ASYMPTOTIC NORMALITY FOR \( m \)-DEPENDENT AND
CONstrained \( U \)-STATISTICS, WITH APPLICATIONS TO
PATTERN MATCHING IN RANDOM STRINGS AND
PERMUTATIONS

SVANTE JANSON

Abstract. We study (asymmetric) \( U \)-statistics based on a stationary sequence
of \( m \)-dependent variables; moreover, we consider constrained \( U \)-statistics, where
the defining multiple sum only includes terms satisfying some restrictions on the
gaps between indices. Results include a law of large numbers and a central limit
theorem. Special attention is paid to degenerate cases where, after the standard
normalization, the asymptotic variance vanishes; in these cases non-normal limits
occur after a different normalization.

The results are motivated by applications to pattern matching in random strings
and permutations. We obtain both new results and new proofs of old results.

1. Introduction

The purpose of the present paper is to present some new results for (asymmetric)
\( U \)-statistics together with some applications. (See Section 3 for definitions.) The
results include a strong law of large numbers and a central limit theorem (asymptotic
normality).

Many results of these types have been proved for \( U \)-statistics under different hy-
potheses by a large number of authors, from Hoeffding [17] and on. The new feature
of the results here, which are motivated by applications discussed below, is the com-
bination of the following:

(i) We consider, as in e.g. [22] and [24] but unlike many other authors, asymmetric
\( U \)-statistics and not just the symmetric case. (See Remark 3.3.)
(ii) We consider also constrained \( U \)-statistics, where the summations are restricted
as in (3.2) or (3.3).
(iii) The \( U \)-statistics are based on an underlying sequence that is not necessarily
i.i.d. (as is usually assumed); we assume only that the sequence is stationary
and \( m \)-dependent. (This case has been studied earlier by e.g. [38], but not in
the present asymmetric case.)

The extension to the \( m \)-dependent case might be of interest for some applications,
but for us the main motivation is that it allows us to reduce the constrained versions
to ordinary \( U \)-statistics; hence this extension is implicitly used also when we apply
the results for constrained \( U \)-statistics based on i.i.d. sequences.
The background motivating these general results is partly some parallel results for pattern matching in random strings and in random permutations that earlier have been shown by different methods, but easily follow from our results; we describe these results here and return to them (and some new results) in Sections 9 and 10.

First, consider a random string $\Xi_n = \xi_1 \cdots \xi_n$ consisting of $n$ i.i.d. random letters from a finite alphabet $A$ (in this context, this is known as a memoryless source), and consider the number of occurrences of a given word $w = w_1 \cdots w_\ell$ as a subsequence; to be precise, an occurrence of $w$ in $\Xi_n$ is an increasing sequence of indices $i_1 < \cdots < i_\ell$ in $[n] = \{1, \ldots, n\}$ such that
\[
\xi_{i_1} \xi_{i_2} \cdots \xi_{i_\ell} = w, \quad \text{i.e., } \xi_{i_k} = w_k \text{ for every } k \in [\ell]. \tag{1.1}
\]

This number, $N_n(w)$ say, was studied by Flajolet, Szpankowski and Vallée [15] who proved that $N_n(w)$ is asymptotically normal as $n \to \infty$.

Flajolet, Szpankowski and Vallée [15] studied also a constrained version, where we are given also numbers $d_1, \ldots, d_{\ell-1} \in \mathbb{N} \cup \{\infty\} = \{1, 2, \ldots, \infty\}$ and count only occurrences of $w$ such that
\[
i_{j+1} - i_j \leq d_j, \quad 1 \leq j < \ell. \tag{1.2}
\]
(Thus the $j$th gap in $i_1, \ldots, i_\ell$ has length strictly less than $d_j$.) We write $D := (d_1, \ldots, d_{\ell-1})$, and let $N_n(w; D)$ be the number of occurrences of $w$ that satisfy the constraints (1.2). It was shown in [15] that, for any fixed $w$ and $D$, $N_n(w; D)$ is asymptotically normal as $n \to \infty$. See also the book by Jacquet and Szpankowski [20], Chapter 5.

Remark 1.1. Note that $d_j = \infty$ means no constraint for the $j$th gap. In particular, $d_1 = \cdots = d_{\ell-1} = \infty$ yields the unconstrained case; we denote this trivial (but important) constraint $D$ by $D_{\infty}$.

In the other extreme case, if $d_j = 1$, then $i_j$ and $i_{j+1}$ have to be adjacent. In particular, in the completely constrained case $d_1 = \cdots = d_{\ell-1} = 1$, then $N_n(w; D)$ counts occurrences of $w$ as a substring $\xi_{i+1} \cdots \xi_{i+\ell-1}$. Substring counts have been studied by many authors; some references with central limit theorems or local limit theorems under varying conditions are [1], [34], [29], [14, Proposition IX.10, p. 660].

See also [40], Section 7.6.2 and Example 8.8 and [20]; the latter book discusses not only substring and subsequence counts but also other versions of substring matching problems in random strings.

Note also that the case when all $d_i \in \{1, \infty\}$ means that $w$ is a concatenation $w_1 \cdots w_b$ (with $w$ broken at positions where $d_i = \infty$), such that an occurrence now is an occurrence of each $w_i$ as a substring, with these substrings in order and non-overlapping, and with arbitrary gaps in between. (A special case of the generalized subsequence problem in [20], Section 5.6; the general case can be regarded as a sum of such counts over a set of $w_i$.)

There are similar results for random permutations. Let $\mathfrak{S}_n$ be the set of the $n!$ permutations of $[n]$. If $\pi = \pi_1 \cdots \pi_n \in \mathfrak{S}_n$ and $\tau = \tau_1 \cdots \tau_\ell \in \mathfrak{S}_\ell$, then an occurrence of the pattern $\tau$ in $\pi$ is an increasing sequence of indices $i_1 < \cdots < i_\ell$ in $[n] = \{1, \ldots, n\}$ such that the order relations in $\pi_{i_1} \cdots \pi_{i_\ell}$ are the same as in $\tau_1 \cdots \tau_\ell$, i.e., $\pi_{i_j} < \pi_{i_k} \iff \tau_j < \tau_k$.

Let $N_n(\tau)$ be the number of occurrences of $\tau$ in $\pi$ when $\pi = \pi^{(n)}$ is uniformly random in $\mathfrak{S}_n$. Bóna [2] proved that $N_n(\tau)$ is asymptotically normal as $n \to \infty$, for any fixed $\tau$. 

Also for permutations, one can consider, and count, constrained occurrences by again imposing the restriction \(1.2\) for some \(D = (d_1, \ldots, d_{\ell-1})\). In analogy with strings, we let \(N_n(\tau, D)\) be the number of constrained occurrences of \(\tau\) in \(\pi^{(n)}\) when \(\pi^{(n)}\) is uniformly random in \(S_n\). This random number seems to mainly have been studied in the case when each \(d_i \in \{1, \infty\}\), i.e., some \(i_j\) are required to be adjacent to the next one – such constrained patterns are in the permutation context known as vincular patterns. Hofer [19] proved asymptotic normality of \(N_n(\tau, D)\) as \(n \to \infty\), for any fixed \(\tau\) and vincular \(D\). The extreme case with \(d_1 = \cdots = d_{\ell-1} = 1\) was earlier treated by Bóna [4].

