

# DERIVATION OF THE HALL-MHD EQUATIONS FROM THE NAVIER-STOKES-MAXWELL EQUATIONS

YI PENG, HUAQIAO WANG, AND QIUJU XU

**ABSTRACT.** By using a set of scaling limits, the authors in [1, 36] proposed a framework of deriving the Hall-MHD equations from the two-fluids Euler-Maxwell equations for electrons and ions. In this paper, we derive the Hall-MHD equations from the Navier-Stokes-Maxwell equations with generalized Ohm's law in a mathematically rigorous way via the spectral analysis and energy methods.

## 1. INTRODUCTION

The Hall-MHD equations have the following form in  $[0, T] \times \mathbb{R}^3$ :

$$\begin{cases} \partial_t u + \operatorname{div}(u \otimes u) - \Delta u + \nabla p = (\nabla \times B) \times B, & \operatorname{div} u = 0, \\ \partial_t B + \nabla \times ((\nabla \times B) \times B) - \nabla \times (u \times B) = \Delta B, & \operatorname{div} B = 0. \end{cases} \quad (1.1)$$

Here,  $u(t, x)$  and  $B(t, x)$  are the fluid velocity and magnetic field, and  $p$  is the pressure. The equations (1.1) have been studied in physics for a long time and have many applications in the field of physics such as earth generators, etc. In general, the Hall term  $\nabla \times ((\nabla \times B) \times B)$  does not affect the properties of the magnetohydrodynamic equations. Under strong magnetic field or when the plasma density is relatively small, such as the magnetic field reconnection in space plasmas [21, 24], star formation [4, 40], geo-dynamo [31] and so on, the Hall effect can not be ignored. Lighthill [29] first studied the Hall effects and physically derived the Hall terms. Next, we sketch the formal derivation in [29]. Since the fluids are composed of charged particles, their flow generates electric field  $E$  and magnetic field  $B$ . Here the magnetic field  $B$  satisfies Ampere's law:

$$j = \nabla \times B, \quad (1.2)$$

where  $j$  is the current density, while the electric field  $E$  satisfies Faraday's law:

$$\partial_t B = -\nabla \times E. \quad (1.3)$$

If  $n_e$  and  $n_i$  are the number densities of ions and electrons, we have

$$\rho = n_i m_i + n_e m_e, \quad u = \frac{n_i m_i u_i + n_e m_e u_e}{n_i m_i + n_e m_e},$$

where  $m_i, m_e$  are the masses of ion and electron,  $u_i$  and  $u_e$  denote the velocities,  $\rho$  stands for the charge density. Since  $m_i$  is much larger than  $m_e$  (more than 1800 times),  $u$  is very close to  $u_i$ ,  $j$  can be approximated as

$$j = en_e(u - u_e), \quad (1.4)$$

where  $-en_e$  is the electron charge density. The electrons and ions momentum equations have the following form:

$$n_e m_e (\partial_t u_e + u_e \cdot \nabla u_e) = -\nabla p_e - M - n_e e (E + u_e \times B), \quad (1.5)$$

$$n_i m_i (\partial_t u_i + u_i \cdot \nabla u_i) = -\nabla p_i + M + n_i Z e (E + u_i \times B), \quad (1.6)$$

where  $Z$  is the average charge of the ions,  $p_i$  and  $p_e$  are the pressures of ions and electrons,  $M = -n_e e \kappa j$  denotes the momentum loss of electrons per unit volume during the collision and  $\kappa$  represents the resistivity. Since the left-hand side of (1.5) is very small compared to the left-hand side of (1.6), by putting the left-hand side of (1.5) equal to zero, we can get the following approximation:

$$E = \kappa j + \frac{\nabla p_e}{n_e e} - u_e \times B. \quad (1.7)$$

Combining (1.2), (1.3), (1.4) and (1.7), we can formally derive the second equation of (1.1) when  $en_e = 1$  and  $\kappa = 1$  (see [6, 29] and the references therein for more details).

However, the above formal derivation about Hall term may not be satisfactory. Since, in general, Ampere's law with Maxwell's correction

$$j + \partial_t E = \nabla \times B$$

is required in electromagnetic effects.

Notice that from the two-phase flow model or dynamic model, the Hall-MHD system is derived through the two-layer scale limit (scaling limits) in reference [1, 36]. However, in these literature, only a framework is provided and rigorous mathematical proof is not given. In this paper, we want to rigorously derive Hall-MHD system (1.1) (a dimensionless version) from the incompressible Navier-Stokes-Maxwell equations with generalized Ohm's law, which takes into account the full electromagnetic phenomenon described by the Maxwell system. We first consider the following scaled two-fluid incompressible Navier-Stokes-Maxwell system stemming from [1] with parameters  $\varepsilon$  and  $\gamma$ :

$$\begin{cases} \varepsilon^2 (\partial_t u_e + \operatorname{div}(u_e \otimes u_e) - \Delta u_e) + \nabla p_e = -\alpha^2 (E + u_e \times B) - \beta(u_e - u_i), & \operatorname{div} u_e = 0, \\ \partial_t u_i + \operatorname{div}(u_i \otimes u_i) - \Delta u_i + \nabla p_i = \alpha^2 (E + u_i \times B) - \beta(u_i - u_e), & \operatorname{div} u_i = 0, \\ \gamma^2 \partial_t E - \nabla \times B = -j, \\ \partial_t B + \nabla \times E = 0, & \operatorname{div} B = 0, \\ j = \frac{1}{\eta}(u_i - u_e), \end{cases} \quad (1.8)$$

where  $0 < \varepsilon^2 \ll 1$  denotes the mass ratio of the electron to the ion,  $\alpha$  denotes the ratio of the electric energy to the thermal energy,  $\beta$  stands for the relaxation frequency of the electron and ion velocities due to collisions.  $\eta$  denotes the ratio of the charge current scale to the electron or ion current scales.  $\gamma > 0$  is the ratio of the fluid velocity to the speed of light.

Next, we will give a formal asymptotic analysis of equations (1.8). For fixed  $\gamma$ , setting  $\alpha^2 \eta = 1$ , and letting  $u_i = u$ ,  $p = p_i + p_e$ , and  $\varepsilon \rightarrow 0$ , we can formally get the following incompressible Navier-Stokes-Maxwell system with generalized Ohm's law:

$$\begin{cases} \frac{1}{\eta}(E + u \times B) - \beta \eta j + \nabla p_e = j \times B, & \operatorname{div} j = 0, \\ \partial_t u + \operatorname{div}(u \otimes u) - \Delta u + \nabla p = j \times B, & \operatorname{div} u = 0, \\ \gamma^2 \partial_t E - \nabla \times B = -j, \\ \partial_t B + \nabla \times E = 0, & \operatorname{div} B = 0, \end{cases} \quad (1.9)$$

which enjoys the formal energy conservation law:

$$\frac{1}{2} \frac{d}{dt} \left( \|u\|_{L_x^2}^2 + \|B\|_{L_x^2}^2 + \|\gamma E\|_{L_x^2}^2 \right) + \|\nabla u\|_{L_x^2}^2 + \beta \eta^2 \|j\|_{L_x^2}^2 = 0. \quad (1.10)$$

Furthermore, letting  $\gamma \rightarrow 0$ , and then cancelling out the terms  $E$  and  $j$ , the Hall-MHD system (1.1) (a dimensionless version) is obtained formally. We know that for any

initial data  $(u^0, B^0) \in L^2(\mathbb{R}^3)$  such that  $\operatorname{div} u^0 = 0$ , there exists a global weak solution  $(u, B) \in L^\infty(\mathbb{R}_+, L^2(\mathbb{R}^3)) \cap L^2(\mathbb{R}_+, H^1(\mathbb{R}^3))$  to the system (1.1) (for example, see [7]).

Now, we begin to introduce the research history of the above systems. For the following Navier-Stokes-Maxwell system with ideal Ohm's law

$$\begin{cases} \partial_t u + \operatorname{div}(u \otimes u) - \Delta u = -\nabla p + j \times B, & \operatorname{div} u = 0, \\ \partial_t E - \nabla \times B = -j, & j = \sigma(E + u \times B), \\ \partial_t B + \nabla \times E = 0, & \operatorname{div} B = 0, \end{cases} \quad (1.11)$$

where  $\sigma > 0$  is the electrical conductivity of the fluid, the existence of global and finite energy weak solutions remains an interesting open problem, in both the dimensions  $d = 2, 3$ , for lack of compactness in the magnetic field  $B$ , which prevents taking limits in the Lorentz force  $j \times B$ . However, existence results are available when more regularity on the initial data is imposed. Masmoudi [30] built up the global existence and uniqueness of the strong solutions to (1.11) in two dimensions with any large initial data  $(u_0, E_0, B_0) \in L^2 \times H^s$ ,  $s > 0$ . Later, Ibrahim-Keraani [25] established the global existence of strong solutions to (1.11) for the small initial data  $(u_0, E_0, B_0) \in \dot{B}_{2,1}^{1/2} \times H^{1/2}$  in three dimensions, and the initial data  $(u_0, E_0, B_0) \in \dot{B}_{2,1}^0 \times L_{\log}^2$  in two dimensions. These results are extended in [22] to small initial data  $(u_0, E_0, B_0) \in H^{1/2}$  in three dimensions, and  $(u_0, E_0, B_0) \in L^2 \times L_{\log}^2$  in two dimensions by applying fixed point arguments. Recently, Arsénio-Gallagher [2] studied global existence of weak solutions in largest possible functional spaces based on a new maximal estimate on the heat equation in Besov spaces, under the hypothesis that the initial data  $(u_0, E_0)$  lies in the energy space, and that the initial magnetic field  $B_0$  is sufficient small in  $H^s(\mathbb{R}^3)$  with  $s \in [\frac{1}{2}, \frac{3}{2})$ . For the initial data without any restriction, they also built up the global existence of weak solutions to (1.11) in  $\mathbb{R}^2$ . In particular, the result in two-dimensional space improves the asymptotic limit established in [3] and the global well-posedness result obtained in [30]. See also [26, 23] and the references therein for more well-posedness results of the system (1.11).

