A RECURSIVE LOVÁSZ THETA NUMBER FOR SIMPLEX-AVOIDING SETS

DAVI CASTRO-SILVA, FERNANDO MÁRIO DE OLIVEIRA FILHO, LUCAS SLOT, AND FRANK VALLENTIN

Abstract. We recursively extend the Lovász theta number to geometric hypergraphs on the unit sphere and on Euclidean space, obtaining an upper bound for the independence ratio of these hypergraphs. As an application we reprove a result in Euclidean Ramsey theory in the measurable setting, namely that every $k$-simplex is exponentially Ramsey, and we improve existing bounds for the base of the exponential.

1. Introduction

The Lovász theta number $\vartheta(G)$ of a finite graph $G$ satisfies $\alpha(G) \leq \vartheta(G) \leq \chi(\overline{G})$, where $\alpha(G)$ is the independence number of $G$ and $\chi(\overline{G})$ is the chromatic number of the complement of $G$, that is, the edges of $\overline{G}$ are the non-edges of $G$ and vice versa; the theta number can be computed efficiently using semidefinite programming.

Originally, Lovász [14] introduced $\vartheta$ to determine the Shannon capacity of the 5-cycle. The theta number turned out to be a versatile tool in optimization, with applications in combinatorics and geometry. It is related to spectral bounds like Hoffman’s bound, as noted by Lovász in his paper (cf. Bachoc, DeCorte, Oliveira, and Vallentin [2]), and also to Delsarte’s linear programming bound in coding theory, as observed independently by McEliece, Rodemich, and Rumsey [15] and Schrijver [24].

Bachoc, Nebe, Oliveira, and Vallentin [3] extended $\vartheta$ to infinite geometric graphs on compact metric spaces. They also showed that this extension leads to the classical linear programming bound for spherical codes of Delsarte, Goethals, and Seidel [7]; the linear programming bound of Cohn and Elkies for the sphere-packing density [4] can also be seen as an appropriate extension of $\vartheta$ [13, 17]. These many applications illustrate the power of the Lovász theta number as a unifying concept in optimization; Goemans [12] even remarked that “it seems all paths lead to $\vartheta$!”.

We will show how a recursive variant of $\vartheta$ can be used to find upper bounds for the independence ratio of geometric hypergraphs on the sphere and on Euclidean space; this will lead to new bounds for a problem in Euclidean Ramsey theory.

1.1. Unit sphere. We call a set $\{x_1, \ldots, x_k\}$ of $k \geq 2$ points in the $(n - 1)$-dimensional unit sphere $S^{n-1} = \{ x \in \mathbb{R}^n : \|x\| = 1 \}$ a $(k, t)$-simplex if $x_i \cdot x_j = t$ for all $i \neq j$. Note that a $(k, t)$-simplex has dimension $k - 1$. There is a $(k, t)$-simplex in $S^{n-1}$ for every $k \leq n$ and $t \in [-1/(k - 1), 1)$.

The fourth author is partially supported by the SFB/TRR 191 “Symplectic Structures in Geometry, Algebra and Dynamics” and by the project “Spectral bounds in extremal discrete geometry” (project number 414898050), both funded by the DFG.
Fix \( n \geq k \geq 2 \) and \( t \in [-1/(k-1), 1) \). A set of points in \( S^{n-1} \) avoids \((k, t)\)-simplices if no \( k \) points in the set form a \((k, t)\)-simplex. We are interested in the parameter
\[
\alpha(S^{n-1}, k, t) = \sup \{ \omega(I) : I \subseteq S^{n-1} \text{ is measurable and avoids } (k, t)\text{-simplices} \},
\]
where \( \omega \) is the surface measure on the sphere normalized so the total measure is 1. This is the independence ratio of the hypergraph whose vertex set is \( S^{n-1} \) and whose edges are all \((k, t)\)-simplices.

In \( \S 2 \) we will define the parameter \( \vartheta(S^{n-1}, k, t) \) recursively as the optimal value of the problem
\[
\sup \int_{S^{n-1}} \int_{S^{n-1}} f(x \cdot y) \, d\omega(y) \, d\omega(x)
\]
\[
f(1) = 1,
\]
\[
f(t) \leq \vartheta(S^{n-2}, k-1, t/(1+t)),
\]
\[
f \in C([-1, 1])
\]
for \( k \geq 3 \). The base of the recursion is \( k = 2 \): \( \vartheta(S^{n-1}, 2, t) \) is the optimal value of the problem above when \( f(t) \leq \vartheta(S^{n-2}, k-1, t/(1+t)) \) is replaced by \( f(t) = 0 \).

From Theorem \( \S 2.1 \) below it follows that \( \vartheta(S^{n-1}, k, t) \geq \alpha(S^{n-1}, k, t) \). Using extremal properties of ultraspherical polynomials, an explicit formula can be computed for this bound, as shown in Theorem \( \S 2.2 \).

1.2. Euclidean space. Transferring these concepts from the compact unit sphere to the non-compact Euclidean space requires a bit of care; this is done in \( \S 3 \).