We unify these results by considering \(U\)-statistics. It is well known and easy to see that the number \(N_n(w)\) of unconstrained occurrences of a given subsequence \(w\) in a random string \(\Xi_n\) can be written as an asymmetric \(U\)-statistic; see Section 9 and (9.2) for details. There are general results on asymptotic normality of \(U\)-statistics that extend the basic result by [17] to the asymmetric case, e.g., [22, Corollary 11.20], [24]. Hence, asymptotic normality of \(N_n(w)\) follows directly from these general results. Similarly, it is well known that the pattern count \(N_n(\tau)\) in a random permutation also can be written as a \(U\)-statistic, see Section 10 for details, and again this can be used to prove asymptotic normality. (See [26], with an alternative proof by this method of the result by Bóna [2].)

The constrained case is different, since the constrained pattern counts are not \(U\)-statistics. However, they can be regarded as constrained \(U\)-statistics, which we define in (3.2) below in analogy with the constrained counts above. As said above, we show in the present paper general limit theorems for such constrained \(U\)-statistics, which thus immediately apply to the constrained pattern counts discussed above in random strings and permutations.

The basic idea in the proofs is that a constrained \(U\)-statistic based on a sequence \((X_i)\) can be written (possibly up to a small error) as an unconstrained \(U\)-statistic based on another sequence \((Y_i)\) of random variables, where the new sequence \((Y_i)\) is \(m\)-dependent (with a different \(m\)) if \((X_i)\) is. (However, even if \((X_i)\) is independent, \((Y_i)\) is in general not; this is our main motivation for considering \(m\)-dependent sequences.) The unconstrained \(m\)-dependent case then is treated by standard methods from the independent case, with appropriate modifications.

Section 2 contains some preliminaries. The unconstrained and constrained \(U\)-statistics are defined in Section 3, where also the main theorems are stated. The reduction to the unconstrained case and some other lemmas are given in Section 4 and then the proofs of the main theorems are completed in Sections 5–7. Section 8 discusses the degenerate case, when the asymptotic variance in the central limit theorem Theorem 3.8 or 3.9 vanishes; Theorems 8.1 and 8.4 give criteria that can be used to show that this is not the case in an application. On the other hand, Example 8.6 shows that the degenerate case can occur in new ways for constrained \(U\)-statistics. Section 9 gives applications to the problem on pattern matching in random strings discussed above. Similarly, Section 10 gives applications to pattern matching in random permutations. Some further comments and open problems are given in Section 11. The appendix contains some further results on subsequence counts in random strings.
2. Preliminaries

2.1. Some notation. A \textit{constraint} is, as in Section 1, a sequence $D = (d_1, \ldots, d_{\ell - 1}) \in (\mathbb{N} \cup \{\infty\})^{\ell - 1}$, for some given $\ell \geq 1$. Recall that the special constraint $(\infty, \ldots, \infty)$ is denoted by $D_\infty$. Given a constraint $D$, define $b = b(D)$ by

$$b = b(D) := \ell - |\{j : d_j < \infty\}| = 1 + |\{j : d_j = \infty\}|.$$  \hfill (2.1)

We say that $b$ is the number of \textit{blocks} defined by $D$, see further Section 4 below.

Some standard notation: $[n] := \{1, \ldots, n\}$. $\max \emptyset := 0$. Unspecified limits are as $n \to \infty$. $C$ denotes unspecified constants, that may be different at each occurrence. All functions are tacitly assumed to be measurable.

2.2. $m$-dependent variables. For reasons mentioned in the introduction, we will consider $U$-statistics not only based on sequences of independent random variables, but also based on $m$-dependent variables.

Recall that a (finite or infinite) sequence of random variables $(X_i)_i$ is \textit{$m$-dependent} if the two families $(X_i)_{i \leq k}$ and $(X_i)_{i > k + m}$ of random variables are independent of each other for every $k$. (Here, $m \geq 0$ is a given integer.) In particular, $0$-dependent is the same as independent; thus the important independent case is included as the special case $m = 0$ below.

It is well known that if $(X_i)_{i \in I}$ is $m$-dependent, and $I_1, \ldots, I_r \subseteq I$ are sets of indices such that $\text{dist} (I_j, I_k) := \inf \{|i - i'| : i \in I_j, i' \in I_k\} > m$ when $j \neq k$, then the families (vectors) of random variables $(X_i)_{i \in I_1}, \ldots, (X_i)_{i \in I_r}$ are mutually independent of each other. (To see this, note first that it suffices to consider the case when each $I_j$ is an interval; then use the definition and induction on $r$.) We will use this property without further comment.

In practice, $m$-dependent sequences usually occur as \textit{block factors}, i.e. they can be expressed as

$$X_i := h(\xi_i, \ldots, \xi_{i+m})$$  \hfill (2.2)

for some i.i.d. sequence $(\xi_i)$ of random variables (in some measurable space $\mathcal{S}_0$), and a fixed function $h$ on $\mathcal{S}_0^{m+1}$. (It is obvious that (2.2) then defines a stationary $m$-dependent sequence.)

3. $U$-statistics and main results

Let $X_1, X_2, \ldots$ be a sequence of random variables, taking values in some measurable space $\mathcal{S}$, and let $f : \mathcal{S}^\ell \to \mathbb{R}$ be a (measurable) function of $\ell$ variables, for some $\ell \geq 1$. Then the corresponding $U$-\textit{statistic} is the (real-valued) random variable defined for each $n \geq 0$ by

$$U_n = U_n(f) = U_n(f; (X_i)) := \sum_{1 \leq i_1 < \cdots < i_\ell \leq n} f(X_{i_1}, \ldots, X_{i_\ell}).$$  \hfill (3.1)

$U$-statistics were introduced by Hoeffding [17], who proved a general central limit theorem; the present paper gives an extension of his result that builds on his methods.

Remark 3.1. Of course, for the definition (3.1) it suffices to have a finite sequence $(X_i)_1^n$, but we will in the present paper only consider the initial segments of an infinite sequence.
Remark 3.2. Many authors, including Hoeffding [17], define $U_n$ by dividing the sum in (3.1) by $\binom{n}{\ell}$, the number of terms in it. We find it more convenient for our purposes to use the unnormalized version above. □

Remark 3.3. Many authors, including Hoeffding [17], assume that $f$ is a symmetric function of its $\ell$ variables. In this case, the order of the variables does not matter, and we can in (3.1) sum over all sequences $i_1, \ldots, i_\ell$ of $\ell$ distinct elements of $\{1, \ldots, n\}$, up to an obvious factor of $\ell!$. ([17] gives both versions.) Conversely, if we sum over all such sequences, we may without loss of generality assume that $f$ is symmetric. However, in the present paper we consider the general case of (3.1) without assuming symmetry, which we for emphasis call an asymmetric $U$-statistic. (This is essential in our applications to pattern matching.) Note that for independent $(X_i)_n^1$, the asymmetric case can be reduced to the symmetric case by the trick in [22, Remark 11.21, in particular (11.20)], see also [26, (15)] and (A.13) below. However, this trick does not work in the $m$-dependent or constrained cases studied here, so we cannot use it here. □

As said in the introduction, we also consider constrained $U$-statistics. Given a constraint $\mathcal{D} = (d_1, \ldots, d_{\ell-1})$, we define the constrained $U$-statistic

$$U_n(f; \mathcal{D}) = U_n(f; \mathcal{D}; (X_i)) := \sum_{1 \leq i_1 < \cdots < i_\ell \leq n \atop i_{j+1}-i_j \leq d_j} f(X_{i_1}, \ldots, X_{i_\ell}), \quad n \geq 0,$$

(3.2)

where we thus impose the constraints (1.2) on the indices.