There have been many research results for the Hall-MHD equations. Acheritogaray-Degond-Frouvelle-Liu [1] proposed a framework of deriving the Hall-MHD equations from the two-fluids Euler-Maxwell system for electrons and ions (see also [36]) and proved the global existence of weak solutions in the periodic domain. Chae-Degond-Liu [7] obtained the global existence of weak solutions and the local well-posedness of classical solutions in the three-dimensional whole space. They also established the blow-up criterion and the global existence of classical solutions for small initial data. Later, Chae-Lee [8] generalized the results of [7]. Chae-Wolf [12] investigated the partial regularity of the weak solutions of the three-dimensional Hall-MHD equations on the plane and obtained that the space-time Hausdorff dimension of the set of possible singularities for a weak solution is at most 2. Chae-Schonbek [9] established the optimal time decay rate of weak solutions in the three-dimensional whole space. Chae-Weng [12] considered the singularity formation for the Hall-MHD equations without resistivity in  $\mathbb{R}^3$ . Dumas-Sueur [18] investigated energy conservation of weak solutions to the three-dimensional Hall-MHD equations. Dai [13] established the regularity criterion of the 3D incompressible resistive viscous Hall-MHD equations. Benvenuti-Ferreira [5] considered the stability of global large strong solutions. Very recently, Dai [14] obtained the non-uniqueness of the Leray-Hopf weak solution by using the convex integration scheme. For more results on the Hall-MHD equations, see [17, 19, 34, 39]. For the generalized Hall-MHD equations, Dai-Liu [16] established the local well-posedness in the Besov space. Chae-Wan-Wu [10] obtained the local well-posedness of the smooth solution of the Hall-MHD equations with fractional magnetic diffusion. We

refer the readers to [15, 27, 32, 37, 38, 41, 42] and the references therein for the well-posedness results and the regularity criteria of the generalized Hall-MHD equations.

Compared to the system (1.11), there are very little researches have been done on (1.9). The existence of weak solutions to (1.9) in energy space seems very challenging for lacking of weak stability of the Lorentz force  $j \times B$  included both in generalized Ohm's law and the momentum conservation equation, which also reflects the difficulties we encounter in the asymptotic analysis of (1.9). In the present paper, we impose the hypothesis of existence of the global and finite energy weak solutions to system (1.9).

Before starting the main result of this paper, let us first introduce the notations and conventions used throughout this paper.

**Notations:**

- (1) For any positive  $A$  and  $B$ , we use the notation  $A \lesssim B$  to mean that there exists a positive constant  $C$  such that  $A \leq CB$ .
- (2) The Fourier transform is defined by

$$\mathcal{F}f(\xi) = \hat{f}(\xi) := \frac{1}{(2\pi)^{\frac{3}{2}}} \int_{\mathbb{R}^3} e^{-ix \cdot \xi} f(x) dx,$$

and its inverse is defined by

$$\mathcal{F}^{-1}g(x) = \check{g}(x) := \frac{1}{(2\pi)^{\frac{3}{2}}} \int_{\mathbb{R}^3} e^{ix \cdot \xi} g(\xi) d\xi.$$

- (3) For every  $p \in [1, \infty]$ , we denote the norm in the Lebesgue space  $L^p$  by  $\|\cdot\|_{L^p}$ .
- (4) For any normed space  $X$ , we employ the notation  $L^p([0, T], X)$  to denote the space of functions  $f$  such that for almost all  $t \in (0, T)$ ,  $f(t) \in X$  and  $\|f(t)\|_X \in L^p(0, T)$ . We simply denote the notation  $L^p([0, T], X)$  by  $L_T^p X$ .
- (5) The homogeneous Sobolev space  $\dot{H}^s(\mathbb{R}^3)$ , for any  $s \in \mathbb{R}$ , as the subspace of tempered distributions whose Fourier transform is locally integrable endowed with the norm

$$\|f\|_{\dot{H}^s} = \left( \int_{\mathbb{R}^3} |\xi|^{2s} |\hat{f}(\xi)|^2 d\xi \right)^{\frac{1}{2}}.$$

Now, we are ready to state our main result in this paper.

**Theorem 1.1.** *Let  $s \in (\frac{1}{2}, 1)$  be fixed. For any  $\gamma > 0$ , we assume that  $(u^\gamma, E^\gamma, B^\gamma)$  is the global and finite energy weak solution to the incompressible Navier-Stokes-Maxwell system with generalized Ohm's law (1.9) for some uniformly bounded initial data*

$$(u^{0\gamma}, E^{0\gamma}, B^{0\gamma}) \in \left( H^s \times (L^2)^2 \right) (\mathbb{R}^3),$$

*with  $\operatorname{div} u^{0\gamma} = \operatorname{div} B^{0\gamma} = 0$ , and suppose that the initial data converges weakly in  $H^s \times (L^2)^2$ , as  $\gamma \rightarrow 0$ , to some quantity*

$$(u^0, E^0, B^0) \in \left( H^s \times (L^2)^2 \right) (\mathbb{R}^3),$$

*with  $\operatorname{div} u^0 = \operatorname{div} B^0 = 0$ . Besides, we also assume that*

$$u^\gamma \in L_t^2 \dot{H}_x^{1+s} \text{ are uniformly bounded,} \quad (1.12)$$

*and that for any  $\delta > 0$ ,*

$$\limsup_{\gamma \rightarrow 0} \|j_{\gg}^\gamma\|_{L_{t,x,\text{loc}}^2} = 0, \quad (1.13)$$

*where*

$$j_{\gg}^\gamma = \mathcal{F}^{-1} \left( \chi_{\{|\xi| \geq \phi(\frac{\gamma}{\delta})\}} \mathcal{F} j^\gamma \right), \quad \phi(\gamma) = \gamma^{\frac{2}{2s-3}}.$$

Then, taking  $\gamma \rightarrow 0$ , up to extraction of a subsequence,  $(u^\gamma, B^\gamma)$  converges weakly to a global and finite energy weak solution  $(u, B)$  of the Hall-MHD equations (1.1) (a dimensionless version) with initial data  $(u^0, B^0)$ .

Now, we sketch the strategy of proving this theorem and point out some of the main difficult and techniques involved in the process. The convergence of the linear terms in (1.9) is easy to handle with thanks to the formal energy conservation law. Furthermore, the dissipation on  $u$  is clearly sufficient to establish the weak stability of the nonlinear terms  $u \times B$  and  $\operatorname{div}(u \otimes u)$ . Thus, in order to prove the asymptotic limit of (1.9) rigorously, it is sufficient to establish the convergence of the Lorentz force  $j^\gamma \times B^\gamma$  towards  $j \times B$ , in the sense of distribution. To this end, inspired by [3], we will take a careful analysis of the frequency distribution of magnetic field  $B^\gamma$ , which is based on the spectral properties of Maxwell operator. Unfortunately, it seems hopeless to prove that the operator

$$\begin{pmatrix} -\frac{\operatorname{Id}}{\beta\eta^2\gamma^2} & \frac{1}{\gamma^2}\nabla \times \\ -\nabla \times & 0 \end{pmatrix}$$

is the infinitesimal generator of some contraction semi-group, which means that applying Duhamel's formula may be impossible. Moreover, the modified antisymmetric operators

$$\begin{pmatrix} -\frac{\operatorname{Id}}{\beta\eta^2\gamma^2} & \frac{1}{\gamma^2}\nabla \times \\ -\frac{1}{\gamma^2}\nabla \times & 0 \end{pmatrix} \text{ and } \begin{pmatrix} -\frac{\operatorname{Id}}{\beta\eta^2\gamma^2} & \nabla \times \\ -\nabla \times & 0 \end{pmatrix},$$

both of them can be the infinitesimal generator of some contraction semi-group. However, the analysis of the frequencies of  $B^\gamma$  seems difficult since the tricky term  $B^\gamma$  in the right-hand side can't be canceled out according to the Duhamel's formula. Luckily, the same problem doesn't trouble us when we choose the modified antisymmetric operator as

$$\begin{pmatrix} -\frac{\operatorname{Id}}{\beta\eta^2\gamma^2} & \frac{1}{\gamma}\nabla \times \\ -\frac{1}{\gamma}\nabla \times & 0 \end{pmatrix}$$

(see (2.4) in Section 2), since the term  $B^\gamma$  in the right-hand side will vanish after integrating by parts (see (3.12) in Section 3). Furthermore, the systems we are dealing with are more complex and require more sophisticated analysis and energy estimates.

The rest of the paper is arranged as follows. In Section 2, we establish spectral analysis of linear Maxwell system in (1.9) and two useful lemmas. We provide a rigorous proof of Theorem 1.1 in Section 3.

