the RHS correspond to \( j \)'s such that \( x_j \) does not overlap with \( x_i \), to \( j = i \) and to \( j \)'s such that \( x_j \) overlaps with \( x_i \), respectively. We recall that, in patch notation, \( k_1^{(s-o)} \) denotes the subsequence of \( k \) formed with the first \( s-o \) components and \( k_1^{(o)} \) the subsequence formed with the last \( o \) components.

By taking \( k \) and \( q \) in \( \mathcal{F}^s \), as \( k_1, k_s \neq 0 \) and \( q_1, q_s \neq 0 \), Eq. (S35) implies

\[ \langle \Phi_k, \Phi_q \rangle = \delta(k, q). \]  

(S36)

In addition, by taking \( k \in \mathcal{F}^s \) and \( q = q_1^{(u)} \in \mathcal{F}^u \) with \( u < s \),

\[ \langle \Phi_k, \Phi_{q_1^{(u)}} \rangle = 0 \quad \forall u < s. \]  

(S37)

Thus the \( \Phi_k \)'s with \( k \in \mathcal{F}^s \) are orthonormal between each other and orthogonal to all \( \Phi_{q_1^{(u)}} \)'s with \( u < s \). Similarly, by taking \( k \in \mathcal{F}^u \) with \( u < s \) and \( q \in \mathcal{F}^v \) with \( v \leq u \), orthonormality is proven down to \( \Phi_{k_1^{(1)}} \). The zero-th eigenfunction \( \Phi_0(x) = 1 \) is also orthogonal to all other eigenfunctions by Eq. (S35) with \( k = 0 \) and trivially normalised to 1.

Secondly, we prove that eigenfunctions from Eq. (S33) and eigenvalues from Eq. (S34) satisfy the kernel eigenproblem of \( K^{CN} \). For \( k = 0 \),

\[ \int_{[0,1]^d} d^d y K^{CN}(x, y) = \frac{1}{d} \sum_{i,j=1}^d \int_{[0,1]^d} d^d y \sum_q \lambda_k e^{i\langle q, x - y \rangle} = \lambda_0, \]

proving that \( \Lambda_0 \) and \( \Phi_0 \) satisfy the eigenproblem. For \( k \neq 0 \),
When $k \in \mathcal{F}^s$, the deltas coming from the terms with $j \in \mathcal{P}_{j,\pm}$ vanish, showing that the eigenproblem is satisfied with $\Lambda_k = \lambda_k/d$ and $\Phi_k(x) = \sum_{i} e^{i k \cdot x}/\sqrt{d}$. When $k \in \mathcal{F}^u$ with $u < s$, as the last $s-u$ components of $k$ vanish, there are several $q$’s satisfying the deltas in the bracket. There is $q = k$, from the $l = j$ term, then there are the $s-u$ $q$’s such that $\delta(q_{(s-o)}^{(s)}, 0) \delta(q_{(s-o+1)}^{(o)}, 1) \delta(k_{(s-o)}, 0) = 1$.

These are all the $q$’s having a $u$-dimensional patch equal to $k_{(u)}$ and all the other elements set to zero, thus there are $(s-u+1)$ such $q$’s. Moreover, as $\lambda_q$ depends only on the modulus of $q$, all these $q$’s result in the same eigenvalue, and in the same eigenfunction $\sum_{i} e^{i q \cdot x}/\sqrt{d}$, after the sum over patches. Therefore,

$$\int_{[0, 1]^d} d^d y \ K^{CN}(x, y) \Phi_{k_{(u)}}(y) = \frac{(s-u+1)}{d} \lambda_{k_{(u)}} \Phi_{k_{(u)}} = \Lambda_{k_{(u)}} \Phi_{k_{(u)}} \ . \quad (S40)$$

Finally, we prove the expansion of the kernel in Eq. (S32)

$$K^{CN}(x, y) = \frac{1}{d^2} \sum_{i, j \in \mathcal{P}} C(x_i, y_j) \quad (S41)$$

$$= \sum_{k} \frac{1}{d^2} \lambda_k \left( \frac{1}{\sqrt{d}} \sum_{i \in \mathcal{P}} \phi_k(x_i) \right) \left( \frac{1}{\sqrt{d}} \sum_{j \in \mathcal{P}} \phi_k(y_j) \right) \ . \quad (S42)$$

The terms on the RHS of Eq. (S41) are trivially equal to those of Eq. (S32) for $k \in \mathcal{F}^s$. All the $k$ having $s-u$ vanishing extremal components can be written as shifts of $k_{(u)}^{(s)} \in \mathcal{F}^u$, which has the last $s-u$ components vanishing. But a shift of $k$ does not affect $\lambda_k$ nor $\sum_{i} e^{i k \cdot x}$, leading to a degeneracy of eigenvalues having $k$ which can be obtained from a shift of $k_{(s)}^{(s)} \in \mathcal{F}^u$. Such degeneracy is removed by restricting the sum over $k$ to the sets $\mathcal{F}^u$, $u \leq s$, of wavevectors with non-vanishing extremal components, and rescaling the remaining eigenvalues with a factor of $(s-u+1)/d$, so that Eq. (S32) is obtained.