A unit \( k \)-simplex in \( \mathbb{R}^n \) is a set \( \{x_1, \ldots, x_k\} \) of \( k \leq n + 1 \) points such that \( \|x_i - x_j\| = 1 \) for all \( i \neq j \). As before, note that the dimension of a unit \( k \)-simplex is \( k - 1 \). A set of points in \( \mathbb{R}^n \) avoids unit \( k \)-simplices if no \( k \) points in the set form a unit \( k \)-simplex. We are interested in the parameter
\[
\alpha(\mathbb{R}^n, k) = \sup \{ \delta(I) : I \subseteq \mathbb{R}^n \text{ is measurable and avoids unit } k\text{-simplices} \},
\]
where \( \delta(X) \) is the upper density of \( X \subseteq \mathbb{R}^n \), that is,
\[
\delta(X) = \limsup_{T \to \infty} \frac{\text{vol}(X \cap [-T,T]^n)}{\text{vol}([-T,T]^n)}.
\]

Again, this parameter has an interpretation in terms of a hypergraph on the Euclidean space and again we can bound the independence ratio of this hypergraph from above by an appropriately defined parameter \( \vartheta(\mathbb{R}^n, k) \). Theorem 3.2 below gives an explicit expression for \( \vartheta(\mathbb{R}^n, k) \) in terms of Bessel functions and ultraspherical polynomials.

1.3. Euclidean Ramsey theory. The central question of Euclidean Ramsey theory is: given a finite configuration \( P \) of points in \( \mathbb{R}^n \) and an integer \( r \geq 1 \), does every \( r \)-coloring of \( \mathbb{R}^n \) contain a monochromatic congruent copy of \( P \)?

The simplest point configurations are unit \( k \)-simplices, which are known to have the exponential Ramsey property: exponentially many colors (in the dimension) are needed to avoid monochromatic unit \( k \)-simplices in \( \mathbb{R}^n \). This was first proved by Frankl and Wilson \( \S 11 \) for \( k = 2 \) and by Frankl and Rödl \( \S 10 \) for \( k > 2 \). Results in this area are usually proved by the linear algebra method; see also Sagdeev \( \S 20 \).

In \( \S 4 \) we analyze the upper bounds \( \vartheta(S^{n-1}, k, t) \) for simplex-avoiding sets on the sphere and \( \vartheta(\mathbb{R}^n, k) \) for simplex-avoiding sets on Euclidean space by using properties of ultraspherical polynomials, obtaining the following theorem.

**Theorem 1.1.** If \( k \geq 2 \), then:

(i) for every \( t \in (0, 1) \), there is a constant \( c = c(k, t) \in (0,1) \) such that
\[
\vartheta(S^{n-1}, k, t) \leq (c + o(1))^n;
\]

(ii) there is a constant \( c = c(k) \in (0,1) \) such that \( \vartheta(\mathbb{R}^n, k) \leq (c + o(1))^n \).
\[
\chi(\mathbb{R}^n, 3) \geq (1.01466 + o(1))^n,
\]
where \(\chi(\mathbb{R}^n, 3)\) is the minimum number of colors needed to color the points of \(\mathbb{R}^n\) in such a way that the vertices of any equilateral triangle of unit side length do not all get the same color. This is the best lower bound known at the moment.

For simplices of higher dimension there are also explicit lower bounds known for the chromatic number \(\chi(\mathbb{R}^n, k)\). Currently, the best such bound was obtained by Sagdeev [21] using a quantitative version of the Frankl-Rödl theorem:
\[
\chi(\mathbb{R}^n, k) \geq \left(1 + \frac{1}{2^{k+2}} + o(1)\right)^n.
\]

If we restrict our colorings to have measurable color classes, then from Theorem 1.1 we get an exponential lower bound for \(\chi_m(\mathbb{R}^n, k)\), the measurable counterpart of \(\chi(\mathbb{R}^n, k)\), since
\[
\chi_m(\mathbb{R}^n, k) \alpha(\mathbb{R}^n, k) \geq 1.
\]
Rigorous estimates of the constant \(c\) in Theorem 1.1 then yield significantly better lower bounds than those currently known.

Indeed, in the case \(k = 3\) we obtain (see §4.1)
\[
\alpha(\mathbb{R}^n, 3) \leq (0.95622 + o(1))^n,
\]
and so
\[
\chi_m(\mathbb{R}^n, 3) \geq (1.04578 + o(1))^n.
\]

We also obtain the rougher estimate
\[
\alpha(\mathbb{R}^n, k) \leq \left(1 - \frac{1}{9(k-1)^2} + o(1)\right)^n,
\]
valid for all \(k \geq 3\), which immediately implies
\[
\chi_m(\mathbb{R}^n, k) \geq \left(1 + \frac{1}{9(k-1)^2} + o(1)\right)^n.
\]

1.4. Notation and preliminaries. We will denote the Euclidean inner product between \(x, y \in \mathbb{R}^n\) by \(x \cdot y\). The surface measure on the sphere is denoted by \(\omega\) and is always normalized so the total measure is 1.

We always normalize the Haar measure on a compact group so the total measure is 1. By \(O(n)\) we denote the group of \(n \times n\) orthogonal matrices. If \(X \subseteq S^{n-1}\) is any measurable set and if \(\mu\) is the Haar measure on \(O(n)\), then for every \(e \in S^{n-1}\) we have
\[
\mu(\{ T \in O(n) : Te \in X \}) = \omega(X).
\]

We will need the following technical lemma, which will be applied to the sphere and the torus. For a proof, see Lemma 5.5 in DeCorte, Oliveira, and Vallentin [6].