## 2. SPECTRAL ANALYSIS

Now, let's move on to the detailed spectral analysis on the Maxwell operator. Define

$$\begin{cases} G_1 := \left(\frac{1}{\gamma^2} - \frac{1}{\gamma}\right) \nabla \times B + \frac{1}{\beta\eta^2\gamma^2} P \left( \partial_t u + \operatorname{div} G_4 - \Delta u - \frac{1}{\eta} G_3 \right), \\ G_2 := \left(\frac{1}{\gamma} - 1\right) \nabla \times E = \left(1 - \frac{1}{\gamma}\right) \partial_t B, \\ G_3 := u \times B, \\ G_4 := u \otimes u, \end{cases} \quad (2.1)$$

where  $P$  is the Leray projector onto divergence-free vector fields. Clearly, the Maxwell's system in (1.9) can be rewritten as

$$\begin{cases} \partial_t E = -\frac{1}{\beta\eta^2\gamma^2} E + \frac{1}{\gamma} \nabla \times B + G_1, \\ \partial_t B = \frac{1}{\gamma} \nabla \times E + G_2, \\ \operatorname{div} B = 0, \end{cases} \quad (2.2)$$

or, equivalently,

$$\partial_t \begin{pmatrix} E \\ B \end{pmatrix} = \mathbf{A} \begin{pmatrix} E \\ B \end{pmatrix} + \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}, \quad (2.3)$$

where Maxwell's operator  $\mathbf{A}$  is given by

$$\mathbf{A} := \begin{pmatrix} -\frac{\mathbf{Id}}{\beta\eta^2\gamma^2} & \frac{1}{\gamma}\nabla \times \\ -\frac{1}{\gamma}\nabla \times & 0 \end{pmatrix}. \quad (2.4)$$

More precisely, define

$$X := \left\{ (E, B) \in (L^2(\mathbb{R}^3))^2 : \operatorname{div} B = 0 \right\},$$

$$\mathcal{D}(\mathbf{A}) := \left\{ (E, B) \in X : (PE, B) \in (H^1(\mathbb{R}^3))^2 \right\} \subset X,$$

then one can verify that the unbounded linear operator  $\mathbf{A} : \mathcal{D}(\mathbf{A}) \rightarrow X$  is closed and that  $\mathcal{D}(\mathbf{A})$  is dense in  $X$ . Moreover, for any  $\lambda > 0$ , a direct computation shows that the operator

$$\lambda \mathbf{Id} - \mathbf{A} : \mathcal{D}(\mathbf{A}) \rightarrow X$$

is bijective and that  $\|(\lambda \mathbf{Id} - \mathbf{A})^{-1}\| \leq \frac{1}{\lambda}$ . In view of the Hille-Yosida theorem, there exists a contraction semigroup denoted by  $\{e^{t\mathbf{A}}\}_{t \geq 0}$  with  $\mathbf{A}$  being the infinitesimal generator of it. Therefore, for any initial data  $(E^0, B^0) \in \mathcal{D}(\mathbf{A})$  and any inhomogeneous term  $(G_1, G_2) \in C^1((\mathbb{R}^+), X)$ , the solution to (2.3) can be given by Duhamel's formula:

$$\begin{pmatrix} E \\ B \end{pmatrix} = e^{t\mathbf{A}} \begin{pmatrix} E^0 \\ B^0 \end{pmatrix} + \int_0^t e^{(t-\tau)\mathbf{A}} \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}(\tau) d\tau. \quad (2.5)$$

Moreover, the Duhamel's formula (2.5) remains well-defined provided  $(G_1, G_2) \in L^1(0, T, X)$ ,  $(E^0, B^0) \in X$ . In fact,  $e^{(t-\tau)\mathbf{A}} \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}(\tau)$  is strongly measurable, since it is weakly measurable for any  $t > 0$ , and  $L^2(\mathbb{R}^3)$  is separable. Notice that

$$\tau \rightarrow \left\| e^{(t-\tau)\mathbf{A}} \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}(\tau) \right\|_X$$

is integrable, therefore

$$e^{(t-\tau)\mathbf{A}} \begin{pmatrix} G_1 \\ G_2 \end{pmatrix}(\tau)$$

is Bochner integrable. Furthermore, one can easily verify that (2.5) is a weak solution of (2.3) through approximation arguments in this setting.

In order to conduct a spectral analysis of  $\mathbf{A}$ , taking the Fourier transform on (2.5), we get

$$\partial_t \begin{pmatrix} \hat{E} \\ \hat{B} \end{pmatrix} = \hat{\mathbf{A}}(\xi) \begin{pmatrix} \hat{E} \\ \hat{B} \end{pmatrix} + \begin{pmatrix} \hat{G}_1 \\ \hat{G}_2 \end{pmatrix}, \quad (2.6)$$

where

$$\hat{\mathbf{A}}(\xi) = \begin{pmatrix} -\frac{\mathbf{Id}}{\beta\eta^2\gamma^2} & \frac{1}{\gamma}i\xi \times \\ -\frac{1}{\gamma}i\xi \times & 0 \end{pmatrix}.$$

More precisely, for every  $\xi \in \mathbb{R}^3 \setminus \{0\}$ , following [3], we define the 5-dimensional vector subspace of  $\mathbb{C}^3 \times \mathbb{C}^3$  as:

$$\mathcal{E}(\xi) := \{(e, b) \in \mathbb{C}^3 \times \mathbb{C}^3 : \xi \cdot b = 0\},$$

then  $\hat{\mathbf{A}}(\xi) : \mathcal{E}(\xi) \rightarrow \mathcal{E}(\xi)$  is a linear finite-dimensional operator.

Now, we are ready to give a detailed analysis on the properties of the semigroup.

**Lemma 2.1.** *For any  $\xi \in \mathbb{R}^3 \setminus \{0\}$ , such that  $|\xi| \neq \frac{1}{2\beta\eta^2\gamma}$ , there are three different eigenvalues of  $\hat{\mathbf{A}}(\xi)$  denoted by  $\lambda_0 = -\frac{1}{\beta\eta^2\gamma^2}$ ,  $\lambda_+(\xi)$ ,  $\lambda_-(\xi)$  with*

$$\lambda_{\pm}(\xi) = \frac{-1 \pm \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}}{2\beta\eta^2\gamma^2}. \quad (2.7)$$

*Additionally, the basis of the subspace  $\mathcal{E}(\xi)$  can be made up by eigenvectors, which means  $\hat{\mathbf{A}}(\xi)$  is diagonalizable, moreover, the eigenspaces corresponding to  $\lambda_0$ ,  $\lambda_+(\xi)$  and  $\lambda_-(\xi)$  are respectively given by*

$$\mathcal{E}_0(\xi) = \text{span} \left\{ \begin{pmatrix} \xi \\ 0 \end{pmatrix} \right\},$$

$$\begin{aligned} \mathcal{E}_+(\xi) &= \left\{ \begin{pmatrix} e \\ -\frac{i}{\gamma\lambda_+}\xi \times e \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : e \in \mathbb{C}^3, \xi \cdot e = 0 \right\} \\ &= \left\{ \begin{pmatrix} -\frac{i}{\gamma\lambda_-}\xi \times b \\ b \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : b \in \mathbb{C}^3, \xi \cdot b = 0 \right\}, \end{aligned} \quad (2.8)$$

$$\begin{aligned} \mathcal{E}_-(\xi) &= \left\{ \begin{pmatrix} e \\ -\frac{i}{\gamma\lambda_-}\xi \times e \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : e \in \mathbb{C}^3, \xi \cdot e = 0 \right\} \\ &= \left\{ \begin{pmatrix} -\frac{i}{\gamma\lambda_+}\xi \times b \\ b \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : b \in \mathbb{C}^3, \xi \cdot b = 0 \right\}. \end{aligned} \quad (2.9)$$

*For any  $\xi \in \mathbb{R}^3 \setminus \{0\}$  with  $|\xi| = \frac{1}{2\beta\eta^2\gamma}$ , there are two different eigenvalues of  $\hat{\mathbf{A}}(\xi)$  denoted by  $\lambda_0 = -\frac{1}{\beta\eta^2\gamma^2}$ ,  $\lambda_1 = -\frac{1}{2\beta\eta^2\gamma^2}$ , and the corresponding eigenspaces are respectively given by*

$$\begin{aligned} \mathcal{E}_0(\xi) &= \text{span} \left\{ \begin{pmatrix} \xi \\ 0 \end{pmatrix} \right\}, \\ \mathcal{E}_1(\xi) &= \left\{ \begin{pmatrix} e \\ -\frac{i}{\lambda_1\gamma}\xi \times e \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : e \in \mathbb{C}^3, \xi \cdot e = 0 \right\} \\ &= \left\{ \begin{pmatrix} -\frac{i}{\lambda_1\gamma}\xi \times b \\ b \end{pmatrix} \in \mathbb{C}^3 \times \mathbb{C}^3 : b \in \mathbb{C}^3, \xi \cdot b = 0 \right\}. \end{aligned} \quad (2.10)$$

*In this case,  $\hat{\mathbf{A}}(\xi)$  is not diagonalizable.*

*Proof.* Suppose

$$\lambda \begin{pmatrix} e \\ b \end{pmatrix} = \hat{\mathbf{A}}(\xi) \begin{pmatrix} e \\ b \end{pmatrix},$$

where  $\lambda$  and  $\begin{pmatrix} e \\ b \end{pmatrix}$  are eigenvalue and eigenvector of  $\hat{\mathbf{A}}(\xi)$ , respectively. Then we have

$$\begin{cases} \left( \lambda + \frac{1}{\beta\eta^2\gamma^2} \right) e = \frac{i}{\gamma}\xi \times b, \\ \lambda b = -\frac{i}{\gamma}\xi \times e. \end{cases} \quad (2.11)$$

Firstly,  $e \neq 0$ , otherwise  $b = 0$ . Notice that  $\xi \cdot b = 0$ , then  $b = 0$  and  $\xi \times e = 0$  provided  $\lambda = -\frac{1}{\beta\eta^2\gamma^2}$ . Thus  $\lambda = -\frac{1}{\beta\eta^2\gamma^2}$  is an eigenvalue of  $\hat{\mathbf{A}}(\xi)$  with the corresponding eigenspace given by  $\mathcal{E}_0(\xi) = \text{span} \left\{ \begin{pmatrix} \xi \\ 0 \end{pmatrix} \right\}$ .