**Lemma B.2** (Spectra of overlapping local kernels). Let $K^{LC}$ be a local kernel defined as in Eq. (16b) with $\mathcal{P} = \{1, \ldots, d\}$ and constituent kernel $C$ satisfying assumptions i), ii) above. Then, $K^{LC}$ admits the following Mercer’s decomposition,

$$K^{LC}(x, y) = \Lambda_0 + \sum_{u=1}^{s} \sum_{k \in \mathcal{F}^u} \sum_{i=1}^{d} \Lambda_{k_i} \Phi_{k_i}(x) \Phi_{k_i}(y) \quad (S43)$$

with eigenfunctions

$$\Phi_0(x) = 1, \quad \Phi_{k_i}(x) = \phi_k(x_i) \quad \forall k \in \mathcal{F}^u \text{ with } 1 \leq u \leq s \text{ and } i = 1, \ldots, d, \quad (S44)$$

and eigenvalues
\[ \lambda_0 = \lambda_0, \Lambda_{k,i} = \frac{s - u + 1}{d} \lambda_k \quad \forall k \in \mathcal{F}^u \text{ with } u \leq s \text{ and } i = 1, \ldots, d. \quad (S45) \]

**Proof.** We start by proving the orthonormality of the eigenfunctions. The scalar product \( \langle \Phi_{k,i}, \Phi_{q,j} \rangle \) depends on the relation between the \( i \)-th and \( j \)-th patches.

\[
\int_{[0,1]^d} d^d x \, \delta(\mathbf{x}) \, \delta_q(\mathbf{y}) \, = \delta(\mathbf{k}^{(s-o)}, 0) \delta(\mathbf{k}_s^{(s-o+1)}, \mathbf{q}_1^{(s-o)}) \, \delta(\mathbf{q}_o^{(s-o)}, 0), \quad \text{if } j \in \mathcal{P}_{i,+}, \quad (S46a)
\]

\[
= \delta(q_1^{(s-o)}, 0) \delta(\mathbf{k}_1^{(s-o)}, q_s^{(s-o+1)}) \, \delta(\mathbf{k}_o^{(s-o)}, 0), \quad \text{if } j \in \mathcal{P}_{i,-}, \quad (S46b)
\]

\[
= \delta(k, 0) \delta(\mathbf{q}_o, 0), \quad \text{if } j \notin \mathcal{P}_i, \quad (S46c)
\]

\[
= \delta(k, q), \quad \text{if } j = i. \quad (S46d)
\]

Clearly, \( \langle \Phi_0, \Phi_0 \rangle = 1 \) and setting one of \( q \) and \( k \) to 0 in Eq. (S46) yields orthogonality between \( \Phi_0 \) and \( \Phi_{k,i} \) for all \( k \neq 0 \) and \( i = 1, \ldots, d \). For any \( k \neq 0 \), Eq. (S46d) implies

\[
\langle \Phi_{k,i}, \Phi_{q,j} \rangle = \delta(k, q) \delta_{i,j} \quad (S47)
\]

unless \( k = k_1^{(s-o)} \in \mathcal{F}^u \) and \( q \) is a shift of \( k^{(s-o)} \). But such a \( q \) would have \( q_1 = 0 \) and there is no eigenfunction \( \Phi_q \) with \( q_1 = 0 \), apart from \( \Phi_0 \). Hence, orthonormality is proven.

We then prove that eigenfunctions and eigenvalues defined in Eq. (S44) and Eq. (S45) satisfy the kernel eigenproblem of \( K^{LC} \). For \( k = 0 \),

\[
\int_{[0,1]^d} d^d y \, K^{LC}(\mathbf{x}, \mathbf{y}) = \frac{1}{d} \sum_{i=1}^d \int_{[0,1]^d} d^d y \, \sum_q \lambda_k \delta_{i,j} = \lambda_0 \quad (S48)
\]