We define further the exactly constrained $U$-statistic

$$U_n(f; \mathcal{D}=) = U_n(f; \mathcal{D}=; (X_i)) := \sum_{1 \leq i_1 < \cdots < i_\ell \leq n \atop i_{j+1}-i_j = d_j \text{ if } d_j < \infty} f(X_{i_1}, \ldots, X_{i_\ell}), \quad n \geq 0,$$

(3.3)

where we thus specify each gap either exactly or (when $d_j = \infty$) not at all. In the vincular case, when all $d_j$ are either 1 or $\infty$, there is no difference and we have $U_n(f; \mathcal{D}) = U_n(f; \mathcal{D}=)$.

Note that, trivially, each constrained $U$-statistic can be written as a sum of exactly constrained $U$-statistics:

$$U_n(f; \mathcal{D}) = \sum_{\mathcal{D}'} U_n(f; \mathcal{D}='),$$

(3.4)

where we sum over all constraints $\mathcal{D}' = (d'_1, \ldots, d'_\ell)$ with

$$\begin{cases} 1 \leq d'_j \leq d_j, & d_j < \infty, \\ d'_j = \infty, & d_j = \infty. \end{cases}$$

(3.5)

Remark 3.4. The [exactly] constrained $U$-statistics thus belong to the large class of incomplete $U$-statistics, where the summation in (3.1) is restricted to some, in principle arbitrary, subset of the set of all $\ell$-tuples $(i_1, \ldots, i_\ell)$ in $[n]$. □

The standard setting, in [17] and many other papers, is to assume that the underlying random variables $X_i$ are i.i.d.; we consider in the present paper a more general case, and we will assume only that $X_1, X_2, \ldots$ is an infinite stationary $m$-dependent sequence, for some fixed integer $m \geq 0$; See Section 2.2 for the definition, and recall in particular that the special case $m = 0$ yields the case of independent variables $X_i$. 
We will consider limits as \( n \to \infty \). The sequence \( X_1, X_2, \ldots \) (and thus the space \( S \) and the integer \( m \)) and the function \( f \) (and thus \( \ell \)) will be fixed, and do not depend on \( n \).

We will throughout assume the following rather weak technical condition.

\[
\begin{align*}
(A) \quad & E |f(X_{i_1}, \ldots, X_{i_\ell})|^2 < \infty \quad \text{for every } i_1 < \cdots < i_\ell.
\end{align*}
\]

Note that in the independent case \( (m = 0) \), it suffices to verify this for a single sequence \( i_1, \ldots, i_\ell, \) for example \( 1, \ldots, \ell \). In general, it suffices to verify \((A)\) for all sequences with \( i_1 = 1 \) and \( i_{j+1} - i_j \leq m + 1 \) for every \( j \leq \ell - 1 \), since the stationarity and \( m\)-dependence imply that every larger gap can be reduced to \( m + 1 \) without changing the distribution of \( f(X_{i_1}, \ldots, X_{i_\ell}) \). Since there is only a finite number of such sequences, it follows that that \((A)\) is equivalent to the uniform bound

\[
E |f(X_{i_1}, \ldots, X_{i_\ell})|^2 \leq C \quad \text{for every } i_1 < \cdots < i_\ell.
\]

3.1. Main results. We first make an elementary observation on the expectations \( E U_n(f; D) \) and \( E U_n(f; D=) \). These can be calculated exactly by taking the expectation inside the sums in (3.2) and (3.3). In the independent case, all terms have the same expectation, so it remains only to count the number of them. In general, because of the \( m\)-dependence of \( (X_i) \), the expectations of the terms in (3.3) are not all equal, but most of them coincide, and it is still easy to find the asymptotics.

**Theorem 3.5.** Let \( (X_i)_{i=1}^\infty \) be a stationary \( m\)-dependent sequence of random variables with values in a measurable space \( S \), let \( \ell \geq 1 \), and let \( f : S^\ell \to \mathbb{R} \) satisfy \((A)\). Then, as \( n \to \infty \), with \( \mu \) given by (5.1) below,

\[
E U_n(f) = \binom{n}{\ell} \mu + O(n^{\ell-1}) = \frac{n^\ell}{\ell!} \mu + O(n^{\ell-1}).
\]

More generally, let \( D = (d_1, \ldots, d_{\ell-1}) \) be a constraint, and let \( b := b(D) \). Then, as \( n \to \infty \), for some real numbers \( \mu_D \) and \( \mu_{D=} \) given by (5.3) and (5.4),

\[
E U_n(f; D) = \frac{n^b}{b!} \mu_D + O(n^{b-1}), \quad E U_n(f; D=) = \frac{n^b}{b!} \mu_{D=} + O(n^{b-1}).
\]

If \( m = 0 \), i.e., the sequence \( (X_i)_{i=1}^\infty \) is i.i.d., then, moreover,

\[
\mu = \mu_D = \mathbb{E} f(X_1, \ldots, X_\ell), \quad \mu_D = \mu \prod_{j : d_j < \infty} d_j = \prod_{j : d_j < \infty} d_j \cdot \mathbb{E} f(X_1, \ldots, X_\ell).
\]

The straightforward proof is given in Section 5 where we also give formulas for \( \mu_D \) and \( \mu_{D=} \) in the general case, although in an application it might be simpler to find the leading term of the expectation directly.

Next, we have a corresponding strong law of large numbers, proved in Section 4. This extends well known results in the independent case, see [37, 18, 24].

**Theorem 3.6.** Let \( (X_i)_{i=1}^\infty \) be a stationary \( m\)-dependent sequence of random variables with values in a measurable space \( S \), let \( \ell \geq 1 \), and let \( f : S^\ell \to \mathbb{R} \) satisfy \((A)\). Then, as \( n \to \infty \), with \( \mu \) given by (5.1),

\[
n^{-\ell} U_n(f) \xrightarrow{a.s.} \frac{1}{\ell!} \mu.
\]
More generally, let $\mathcal{D} = (d_1, \ldots, d_{\ell-1})$ be a constraint, and let $b := b(\mathcal{D})$. Then, as $n \to \infty$,

$$
n^{-b}U_n(f; \mathcal{D}) \xrightarrow{a.s.} \frac{1}{b!}\mu_{\mathcal{D}},
$$

and

$$
n^{-b}U_n(f; \mathcal{D}=) \xrightarrow{a.s.} \frac{1}{b!}\mu_{\mathcal{D}=},
$$

where $\mu_{\mathcal{D}}$ and $\mu_{\mathcal{D}=}$, as in Theorem 3.2, are given by (5.5) and (5.4). Equivalently,

$$
n^{-\ell}[U_n(f) - \mathbb{E}U_n(f)] \xrightarrow{a.s.} 0,
$$

$$
n^{-b}[U_n(f; \mathcal{D}) - \mathbb{E}U_n(f; \mathcal{D})] \xrightarrow{a.s.} 0,
$$

and

$$
n^{-b}[U_n(f; \mathcal{D}=) - \mathbb{E}U_n(f; \mathcal{D}=)] \xrightarrow{a.s.} 0.
$$

**Remark 3.7.** For convenience, we assume ([A]) in Theorem 3.6 as in the rest of the paper, which leads to a simple proof. We conjecture that the theorem holds assuming only finite first moments instead of ([A]) as in [18; 24] for the independent case. □

Finally, we have the following theorems yielding asymptotic normality. The proofs will be given in Section 3.