Now, setting  $\lambda \neq -\frac{1}{\beta\eta^2\gamma^2}$ , multiplying (2.11) by  $\xi$ , we have

$$\xi \cdot e = 0, \quad \beta\eta^2\gamma^2\lambda^2 + \lambda + \beta\eta^2\xi^2 = 0,$$

whose roots  $\lambda_+(\xi)$  and  $\lambda_-(\xi)$  are exactly given by (2.7).

While  $|\xi| = \frac{1}{2\beta\eta^2\gamma}$ ,  $\lambda_+(\xi) = \lambda_-(\xi) = -\frac{1}{2\beta\eta^2\gamma^2}$  and the corresponding eigenspace  $\mathcal{E}_1(\xi)$  is defined by (2.10), then one can verify that the operator  $\hat{\mathbf{A}}(\xi)$  is not diagonalizable in this condition.

Next, setting  $|\xi| \neq \frac{1}{2\beta\eta^2\gamma}$ ,  $\lambda_+(\xi)$  and  $\lambda_-(\xi)$  are different. The corresponding eigenspaces  $\mathcal{E}_+(\xi)$  and  $\mathcal{E}_-(\xi)$  are given by (2.8) and (2.9), respectively. Therefore,  $\hat{\mathbf{A}}(\xi)$  is diagonalizable in this case. Furthermore, these eigenspaces are not orthogonal to each other since the operator  $\hat{\mathbf{A}}(\xi)$  is not symmetric. We complete the proof of Lemma 2.1.  $\square$

**Lemma 2.2.** *Suppose that  $1 < K < 2$  is a fixed constant. For any  $\xi \in \mathbb{R}^3 \setminus \{0\}$ ,  $\lambda_{\pm}(\xi)$  are the eigenvalues of  $\hat{\mathbf{A}}(\xi)$  defined by (2.7), then we have the following estimates.*

If  $|\xi| \leq \frac{1}{2\beta\eta^2\gamma}$ ,

$$-2\beta\eta^2|\xi|^2 \leq \lambda_+(\xi) \leq -\beta\eta^2|\xi|^2, \quad -\frac{1}{\beta\eta^2\gamma^2} \leq \lambda_-(\xi) \leq -\frac{1}{2\beta\eta^2\gamma^2},$$

moreover, if  $|\xi| \leq \frac{1}{2K\beta\eta^2\gamma}$ ,

$$\left| \frac{\lambda_-(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| \leq \frac{K}{\sqrt{K^2 - 1}}, \quad \left| \frac{\lambda_+(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| \lesssim \gamma^2|\xi|^2.$$

If  $|\xi| > \frac{1}{2\beta\eta^2\gamma}$ ,

$$|\lambda_+(\xi)| = |\lambda_-(\xi)| = \frac{|\xi|}{\gamma}, \quad \Re(\lambda_+(\xi)) = \Re(\lambda_-(\xi)) = -\frac{1}{2\beta\eta^2\gamma^2},$$

moreover, if  $|\xi| \geq \frac{K}{2\beta\eta^2\gamma}$ ,

$$\left| \frac{\lambda_{\pm}(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| \leq \frac{K}{2\sqrt{K^2 - 1}}, \quad \left| \frac{1}{\lambda_-(\xi) - \lambda_+(\xi)} \right| \leq \frac{K}{2\sqrt{K^2 - 1}} \frac{\gamma}{|\xi|}.$$

*Proof.* We first consider the case  $|\xi| \leq \frac{1}{2\beta\eta^2\gamma}$ . Note that

$$\begin{aligned} \lambda_+(\xi) &= \frac{-1 + \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}}{2\beta\eta^2\gamma^2} = \frac{-4\beta^2\eta^4\gamma^2|\xi|^2}{2\beta\eta^2\gamma^2 \left(1 + \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}\right)} \\ &= \frac{-2\beta\eta^2|\xi|^2}{1 + \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}}, \end{aligned}$$

then we have  $-2\beta\eta^2|\xi|^2 \leq \lambda_+(\xi) \leq -\beta\eta^2|\xi|^2$ . The similar estimate on  $\lambda_-(\xi)$  is trivial. Furthermore, one has

$$\begin{aligned} \left| \frac{\lambda_-(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| &= \frac{1 + \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}}{2\sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}} \leq \frac{1}{\sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}} \leq \frac{K}{\sqrt{K^2 - 1}}, \\ \left| \frac{\lambda_+(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| &= \frac{1 - \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}}{2\sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}} \\ &= \frac{2\beta^2\eta^4\gamma^2|\xi|^2}{\sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2} \left(1 + \sqrt{1 - 4\beta^2\eta^4\gamma^2|\xi|^2}\right)} \\ &\lesssim \gamma^2|\xi|^2, \end{aligned}$$

provided  $|\xi| \leq \frac{1}{2K\beta\eta^2\gamma}$ .

Next, focusing on the case  $|\xi| > \frac{1}{2\beta\eta^2\gamma}$ , writing

$$\lambda_{\pm}(\xi) = \frac{1}{2\beta\eta^2\gamma^2} \left( -1 \pm i\sqrt{4\beta^2\eta^4\gamma^2|\xi|^2 - 1} \right),$$

we get

$$|\lambda_+(\xi)| = |\lambda_-(\xi)| = \frac{|\xi|}{\gamma}, \quad \Re(\lambda_+(\xi)) = \Re(\lambda_-(\xi)) = -\frac{1}{2\beta\eta^2\gamma^2}.$$

Furthermore, assuming  $|\xi| \geq \frac{K}{2\beta\eta^2\gamma}$ , one has

$$\left| \frac{\lambda_{\pm}(\xi)}{\lambda_-(\xi) - \lambda_+(\xi)} \right| = \frac{\beta\eta^2\gamma^2}{\sqrt{4\beta^2\eta^4\gamma^2|\xi|^2 - 1}} \frac{|\xi|}{\gamma} = \frac{1}{\sqrt{4 - \frac{1}{\beta^2\eta^4\gamma^2|\xi|^2}}} \leq \frac{K}{2\sqrt{K^2 - 1}},$$

and the last estimate is followed.  $\square$

### 3. PROOF OF THE MAIN RESULT

In this section, we study the asymptotic limit of the incompressible Navier-Stokes-Maxwell system with generalized Ohm's law (1.9) based on the spectral analysis established in Section 2.

Here, we consider a family of global and finite energy weak solutions  $(u^\gamma, E^\gamma, B^\gamma)$  to (1.9) with uniformly bounded initial data:

$$(u^{0\gamma}, E^{0\gamma}, B^{0\gamma}) \in L^2(\mathbb{R}^3) \times L^2(\mathbb{R}^3) \times L^2(\mathbb{R}^3).$$

Recall that the formal energy conservation law (1.10) implies that the following uniform bounds of the weak solutions  $(u^\gamma, E^\gamma, B^\gamma)$ :

$$u^\gamma \in L_t^\infty L_x^2 \cap L_t^2 \dot{H}_x^1, \quad (B^\gamma, \gamma E^\gamma) \in L_t^\infty L_x^2, \quad j^\gamma \in L_{t,x}^2.$$

Therefore, up to extraction of subsequences, we have the following weak convergences as  $\gamma \rightarrow 0$ :

$$\begin{aligned} (u^{0\gamma}, E^{0\gamma}, B^{0\gamma}) &\rightharpoonup (u^0, E^0, B^0) \text{ in } L_x^2, \\ (u^\gamma, B^\gamma) &\rightharpoonup^* (u, B) \text{ in } L_t^\infty L_x^2, \\ j^\gamma &\rightharpoonup j \text{ in } L_{t,x}^2. \end{aligned}$$

From the Faraday's equation in (1.9), we know that

$$E^\gamma = -\partial_t A^\gamma, \text{ where } \nabla \times A^\gamma = B^\gamma \text{ and } \operatorname{div} A^\gamma = 0,$$

which implies  $E^\gamma$  enjoys some kind of uniform weak bound. Thus, the weak stability of linear terms in (1.9) is deduced. Furthermore, combining the generalized Ohm's law and the momentum conservation equation in (1.9), we find that

$$\partial_t u^\gamma \text{ is uniformly bounded in } L_{t,\text{loc}}^2 H_x^{-3}. \quad (3.1)$$