Lemma 1.2. Let \(V\) be a metric space and \(\Gamma\) be a compact group that acts transitively on \(V\); let \(\nu\) be a finite Borel measure on \(V\) that is positive on open sets. Denote by \(\mu\) the Haar measure on \(\Gamma\). If the metric on \(V\) and the measure \(\nu\) are \(\Gamma\)-invariant and if \(f \in L^2(V; \nu)\), then the function \(K: V \times V \to \mathbb{R}\) such that
\[
K(x, y) = \int_{\Gamma} f(\sigma x) f(\sigma y) d\mu(\sigma)
\]
is continuous.

1The slice-rank method is only implicit in the original works; the actual notion of slice rank for a tensor was introduced by Tao in a blog post [26].
2. Simplicy-avoiding sets on the sphere

We call a continuous kernel \( K : S^{n-1} \times S^{n-1} \to \mathbb{R} \) positive if for every finite set \( U \subseteq S^{n-1} \) the matrix \( \{ K(x, y) \}_{x, y \in U} \) is positive semidefinite. A continuous function \( f : [-1, 1] \to \mathbb{R} \) is of positive type for \( S^{n-1} \) if the kernel \( K \in C(S^{n-1} \times S^{n-1}) \) given by \( K(x, y) = f(x \cdot y) \) is positive.

Fix \( n \geq k \geq 3 \) and \( t \in [-1/(k-1), 1) \). For any \( \gamma \geq 0 \), consider the optimization problem

\[
\sup \int_{S^{n-1}} \int_{S^{n-1}} f(x \cdot y) \, d\omega(y) \, d\omega(x) = f(1), \quad f(t) \leq \gamma, \quad f \in C([-1, 1]) \text{ is a function of positive type for } S^{n-1}.
\]

**Theorem 2.1.** Fix \( n \geq k \geq 3 \), \( t \in [-1/(k-1), 1) \). If \( \gamma \geq \alpha(S^{n-2}, k-1, t/(1+t)) \), then the optimal value of (1) is an upper bound for \( \alpha(S^{n-1}, k, t) \).

**Proof.** Let \( I \subseteq S^{n-1} \) be a measurable set that avoids \((k, t)\)-simplices and assume \( \omega(I) > 0 \). Consider the kernel \( K : S^{n-1} \times S^{n-1} \to \mathbb{R} \) such that

\[
K(x, y) = \int_{O(n)} \chi_I(Tx) \chi_I(Ty) \, d\mu(T),
\]

where \( \chi_I \) is the characteristic function of \( I \) and where \( \mu \) is the Haar measure on \( O(n) \).

By taking \( V = S^{n-1} \) and \( \Gamma = O(n) \) in Lemma 1.2, we see that \( K \) is continuous. By construction, \( K \) is also positive and invariant, that is, \( K(Tx, Ty) = K(x, y) \) for all \( T \in O(n) \) and \( x, y \in S^{n-1} \). Such kernels are of the form \( K(x, y) = g(x \cdot y) \), where \( g \in C([-1, 1]) \) is of positive type for \( S^{n-1} \). Note that

\[
K(x, x) = \int_{O(n)} \chi_I(Tx) \, d\mu(T) = \omega(I),
\]

so \( g(1) = \omega(I) > 0 \).

Set \( f = g/g(1) \). Immediately we have that \( f \) is continuous and of positive type and that \( f(1) = 1 \); moreover

\[
\int_{S^{n-1}} \int_{S^{n-1}} f(x \cdot y) \, d\omega(y) \, d\omega(x) = \omega(I).
\]

Hence, if we show that \( f(t) \leq \gamma \), the theorem will follow.

If \( x \in S^{n-1} \) is a point in a \((k, t)\)-simplex, all other points in the simplex are in \( U_{x,t} = \{ y \in S^{n-1} : y \cdot x = t \} \). Note that \( U_{x,t} \) is an \((n-2)\)-dimensional sphere with radius \((1-t^2)^{1/2} \); let \( \nu \) be the surface measure on \( U_{x,t} \) normalized so the total measure is 1.

If \( T \in O(n) \) is any orthogonal matrix, then \( TI \) avoids \((k, t)\)-simplices. Hence if \( x \in TI \), then \( TI \cap U_{x,t} \) cannot contain \( k-1 \) points with pairwise inner product \( t \), and so \( \nu(TI \cap U_{x,t}) \leq \alpha(S^{n-2}, k-1, t/(1+t)) \leq \gamma \). Indeed, the natural bijection between \( U_{x,t} \) and \( S^{n-2} \) maps pairs of points with inner product \( t \) to pairs of points with inner product \( t/(1+t) \), and so \( TI \cap U_{x,t} \) is mapped to a subset of \( S^{n-2} \) avoiding \((k-1, t/(1+t))\)-simplices.