In general,

\[
\int_{[0,1]^d} d^d y \, K^{LC}(\mathbf{x}, \mathbf{y}) e^{i k \cdot \mathbf{y}} = \frac{1}{d} \sum_{i=1}^d \int_{[0,1]^d} d^d y \, \sum_q \lambda_k \delta_{i,j} e^{i k \cdot \mathbf{y}}
\]

\[
= \frac{1}{d} \sum_q \lambda_q \left( \delta(k, q) e^{i k \cdot \mathbf{x}_i} + \sum_{i \notin \mathcal{P}_i} \delta(q, 0) \delta(k, 0) + \sum_{i \in \mathcal{P}_{i,+}} e^{i q \cdot x_i} \delta(k^{(s-o)}, 0) \delta(q^{(s-o)}, q_1^{(s-o)}) \delta(k_o^{(s-o)}, 0) \right.
\]

\[
\left. + \sum_{i \in \mathcal{P}_{i,-}} e^{i q \cdot x_i} \delta(q_1^{(s-o)}, 0) \delta(k_1^{(s-o)}, q^{(s-o)}, q^{(s-o+1)}) \delta(k_o^{(s-o)}, 0) \right). \quad (S49)
\]

For \( k \in \mathcal{F}^u \), with \( u = 1, \ldots, s \), the deltas which set the first component of \( k \) to 0 are never satisfied, therefore

\[
\int_{[0,1]^d} d^d y \, K^{LC}(\mathbf{x}, \mathbf{y}) e^{i k \cdot \mathbf{y}}
\]

\[
= \frac{1}{d} \sum_q \lambda_q \left( \delta(k, q) e^{i k \cdot x_i} + \sum_{i \in \mathcal{P}_{i,-}} e^{i q \cdot x_i} \delta(q_1^{(s-o)}, 0) \delta(k_1^{(s-o)}, q^{(s-o)}, q^{(s-o+1)}) \delta(k_o^{(s-o)}, 0) \right). \quad (S50)
\]
The second term in brackets vanishes for \( k \in \mathcal{F}^s \) and the eigenvalue equation is satisfied with \( \lambda_{k, \ell} = \lambda_k / d \). For \( k = k_1^{(u)} \in \mathcal{F}^u \) with \( u < s \), \( \delta(k_1^{(u+1)}, 0) = 1 \) for any \( o > u \). As a result of the remaining deltas, the RHS of Eq. (S50) becomes a sum over all \( q \)'s which can be obtained from shifts of \( k_1^{(u)} \), which are \( s - u + 1 \) (including \( k_1^{(u)} \) itself). The patch \( x_i \), which is multiplied by \( q \) in the exponent is also a shift of \( x_i \), thus all the factors \( e^{i q \cdot x_i} \) appearing in the sum coincide with \( e^{i k_1^{(u)} \cdot x_i} \). As \( \lambda_q \) depends on the modulus of \( q \), all these terms correspond to the same eigenvalue, \( \lambda_{k_1^{(u)}} \), so that

\[
\int_{[0,1]^d} d^d y \, K_{LC}^{\mathcal{LP}}(x, y) e^{i k_1^{(u)} \cdot y} = \left( \frac{s - u + 1}{d} \lambda_{k_1^{(u)}} \right) e^{i k_1^{(u)} \cdot x_i}. \quad (S51)
\]

Finally, we prove the expansion of the kernel in Eq. (S43)

\[
K_{LC}(x, y) = \frac{1}{d} \sum_{i \in P} C(x_i, y_i) = \sum_k \frac{1}{d} \lambda_k \sum_{i \in P} \phi_k(x_i) \phi_k(y_i). \quad (S52)
\]

As in the proof of the eigendecomposition of convolutional kernels, all the \( k \) having \( s - u \) vanishing extremal components can be written as shifts of \( k_1^{(u)} \in \mathcal{F}^u \), which has the last \( s - u \) components vanishing. The shift of \( k \) does not affect \( \lambda_k \) nor the product \( \phi_k(x_i) \phi_k(y_i) \), after summing over \( i \) leading to a degeneracy of eigenvalues which is removed by restricting the sum over \( k \) to the sets \( \mathcal{F}^u, u \leq s \), and rescaling the remaining eigenvalues \( \lambda_{k_1^{(u)}} \) with a factor of \( (s - u + 1)/d \), leading to Eq. (S43).

\[\]

C Proof of Theorem 4.1

**Theorem C.1** (Theorem 4.1 in the main text). Let \( K_T \) be a \( d \)-dimensional convolutional kernel with an isotropic, translationally-invariant \( t \)-dimensional constituent and leading nonanalyticity at the origin controlled by the exponent \( \alpha_t > 0 \). Let \( K_S \) be a \( d \)-dimensional convolutional or local student kernel with an isotropic, translationally-invariant \( s \)-dimensional constituent, and with a nonanalyticity at the origin controlled by the exponent \( \alpha_s > 0 \). If all the \( t \)-dimensional patches of the teacher are contained in at least one of the \( s \)-dimensional patches of the student, and data are uniformly distributed on a \( d \)-dimensional torus, the following asymptotic equivalence holds in the limit \( P \to \infty \),

\[
B(P) \sim P^{-\beta}, \quad \beta = \alpha_t / s. \quad (S53)
\]