By virtue of the Sobolev embedding and the regularity hypothesis (1.12),  $u^\gamma$  is uniformly bounded in

$$L_t^\infty L_x^2 \cap L_t^2 \dot{H}_x^1 \cap L_t^2 \dot{H}_x^{1+s} \subset L_t^\infty L_x^2 \cap L_t^2 L_x^6 \cap L_t^2 L_x^\infty,$$

then a routine application of classical compactness result by Aubin and Lions [35] implies that  $u$  is relatively compact in the strong topology of  $L_{t,x,\text{loc}}^2$ . Inserting the bounds on  $B^\gamma$ , we have

$$u^\gamma \times B^\gamma \in L_t^2 L_x^2, \quad u^\gamma \otimes u^\gamma \in L_t^2 L_x^2, \quad \nabla(u^\gamma \otimes u^\gamma) \in L_t^2 L_x^{\frac{3}{3-s}}, \quad (3.2)$$

whence,

$$\begin{aligned} G_3^\gamma &:= u^\gamma \times B^\gamma \rightharpoonup G_3 := u \times B \text{ in } L_{t,x}^2, \\ G_4^\gamma &:= u^\gamma \otimes u^\gamma \rightharpoonup G_4 := u \otimes u \text{ in } L_{t,x}^2. \end{aligned} \quad (3.3)$$

From the Faraday's law, one has

$$\partial_t B^\gamma = \nabla \times G_3^\gamma - \beta \eta^2 \nabla \times j^\gamma - \eta \nabla \times (j^\gamma \times B^\gamma),$$

then  $B^\gamma$  is relatively compact in  $C([0, T], H^{-1})$  through standard compactness arguments. Therefore, taking the weak limit in the Faraday's law, one obtains that  $B \in L_t^\infty L_x^2$  solves

$$\partial_t B = \beta \eta^2 \Delta B + \nabla \times G_3 - \eta \nabla \times (\partial_t u + \operatorname{div} G_4 - \Delta u)$$

with the initial data  $B^0 \in L_x^2$ . Finally, we have from Duhamel's principle that:

$$B = e^{\beta \eta^2 \Delta t} B^0 + \int_0^t e^{\beta \eta^2 \Delta(t-\tau)} [\nabla \times G_3 - \eta \nabla \times (\partial_\tau u + \operatorname{div} G_4 - \Delta u)] d\tau,$$

then, after taking Fourier transformation, we have

$$\hat{B} = e^{-\beta \eta^2 |\xi|^2 t} \hat{B}^0 + \int_0^t e^{-\beta \eta^2 |\xi|^2 (t-\tau)} \left[ i\xi \times \hat{G}_3 - \eta i\xi \times \left( \partial_\tau \hat{u} + i\xi \cdot \hat{G}_4 + |\xi|^2 \hat{u} \right) \right] d\tau. \quad (3.4)$$

Thus, in order to establish the asymptotic limit of the Navier-Stokes-Maxwell system (1.9), there only remains to establish the weak stability of the Lorentz force  $j^\gamma \times B^\gamma$ , which will follow from a careful combination of frequency analysis on  $B^\gamma$  and the hypothesis (1.13) on the very high frequencies of  $j$ . Therefore, we decompose the initial data  $(\hat{E}^{0\gamma}, \hat{B}^{0\gamma}) \in X$  and the inhomogeneous terms  $(\hat{G}_1^\gamma, \hat{G}_2^\gamma) \in L^1(0, T, X)$  based on the spectral analysis in Section 2.

Applying Lemma 2.1, for almost every  $\xi \in \mathbb{R}^3$ , one has

$$\begin{pmatrix} \hat{E}^{0\gamma} \\ \hat{B}^{0\gamma} \end{pmatrix} = \begin{pmatrix} \frac{\hat{E}^{0\gamma} \cdot \xi}{|\xi|^2} \xi \\ 0 \end{pmatrix} + \begin{pmatrix} -\frac{i}{\gamma \lambda_-} \xi \times \hat{B}^{0\gamma} \\ \hat{B}^{0\gamma} \end{pmatrix} + \begin{pmatrix} e^{0\gamma} \\ -\frac{i}{\gamma \lambda_-} \xi \times e^{0\gamma} \end{pmatrix}, \quad (3.5)$$

or, equivalently,

$$\begin{cases} s e^{0\gamma} = \hat{E}^{0\gamma} + \frac{i}{\gamma \lambda_-} \xi \times \hat{B}^{0\gamma}, \\ s \hat{B}^{0\gamma} = \hat{B}^{0\gamma} + \frac{i}{\gamma \lambda_-} \xi \times \hat{E}^{0\gamma}, \end{cases} \quad (3.6)$$

where  $s = \frac{\lambda_-(\xi) - \lambda_+(\xi)}{\lambda_-(\xi)}$ ,  $\xi \cdot e^{0\gamma} = \xi \cdot \hat{B}^{0\gamma} = 0$ . Therefore, according to Lemma 2.2, we get

$$|s e^{0\gamma}| \leq |\hat{E}^{0\gamma}| + |\hat{B}^{0\gamma}|, \quad |s \hat{B}^{0\gamma}| \leq |\hat{E}^{0\gamma}| + |\hat{B}^{0\gamma}|. \quad (3.7)$$

Similarly, define

$$\begin{cases} \hat{G}_1^\gamma := \frac{1}{\gamma^2} \left\{ (1 - \gamma) i\xi \times \hat{B}^\gamma + \frac{1}{\beta \eta} \left[ \partial_t \hat{u}^\gamma + i\xi \cdot \hat{G}_4^\gamma + |\xi|^2 \hat{u}^\gamma - \frac{1}{\eta} \hat{G}_3^\gamma \right] \right\}, \\ \hat{G}_2^\gamma := \left( 1 - \frac{1}{\gamma} \right) \partial_t \hat{B}^\gamma, \end{cases} \quad (3.8)$$

and then applying Lemma 2.1, one has

$$\begin{pmatrix} \hat{G}_1^\gamma \\ \hat{G}_2^\gamma \end{pmatrix} = \begin{pmatrix} \frac{\hat{G}_1^\gamma \cdot \xi}{|\xi|^2} \xi \\ 0 \end{pmatrix} + \begin{pmatrix} -\frac{i}{\gamma \lambda_-} \xi \times \hat{G}_2^\gamma \\ \hat{G}_2^\gamma \end{pmatrix} + \begin{pmatrix} e^\gamma \\ -\frac{i}{\gamma \lambda_-} \xi \times e^\gamma \end{pmatrix}, \quad (3.9)$$

for almost every  $\xi \in \mathbb{R}^3$ , or, equivalently,

$$\begin{cases} s e^\gamma = \hat{G}_1^\gamma + \frac{i}{\gamma \lambda_-} \xi \times \hat{G}_2^\gamma, \\ s \hat{G}_2^\gamma = \hat{G}_2^\gamma + \frac{i}{\gamma \lambda_-} \xi \times \hat{G}_1^\gamma, \end{cases} \quad (3.10)$$

where  $\xi \cdot e^\gamma = \xi \cdot b^\gamma = 0$ . Hence, from Lemma 2.2, we obtain

$$|se^\gamma| \leq |\hat{G}_1^\gamma| + |\hat{G}_2^\gamma|, \quad |sb^\gamma| \leq |\hat{G}_1^\gamma| + |\hat{G}_2^\gamma|. \quad (3.11)$$

Letting the operator  $e^{t\hat{\mathbf{A}}}$  acts on (3.5) and on (3.9) respectively, combining Lemma 2.1, then we have

$$e^{t\hat{\mathbf{A}}} \begin{pmatrix} \hat{E}^{0\gamma} \\ \hat{B}^{0\gamma} \end{pmatrix} = e^{-\frac{1}{\beta\eta^2\gamma^2}} \begin{pmatrix} \frac{\hat{E}^{0\gamma}\xi}{|\xi|^2} \\ 0 \end{pmatrix} + e^{t\lambda_+} \begin{pmatrix} -\frac{i}{\gamma\lambda_-}\xi \times b^{0\gamma} \\ b^{0\gamma} \end{pmatrix} + e^{t\lambda_-} \begin{pmatrix} -\frac{i}{\gamma\lambda_-}\xi \times e^{0\gamma} \\ e^{0\gamma} \end{pmatrix},$$

and

$$e^{t\hat{\mathbf{A}}} \begin{pmatrix} \hat{G}_1^\gamma \\ \hat{G}_2^\gamma \end{pmatrix} = e^{-\frac{1}{\beta\eta^2\gamma^2}} \begin{pmatrix} \frac{\hat{G}_1^\gamma\xi}{|\xi|^2} \\ 0 \end{pmatrix} + e^{t\lambda_+} \begin{pmatrix} -\frac{i}{\gamma\lambda_-}\xi \times b^\gamma \\ b^\gamma \end{pmatrix} + e^{t\lambda_-} \begin{pmatrix} -\frac{i}{\gamma\lambda_-}\xi \times e^\gamma \\ e^\gamma \end{pmatrix}.$$

Substituting them into (2.5) implies that

$$\hat{B}^\gamma = e^{t\lambda_+} b^{0\gamma} - \frac{i}{\gamma\lambda_-} e^{t\lambda_-} \xi \times e^{0\gamma} + \int_0^t e^{(t-\tau)\lambda_+} b^\gamma - \frac{i}{\gamma\lambda_-} e^{(t-\tau)\lambda_-} \xi \times e^\gamma d\tau.$$