The first theorem is for the unconstrained case, and extends the basic theorem by Hoeffding [17] for symmetric $U$-statistics based on independent $(X_i)_{i=1}^\infty$ to the asymmetric and $m$-dependent case. Note that both these extensions have earlier been treated, but separately. For symmetric $U$-statistics in the $m$-dependent setting, asymptotic normality was proved by Sen [38] (at least assuming a third moment); moreover, bounds on the rate of convergence (assuming a moment condition) were given by Malevich and Abdalimov [28]. The asymmetric case with independent $(X_i)_{i=1}^\infty$ has been treated e.g. in [22, Corollary 11.20] and [24]; furthermore, as said in Remark 3.3, for independent $(X_i)$, the asymmetric case can be reduced to the symmetric case by the method in [22, Remark 11.21].

**Theorem 3.8.** Let $(X_i)_{i=1}^\infty$ be a stationary $m$-dependent sequence of random variables with values in a measurable space $\mathcal{S}$, let $\ell \geq 1$, and let $f : \mathcal{S}^\ell \to \mathbb{R}$ satisfy ([A]). Then, as $n \to \infty$,

$$
\text{Var}[U_n(f)] / n^{2\ell-1} \to \sigma^2
$$

for some $\sigma^2 = \sigma^2(f) \in [0, \infty)$, and

$$
\frac{U_n(f) - \mathbb{E}U_n(f)}{n^{\ell/2}} \xrightarrow{d} \mathcal{N}(0, \sigma^2).
$$

The second theorem extends Theorem 3.8 to the constrained cases.

**Theorem 3.9.** Let $(X_i)_{i=1}^\infty$ be a stationary $m$-dependent sequence of random variables with values in a measurable space $\mathcal{S}$, let $\ell \geq 1$, and let $f : \mathcal{S}^\ell \to \mathbb{R}$ satisfy ([A]). Let $\mathcal{D} = (d_1, \ldots, d_{\ell-1})$ be a constraint, and let $b := b(\mathcal{D})$. Then, as $n \to \infty$,

$$
\text{Var}[U_n(f; \mathcal{D})] / n^{2b-1} \to \sigma^2
$$

for some $\sigma^2 = \sigma^2(f; \mathcal{D}) \in [0, \infty)$, and

$$
\frac{U_n(f; \mathcal{D}) - \mathbb{E}U_n(f; \mathcal{D})}{n^{b-1/2}} \xrightarrow{d} \mathcal{N}(0, \sigma^2).
$$
The same holds, with some (generally different) \( \sigma^2 = \sigma^2(f; D) = \), for the exactly constrained \( U_n(f; D) \).

Remark 3.10. It follows immediately by the Cramér–Wold device [16, Theorem 5.10.5] (i.e., considering linear combinations), that Theorem 3.8 extends in the obvious way to joint convergence for any finite number of different \( f : S^\ell \to \mathbb{R} \), with \( \sigma^2 \) now a covariance matrix. Moreover, the proof shows that this holds also for a family of different \( f \) with (possibly) different \( \ell \geq 1 \).

Similarly, Theorem 3.9 extends to joint convergence for any finite number of different \( f \) (possibly with different \( \ell \) and \( D \)); this follows by the proof below, which reduces the results to Theorem 3.8. □

Remark 3.11. The asymptotic variance \( \sigma^2 \) in Theorems 3.8 and 3.9 can be calculated explicitly, see Remark 6.2. □

Remark 3.12. Note that it is possible that the asymptotic variance \( \sigma^2 = 0 \) in Theorems 3.8 and 3.9; in this case, (3.19) and (3.21) just give convergence in probability to 0. This degenerate case is discussed in Section 8. □

Remark 3.13. We do not consider extensions to triangular arrays where \( f \) or \( X_i \) (or both) depend on \( n \). In the symmetric \( m \)-dependent case, such a result (with fixed \( \ell \) but possibly increasing \( m \), under suitable conditions) has been shown by [28], with a bound on the rate of convergence. In the independent case, results for triangular arrays are given by e.g. [36] and [21]; see also [27] for the special case of substring counts \( N_n(w) \) with \( w \) depending on \( n \) (and growing in length). It seems to be an interesting (and challenging) open problem to formulate useful general theorems for constrained \( U \)-statistics in such settings. □

4. Some lemmas

We give here some lemmas that will be used in the proofs in later sections. In particular, they will enable us to reduce the constrained cases to the unconstrained one.

Let \( D = (d_1, \ldots, d_{\ell-1}) \) be a given constraint. Recall that \( b = b(D) \) is given by (2.1), and let \( 1 = \beta_1 < \cdots < \beta_b \) be the indices in \( \ell \) just after the unconstrained gaps; in other words, \( \beta_j \) are defined by \( \beta_1 := 1 \) and \( d_{\beta_j - 1} = \infty \) for \( j = 2, \ldots, b \). For convenience we also define \( \beta_{b+1} := \ell + 1 \). We say that the constraint \( D \) separates the index set \( \ell \) into the \( b \) blocks \( B_1, \ldots, B_b \), where \( B_k := \{ \beta_k, \ldots, \beta_{k+1} - 1 \} \). Note that the constraints (1.2) thus are constraints on \( i_j \) for \( j \) in each block separately.

Lemma 4.1. Let \( (X_i)_{i=1}^\infty \) be a stationary \( m \)-dependent sequence of random variables with values in \( S \), let \( \ell \geq 1 \), and let \( f : S^\ell \to \mathbb{R} \) satisfy (A). Let \( D = (d_1, \ldots, d_{\ell-1}) \) be a constraint. Then

\[
\text{Var}[U_n(f; D)] = O(n^{2b(D)}), \quad n \geq 1.
\]

(4.1)

Furthermore,

\[
\text{Var}[U_n(f; D) - U_{n-1}(f; D)] = O(n^{2b(D)}), \quad n \geq 1.
\]

(4.2)

Moreover, the same estimates hold for \( U_n(f; D) = \).
Proof. The definition (3.2) yields
\[
\text{Var}
\left(U_n(f; \mathcal{D})\right) = \sum_{1 \leq i_1 < \cdots < i_k \leq n} \sum_{1 \leq j_1 < \cdots < j_k \leq n} \text{Cov}
\left(f(X_{i_1}, \ldots, X_{i_k}), f(X_{j_1}, \ldots, X_{j_k})\right).
\] (4.3)

Let \(d_s\) be the largest finite \(d_j\) in the constraint \(\mathcal{D}\), i.e.,
\[
d_s := \max\{d_j : d_j < \infty\}. \quad (4.4)
\]

The constraints imply that for each block \(B_q\) and all indices \(k \in B_q\), coarsely,
\[
0 \leq i_k - i_\beta_q \leq d_s \ell \quad \text{and} \quad 0 \leq j_k - j_\beta_q \leq d_s \ell. \quad (4.5)
\]

It follows that if \(|i_\beta_q - j_\beta_q| > d_s \ell + m\) for all \(r, s \in [b]\), then \(|i_\alpha - j_\beta| > m\) for all \(\alpha, \beta \in \ell\). Since \((X_i)^\infty\) is \(m\)-dependent, this implies that the two random vectors \((X_{i_1}, \ldots, X_{i_k})\) and \((X_{j_1}, \ldots, X_{j_k})\) are independent, and thus the corresponding term in (4.3) vanishes.