**Proof.** For the sake of clarity, we start with the proof in the nonoverlapping-patches case, and then extend it to the overlapping-patches case. Since \( K_T \) and \( K_S \) have translationally-invariant constituent kernels and data are uniformly distributed on a \( d \)-dimensional torus, the kernels can be diagonalised in Fourier space. Let us start by considering a convolutional student: because of the constituent kernel’s isotropy, the Fourier coefficients \( \Lambda_k^{(s)} \) of \( K_S \) depend on \( k \) (modulus of \( k \)) only. Notice the superscript indicating the dimensionality of the student constituents. In particular, \( \Lambda_k^{(s)} \) is a decreasing function of \( k \) and, for large \( k \), \( \Lambda_k \sim k^{-(s + \alpha_s)} \). Then, \( B(P) \) reads

\[
B(P) = \sum_{\{k | k > k_c(P)\}} \mathbb{E}[|c_k|^2], \quad (S54)
\]

where \( k_c(P) \) is defined as the wavevector modulus of the \( P \)-th largest eigenvalue and \( \mathbb{E}[|c_k|^2] \) denotes the variance of the target coefficients in the student eigenbasis. \( k_c(P) \) is such that there are exactly \( P \) eigenvalues with \( k \leq k_c(P) \),

\[
P = \sum_{\{k | k < k_c(P)\}} 1 \sim \int \frac{d^s k}{(2\pi)^s} \theta(k_c(P) - k) = \frac{1}{(2\pi)^s} \frac{\pi^{s/2}}{\Gamma(s/2 + 1)} k_c(P)^s, \quad (S55)
\]

i.e. \( k_c(P) \sim P^{1/s} \).
By denoting the eigenfunctions of the student with $\Phi^{(s)}_k$, the superscript $(s)$ indicating the dimension of the constituent’s plane waves,

$$
E[|c_k|^2] = \int_{[0,1]^d} d^d x \Phi^{(s)}_k(x) \int_{[0,1]^d} d^d y \Phi^{(s)}_k(y) E[f^*(x)f^*(y)]
$$

(S56)

$$
= \int_{[0,1]^d} d^d x \Phi^{(s)}_k(x) \int_{[0,1]^d} d^d y \Phi^{(s)}_k(y) K_T(x,y).
$$

Decomposing the teacher kernel $K_T$ into its eigenvalues $\Lambda^{(t)}_q$ and eigenfunctions $\Phi^{(t)}_q(y)$,

$$
E[|c_k|^2] = \int_{[0,1]^d} d^d x \Phi^{(s)}_k(x) \int_{[0,1]^d} d^d y \Phi^{(s)}_k(y) \left( \Lambda^{(t)}_0 + \frac{2}{d} \sum_{q \neq 0} \frac{\Lambda^{(t)}_q}{q} \sum_{i \in P^{(t)}} \phi^{(t)}_q(x_i) \sum_{j \in P^{(t)}} \phi^{(t)}_q(y_j) \right).
$$

(S57)

The $q = 0$ mode of the teacher can give non-vanishing contributions to $c_0$ only, therefore it does not enter any term of the sum in Eq. (S54). Once we removed the term with $q = 0$, consider the $y$-integral:

$$
\mathcal{I}_k(x) = \int_{[0,1]^d} d^d y \sqrt{\frac{s}{d}} \sum_{m \in P^{(s)}} \phi^{(s)}_k(y_m) \frac{s}{d} \sum_{q \neq 0} \frac{\Lambda^{(t)}_q}{q} \sum_{i \in P^{(t)}} \phi^{(t)}_q(x_i) \sum_{j \in P^{(t)}} \phi^{(t)}_q(y_j)
$$

(S58)

$$
= \left( \frac{s}{d} \right)^{\frac{3}{2} - s} \frac{\sum_{m \in P^{(s)}} \phi^{(s)}_k(y_m) \sum_{i \in P^{(t)}} \phi^{(t)}_q(x_i) \sum_{j \in P^{(t)}} \int_{[0,1]^d} d^d y \phi^{(s)}_k(y_m) \phi^{(t)}_q(y_j)}{d}.
$$

As all the $t$-dimensional patches of the teacher must be contained in at least one of the $s$-dimensional patches of the student, in the nonoverlapping case we require that $s$ is an integer multiple of $t$. Then, each of the teacher patches is entirely contained in one and only one patch of the student. If the teacher patch $y_j$ is not contained in the student patch $y_m$, we can factorise the integration over $y$ into two integrals over $y_j$ and $y_m$. These terms give vanishing contributions to $\mathcal{I}_k(x)$ since the integral of a plane wave over a period is always zero for non-zero wavevectors. Instead, if the teacher patch $y_j$ is contained in the student patch $y_m$, denoting with $l$ the index of the element of $y_m$ which coincides with the first element of $y_j$, we can factorise the student eigenfunctions as follows

$$
\phi^{(s)}_k(y_m) = \phi^{(t)}_{k_{l}}(y_j) \phi^{(s-t)}_{k_{l}}(y_{m \times j}).
$$

