Abstract

This is a short technical report introducing the solution of the Team TCParse for Short-video Face Parsing Track of The 3rd Person in Context (PIC) Workshop and Challenge at CVPR 2021.

*In this paper, we introduce a strong backbone which is cross-window based Shuffle Transformer for presenting accurate face parsing representation. To further obtain the finer segmentation results, especially on the edges, we introduce a Feature Alignment Aggregation (FAA) module. It can effectively relieve the feature misalignment issue caused by multi-resolution feature aggregation. Benefiting from the stronger backbone and better feature aggregation, the proposed method achieves 86.9519% score in the Short-video Face Parsing track of the 3rd Person in Context (PIC) Workshop and Challenge, ranked **the first place**.*

1. Introduction

Face parsing has been applied in a variety of scenarios such as face understanding, editing, synthesis, and animation. As a particular task in semantic segmentation, Face parsing assigns different labels to the corresponding regions on human faces, e.g., hair, facial skins, eyes, nose, mouth and etc., which relies highly on the accuracy of facial components' representation. As a consequence, this is very important to find a way to improve the representation ability.

Traditionally, [18, 21, 9] use hand crafted features including SIFT or machine learning method including Restricted Boltzmann Machine (RBM) to extract local and global features. Current state-of-the-art semantic segmentation approaches [2, 22, 24, 23, 16, 7, 17, 10, 3, 4] based on the fully convolutional network (FCN) [14] have made remarkable progress. For face parsing, CNN-based features are imported into network to extract multi-scale or

independent-part facial features [12, 15, 25]. Lin et al. propose two branches with the local-based for inner facial components and the global based for outer facial ones [11]. Te et al. propose to learn graph representations over facial images, which model the relations between regions [19]. These local-based methods almost adopt the coarse-to-fine strategy, training separated models for various facial components (e.g. eyes, nose etc.) to extract features for each part individually. However, this kind of method achieves good performance at the expense of large memory and computation consumption.

In this paper, we introduce a cross-window based Shuffle Transformer with feature alignment for better improving the face parsing representation ability. Transformers [5, 1, 20, 13] have achieved excellent performance on a wide range of visual tasks including image-level classification, object detection, and semantic segmentation. And Shuffle Transformer [6] is confirmed as a strong backbone for many vision tasks. Furthermore we import a feature alignment aggregation module to pass information between high-resolution and low-resolution feature maps precisely. The proposed method achieves a good performance in the Short-video Face Parsing track (SFP) of the 3rd Person in Context (PIC) Workshop and achieved the accuracy of 86.9519%, ranked the first place.

2. Method

The overall network architecture is visualized in Figure 1, which is similar with the AlignSeg [8]. Different from [8], we use Shuffle Transformer [6] as a strong backbone and simplified Aligned Feature Aggregation for aligning features from different stages with different resolutions. The simplified Aligned Feature Aggregation, named as Feature Alignment Aggregation (FAA), only learns the offsets maps Δ for aligning low-resolution high-level feature maps. Meanwhile, we append the Pyramid pooling module