Consequently, we only have to consider terms in the sum in (4.3) such that
\[
|i_\beta_q - j_\beta_q| \leq d_s \ell + m \quad (4.6)
\]
for some \(r, s \in [b]\). For each of the \(O(1)\) choices of \(r\) and \(s\), we can choose \(i_\beta_1, \ldots, i_\beta_q\) in at most \(n^b\) ways; then \(j_\beta_q\) in \(O(1)\) ways such that (4.6) holds; then the remaining \(j_\beta_q\) in \(O(n^{b-1})\) ways; then, finally, all remaining \(i_k\) and \(j_k\) in \(O(1)\) ways because of (4.5). Consequently, the number of non-vanishing terms in (4.3) is \(O(n^{2b-1})\). Moreover, each term is \(O(1)\) by (3.6) and the Cauchy–Schwarz inequality, and thus (4.1) follows.

For (4.2), we note that \(U_n(f; \mathcal{D}) - U_{n-1}(f; \mathcal{D})\) is the sum in (3.2) with the extra restrictions \(\ell_i = n\). Hence, its variance can be expanded as in (4.3), with the extra restrictions \(\ell_i = j_i = n\). We then argue as above, but note that (4.5) and \(i_\ell = n\) imply that there are only \(O(1)\) choices of \(i_\ell\), and hence \(O(n^{b-1})\) choices of \(i_1, \ldots, i_b\). We thus obtain \(O(n^{2b-2})\) non-vanishing terms in the sum, and (4.2) follows.

The argument for the exactly constrained \(U_n(f; \mathcal{D} =)\) is the same (and slightly simpler). (Alternatively, we could do this case first, and then use (3.4) to obtain the results for \(U_n(f; \mathcal{D})\).) \(\square\)

The next lemma is the central step in the reduction to the unconstrained case.

**Lemma 4.2.** Let \((X_i)^\infty\), \(f : S^f \to \mathbb{R}\), and \(\mathcal{D} = (d_1, \ldots, d_{\ell-1})\) be as in Lemma 4.1 and let
\[
D := \sum_{j : d_j < \infty} d_j. \quad (4.7)
\]

Let \(M > D\) and define
\[
Y_i := (X_i, X_{i+1}, \ldots, X_{i+M-1}) \in S^M, \quad i \geq 1. \quad (4.8)
\]

Then there exists a function \(g = g_D : (S^M)^b \to \mathbb{R}\) such that for every \(n \geq D\),
\[
U_n(f; \mathcal{D} =; (X_i)) = \sum_{j_1 < \cdots < j_b \leq n-D} g(Y_{j_1}, \ldots, Y_{j_b}) = U_{n-D}(g; (Y_i)). \quad (4.9)
\]

Furthermore,
\[
\mathbb{E}|g(Y_{j_1}, \ldots, Y_{j_b})|^2 < \infty, \quad (4.10)
\]
for every \(j_1 < \cdots < j_b\).
Lemma 4.3. Let \( X_i \) be as in Lemma 4.1 and \( \mathcal{Y} \) be as in Lemma 4.2. For every \( f : \mathcal{S}^d \to \mathbb{R} \) such that (A) holds, there exist functions \( g_{\mathcal{D}}, g_{\mathcal{D}^c} : (\mathcal{S}^M)^d \to \mathbb{R} \) such that (4.10) holds for both, and

\[
\text{Var} \left[ U_n(f; \mathcal{D}; (X_i)) - U_n(g_{\mathcal{D}}; (Y_i)) \right] = O(n^{2B(\mathcal{D})-2}), \quad \text{Var} \left[ U_n(f; \mathcal{D}^c; (X_i)) - U_n(g_{\mathcal{D}^c}; (Y_i)) \right] = O(n^{2B(\mathcal{D})-2}).
\]

Proof. First, letting \( g_{\mathcal{D}_0} \) be as in Lemma 4.2 we have by (4.9),

\[
U_n(f; \mathcal{D}_0; (X_i)) - U_n(g_{\mathcal{D}_0}; (Y_i)) = U_{n-D}(g_{\mathcal{D}_0}) - U_n(g_{\mathcal{D}_0})
\]
Thus (4.21) follows by (4.2) in Lemma 4.1 applied to\(g_{D} = \infty\), the trivial constraint\(D_{\infty}\) (i.e., no constraint), and \((Y_{i})_{i=1}^{\infty}\).

Next, we recall (3.4) and define
\[
g_{D} = \sum_{D'} g_{D'},
\]
again summing over all constraints \(D'\) satisfying (3.5). This is a finite sum, and by (3.4) and (4.23),
\[
U_{n}(f; (X_{i})) - U_{n}(g_{D}; (Y_{i})) = \sum_{D'} (U_{n}(f; D'; (X_{i})) - U_{n}(g_{D'}; (Y_{i})))
\]
and thus (4.20) follows from (4.21).

To avoid some of the problems caused by dependencies between the \(X_{i}\), we follow Sen [38] and introduce another type of constrained \(U\)-statistics, where we require the gaps between the summation indices to be large, instead of small as in (3.2). We need only one case, and define
\[
U_{n}(f; > m) := \sum_{1 \leq i_{1} < \cdots < i_{\ell} \leq n \atop i_{j+1} - i_{j} > m} f(X_{i_{1}}, \ldots, X_{i_{\ell}}), \quad n \geq 0,
\]
summing only over terms where all gaps \(i_{j+1} - i_{j} > m\), \(j = 1, \ldots, \ell - 1\). (The advantage is that in each term in (4.25), the variables \(X_{i_{1}}, \ldots, X_{i_{\ell}}\) are independent.)

**Lemma 4.4.** Let \((X_{i})_{i=1}^{\infty}\) and \(f: S^{\ell} \to \mathbb{R}\) be as in Lemma 4.1. Then,
\[
\text{Var}(U_{n}(f) - U_{n}(f; > m)) = O(n^{2\ell-3}).
\]

**Proof.** We can express the type of constrained \(U\)-statistic in (4.25) as a combination of constrained \(U\)-statistics of the previous type by the following inclusion–exclusion argument:
\[
U_{n}(f; > m) = \sum_{1 \leq i_{1} < \cdots < i_{\ell} \leq n} f(X_{i_{1}}, \ldots, X_{i_{\ell}}) \prod_{j=1}^{\ell-1} 1\{i_{j+1} - i_{j} > m\}
= \sum_{1 \leq i_{1} < \cdots < i_{\ell} \leq n} f(X_{i_{1}}, \ldots, X_{i_{\ell}}) \prod_{j=1}^{\ell-1} \left(1 - 1\{i_{j+1} - i_{j} \leq m\}\right)
= \sum_{J \subseteq [\ell-1]} (-1)^{|J|} \sum_{1 \leq i_{1} < \cdots < i_{\ell} \leq n} f(X_{i_{1}}, \ldots, X_{i_{\ell}}) \prod_{j \in J} 1\{i_{j+1} - i_{j} \leq m\}
= \sum_{J \subseteq [\ell-1]} (-1)^{|J|} U_{n}(f; D_{J}),
\]
where we sum over the \(2^{\ell-1}\) subsets \(J\) of \([\ell-1]\), and use the constraints
\[
D_{J} := (d_{J})_{j=1}^{\ell-1} \quad \text{with} \quad d_{Jj} = \begin{cases} m, & j \in J, \\ \infty, & j \notin J. \end{cases}
\]
We have $b(D_J) = \ell - |J|$, and thus $b(D_J) < \ell$ unless $J = \emptyset$. Moreover, $D_\emptyset = (\infty, \ldots, \infty) = D_\infty$, and thus means no constraint, so $U_n(f; D_\emptyset) = U_n(f)$, the unconstrained $U$-statistic. Consequently, by (4.27) and Lemma 4.1,

$$\text{Var}(U_n(f) - U_n(f; > m)) = \text{Var}\left(\sum_{J \neq \emptyset} (-1)^{|J| - 1} U_n(f; D_J)\right) = O(n^{2\ell - 3}),$$

(4.29)

which proves the estimate (4.26). □

4.1. Triangular arrays. We will also use a central limit theorem for $m$-dependent triangular arrays satisfying the Lindeberg condition, which we state as Theorem 4.5 below. The theorem is implicit in Orey [31]; it follows from his theorem there exactly as his corollary, which however is stated for a sequence and not for a triangular array. See also Peligrad [32, Theorem 2.1], which contains the theorem below (at least for $\sigma^2 > 0$; the case $\sigma^2 = 0$ is trivial), and is much more general in that it only assumes strong mixing instead of $m$-dependence.