(S59)

Here $k_{l}^{(t)}$ denotes the $t$-dimensional patch of $k$ starting at $l$ and $k \sim k_{l}^{(t)}$ the sequence of elements which are in $k$ but not in $k_{l}^{(t)}$. As $s$ is an integer multiple of $t$, $l = l \times s/t$ with $l = 1, \ldots, t$. Inserting Eq. (S59) into Eq. (S58),

$$
\mathcal{I}_k(x) = \sum_{l=s/t, l=1}^{t} \delta(k \sim k_{l}^{(t)}, 0) \Lambda^{(t)}_{k_{l}^{(t)}} \sqrt{\frac{s}{d}} \sum_{i \in P^{(t)}} \phi^{(t)}_{k_{l}^{(t)}}(x_i).
$$

(S60)

The $x$-integral of Eq. (S56) can be performed by the same means after expanding $\Phi^{(s)}_k$ as a sum of $s$-dimensional plane waves, so as to get,

$$
E[|c_k|^2] = \sum_{l=s/t, l=1}^{t} \delta(k \sim k_{l}^{(t)}, 0) \Lambda^{(t)}_{k_{l}^{(t)}}.
$$

(S61)
Therefore, \( \mathbb{E}[|c_k|^2] \) is non-zero only for \( k \)'s which have at most \( t \) consecutive components greater or equal than zero, and the remaining \( s-t \) being strictly zero. Inserting Eq. (S61) into Eq. (S54)

\[
B(P) = \sum_{k \in \mathbb{F}^s} \sum_{l=1}^t \delta(k \setminus k_{(l)}^{(t)}, 0) \Lambda_{k_{(l)}} \sim \int_{P^{t/s}} dk k^{-1} k^{-(\alpha_t + t)} \sim P^{-\frac{2\alpha_t}{s}}. \quad (S62)
\]

When using a local student, the convolutional eigenfunctions in the RHS of Eq. (S56) are replaced by the local eigenfunctions \( \Phi_{k_{(1)}}(x) \) of Eq. (20). From there on, the derivation carries over unaltered, except for the sum over the student patches which disappears from all the equations in the local case and a different prefactor in the relation between \( k_{c}(P) \) and \( P \). As a result, \( B(P) \sim P^{-\frac{2\alpha_t}{s}} \) also in this case.

As we showed in Appendix B, when the patches overlap the set of wavevectors which index the eigenvalues is restricted from \( \mathbb{Z}^d \) to the union of the \( \mathcal{F}^u \)'s for \( u = 0, \ldots, s \). In addition, the eigenvalues with \( k \in \mathcal{F}^u \), \( 0 < u < s \), are rescaled by a factor \( (s - u + 1)/d \). Therefore, in the overlapping case the eigenvalues do not decrease monotonically with \( k \) and \( B(P) \) cannot be written as a sum of over \( k \)'s with modulus \( k \) larger than a certain threshold \( k_c \). By considering also that, with \( t \leq s \), \( \mathbb{E}[|c_k|^2] \) is non-zero only for \( k \)'s which have at most \( t \) consecutive nonvanishing components, we have

\[
B(P) = \sum_{u=0}^t \sum_{k \in \mathcal{F}^u} \mathbb{E}[|c_k|^2] \chi(\Lambda_k^{(s)} > \Lambda_P), \quad (S63)
\]

where \( \Lambda_P \) denotes the \( P \)-th largest eigenvalue and the indicator function \( \chi(\Lambda_k^{(s)} > \Lambda_P) \) ensures that the sum runs over all but the first \( P \) eigenvalues of the student. The sets \( \{\mathcal{F}^u\}_{u=t} \) have all null measure in \( \mathbb{Z}^d \), whereas \( \mathcal{F}^t \) is dense in \( \mathbb{Z}^d \), thus the asymptotics of \( B(P) \) are dictated by the sum over \( \mathcal{F}^t \). When \( k \)'s are restricted to the latter set, eigenvalues are again decreasing functions of \( k \) and the constraint \( \Lambda_k^{(s)} > \Lambda_P \) translates into \( k > k_c(P) \). Having changed, with respect to the nonoverlapping case, only an infinitesimal fraction of the eigenvalues, the asymptotic scaling of \( k_c(P) \) with \( P \) remains unaltered and the estimate of Eq. (S62) extends to kernels with nonoverlapping patches.