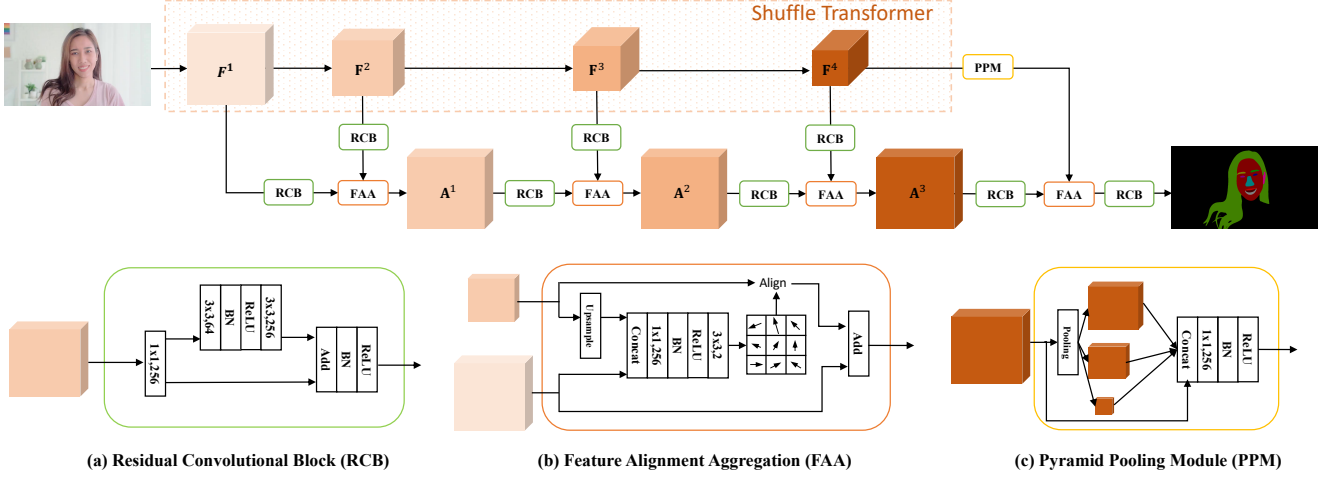

Figure 1. The proposed network architecture.

(PPM) [24] on the top of the output of the Shuffle Transformer. The $\mathbf{F}^i, i = \{1, 2, 3, 4\}$ are the output feature maps from the i th stage of Shuffle Transformer, where $\mathbf{F}^1 \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}, \mathbf{F}^2 \in \mathbb{R}^{2C \times \frac{H}{8} \times \frac{W}{8}}, \mathbf{F}^3 \in \mathbb{R}^{3C \times \frac{H}{16} \times \frac{W}{16}}, \mathbf{F}^4 \in \mathbb{R}^{4C \times \frac{H}{32} \times \frac{W}{32}}$. The aligned feature \mathbf{A}^i has the same resolution as \mathbf{F}^1 . Finally, the feature is passed through several convolutional layers to produce the final segmentation map.

Table 1. Results of SFP, we achieve 86.95%, win the 1st place.

Team	Ranking	Accuracy(%)
TCPParser(ours)	1st	86.95
BUPT-CASIA	2nd	86.84
rat	3rd	86.16

3. Experiments

3.1. Implementation details

Datasets. The total dataset of the SFP challenge contains 1500 videos, each video has 20 images (1 frame per second for each video). SFP has 19535 images for training, 2653 images for validation and 2525 images for testing with 18 categories including face, eye, noes, etc.

Evaluation Metrics. In this challenge, each submission is validated based on the Davis J/F score and temporal decay.

Training. We train the proposed model on the open-source machine learning library Pytorch. We use SGD optimizer with 0.9 momentum and 5e-4 weight decay, learning is scheduled via cosine warm up from 7e-3 warmup learning rate at 10 epochs and start cycle at 100 epochs, stop at 150 epochs. Model input size is 672x672, with 6 batch size on eight NVIDIA V100 GPUs. For backbone we use shuffle transformer(pretrained on ImageNet), and the decoder part is trained from scratch. Besides shuffle transformer, we also train different backbone model based on HRNet-W48

for model ensemble and face detection since most of the faces in SFP dataset only account for a small part of the whole image.

Testing. We add val set into training process, use HRNet-W48 as face detector, apply multi-scale test, flip, and model ensemble to improve results, as shown in table 2.

Table 2. The effect of our models on val set.

	mIoU	J&F-Mean	J-Decay	F-Decay
HRNet-W48	0.7283	0.900	0.004	0.005
Shuffle Transformer	0.7312	0.903	0.005	0.006
Model ensemble	0.7338	0.925	0.004	0.004

3.2. Experimental Results

As shown in Table 1, our proposed method achieves Accuracy score of 86.95% on the challenge test set and ranks first place. Also we evaluate the J/F score and temporal decay of the proposed models as shown in table 2

4. Conclusion

In this paper, we use shuffle transformer as backbone and embed FAA module, which learns the offset maps for aligning low-resolution high-level feature maps. With other tricks mentioned, the proposed method achieves 86.95% accuracy and wins the 1st place in the Short-video Face Parsing track of the 3rd Person in Context (PIC) Workshop. This work hopes to explore a strong feature extractor as well as refine module for face parsing task, we believe it could equally well apply to other similar semantic segmentation tasks.