Notice that

$$\begin{aligned} -\frac{i}{\gamma\lambda_-} \xi \times e^{0\gamma} &= \hat{B}^{0\gamma} - b^{0\gamma}, \\ -\frac{i}{\gamma\lambda_-} \xi \times e^\gamma &= \hat{G}_2^\gamma - b^\gamma, \\ sb^\gamma &= \hat{G}_2^\gamma + \frac{i}{\gamma\lambda_-} \xi \times \hat{G}_1^\gamma, \end{aligned}$$

one has

$$\begin{aligned} \hat{B}^\gamma &= e^{t\lambda_-} \hat{B}^{0\gamma} + (e^{t\lambda_+} - e^{t\lambda_-}) b^{0\gamma} + \int_0^t (e^{(t-\tau)\lambda_+} - e^{(t-\tau)\lambda_-}) b^\gamma + e^{(t-\tau)\lambda_-} \hat{G}_2^\gamma d\tau \\ &= e^{t\lambda_-} \hat{B}^{0\gamma} + (e^{t\lambda_+} - e^{t\lambda_-}) b^{0\gamma} + \int_0^t \left[ \frac{\lambda_-}{\lambda_- - \lambda_+} e^{(t-\tau)\lambda_+} - \frac{\lambda_+}{\lambda_- - \lambda_+} e^{(t-\tau)\lambda_-} \right] \hat{G}_2^\gamma d\tau \\ &\quad + \frac{i}{\gamma(\lambda_- - \lambda_+)} \int_0^t (e^{(t-\tau)\lambda_+} - e^{(t-\tau)\lambda_-}) \xi \times \hat{G}_1^\gamma d\tau. \end{aligned}$$

Combining (3.8) and integrating by parts in  $t$  yields that

$$\begin{aligned} \hat{B}^\gamma &= \gamma e^{t\lambda_-} \hat{B}^{0\gamma} + \gamma(e^{t\lambda_+} - e^{t\lambda_-}) b^{0\gamma} + \frac{1-\gamma}{\lambda_- - \lambda_+} (\lambda_- e^{t\lambda_+} - \lambda_+ e^{t\lambda_-}) \hat{B}^{0\gamma} \\ &\quad + \frac{i}{\beta\eta\gamma^2(\lambda_- - \lambda_+)} \int_0^t (e^{(t-\tau)\lambda_+} - e^{(t-\tau)\lambda_-}) \xi \times \left( \partial_\tau \hat{u}^\gamma + i\xi \cdot \hat{G}_4^\gamma + |\xi|^2 \hat{u}^\gamma - \frac{1}{\eta} \hat{G}_3^\gamma \right) d\tau, \end{aligned} \quad (3.12)$$

where the term  $\hat{B}^\gamma$  in the right-hand side vanishes. In order to cancel out the term  $\partial_t \hat{u}^\gamma$ , we integrate by parts in  $t$  again to get

$$\begin{aligned} \hat{B}^\gamma &= \gamma e^{t\lambda_-} \hat{B}^{0\gamma} + \frac{1-\gamma}{\lambda_- - \lambda_+} (\lambda_- e^{t\lambda_+} - \lambda_+ e^{t\lambda_-}) \hat{B}^{0\gamma} \\ &\quad + \gamma (e^{t\lambda_+} - e^{t\lambda_-}) b^{0\gamma} - \frac{i}{\beta\eta\gamma^2(\lambda_- - \lambda_+)} (e^{t\lambda_+} - e^{t\lambda_-}) \xi \times \hat{u}^{0\gamma} \\ &\quad - \frac{i}{\beta\eta\gamma^2(\lambda_- - \lambda_+)} \int_0^t (\lambda_- e^{(t-\tau)\lambda_-} - \lambda_+ e^{(t-\tau)\lambda_+}) \xi \times \hat{u}^\gamma d\tau \end{aligned}$$

$$+ \frac{i}{\beta\eta\gamma^2(\lambda_- - \lambda_+)} \int_0^t \left( e^{(t-\tau)\lambda_+} - e^{(t-\tau)\lambda_-} \right) \xi \times \left( i\xi \cdot \hat{G}_4^\gamma + |\xi|^2 \hat{u}^\gamma - \frac{1}{\eta} \hat{G}_3^\gamma \right) d\tau. \quad (3.13)$$

Recall that we want to establish the convergence of Lorentz force  $j^\gamma \times B^\gamma$  towards  $j \times B$ , in the sense of distribution. To this end, we strengthen the convergence of  $B^\gamma$  towards  $B$ , which can be given by (3.4). Whence, motivated by [3], we decompose  $B^\gamma$  into five parts

$$B^\gamma = B_{\ll}^\gamma + B_{<}^\gamma + B_{\sim}^\gamma + B_{>}^\gamma + B_{\gg}^\gamma,$$

where

$$\begin{aligned} B_{\ll}^\gamma &= \mathcal{F}^{-1} \left( \chi_{\{0 \leq |\xi| \leq R\}} \hat{B}^\gamma \right), \\ B_{<}^\gamma &= \mathcal{F}^{-1} \left( \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \hat{B}^\gamma \right), \\ B_{\sim}^\gamma &= \mathcal{F}^{-1} \left( \chi_{\{\frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma}\}} \hat{B}^\gamma \right), \\ B_{>}^\gamma &= \mathcal{F}^{-1} \left( \chi_{\{\frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi(\frac{\gamma}{\delta})\}} \hat{B}^\gamma \right), \\ B_{\gg}^\gamma &= \mathcal{F}^{-1} \left( \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \hat{B}^\gamma \right), \end{aligned}$$

for some fixed constant  $1 < K < 2$ , which will be determined later, for any large radius  $0 < R < \frac{1}{2K\beta\eta^2\gamma}$  and for some small parameter  $\delta > 0$ . Hence, for any  $\varphi \in C_c^\infty(\mathbb{R}^+ \times \mathbb{R}^3)$ , we have

$$\begin{aligned} & \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \times B^\gamma - j \times B) \cdot \varphi \, dt dx \\ &= \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times (B_{\ll}^\gamma - B_{\ll}) \cdot \varphi \, dt dx + \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times (B_{\ll} - B) \cdot \varphi \, dt dx \\ &+ \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma - j) \times B \cdot \varphi \, dt dx + \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times (B_{<}^\gamma + B_{\sim}^\gamma + B_{>}^\gamma) \cdot \varphi \, dt dx \\ &+ \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \times B_{\gg}^\gamma) \cdot \varphi \, dt dx. \end{aligned} \quad (3.14)$$

Firstly, we handle with the last term in (3.14), which can be recast as

$$\begin{aligned} \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \times B_{\gg}^\gamma) \cdot \varphi \, dt dx &= \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times \mathcal{F}^{-1} \left( \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \hat{B}^\gamma \right) \cdot \varphi \, dt dx \\ &= \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times \mathcal{F} \left( \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \check{B}^\gamma \right) \cdot \varphi \, dt dx \\ &= \int_{\mathbb{R}^+ \times \mathbb{R}^3} \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \mathcal{F}(j^\gamma \varphi) \times \check{B}^\gamma \, dt dx \\ &= \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \varphi)_{\gg} \times B^\gamma \, dt dx, \end{aligned}$$

where

$$(j^\gamma \varphi)_{\gg} = \mathcal{F}^{-1} \left( \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \mathcal{F}(j^\gamma \varphi) \right).$$

Noted that for any  $\delta > 0$  and  $\varphi \in C_c^\infty(\mathbb{R}^+ \times \mathbb{R}^3)$

$$\|(j^\gamma \varphi)_{\gg}\|_{L_{t,x}^2}^2 = \int_{\mathbb{R}^+ \times \mathbb{R}^3} ((j^\gamma \varphi)_{\gg})_{\gg} j^\gamma \varphi \, dt dx$$

$$\begin{aligned}
&= \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \varphi)_{\gg} j^\gamma \varphi \, dt dx \\
&\lesssim \|(j^\gamma \varphi)_{\gg}\|_{L^2_{t,x,\text{loc}}} ,
\end{aligned}$$

and

$$\begin{aligned}
\|(j^\gamma \varphi)_{\gg}\|_{L^2_{t,x,\text{loc}}} &= \left\| \mathcal{F}^{-1} \left( \int_{\mathbb{R}^3} j^\gamma(y) \varphi(y) e^{-iy \cdot \xi} dy \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \right) \right\|_{L^2_{t,x,\text{loc}}} \\
&= \left\| \mathcal{F}^{-1} \left( \int_{\mathbb{R}^3} j^\gamma \left( \frac{z}{|\xi|} \right) \varphi \left( \frac{z}{|\xi|} \right) e^{\frac{-iz \cdot \xi}{|\xi|}} \frac{1}{|\xi|} dz \chi_{\{|\xi| > \phi(\frac{\gamma}{\delta})\}} \right) \right\|_{L^2_{t,x,\text{loc}}} .
\end{aligned}$$

Letting  $\gamma \rightarrow 0$  in the above equality, and applying the assumption (1.13) on the very high frequencies of  $j^\gamma$ , we have

$$\limsup_{\gamma \rightarrow 0} \|(j^\gamma \varphi)_{\gg}\|_{L^2_{t,x}}^2 \lesssim \limsup_{\gamma \rightarrow 0} \|(j^\gamma)_{\gg}\|_{L^2_{t,x,\text{loc}}} = 0. \quad (3.15)$$