\[\blacksquare\]

### D Asymptotic learning curves with a local teacher

**Theorem D.1.** Let \( K_T \) be a \( d \)-dimensional local kernel with an isotropic, translationally-invariant \( t \)-dimensional constituent and leading nonanalyticity at the origin controlled by the exponent \( \alpha_t > 0 \). Let \( K_S \) be a \( d \)-dimensional local student kernel with an isotropic, translationally-invariant \( s \)-dimensional constituent, and with a nonanalyticity at the origin controlled by the exponent \( \alpha_s > 0 \). If all the \( t \)-dimensional patches of the teacher are contained in at least one of the \( s \)-dimensional patches of the student, and data are uniformly distributed on a \( d \)-dimensional torus, the following asymptotic equivalence holds in the limit \( P \to \infty \),

\[
B(P) \sim P^{-\beta}, \quad \beta = \frac{\alpha_t}{s}. \quad (S64)
\]

**Proof.** The proof is analogous to that of Appendix C, the only difference being that eigenfunctions and eigenvalues are indexed by \( k \) and the patch index \( i \). This results in an additional factor of \( d/s \) in the RHS of Eq. (S55). All the discussion between Eq. (S56) and Eq. (S61) can be repeated by attaching the additional patch index \( i \) to all coefficients. Eq. (S62) for \( B(P) \) is then corrected with an additional sum over patches. The extra sum, however, does not influence the asymptotic scaling with \( P \).

\[\blacksquare\]

### E Proof of Theorem 6.1

**Theorem E.1** (Theorem 6.1 in the main text). Let us consider a positive-definite kernel \( K \) with eigenvalues \( \Lambda_P, \sum_P \Lambda_P < \infty \), and eigenfunctions \( \Phi_P \) learning a (random) target function \( f^* \) in

\[
\sum_P \lambda_P \sum_{i \in C} |\langle \Phi_P, \Phi_i \rangle |^2 \sim \sum_P \Lambda_P \sim \frac{1}{n}. \quad (S65)
\]
kernel ridge regression (Eq. (3)) with ridge \( \lambda \) from \( P \) observations \( f^*_\mu = f^*(x^\mu) \), with \( x^\mu \in \mathbb{R}^d \) drawn from a certain probability distribution. Let us denote with \( \mathcal{D}_T(\lambda) \) the reduced density of kernel eigenvalues with respect to the target and \( \epsilon(\lambda, P) \) the generalisation error and also assume that

i) For any \( P \)-tuple of indices \( \rho_1, \ldots, \rho_P \), the vector \((\Phi_{\rho_1}(x^1), \ldots, \Phi_{\rho_P}(x^P))\) is a Gaussian random vector;

ii) The target function can be written in the kernel eigenbasis with coefficients \( c_\rho \) and \( c_\rho^2(\Lambda_\rho) = \mathbb{E}[|c_\rho|^2] \), with \( \mathcal{D}_T(\lambda) \sim \Lambda^{-(1+r)} \), \( c_\rho^2(\Lambda) \sim \Lambda^q \) asymptotically for small \( \Lambda \) and \( r > 0, r < q < r + 2 \);

Then the following equivalence holds in the joint \( P \to \infty \) and \( \lambda \to 0 \) limit with \( 1/(\lambda \sqrt{P}) \to 0 \):

\[
\epsilon(\lambda, P) \sim \sum_{\rho \mid \Lambda_\rho < \lambda} \mathbb{E}[|c_\rho|^2] = \int_0^\lambda d\Lambda \mathcal{D}_T(\Lambda)c_\rho^2(\Lambda). \tag{S65}
\]

**Proof.** In this proof we make use of results derived in [21]. Our setup for kernel ridge regression correspond to what the authors of [21] call the classical setting. Let us introduce the integral operator \( T_K \) associated with the kernel, defined by

\[
(T_K f)(x) = \int p(d^D y) K(x, y) f(y).
\]

The trace \( T[\mathcal{R}[T_K]] \) coincide with the sum of \( K \)'s eigenvalues and is finite by hypothesis. We define the following estimator of the generalisation error \( \epsilon(\lambda, P) \),

\[
\mathcal{R}(\lambda, P) = \partial_\lambda \vartheta(\lambda) \int p(d^D x) \left( f^*(x) - (A_\vartheta f^*)(x) \right)^2,
\]

where \( \vartheta(\lambda) \) is the signal capture threshold (SCT) [21] and \( A_\vartheta = T_K(1 + \vartheta(\lambda))^{-1} \) is a reconstruction operator [21]. The target function can be written in the kernel eigenbasis by hypothesis (with coefficients \( c_\rho \)) and \( T_K \) has the same eigenvalues and eigenfunctions of the kernel by definition. Hence,