Recall that a triangular array is an array $(\xi_{ni})_{1 \leq i \leq n < \infty}$ of random variables, such that the variables $(\xi_{ni})_{i=1}^n$ in a single row are defined on a common probability space. (As usual, it is only for convenience that we require that the $n$th row has length $n$; the results extend to arbitrary lengths $N_n$.) We are here mainly interested in the case when each row is an $m$-dependent sequence; in this case, we say that $(\xi_{ni})$ is an $m$-dependent triangular array. (We make no assumption on the relation between variables in different rows; these may even be defined on different probability spaces.)

**Theorem 4.5** (Orey [31]). Let $(\xi_{ni})_{1 \leq i \leq n < \infty}$ be an $m$-dependent triangular array of real-valued random variables with $E \xi_{ni} = 0$. Let $S_n := \sum_{i=1}^n \xi_{ni}$. Assume that, as $n \to \infty$,

$$\text{Var} S_n \to \sigma^2 \in [0, \infty),$$

(4.30)

that $\xi_{ni}$ satisfy the Lindeberg condition

$$\sum_{i=1}^n E[\xi_{ni}^2 1\{|\xi_{ni}| > \varepsilon\}] \to 0, \quad \text{for every } \varepsilon > 0,$$

(4.31)

and that

$$\sum_{i=1}^n \text{Var} \xi_{ni} = O(1).$$

(4.32)

Then, as $n \to \infty$,

$$S_n \overset{d}{\to} N(0, \sigma^2).$$

(4.33)

□

Note that Theorem 4.5 extends the standard Lindeberg-Feller central limit theorem for triangular arrays with row-wise independent variables (see e.g. [16, Theorem 7.2.4]), to which it reduces when $m = 0$.

**Remark 4.6.** In fact, the assumption (4.32) is not needed in Theorem 4.5; see [27]. However, it is easily verified in our case (and many other applications), so we need only this classical result. □
5. The expectation

The expectation of a (constrained) \( U \)-statistics, and in particular its leading term, is easily found from the definition. Nevertheless, we give a detailed proof of Theorem 3.5 for completeness and for later reference.

**Proof of Theorem 3.5.** Consider first the unconstrained case. We take expectations in (3.1). The sum in (3.1) has \( \binom{n}{\ell} \) terms. We consider first the terms that satisfy the restriction \( i_{j+1} > i_j + m \) for every \( j \in [\ell - 1] \). (I.e., the terms in (4.25).) As noted above, in each such term, the variables \( X_{j_1}, \ldots, X_{j_\ell} \) are independent. Hence, let \( \hat{X}_{i_1}, \ldots, \hat{X}_{i_\ell} \) be an independent sequence of random variables in \( S \), each with the same distribution as \( X_{i_1} \) (and thus as each \( X_j \)), and define

\[
\mu := \mathbb{E} f(\hat{X}_1, \ldots, \hat{X}_\ell).
\]

Then

\[
\mu = \mathbb{E} f(X_{i_1}, \ldots, X_{i_\ell})
\]

for every sequence of indices \( i_1, \ldots, i_\ell \) with \( i_{j+1} > i_j + m \) for all \( j \in [\ell - 1] \). Moreover, the number of terms in (3.1) that do not satisfy these constraints is \( O(n^{\ell-1}) \), and their expectations are uniformly \( O(1) \) as a consequence of (3.6). Thus, (3.7) follows from (3.1).

Next, consider the exactly constrained case. We use Lemma 4.2 and then apply the unconstrained case just treated to \( g \) and \( (Y_i) \); this yields

\[
\mathbb{E} U_n(f; D) = \mathbb{E} U_{n-D}(g; (Y_i)) = \binom{n-D}{b} \mathbb{E} g(\hat{Y}_1, \ldots, \hat{Y}_b) + O(n^{b-1})
\]

with \( \hat{Y}_1, \ldots, \hat{Y}_b \) independent. Using (4.19), and the notation there, this yields (5.4) with

\[
\mu_D := \mathbb{E} g(Y_{j_1}, \ldots, Y_{j_b}) = \mathbb{E} f((X_{j_1+v_1+t_1})_{r=1}^{\ell_1}, \ldots, (X_{j_b+v_b+t_b})_{r=1}^{\ell_b}),
\]

for any sequence \( j_1, \ldots, j_b \) with \( j_{k+1} - j_k \geq M + M \) for all \( k \in [b-1] \). (Note that \( (Y_i) \) is \((m + M - 1)\)-dependent.)

Finally, the constrained case (3.8) follows by (3.9) and the decomposition (3.4), with

\[
\mu_D := \sum_{D'} \mu_{D'},
\]

summing over all \( D' \) satisfying (5.5).

In the independent case \( m = 0 \), the results above simplify. First, for the unconstrained case, the formula for \( \mu \) in (3.10) is a special case of (5.2). Similarly, in the exactly unconstrained case, (5.1) yields the formula for \( \mu_{D=0} \) in (3.10). Finally, (3.10) shows that \( \mu_{D=0} \) does not depend on \( D \), and thus all terms in the sum in (5.5) are equal to \( \mu \). Furthermore, it follows from (3.9) that the number of terms in the sum is \( \prod_{d_j < \infty} d_j \), and (3.11) follows.

Alternatively, in the independent case, all terms in the sums in (3.1), (3.2) and (3.3) have the same expectation \( \mu \) given by (3.10), and the result follows by counting the number of terms. In particular, exactly,

\[
\mathbb{E} U_n(f) = \binom{n}{\ell} \mu
\]
and, with \( D \) given by (4.7),
\[
\mathbb{E} U_n(f; D=) = \binom{n - D}{b} \mu.
\] (5.7)

\[\square\]

6. Asymptotic normality

The general idea to prove Theorem 3.8 is to use the projection method by Hoeffding [17], together with modifications as in [38] to treat \( m \)-dependent variables and modifications as in e.g. [24] to treat the asymmetric case. We then obtain the constrained version Theorem 3.9 by reduction to the unconstrained case.

**Proof of Theorem 3.8.** We first note that by Lemma 4.4, it suffices to prove (3.18)–(3.19) for \( U_n(f; > m) \). (This uses standard arguments with Minkowski’s inequality and Cramér–Slutsky’s theorem [16, Theorem 5.11.4], respectively; we omit the details. The same arguments are used several times below without comment.)