Now fix \( x \in S^{n-1} \) and note that

\[
g(t) = \int_{U_{x,t}} K(x, y) \, d\nu(y) = \int_{U_{x,t}} \int_{O(n)} \chi_I(Tx) \chi_I(Ty) \, d\mu(T) \, d\nu(y)
\]

\[
= \int_{O(n)} \chi_I(Tx) \int_{U_{x,t}} \chi_I(Ty) \, d\nu(y) \, d\mu(T)
\]

\[
\leq \gamma \omega(I),
\]
Proof of Theorem 2.2. The orthogonality of the Jacobi polynomials implies in particular that, if \( j \geq 1 \), then
\[
\int_{S^{n-1}} \int_{S^{n-1}} P_j^n(x \cdot y) \, d\omega(y) \, d\omega(x) = 0.
\]

whence \( f(t) \leq \gamma \), and we are done.

One obvious choice for \( \gamma \) in Problem (1) is the bound given by the same problem for \((k-1, t/(1+t))\)-simplices. The base for the recursion is \( k = 2 \): then we need an upper bound for the measure of a set of points on the sphere that avoids pairs of points with a fixed inner product. Such a bound was given by Bachoc, Nebe, Oliveira, and Vallentin [3] and looks very similar to (1). They show that, for \( n \geq 2 \) and \( t \in [-1, 1) \), the optimal value of the following optimization problem is an upper bound for \( \alpha(S^{n-1}, 2, t) \):
\[
\sup_{f \in C([-1, 1])} \int_{S^{n-1}} \int_{S^{n-1}} f(x \cdot y) \, d\omega(y) \, d\omega(x)
\]
\[
f(1) = 1,
\]
\[
f(t) = 0,
\]
\[
f \in C([-1, 1]) \text{ is a function of positive type for } S^{n-1}.
\]

Let \( \vartheta(S^{n-1}, 2, t) \) denote the optimal value of the optimization problem above, so \( \vartheta(S^{n-1}, 2, t) \geq \alpha(S^{n-1}, 2, t) \). For \( k \geq 3 \) and \( t \in [-1/(k-1), 1) \), let \( \vartheta(S^{n-1}, k, t) \) be the optimal value of Problem (1) when \( \gamma = \vartheta(S^{n-2}, k-1, t/(1+t)) \). We then have
\[
\vartheta(S^{n-1}, k, t) \geq \alpha(S^{n-1}, k, t).
\]

There is actually a simple analytical expression for \( \vartheta(S^{n-1}, k, t) \), as we see now. For \( n \geq 2 \) and \( j \geq 0 \), let \( P_j^n \) denote the Jacobi polynomial with parameters \( \alpha = \beta = (n-3)/2 \) and degree \( j \), normalized so \( P_j^n(1) = 1 \) (for background on Jacobi polynomials, see the book by Szegő [25]).

In Theorem 6.2 of Bachoc, Nebe, Oliveira, and Vallentin [3] it is shown that for every \( t \in [-1, 1) \) there is some \( j \geq 0 \) such that \( P_j^n(t) < 0 \). Theorem 8.21.8 in the book by Szegő [25] implies that, for every \( t \in (-1, 1) \),
\[
\lim_{j \to \infty} P_j^n(t) = 0.
\]

Hence, for every \( t \in (-1, 1) \) we can define
\[
M_n(t) = \min \{ P_j^n(t) : j \geq 0 \},
\]
and we see that \( M_n(t) < 0 \). With this we have [3, Theorem 6.2]
\[
\vartheta(S^{n-1}, 2, t) = \frac{-M_n(t)}{1 - M_n(t)}.
\]

The expression for \( \vartheta(S^{n-1}, k, t) \) is very similar.

**Theorem 2.2.** If \( n \geq k \geq 3 \) and \( t \in [-1/(k-1), 1) \), then
\[
\vartheta(S^{n-1}, k, t) = \frac{\vartheta(S^{n-2}, k-1, t/(1+t)) - M_n(t)}{1 - M_n(t)}.
\]

The proof requires the following characterization of functions of positive type due to Schoenberg [23]: a function \( f : [-1, 1] \to \mathbb{R} \) is continuous and of positive type for \( S^{n-1} \) if and only if there are nonnegative numbers \( f_0, f_1, \ldots \) such that \( \sum_{j=0}^{\infty} f_j < \infty \) and
\[
f(t) = \sum_{j=0}^{\infty} f_j P_j^n(t),
\]
with uniform convergence in \([-1, 1]\).

**Proof of Theorem 2.2.** The orthogonality of the Jacobi polynomials \( P_j^n \) implies in particular that, if \( j \geq 1 \), then
\[
\int_{S^{n-1}} \int_{S^{n-1}} P_j^n(x \cdot y) \, d\omega(y) \, d\omega(x) = 0.
\]
Use this and Schoenberg's characterization of positive type functions to rewrite (1) with \( \gamma = \vartheta(S^{n-2}, k-1, t/(1+t)) \), obtaining the equivalent problem

\[
\sup_{f_0} \sum_{j=0}^{\infty} f_j = 1, \\
\sum_{j=0}^{\infty} f_j P_n^j(t) \leq \vartheta(S^{n-2}, k-1, t/(1+t)), \\
f_j \geq 0 \text{ for all } j \geq 0.
\]