\[
\mathcal{R}(\lambda, P) = \partial_\lambda \vartheta(\lambda) \sum_{\rho = 1}^{\infty} \frac{\vartheta(\lambda)^2}{(\Lambda_\rho + \vartheta(\lambda))^2} |c_\rho|^2 = \partial_\lambda \vartheta(\lambda) \int_0^\infty d\Lambda \mathcal{D}_T(\Lambda)c_\rho^2(\Lambda) \frac{\vartheta(\lambda)^2}{(\Lambda + \vartheta(\lambda))^2}, \tag{S68}
\]

where \( \mathcal{D}_T \) is the reduced density of eigenvalues [Eq. (27)]. We now derive the asymptotics of \( \mathcal{R}(\lambda, P) \) in the joint \( P \to \infty \) and \( \lambda \to 0 \) limit, then relate the asymptotics of \( \mathcal{R} \) to those of \( \epsilon(\lambda, P) \) via a theorem proven in [21].

Proposition 3 of [21] shows that for any \( \lambda > 0 \), \( \partial_\lambda \vartheta(\lambda) \to 1 \) and \( \vartheta(\lambda) \to \lambda \) with corrections of order \( 1/N \). Thus, we focus on the following integral,

\[
\int_0^\infty d\Lambda \mathcal{D}_T(\Lambda)c_\rho^2(\Lambda) \frac{\lambda^2}{(\Lambda + \lambda)^2}. \tag{S69}
\]

The functions \( \mathcal{D}_T(\Lambda) \) and \( c_\rho^2(\Lambda) \) can be safely replaced with their small-\( \Lambda \) expansions \( \Lambda^{-(1+r)} \) and \( \Lambda^q \) over the whole range of the integral above because of the assumptions \( q > r \) and \( q \leq r + 2 \). In practice, there should be an upper cut-off on the integral coinciding with the largest eigenvalue \( \Lambda_1 \), but the assumption \( q \leq r + 2 \) causes this part of the spectrum to be irrelevant for the asymptotics of the error. In fact, we will conclude that the integral is dominated by the portion of the domain around \( \lambda \). After the change of variables \( y = \Lambda/\lambda \),

\[
\int_0^\infty d\Lambda \mathcal{D}_T(\Lambda)c_\rho^2(\Lambda) \frac{\lambda^2}{(\Lambda + \lambda)^2} = \lambda^{q-r} \int dy \frac{y^{q-1-r}}{(1+y)^2}, \tag{S70}
\]
where one recognises one of the integral representations of the beta function,
\[
B(a, b) = \int_0^\infty \frac{y^{a-1}}{(1+y)^{a+b}} = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}, \tag{S71}
\]
with \(\Gamma\) denoting the gamma function. Therefore,
\[
\int_0^\infty d\Lambda D_T(\Lambda)c^2(\Lambda)\frac{\lambda^2}{(\lambda+\lambda)^2} = \lambda^{q-r}\Gamma(q-r)\Gamma(2-q+r) \tag{S72}
\]
It is interesting to notice how the assumptions \(q > r\) and \(q < r + 2\) are required in order to avoid the poles of the \(\Gamma\) functions in the RHS of Eq. (S72).

We now use Eq. (S72) to infer the asymptotics of \(R(\lambda, P)\) in the scaling limit \(\lambda \to 0\) and \(P \to \infty\) with \(1/(\lambda\sqrt{P}) \to 0\). The latter condition implies that \(\lambda\) decays more slowly than \((P)^{-1/2}\), thus additional terms stemming from the finite-P difference between \(\vartheta\) and \(\lambda\) of order \(P^{1-1}\) are negligible w.r.t. \(\lambda^{q-r}\). The finite-P difference between \(\partial_\lambda \vartheta\), also \(O(P^{-1})\), can be neglected too. Finally,
\[
R(\lambda, P) \sim \int_0^\infty d\Lambda D_T(\Lambda)c^2(\Lambda)\frac{\lambda^2}{(\lambda+\lambda)^2} \sim \lambda^{q-r} \sim \int_0^\lambda d\Lambda D_T(\Lambda)c^2(\Lambda). \tag{S73}
\]

Theorem 6 of [21] shows the convergence of \(\epsilon(\lambda, P)\) towards \(R(\lambda, P)\) when \(P \to \infty\). Specifically,
\[
|\epsilon(\lambda, P) - R(\lambda, P)| \leq \left(\frac{1}{F} + g \left(\frac{Tr[T_K]}{\lambda \sqrt{P}}\right)\right) R(\lambda, P), \tag{S74}
\]
where \(g\) is a polynomial with nonnegative coefficients and \(g(0) = 0\). With a decaying ridge \(\lambda(P)\) such that \(1/(\lambda\sqrt{P}) \to 0\), both \(R/P\) and \(Rg(Tr[T_K]/(\lambda \sqrt{P}))\) tend to zero faster than \(R\) itself, thus the asymptotics of \(\epsilon(\lambda, P)\) coincide with those of \(R(\lambda, P)\) and Eq. (S65) is proven. \(\blacksquare\)