As commented above, the variables inside each term in the sum in (4.25) are independent; this enables us to use Hoeffding’s decomposition for the independent case, which we (in the present, asymmetric case) define as follows.

As in Section 5, let \((\hat{X}_i)^\ell\) be an independent sequence of random variables in \( S \), each with the same distribution as \( X_1 \). Recall \( \mu \) defined in (5.1), and, for \( i = 1, \ldots, \ell \), define the function \( f_i \) as the one-variable projection
\[
f_i(x) := \mathbb{E}(f(\hat{X}_1, \ldots, \hat{X}_\ell) \mid \hat{X}_i = x) - \mu
= \mathbb{E} f(\hat{X}_1, \ldots, \hat{X}_{i-1}, x, \hat{X}_{i+1}, \ldots, \hat{X}_\ell) - \mu.
\] (6.1)

(In general, these are defined only a.e., but it does not matter which version we choose.) Define also the residual function
\[
f_* (x_1, \ldots, x_d) := f(x_1, \ldots, x_d) - \mu - \ell \sum_{j=1}^\ell f_j(x_j).
\] (6.2)

Note that the variables \( f_i(X_j) \) are centered by (5.1) and (6.1):
\[
\mathbb{E} f_i(X_j) = \mathbb{E} f_i(\hat{X}_i) = 0.
\] (6.3)

Furthermore, \([A]\) implies that \( f_i(\hat{X}_i) \), and thus each \( f_i(X_j) \), is square integrable.

The essential property of \( f_* \) is that, as an immediate consequence of the definitions and (6.3), its one-variable projections vanish:
\[
\mathbb{E}(f_*(\hat{X}_1, \ldots, \hat{X}_\ell) \mid \hat{X}_i = x) = \mathbb{E} f_*(\hat{X}_1, \ldots, \hat{X}_{i-1}, x, \hat{X}_{i+1}, \ldots, \hat{X}_\ell) = 0.
\] (6.4)

We assume from now on for simplicity that \( \mu = 0 \); the general case follows by replacing \( f \) by \( f - \mu \). Then (4.25) and (6.2) yield, by counting the terms where \( i_j = k \) for given \( j \) and \( k \),
\[
U_n(f; > m) = \sum_{1 \leq i_1 < \cdots < i_\ell \leq n \atop i_{j+1} > m} \left( \ell \sum_{j=1}^\ell f_j(X_{i_j}) + f_*(X_{i_1}, \ldots, X_{i_\ell}) \right)
\]
\[ U = \sum_{\ell=1}^{\ell} \sum_{k=1}^{n} \left( k - 1 - (j - 1)m \right) f_j(U_k) + U_n(f_* > m). \]  

(6.5)

Let us first dispose of the last term in (6.3). Let \( i_1 < \cdots < i_\ell \) and \( j_1 < \cdots < j_\ell \) be two sets of indices such that the constraints \( i_{k+1} - i_k > m \) and \( j_{k+1} - j_k > m \) in (4.25) hold. First, as in the proof of Lemma 4.1, if also \( |i_\alpha - j_\beta| > m \) for all \( \alpha, \beta \in [\ell] \), then all \( X_{i_\alpha} \) and \( X_{j_\beta} \) are independent; thus \( f_*(X_{i_1}, \ldots, X_{i_\ell}) \) and \( f_*(X_{j_1}, \ldots, X_{j_\ell}) \) are independent, and

\[ \mathbb{E}[f_*(X_{i_1}, \ldots, X_{i_\ell})f_*(X_{j_1}, \ldots, X_{j_\ell})] = \mathbb{E}[f_*(X_{i_1}, \ldots, X_{i_\ell})] \mathbb{E}[f_*(X_{j_1}, \ldots, X_{j_\ell})] = 0. \]  

(6.6)

Moreover, suppose that \( |i_\alpha - j_\beta| > m \) for all but one pair \( (\alpha, \beta) \in [\ell]^2 \), say for \( (\alpha, \beta) \neq (\alpha_0, \beta_0) \). Then the pair \( (X_{i_{\alpha_0}}, X_{j_{\beta_0}}) \) is independent of all the variables \( \{X_{i_\alpha} : \alpha \neq \alpha_0\} \) and \( \{X_{j_\beta} : \beta \neq \beta_0\} \), and all these are mutually independent. Hence, recalling (6.4), a.s.

\[ \mathbb{E}[f_*(X_{i_1}, \ldots, X_{i_\ell})f_*(X_{j_1}, \ldots, X_{j_\ell}) | X_{i_{\alpha_0}}, X_{j_{\beta_0}}] = \mathbb{E}[f_*(X_{i_1}, \ldots, X_{i_\ell})] \mathbb{E}[f_*(X_{j_1}, \ldots, X_{j_\ell}) | X_{j_{\beta_0}}] = 0. \]  

(6.7)

Thus, taking the expectation, we find that unconditionally

\[ \mathbb{E}[f_*(X_{i_1}, \ldots, X_{i_\ell})f_*(X_{j_1}, \ldots, X_{j_\ell})] = 0. \]  

(6.8)

Consequently, if we expand \( \text{Var}[U_n(f_* > m)] \) in analogy with (4.3), then all terms where \( |i_\alpha - j_\beta| \leq m \) for at most one pair \( (\alpha, \beta) \) will vanish. The number of remaining terms, i.e., those with at least two such pairs \( (\alpha, \beta) \), is \( O(n^{2\ell-2}) \), and each term is \( O(1) \), by (A) and the Cauchy–Schwarz inequality. Consequently,

\[ \text{Var}[U_n(f_* > m)] = O(n^{2\ell-2}). \]  

(6.9)

Hence, we may ignore the final term \( U_n(f_* > m) \) in (6.5).

We turn to the main terms in (6.5), i.e., the double sum; we denote it by \( \hat{U}_n \) and write it as

\[ \hat{U}_n = \sum_{\ell=1}^{\ell} \sum_{k=1}^{n} a_{j,k,n} f_j(U_k), \]  

(6.10)

where we thus define

\[ a_{j,k,n} := \binom{k - 1 - (j - 1)m}{j - 1} \binom{n - k - (\ell - j)m}{\ell - j} = \frac{1}{(j-1)! (\ell-j)!} k^{j-1} (n-k)^{\ell-j} + O(n^{\ell-2}). \]  

(6.11)

Define the polynomial functions, for \( j = 1, \ldots, \ell \),

\[ \psi_j(x) := \frac{1}{(j-1)! (\ell-j)!} x^{j-1}(1-x)^{\ell-j}, \quad x \in \mathbb{R}. \]  

(6.12)

Then (6.11) yields

\[ a_{j,k,n} = n^{\ell-1} \psi_j(k/n) + O(n^{\ell-2}). \]  