To solve this problem, note that

\[
\sum_{j=0}^{\infty} f_j P_n^j(t)
\]

is a convex combination of the numbers \( P_n^j(t) \). We want to keep this convex combination below \( \vartheta(S^{n-2}, k-1, t/(1+t)) \) while maximizing \( f_0 \). The best way to do so is to concentrate all the weight of the combination on \( f_0 \) and \( f_{j^*} \), where \( j^* \) is such that \( P_n^{j^*}(t) \) is the most negative number appearing in the convex combination, that is, \( P_n^{j^*}(t) = M_n(t) \). Now solve the problem using only the variables \( f_0 \) and \( f_{j^*} \) to get the optimal value as given in the statement of the theorem. \( \square \)

The expression for \( \vartheta(S^{n-1}, k, 0) \) is particularly simple. Indeed, for \( n \geq 2 \) it follows from the recurrence relation for the Jacobi polynomials that \( M_n(0) = P_n^0(0) = -1/(n-1) \), whence

\[ \vartheta(S^{n-1}, k, 0) = (k-1)/n. \]

Figure 1 shows the behavior of \( \vartheta(S^{n-1}, 3, t) \) for a few values of \( n \) as \( t \) changes. Plots for \( k > 3 \) are very similar.

3. **Simplex-avoiding sets in Euclidean space**

An optimization problem similar to (1) provides an upper bound for \( \alpha(\mathbb{R}^n, k) \). To introduce it, we need some definitions and facts from harmonic analysis on \( \mathbb{R}^n \); for background, see e.g. the book by Reed and Simon [19].

A continuous function \( f: \mathbb{R}^n \to \mathbb{R} \) is of **positive type** if for every finite set \( U \subseteq \mathbb{R}^n \) the matrix \( \left( f(x-y) \right)_{x,y \in U} \) is positive semidefinite. Such a function \( f \) has a well-defined **mean value**

\[
M(f) = \lim_{T \to \infty} \frac{1}{\text{vol}([-T,T]^n)} \int_{[-T,T]^n} f(x) \, dx.
\]

We say that a function \( f: \mathbb{R}^n \to \mathbb{R} \) is **radial** if \( f(x) \) depends only on \( ||x|| \). In this case, for \( t \geq 0 \) we denote by \( f(t) \) the common value of \( f \) for vectors of norm \( t \).
Fix $n \geq 2$ and $k \geq 3$ such that $k \leq n+1$. For every $\gamma \geq 0$, consider the optimization problem

$$\sup M(f)$$

$$f(0) = 1,$$

$$f(1) \leq \gamma,$$

$$f: \mathbb{R}^n \to \mathbb{R}$$ is continuous, radial, and of positive type.

We have the analogue of Theorem 2.1:

**Theorem 3.1.** Fix $n \geq 2$ and $k \geq 3$ such that $k \leq n+1$. If $\gamma \geq \alpha(S^{n-1}, k-1, 1/2)$, then the optimal value of \((8)\) is an upper bound for $\alpha(\mathbb{R}^n, k)$.

We need a few facts about periodic sets and functions. A set $X \subseteq \mathbb{R}^n$ is periodic if it is invariant under some lattice $\Lambda$, that is, if $X + v = X$ for all $v \in \Lambda$. Similarly, a function $f: \mathbb{R}^n \to \mathbb{R}$ is periodic if there is a lattice $\Lambda$ such that $f(x + v) = f(x)$ for all $v \in \Lambda$. We say that $\Lambda$ is a periodicity lattice of $X$ or $f$. A periodic function $f$ with periodicity lattice $\Lambda$ can be seen as a function on the torus $\mathbb{R}^n/\Lambda$; its mean value is

$$\frac{1}{\text{vol}(\mathbb{R}^n/\Lambda)} \int_{\mathbb{R}^n/\Lambda} f(x) \, dx.$$

**Proof of Theorem 3.1.** Let $I \subseteq \mathbb{R}^n$ be a measurable set of positive upper density avoiding unit $k$-simplices. The first step is to see that we can assume that $I$ is periodic. Indeed, fix $T > 1/2$. Erase a border of width $1/2$ around $I \cap [-T, T]^n$ and paste the resulting set periodically in such a way that there is an empty gap of width 1 between any two pasted copies. The resulting periodic set still avoids unit $k$-simplices and is measurable. Its upper density is

$$\frac{\text{vol}(I \cap [-T + 1/2, T - 1/2]^n)}{\text{vol}([-T, T]^n)};$$

by taking $T$ large enough, we can make this density as close as we want to the upper density of $I$.

Assume then that $I$ is periodic, so its characteristic function $\chi_I$ is also periodic; let $\Lambda$ be a periodicity lattice. Set

$$g(x) = \frac{1}{\text{vol}(\mathbb{R}^n/\Lambda)} \int_{\mathbb{R}^n/\Lambda} \chi_I(y) \chi_I(x + y) \, dy.$$

Lemma 1.2 with $V = \Gamma = \mathbb{R}^n/\Lambda$ applied to $\chi_I$ implies that $g$ is continuous. Direct verification yields that $g$ is of positive type, $g(0) = \overline{\delta}(I)$, and $M(y) = \overline{\delta}(I)^2$.