Now, we deal with the term  $B_{\ll}^\gamma - B_{\ll}$ . For any small  $h > 0$ , applying Lemma 2.2 and the estimates (3.7) and (3.11), we find from (3.12) that

$$\begin{aligned}
&\left| \hat{B}_{\ll}^\gamma(t+h) - \hat{B}_{\ll}^\gamma(t) \right| \\
&\lesssim e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \left( |\gamma \hat{B}^{0\gamma}| + |\gamma b^{0\gamma}| + \gamma^2 |\xi|^2 |\hat{B}^{0\gamma}| \right) \chi_{\{0 \leq |\xi| \leq R\}} \\
&\quad + e^{-\beta\eta^2|\xi|^2 t} h |\xi|^2 \left( |\gamma b^{0\gamma}| + |\hat{B}^{0\gamma}| \right) \chi_{\{0 \leq |\xi| \leq R\}} \\
&\quad + \int_0^t \left[ e^{-\beta\eta^2|\xi|^2(t-\tau)} h |\xi|^2 + e^{-\frac{1}{2\beta\eta^2\gamma^2}(t-\tau)} \right] \\
&\quad \quad \left( |\xi| |\partial_\tau \hat{u}^\gamma| + |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\{0 \leq |\xi| \leq R\}} d\tau \\
&\quad + \int_0^\infty \chi_{[0,h]}(v) \left( e^{-\beta\eta^2|\xi|^2 v} + e^{-\frac{1}{2\beta\eta^2\gamma^2}v} \right) \\
&\quad \quad \left( |\xi| |\partial_\tau \hat{u}^\gamma| + |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) (t+h-v) \chi_{\{0 \leq |\xi| \leq R\}} dv.
\end{aligned}$$

Thus

$$\begin{aligned}
&\left\| \hat{B}_{\ll}^\gamma(t+h) - \hat{B}_{\ll}^\gamma(t) \right\|_{L^2_{t,\text{loc}} L^2_\xi} \\
&\lesssim \gamma \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L^2_t} \left( \left\| \hat{E}^{0\gamma} \right\|_{L^2_x} + \left\| \hat{B}^{0\gamma} \right\|_{L^2_x} \right) + h \left\| \left\| e^{-\beta\eta^2|\xi|^2 t} \right\|_{L^2_t} |\xi|^2 \left( |\hat{E}^{0\gamma}| + |\hat{B}^{0\gamma}| \right) \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_\xi} \\
&\quad + h \left\| \left\| e^{-\beta\eta^2|\xi|^2 t} \right\|_{L^1_t} \left\| |\xi|^3 |\partial_t \hat{u}^\gamma| + |\xi|^4 |\hat{G}_4^\gamma| + |\xi|^5 |\hat{u}^\gamma| + |\xi|^3 |\hat{G}_3^\gamma| \right\|_{L^2_{t,\text{loc}}} \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_\xi} \\
&\quad + \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L^1_t} \left\| \left( |\xi| |\partial_t \hat{u}^\gamma| + |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_{t,\text{loc}} L^2_\xi} \\
&\quad + \left\| \left\| e^{-\beta\eta^2|\xi|^2 t} \chi_{[0,h]}(t) \right\|_{L^1_t} \left\| |\xi| |\partial_t \hat{u}^\gamma| + |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right\|_{L^2_{t,\text{loc}}} \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_\xi} \\
&\quad + \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \chi_{[0,h]}(t) \right\|_{L^1_t} \left\| \left( |\xi| |\partial_t \hat{u}^\gamma| + |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_{t,\text{loc}} L^2_\xi} \\
&\lesssim (\gamma^2 + hR) \left( \left\| E^{0\gamma} \right\|_{L^2_x} + \left\| B^{0\gamma} \right\|_{L^2_x} \right) + (h + \gamma^2) (R^4 \left\| \partial_t u^\gamma \right\|_{L^2_{t,\text{loc}} \dot{H}^{-3}_x} + R^2 \left\| u^\gamma \right\|_{L^2_{t,\text{loc}} \dot{H}^1_x}) \\
&\quad + (h + \gamma^2) \left( R^2 \left\| \hat{G}_4^\gamma \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_{t,\text{loc}} L^2_\xi} + R \left\| \hat{G}_3^\gamma \chi_{\{0 \leq |\xi| \leq R\}} \right\|_{L^2_{t,\text{loc}} L^2_\xi} \right).
\end{aligned}$$

By virtue of the uniform estimates of  $G_3^\gamma$  and  $G_4^\gamma$  in (3.3) and  $\|\partial_t u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{-3}}$  in (3.1), and applying Plancherel's theorem, we obtain

$$\limsup_{h \rightarrow 0} \sup_{\gamma} \|B_{\ll}^\gamma(t+h) - B_{\ll}^\gamma(t)\|_{L_{t,\text{loc}}^2 L_\xi^2} = 0,$$

whence, utilizing Riesz-Fréchet-Kolmogorov compactness criterion (for more details, see [43]), the relative compactness of  $B_{\ll}^\gamma$  in the strong topology of  $L_{t,x,\text{loc}}^2$  can be deduced, that is,

$$B_{\ll}^\gamma \rightarrow B_{\ll} \text{ in } L_{t,x,\text{loc}}^2, \quad (3.16)$$

where  $B_{\ll} = \mathcal{F}^{-1} \left( \chi_{\{0 \leq |\xi| \leq R\}} \hat{B} \right)$ .

Next, we handle with the term  $B_{<}^\gamma$ . Employing Lemma 2.2 and the estimates (3.7) and (3.11), from (3.13), we find that

$$\begin{aligned} & \left| \hat{B}_{<}^\gamma \right| \\ & \lesssim \left( e^{-\beta\eta^2|\xi|^2 t} + e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right) \left( |\gamma b^{0\gamma}| + |\hat{B}^{0\gamma}| + |\xi \times \hat{u}^{0\gamma}| \right) \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \\ & \quad + \gamma e^{-\frac{1}{2\beta\eta^2\gamma^2}t} |\hat{B}^{0\gamma}| + \int_0^t \left[ \frac{1}{\gamma^2} e^{-\frac{1}{2\beta\eta^2\gamma^2}(t-\tau)} + |\xi|^2 e^{-\beta\eta^2|\xi|^2(t-\tau)} \right] |\xi \times \hat{u}^\gamma| \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} d\tau \\ & \quad + \int_0^t e^{-\beta\eta^2|\xi|^2(t-\tau)} \left( |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} d\tau. \end{aligned}$$

Then, one has

$$\begin{aligned} & \left\| \hat{B}_{<}^\gamma \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ & \lesssim \left\| \left\| e^{-\beta\eta^2|\xi|^2 t} \right\|_{L_t^2} \left( |\hat{E}^{0\gamma}| + |\hat{B}^{0\gamma}| + |\xi \times \hat{u}^{0\gamma}| \right) \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_\xi^2} \\ & \quad + \left\| |\xi|^2 \left\| e^{-\beta\eta^2|\xi|^2 t} \right\|_{L_t^1} \left\| \xi \times \hat{u}^\gamma \right\|_{L_{t,\text{loc}}^2} \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_\xi^2} \\ & \quad + \frac{1}{\gamma^2} \left\| e^{-\frac{t}{2\beta\eta^2\gamma^2}} \right\|_{L_t^1} \left\| \xi \times \hat{u}^\gamma \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ & \quad + \left\| \left\| e^{-\beta\eta^2|\xi|^2 t} \right\|_{L_t^1} \left\| |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right\|_{L_{t,\text{loc}}^2} \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_\xi^2} \\ & \lesssim \frac{1}{R} \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \left\| \hat{u}^{0\gamma} \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_\xi^2} + \left\| \xi \times \hat{u}^\gamma \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ & \quad + \left\| \hat{G}_4^\gamma \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} + \left\| |\xi|^{-1} \hat{G}_3^\gamma \chi_{\{R < |\xi| \leq \frac{1}{2K\beta\eta^2\gamma}\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ & \lesssim \frac{1}{R} \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \frac{1}{R^s} \left( \|u^{0\gamma}\|_{\dot{H}^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}^{1+s}} \right) \\ & \quad + R^{\frac{1}{2}-s} \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}^{s-\frac{3}{2}}} + \frac{1}{R} \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ & \lesssim \frac{1}{R} \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \frac{1}{R^s} \left( \|u^{0\gamma}\|_{\dot{H}^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}^{1+s}} \right) \\ & \quad + R^{\frac{1}{2}-s} \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 L^{\frac{3}{3-s}}} + \frac{1}{R} \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2}. \end{aligned}$$

In view of the uniform bounds (3.2) of  $G_3^\gamma$  and  $G_4^\gamma$ , we conclude that

$$\limsup_{\gamma \rightarrow 0} \|B_\sim^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2} \lesssim R^{\frac{1}{2}-s}. \quad (3.17)$$

Thirdly, we deal with the term  $B_\sim^\gamma$ . Clearly, (3.13) can be recast as

$$\begin{aligned} \hat{B}^\gamma &= \left[ \gamma e^{t\lambda_-} + (1-\gamma)e^{t\lambda_+} \right] B^{0\gamma} + \gamma \lambda_- t e^{t\lambda_+} \frac{1 - e^{t(\lambda_- - \lambda_+)}}{t(\lambda_- - \lambda_+)} s b^{0\gamma} \\ &\quad + (1-\gamma) \lambda_+ t e^{t\lambda_+} \frac{1 - e^{t(\lambda_- - \lambda_+)}}{t(\lambda_- - \lambda_+)} B^{0\gamma} - \frac{1}{\beta \eta \gamma^2} t e^{t\lambda_+} \frac{1 - e^{t(\lambda_- - \lambda_+)}}{t(\lambda_- - \lambda_+)} \xi \times \hat{u}^{0\gamma} \\ &\quad - \frac{i}{\beta \eta \gamma^2} \int_0^t e^{(t-\tau)\lambda_-} \xi \times \hat{u}^\gamma + \lambda_+(t-\tau) e^{(t-\tau)\lambda_+} \frac{e^{(t-\tau)(\lambda_- - \lambda_+)} - 1}{(t-\tau)(\lambda_- - \lambda_+)} \xi \times \hat{u}^\gamma d\tau \\ &\quad + \frac{1}{\beta \eta \gamma^2} \int_0^t (t-\tau) e^{(t-\tau)\lambda_+} \frac{1 - e^{(t-\tau)(\lambda_- - \lambda_+)}}{(t-\tau)(\lambda_- - \lambda_+)} \xi \times \left( i \xi \cdot \hat{G}_4^\gamma + |\xi|^2 \hat{u}^\gamma - \frac{1}{\eta} \hat{G}_3^\gamma \right) d\tau. \end{aligned}$$