**Remark** The estimate for the exponent \(\beta\) of Corollary 6.1.1 follows from the theorem above with \(r = t/(s + \alpha_s), q = (\alpha_t + t)/(\alpha_s + s)\) and \(\lambda \sim P^{-1}\). Then \(q > r\) because \(\alpha_t > 0\), whereas the condition \(q < r + 2\) is equivalent to the assumption \(\alpha_t < 2(\alpha_s + s)\) required in Section 4 in order to derive the learning curve exponent in Eq. (23) from our estimate of \(B(P)\).

**F Numerical experiments**

**F.1 Details on the simulations**

To obtain the empirical learning curves, we generate \(P + P_{\text{test}}\) random points uniformly distributed in a \(d\)-dimensional hypercube or on the surface of a \(d - 1\)-dimensional hypersphere embedded in \(d\) dimensions. We use \(P \in \{128, 256, 512, 1024, 2048, 4096, 8192\}\) and \(P_{\text{test}} = 8192\). For each value of \(P\), we generate a Gaussian random field with covariance given by the teacher kernel, and we compute the kernel ridgeless regression predictor of the student kernel using Eq. (4) with the \(P\) training samples. The generalisation error defined in Eq. (5) is approximated by computing the empirical mean squared error on the \(P_{\text{test}}\) unseen samples. The expectation with respect to the target function is obtained averaging over 128 independent teacher Gaussian processes, each sampled on different points of the domain. As teacher and student kernels, we consider different combinations of the convolutional and local kernels defined in Eq. (16a) and Eq. (16b) with Laplacian constituents \(C(x_i - x_j) = e^{-\|x_i - x_j\|}\) and overlapping patches. In particular,

- the cases with convolutional teacher and both convolutional and local students with various filter sizes are reported in Fig. 1 and Fig. S2 for data distributed in a hypercube and on a hypersphere respectively;
- the cases with local teacher and both local and convolutional students are reported in Fig. S1 for data distributed in a hypercube.

Experiments are run on NVIDIA Tesla V100 GPUs using the PyTorch package. The approximate total amount of time to reproduce all experiments with our setup is 250 hours.
Figure S1: Learning curves for local teacher and local and convolutional student kernels, with filter sizes denoted by \( t \) and \( s \) respectively. Data are sampled uniformly in the hypercube \([0, 1]^d\), with \( d = 9 \) if not specified otherwise. Solid lines are the results of numerical experiments averaged over 128 realisations and the shaded areas represent the empirical standard deviations. The predicted scaling are shown by dashed lines.

F.2 Additional experiments

**Local teacher** In Fig. S1, we report the empirical learning curves for a local teacher kernel and data uniformly sampled in the hypercube \([0, 1]^d\). In panels G and H, also the student is a local kernel and the same discussion of Section 5 applies. In panel I, the student is a convolutional kernel and the generalisation error does not decrease by increasing the size of the training set. Indeed, a local non-shift-invariant function is not on the span of the eigenfunctions of a convolutional kernel, and therefore the student is not able to learn the target.

**Spherical data** In Fig. S2, we report the empirical learning curves for convolutional teacher and convolutional (left panels) and local (right panels) student kernels. Data are restricted to the unit sphere \( S^{d-1} \). Panels J-M are the analogous of panels A-D of Fig. 1. Notice that when the filter size of the student coincides with \( d \) (panels N, O), the learning curves decay with exponent \( \beta = 1/(d - 1) \) (instead of \( \beta = 1/d \)). Indeed, for data normalised on \( S^{d-1} \), the spectrum of the Laplacian kernel decays at a rate \( O(k^{-\alpha-(d-1)}) \) with \( \alpha = 1 \). However, as the student filter size is lowered, we recover the exponent \( 1/s \) independently of the dimension \( d \) of input space, as derived for data on the torus and shown empirically for data in the hypercube. In fact, we expect that the \( s \)-dimensional marginals of the uniform distribution on \( S^{d-1} \) become insensitive to the spherical constraint when \( s \ll d \).
Figure S2: Learning curves for data uniformly distributed on the unit sphere $S^{d-1}$, with $d = 10$ if not specified otherwise. The teacher and student filter sizes are denoted with $t$ and $s$ respectively. Solid lines are the results of numerical experiments averaged over 128 realisations and the shaded areas represent the empirical standard deviations.