Now set

$$f(x) = \overline{\delta}(I)^{-1} \int_{O(n)} g(Tx) \, d\mu(T),$$

where $\mu$ is the Haar measure on $O(n)$. Note that $f$ is continuous, radial, and of positive type. Moreover, $f(0) = 1$ and $M(f) = \overline{\delta}(I)$. If we show that $f(1) \leq \gamma$, then $f$ is a feasible solution of \((8)\) with $M(f) = \overline{\delta}(I)$, and so the theorem will follow.

To see that $f(1) \leq \gamma$, note that if $x$ is a point of a unit $k$-simplex in $\mathbb{R}^n$, then all the others points in the simplex lie on the unit sphere $x + S^{n-1}$ centered at $x$. Hence if $x \in I$, then $I \cap (x + S^{n-1})$ is a measurable subset of $x + S^{n-1}$ that avoids $(k-1, 1/2)$-simplices, and so the measure of $I \cap (x + S^{n-1})$ as a subset of the unit
sphere is at most $\alpha(S^{n-1}, k - 1, 1/2)$. Hence if $\xi \in \mathbb{R}^n$ is any unit vector, then
\[
f(1) = \bar{d}(I)^{-1} \int_{O(n)} g(T \xi) \, d\mu(T)
\]
\[
= \bar{d}(I)^{-1} \int_{O(n)} \frac{1}{\operatorname{vol}(\mathbb{R}^n/\Lambda)} \int_{\mathbb{R}^n/\Lambda} \chi_I(x) \chi_I(T \xi + x) \, dx \, d\mu(T)
\]
\[
= \bar{d}(I)^{-1} \frac{1}{\operatorname{vol}(\mathbb{R}^n/\Lambda)} \int_{\mathbb{R}^n/\Lambda} \chi_I(x) \int_{O(n)} \chi_I(T \xi + x) \, d\mu(T) \, dx
\]
\[
\leq \alpha(S^{n-1}, k - 1, 1/2) \leq \gamma,
\]
as we wanted. \hfill \Box

Denote by $\vartheta(\mathbb{R}^n, k)$ the optimal value of (8) when setting $\gamma = \vartheta(S^{n-1}, k - 1, 1/2)$. Then $\vartheta(\mathbb{R}^n, k) \geq \alpha(\mathbb{R}^n, k)$.

An expression akin to the one for $\vartheta(S^{n-1}, k, t)$ can be derived for $\vartheta(\mathbb{R}^n, k)$. For $n \geq 2$ and $u \geq 0$, let
\[
\Omega_n(u) = \Gamma(n/2)(2/n^{n-2})/2 J_{(n-2)/2}(u),
\]
where $J_n$ is the Bessel function of the first kind with parameter $\alpha$. Let $m_n$ be the global minimum of $\Omega_n$, which is a negative number (cf. Oliveira and Vallentin [13]). The following theorem is the analogue of Theorem 2.2

**Theorem 3.2.** For $n \geq 2$ we have
\[
\vartheta(\mathbb{R}^n, k) = \vartheta(S^{n-1}, k - 1, 1/2) - m_n
\]

The proof uses again a theorem of Schoenberg [22], that this time characterizes radial and continuous functions of positive type on $\mathbb{R}^n$: these are the functions $f : \mathbb{R}^n \to \mathbb{R}$ such that
\[
f(x) = \int_0^\infty \Omega_n(z \|x\|) \, d\nu(z)
\]  
for some finite Borel measure $\nu$.

**Proof.** If $f$ is given as in [5], then $M(f) = \nu(\{0\})$ (see e.g. §6.2 in DeCorte, Oliveira, and Vallentin [6]). Using Schoenberg’s theorem, we can rewrite (8) (with $\gamma = \vartheta(S^{n-1}, k - 1, 1/2)$) equivalently as:
\[
\sup \nu(\{0\}) = 1,
\]
\[
\int_0^\infty \Omega_n(z) \, d\nu(z) \leq \vartheta(S^{n-1}, k - 1, 1/2),
\]
$\nu$ is a Borel measure.

We are now in the same situation as in the proof of Theorem 2.2. If $z^*$ is such that $m_n = \Omega_n(z^*)$, then the optimal $\nu$ is supported at 0 and $z^*$. Solving the resulting system yields the theorem. \hfill \Box

Table 1 contains some values for $\vartheta(\mathbb{R}^n, k)$.

### 4. Exponential density decay

In this section we analyze the asymptotic behavior of $\vartheta(S^{n-1}, k, t)$ and $\vartheta(\mathbb{R}^n, k)$ as functions of $t_n$, proving Theorem 1.1

The main step in our analysis is to understand the asymptotic behavior of
\[
M_n(t) = \min \{ P^*_j(t) : j \geq 0 \},
\]
as defined in [4]. For $t \in [-1, 0)$, it is possible to show that $\lim_{n \to \infty} M_n(t) = t$, and so $M_n(t)$ does not approach 0. We have seen in §2 that $M_n(0) = -\frac{1}{(n-1)}$, so for $t = 0$ we have that $M_n(t)$ approaches 0 linearly fast as $n$ grows. Things get interesting when $t \in (0, 1)$: then $M_n(t)$ approaches 0 exponentially fast as $n$ grows.

**Theorem 4.1.** For every $t \in (0, 1)$ there is $c \in (0, 1)$ such that $|M_n(t)| \leq (c+o(1)) n$.

We will need the following lemma, whose proof is a refinement of the analysis carried out by Schoenberg [23].