For fixed  $1 < K < \frac{\sqrt{5}}{2}$ , using the complex mean value theorem (see [33]), we can infer that

$$\left| e^{t\lambda_+} \frac{1 - e^{t(\lambda_- - \lambda_+)}}{t(\lambda_- - \lambda_+)} \right| \leq e^{-\frac{\omega}{\gamma^2} t}$$

for some constant  $\omega > 0$  depending on  $K$ , provided  $\frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma}$ . Combining Lemma 2.2, estimates (3.7) and (3.11), we have

$$\begin{aligned} |\hat{B}_\sim^\gamma| &\lesssim \left( \gamma e^{-\frac{1}{2\beta\eta^2\gamma^2}t} + e^{-\frac{-K+\sqrt{K^2-1}}{2K\beta\eta^2\gamma^2}t} + \frac{1}{\gamma^2} t e^{-\frac{\omega}{\gamma^2}t} \right) |\hat{B}^{0\gamma}| + \frac{1}{\gamma} t e^{-\frac{\omega}{\gamma^2}t} (|\hat{B}^{0\gamma}| + |\hat{E}^{0\gamma}|) \\ &\quad + \frac{1}{\gamma^2} t e^{-\frac{\omega}{\gamma^2}t} |\xi \times \hat{u}^{0\gamma}| \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} \\ &\quad + \frac{1}{\gamma^2} \int_0^t \left[ e^{-\frac{1}{2\beta\eta^2\gamma^2}(t-\tau)} + \frac{1}{\gamma^2} (t-\tau) e^{-\frac{\omega}{\gamma^2}(t-\tau)} \right] |\xi \times \hat{u}^\gamma| \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} d\tau \\ &\quad + \frac{1}{\gamma^2} \int_0^t (t-\tau) e^{-\frac{\omega}{\gamma^2}(t-\tau)} \left( |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} d\tau. \end{aligned}$$

Thus, we get

$$\begin{aligned} &\left\| \hat{B}_\sim^\gamma \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\lesssim \left( \left\| e^{-\frac{-K+\sqrt{K^2-1}}{2K\beta\eta^2\gamma^2}t} \right\|_{L_t^1} + \frac{1}{\gamma^2} \left\| t e^{-\frac{\omega}{\gamma^2}t} \right\|_{L_t^2} \right) \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) \\ &\quad + \frac{1}{\gamma^2} \left\| t e^{-\frac{\omega}{\gamma^2}t} \right\|_{L_t^2} \left\| \xi \times \hat{u}^{0\gamma} \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} \right\|_{L_\xi^2} \\ &\quad + \frac{1}{\gamma^2} \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L_t^1} \left\| \xi \times \hat{u}^\gamma \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\quad + \frac{1}{\gamma^2} \left\| t e^{-\frac{\omega}{\gamma^2}t} \right\|_{L_t^1} \left\| \left( |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\left\{ \frac{1}{2K\beta\eta^2\gamma} < |\xi| \leq \frac{K}{2\beta\eta^2\gamma} \right\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\lesssim \gamma \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \gamma^s \left( \|u^{0\gamma}\|_{\dot{H}_x^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} \right) \\ &\quad + \gamma^{s-\frac{1}{2}} \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}^{s-\frac{3}{2}}} + \gamma \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2} \end{aligned}$$

$$\begin{aligned} &\lesssim \gamma \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \gamma^s \left( \|u^{0\gamma}\|_{\dot{H}_x^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} \right) \\ &\quad + \gamma^{s-\frac{1}{2}} \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 L_x^{\frac{3}{3-s}}} + \gamma \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_x^2}. \end{aligned}$$

By virtue of the uniform bounds (3.2) of  $G_3^\gamma$  and  $G_4^\gamma$ , we deduce that

$$\limsup_{\gamma \rightarrow 0} \|B_\sim^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2} = 0. \quad (3.18)$$

Finally, we deal with the term  $B_{>}^\gamma$ . Combining Lemma 2.2, estimates (3.7) and (3.11), it follows from (3.13) that

$$\begin{aligned} |\hat{B}_{>}^\gamma| &\lesssim e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \left( |\hat{B}^{0\gamma}| + |\hat{E}^{0\gamma}| \right) + \frac{1}{\gamma} e^{-\frac{1}{2\beta\eta^2\gamma^2}t} |\hat{u}^{0\gamma}| \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} \\ &\quad + \frac{1}{\gamma^2} \int_0^t e^{-\frac{1}{2\beta\eta^2\gamma^2}(t-\tau)} |\xi \times \hat{u}^\gamma| \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} d\tau \\ &\quad + \frac{1}{\gamma|\xi|} \int_0^t e^{-\frac{1}{2\beta\eta^2\gamma^2}(t-\tau)} \left( |\xi|^2 |\hat{G}_4^\gamma| + |\xi|^3 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} d\tau. \end{aligned}$$

Therefore, we have

$$\begin{aligned} &\left\| \hat{B}_{>}^\gamma \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\lesssim \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L_t^2} \left( \left\| E^{0\gamma} \right\|_{L_x^2} + \left\| B^{0\gamma} \right\|_{L_x^2} + \frac{1}{\gamma} \left\| \hat{u}^{0\gamma} \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} \right\|_{L_\xi^2} \right) \\ &\quad + \frac{1}{\gamma^2} \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L_t^1} \left\| \xi \times \hat{u}^\gamma \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\quad + \frac{1}{\gamma} \left\| e^{-\frac{1}{2\beta\eta^2\gamma^2}t} \right\|_{L_t^1} \left\| \left( |\xi| |\hat{G}_4^\gamma| + |\xi|^2 |\hat{u}^\gamma| + |\xi| |\hat{G}_3^\gamma| \right) \chi_{\left\{ \frac{K}{2\beta\eta^2\gamma} < |\xi| \leq \phi\left(\frac{\gamma}{\delta}\right) \right\}} \right\|_{L_{t,\text{loc}}^2 L_\xi^2} \\ &\lesssim \gamma \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \gamma^s \left( \|u^{0\gamma}\|_{\dot{H}_x^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} \right) \\ &\quad + \gamma \left( \phi\left(\frac{\gamma}{\delta}\right)^{\frac{3}{2}-s} \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{s-\frac{3}{2}}} + \phi\left(\frac{\gamma}{\delta}\right)^{1-s} \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} + \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_x^2} \right) \\ &\lesssim \gamma \left( \|E^{0\gamma}\|_{L_x^2} + \|B^{0\gamma}\|_{L_x^2} \right) + \gamma^s \left( \|u^{0\gamma}\|_{\dot{H}_x^s} + \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} \right) \\ &\quad + \delta \|\nabla G_4^\gamma\|_{L_{t,\text{loc}}^2 L_x^{\frac{3}{3-s}}} + \gamma^{\frac{1}{3-2s}} \|u^\gamma\|_{L_{t,\text{loc}}^2 \dot{H}_x^{1+s}} + \gamma \|G_3^\gamma\|_{L_{t,\text{loc}}^2 L_x^2}, \end{aligned}$$

whence, in view of the uniform bounds (3.2) of  $G_3^\gamma$  and  $G_4^\gamma$ , one has

$$\limsup_{\gamma \rightarrow 0} \|B_{<}^\gamma\|_{L_{t,\text{loc}}^2 L_\xi^2} \lesssim \delta. \quad (3.19)$$

Now, we are ready to prove the weak stability of the Lorentz force  $j^\gamma \times B^\gamma$ . Combining the estimates (3.15), (3.16), (3.17), (3.18), (3.19) and the fact that  $j^\gamma \rightharpoonup j$  in  $L_{t,x}^2$ , we can deduce from (3.14) that

$$\begin{aligned} &\limsup_{\gamma \rightarrow 0} \left| \int_{\mathbb{R}^+ \times \mathbb{R}^3} (j^\gamma \times B^\gamma - j \times B) \cdot \varphi \, dt dx \right| \\ &\lesssim \int_{\mathbb{R}^+ \times \mathbb{R}^3} j \times (B_{\ll} - B) \cdot \varphi \, dt dx + \delta + R^{\frac{1}{2}-s} \end{aligned}$$

Notice that as  $R \rightarrow \infty$ ,

$$B_{\ll} \rightarrow B \text{ in } L_{t,\text{loc}}^2 L_x^2,$$

by the arbitrariness of  $R > 0$  (large) and  $\delta > 0$  (small), we have

$$\lim_{\gamma \rightarrow 0} \int_{\mathbb{R}^+ \times \mathbb{R}^3} j^\gamma \times B^\gamma \cdot \varphi \, dt dx = \int_{\mathbb{R}^+ \times \mathbb{R}^3} j \times B \cdot \varphi \, dt dx,$$

which concludes the desired results of Theorem 1.1.  $\square$