**Lemma 4.2.** If for $\theta \in (0, \pi)$ and $\delta \in (0, \pi/2)$ we write

$$C = (\cos^2 \theta + \sin^2 \theta \sin^2 \delta)^{1/2},$$

then $|P_n^j(\cos \theta)| \leq \pi n^{1/2} \cos^{-3} \delta + C$$^j$ for all $n \geq 3$.

**Proof.** An integral representation of Gegenbauer for the ultraspherical polynomials (take $\lambda = (n-2)/2$ in Theorem 6.7.4 from Andrews, Askey, and Roy [11]) gives us the formula

$$P_n^j(\cos \theta) = R(n)^{-1} \int_0^\pi F(\phi)^j \sin^{n-3} \phi d\phi,$$

where

$$F(\phi) = \cos \theta + i \sin \theta \cos \phi \quad \text{and} \quad R(n) = \int_0^\pi \sin^{n-3} \phi d\phi.$$

Note that $|F(\phi)|^2 = \cos^2 \theta + \sin^2 \theta \cos^2 \phi$ and that $|F(\phi)| \leq 1$. Split the integration domain into the intervals $[0, \pi/2 - \delta]$, $[\pi/2 - \delta, \pi/2 + \delta]$, and $[\pi/2 + \delta, \pi]$ to obtain

$$|P_n^j(\cos \theta)| \leq R(n)^{-1} \int_0^{\pi/2 - \delta} |F(\phi)|^2 \sin^{n-3} \phi d\phi + R(n)^{-1} \int_{\pi/2 - \delta}^{\pi/2 + \delta} |F(\phi)|^2 \sin^{n-3} \phi d\phi + R(n)^{-1} \int_{\pi/2 + \delta}^{\pi} |F(\phi)|^2 \sin^{n-3} \phi d\phi.$$

For the first term above, note that

$$R(n) = \frac{\pi^{1/2} \Gamma(n/2 - 1)}{\Gamma((n-1)/2)}.$$

Use Gautschi's inequality to conclude that

$$R(n)^{-1} < \pi^{-1/2}(n-1/2)^{1/2} < n^{1/2}.$$
Now
\[
2R(n)^{-1} \int_0^{\pi/2-\delta} \sin^{n-3} \phi d\phi \leq 2n^{1/2} \int_0^{\pi/2-\delta} \sin^{n-3}(\pi/2 - \delta) d\phi \\
= 2n^{1/2}(\pi/2 - \delta) \cos^{n-3} \delta \\
\leq \pi n^{1/2} \cos^{n-3} \delta.
\]

For the second term we get directly
\[
R(n)^{-1} \int_{\pi/2-\delta}^{\pi/2+\delta} |F(\phi)|^2 \sin^{n-3} \phi d\phi \leq R(n)^{-1} \int_{\pi/2-\delta}^{\pi/2+\delta} C' \sin^{n-3} \phi d\phi \leq C',
\]
and we are done. \(\square\)

We can now prove the theorem.

**Proof of Theorem 4.1.** Our strategy is to find a lower bound on the largest \(j_0\) such that \(P^n_j(t) \geq 0\) for all \(j \leq j_0\). Then we know that \(M_n(t)\) is attained by some \(j \geq j_0\), and we can use Lemma 4.2 to estimate \(|M_n(t)|\).

Recall [25] that the zeros of \(P^n_j\) are all in \([-1, 1]\) and that the rightmost zero of \(P^n_{j+1}\) is to the right of the rightmost zero of \(P^n_j\). Let \(C^\lambda_j\) denote the ultraspherical (or Gegenbauer) polynomial with parameter \(\lambda\) and degree \(j\), so
\[
P^n_j(t) = \frac{C^{(n-2)/2}_j(t)}{C^{(n-2)/2}_j(1)}. \tag{10}
\]

Let \(x_j\) be the largest zero of \(C^\lambda_j\). Elbert and Laforgia [8, p. 94] show that, for \(\lambda \geq 0\),
\[
x_j^2 < \frac{j^2 + 2\lambda j}{(j + \lambda)^2}.
\]
If for a given \(j\) we have that
\[
\frac{j^2 + 2\lambda j}{(j + \lambda)^2} \leq t^2, \tag{11}
\]
then we know that the rightmost zero of \(C^\lambda_j\) is to the left of \(t\), and so \(C^\lambda_j(t) \geq 0\).

Note that the left-hand side in (11) is increasing in \(j\). Let us estimate the largest \(j\) for which (11) holds. We want
\[
j^2 + 2\lambda j - t^2(j + \lambda)^2 \leq 0.
\]
The left-hand side above is quadratic in \(j\), and since \(t^2 < 1\) the coefficient of \(j^2\) is positive. So all we have to do is to compute the largest root of the left-hand side, which is \(2a(t)\lambda\), where \(a(t) = ((1 - t^2)^{-1/2} - 1)/2\).

Hence for \(j \leq 2a(t)\lambda\) we have \(C^\lambda_j(t) \geq 0\). From (10) we see that \(P^n_j(t) \geq 0\) if \(j \leq a(t)n - 2a(t)\).

Now plug the right-hand side above into the upper bound of Lemma 4.2 to get
\[
|M_n(t)| \leq (\pi n^{1/2} \cos^{-3} \delta) \cos^n \delta + C^{n(t)n - 2a(t)} \cos^n \delta + O(1)(C^n(t)n) \cos^n \delta,
\]
with \(C\) as defined in Lemma 4.2 with \(\cos \theta = t\). For any choice of \(\delta \in (0, \pi/2)\), we have that \(\cos \delta, C \in (0, 1)\), and since \(a(t) > 0\) for all \(t \in (0, 1)\), the theorem follows. \(\square\)
We now get exponential decay for $\vartheta(S^{n-1}, k, t)$ for any $k \geq 3$ and $t \in (0, 1)$. Indeed, consider the recurrence $F_0 = t$ and $F_i = F_{i-1}/(1 + t F_{i-1})$ for $i \geq 1$, whose solution is $F_i = t/(1 + it)$. Using Theorem 4.1 to develop our analytic solution (6), we get

$$\vartheta(S^{n-1}, k, t) \sim k - 2 \sum_{i=0}^{k-2} |M_{n-i}(F_i)| = k - 2 \sum_{i=0}^{k-2} |M_{n-i}(t/(1 + it))|,$$

(12)

where $a_n \sim b_n$ means that $\lim_{n \to \infty} a_n/b_n = 1$. Since $t/(1 + it) > 0$ for all $i$, each term decays exponentially fast, and so we get exponential decay for the sum.

We also get exponential decay for $\vartheta(\mathbb{R}^n, k)$ for any $k \geq 3$. Indeed, from Theorem 3.2 we have that

$$\vartheta(\mathbb{R}^n, k) \sim |m_n| + \sum_{i=0}^{k-3} |M_{n-i}(1/(2 + i))|.$$

(13)

From Theorem 4.1 we know that every term in the summation above decays exponentially fast. Bachoc, Nebe, Oliveira, and Vallentin [3] give an asymptotic bound for $|m_n|$ that shows that it also decays exponentially in $n$, namely

$$|m_n| \leq (2/e + o(1))^{n/2} = (0.8577\ldots + o(1))^n.$$

This finishes the proof of Theorem 1.1.

4.1. Explicit bounds. We now compute explicit constants $c(k, t)$ and $c(k)$ which can serve as bases for the exponentials in Theorem 1.1 in particular obtaining the bounds advertised in §1.3.

The constant $c$ given in Theorem 4.1 depends on $t$. Following the proof, we can find the best constant for every $t \in (0, 1)$ by finding $\delta \in (0, \pi/2)$ such that $\cos \delta = C^t(\delta)$, that is, by solving the equation

$$\cos^4 \delta = (t^2 + (1 - t^2) \sin^2 \delta)^{(1-t^2)^{-1/2}-1}$$

(14)

and taking $c = \cos \delta > 0$.

For any given $t \in (0, 1)$ it is easy to solve (14) numerically. For $t = 1/2$ we get $\cos \delta = 0.95621\ldots$ as a solution, and so $|M_n(1/2)| \leq (0.95622 + o(1))^n$, leading to the the bound

$$\vartheta(\mathbb{R}^n, 3) \sim |M_n(1/2)| \leq (0.95622 + o(1))^n.$$

Figure 2 shows a plot of the best constant $c$ for every $t \in (0, 1)$.

With a little extra work, it is possible to show that, for all $k \geq 2$,

$$|M_n(1/k)| \leq \left(1 - \frac{1}{9k^2} + o(1)\right)^n,$$

(15)
whence
\[ \vartheta(R^n, k) \sim |M_{n-k+3}(1/(k-1))| \leq \left( 1 - \frac{1}{9(k-1)^2} + o(1) \right)^n \]
for all \( k \geq 3 \).

Direct verification shows that (15) holds for \( k = 2 \), so let us assume \( k \geq 3 \).

Writing \( c \) for the (unique) positive solution \( \cos \delta \) of (14) and taking \( \theta \in (0, \pi/2) \) such that \( \cos \theta = t \), we can rewrite (14) in the more convenient form
\[ c^4 \sin \theta / (1 - \sin \theta) = 1 - c^2 \sin 2 \theta. \] (16)

Now say \( c = 1 - x \) and use Bernoulli’s inequality to get
\[ (1 - x)^{4 \sin \theta / (1 - \sin \theta)} \geq 1 - \frac{4 \sin \theta}{1 - \sin \theta} x \quad \text{and} \]
\[ 1 - (1 - x)^2 \sin^2 \theta \leq 1 - (1 - 2x) \sin^2 \theta. \]

Equating the left-hand sides of both inequalities above and solving for \( x \), we get
\[ c = 1 - x \leq 1 - \frac{\sin \theta / (1 - \sin \theta)}{4 + 2 \sin \theta (1 - \sin \theta)}. \]

In particular, when \( \cos \theta = 1/k \) we get
\[ |M_n(1/k)| \leq \left( 1 - \frac{1}{4k^2(1 + \sqrt{k^2/(k^2 - 1)}) + 2} + o(1) \right)^n \]
\[ \leq \left( 1 - \frac{1}{9k^2} + o(1) \right)^n \]
for all \( k \geq 3 \).

ACKNOWLEDGMENTS

We would like to thank Christine Bachoc for helpful discussions and comments at an early stage of this work.