(6.13)
The expansion (6.10) yields
\[
\text{Var} \hat{U}_n = \sum_{i=1}^{\ell} \sum_{j=1}^{\ell} \sum_{k=1}^{n} a_{i,k,n} a_{j,q,n} \text{Cov} \left[ f_i(X_k), f_j(X_q) \right],
\]
(6.14)
where all terms with \( |k - q| > m \) vanish because the sequence \((X_i)\) is \(m\)-dependent. Hence, with \( r_- := \max\{ -r, 0 \} \) and \( r_+ := \max\{ r, 0 \} \),
\[
\text{Var} \hat{U}_n = \sum_{i=1}^{\ell} \sum_{j=1}^{\ell} \sum_{r=-m}^{m} \sum_{k=1}^{n} a_{i,k,n} a_{j,k+r,n} \text{Cov} \left[ f_i(X_k), f_j(X_{k+r}) \right].
\]
(6.15)
The covariance in (6.15) is independent of \( k \); we thus define, for any \( k > r_- \),
\[
\gamma_{i,j,r} := \text{Cov} \left[ f_i(X_k), f_j(X_{k+r}) \right]
\]
(6.16) and obtain
\[
\text{Var} \hat{U}_n = \sum_{i=1}^{\ell} \sum_{j=1}^{\ell} \sum_{r=-m}^{m} \sum_{k=1}^{n} a_{i,k,n} a_{j,k+r,n} \gamma_{i,j,r}.
\]
(6.17)
Furthermore, by (6.13),
\[
n^{2-2\ell} \sum_{k=1+r_-}^{n} a_{i,k,n} a_{j,k+r,n} = \sum_{k=1+r_-}^{n} \left( \psi_i(k/n) + O(n^{-1}) \right) \left( \psi_j(k/n) + O(n^{-1}) \right)
\]
\[
= \sum_{k=1+r_-}^{n} \left( \psi_i(k/n) \psi_j(k/n) + O(n^{-1}) \right)
\]
\[
= \sum_{k=1}^{n} \psi_i(k/n) \psi_j(k/n) + O(1)
\]
\[
= \int_{0}^{1} \psi_i(t) \psi_j(t) \, dt + O(1).
\]
(6.18)
Consequently, (6.17) yields
\[
n^{1-2\ell} \text{Var} \hat{U}_n = \sum_{i=1}^{\ell} \sum_{j=1}^{\ell} \sum_{r=-m}^{m} \gamma_{i,j,r} \int_{0}^{1} \psi_i(t) \psi_j(t) \, dt + O(n^{-1}).
\]
(6.19)
Since (4.26), (6.5), and (6.9) yield
\[
\text{Var} \left[ U_n(f) - \hat{U}_n \right] = O(n^{2\ell-2}),
\]
(6.20)
the result (3.18) follows from (6.19), with
\[
\sigma^2 = \sum_{i=1}^{\ell} \sum_{j=1}^{\ell} \sum_{r=-m}^{m} \gamma_{i,j,r} \int_{0}^{1} \psi_i(t) \psi_j(t) \, dt.
\]
(6.21)
Next, we use (6.10) and write
\[
n^{\frac{1}{2}-\ell} \hat{U}_n = \sum_{k=1}^{n} Z_{kn},
\]
(6.22)
with
\[ Z_{kn} := \sum_{j=1}^\ell n^{\frac{1}{2} - \ell} a_{j,k,n} f_j(X_k). \] (6.23)

Since \( Z_{kn} \) is a function of \( X_k \), it is evident that \( (Z_{kn}) \) is an \( m \)-dependent triangular array with centered variables. Furthermore, \( \mathbb{E} Z_{kn} = 0 \) as a consequence of (6.3).

We apply Theorem 4.3 to \( (Z_{kn}) \), so \( S_n = n^{\frac{1}{2} - \ell} \bar{U}_n \) by (6.22), and verify first its conditions. The condition (4.30) holds by (6.19) and (6.24). Write \( Z_{kn} = \sum_{j=1}^\ell Z_{jkn} \) with
\[ Z_{jkn} := n^{\frac{1}{2} - \ell} a_{j,k,n} f_j(X_k). \] (6.24)

Since (6.11) yields \( |a_{j,k,n}| \leq n^{\ell - 1} \), we have, for \( \varepsilon \geq 0 \),
\[ \mathbb{E} \left[ Z_{jkn}^2 1\{|Z_{jkn}| > \varepsilon\} \right] \leq n^{-1} \mathbb{E} \left[ |f_j(X_k)|^2 1\{|f_j(X_k)| > \varepsilon n^{1/2}\} \right] \] (6.25)

The distribution of \( f_j(X_k) \) does not depend on \( k \), and thus the Lindeberg condition (4.31) for each triangular array \( (Z_{jkn})_{k,n} \) follows from (6.24). The Lindeberg condition (4.31) for \( (Z_{kn})_{k,n} \) then follows easily. Finally, taking \( \varepsilon = 0 \) in (6.25) yields \( \mathbb{E} Z_{jkn}^2 \leq Cn^{-1} \), and thus \( \mathbb{E} Z_{kn}^2 \leq Cn^{-1} \), which shows (4.32).

We have shown that Theorem 4.3 applies, and thus, recalling (6.22) and (6.3),
\[ n^{\frac{1}{2} - \ell} (\bar{U}_n - \mathbb{E} \bar{U}_n) = n^{\frac{1}{2} - \ell} \bar{U}_n = \sum_{k=1}^n Z_{k} \xrightarrow{d} \mathcal{N}(0,\sigma^2). \] (6.26)

The result (3.19) now follows from (6.26) and (6.20). \( \square \)

**Proof of Theorem 3.9** Lemma 4.3 implies that it suffices to consider \( U_n(g; Y_i) \) instead of \( U_n(f; D) \) or \( U_n(f; D=) \). Note that the definition (4.8) implies that \( (Y_i)_{i=1}^\infty \) is a stationary \( m' \)-dependent sequence, with \( m' := m + M - 1 \). Hence, the result follows from Theorem 3.8 applied to \( g \) and \( (Y_i)_{i=1}^\infty \). \( \square \)

**Remark 6.1.** The integrals in (6.21) are standard Beta integrals [30, 5.12.1]; we have
\[ \int_0^1 \psi_i(t) \psi_j(t) \, dt = \frac{1}{(i-1)! (j-1)! (\ell - i)! (\ell - j)!} \int_0^1 t^{i+j-2} (1-t)^{2\ell-i-j} \, dt \]
\[ = \frac{(i+j-2)! (2\ell-i-j)!}{(i-1)! (j-1)! (\ell - i)! (\ell - j)! (2\ell-1)!}. \] (6.27)

**Remark 6.2.** In unconstrained case Theorem 3.8 the asymptotic variance \( \sigma^2 \) is given by (6.21) together with (6.16), (6.1) and (6.27).

In the constrained cases, the proof above shows that \( \sigma^2 \) is given by (6.21) applied to the function \( g \) given by Lemma 4.3 and \( (Y_i)_{i=1}^\infty \) given by (4.8) (with \( M = D + 1 \) for definiteness); note that this also entails replacing \( \ell \) by \( b \) and \( m \) by \( m + M - 1 = m + D \) in the formulas above. In particular, in the exactly constrained case (4.30), it follows from (6.1) and (4.18) that, with \( y = (x_1, \ldots, x_M) \in \mathcal{S}^M \) and other notation as in (4.11)–(4.14) and (5.4),
\[ g_i(x_1, \ldots, x_M) = \mathbb{E} f((X_{j_1+1}+t_{v_1})_{r=1}^{\varepsilon_i}, \ldots, (X_{j_M+1}+t_{v_M})_{r=1}^{\varepsilon_i}, \ldots, (X_{jk+1}+t_{v_M})_{r=1}^{\varepsilon_i}) - \mu_{D=}, \] (6.28)
where the $i$th group of variables consists of the given $x_i$, and the other $b-1$ groups contain variables $X_i$, and $j_1, \ldots, j_b$ is any sequence of indices that has large enough gaps: $j_{i+1} - j_i > m + M - 1 = m + D$.

In the constrained case (3.2), $g = g_D$ is obtained as the sum (4.23), and thus each $g_i$ is a similar sum of functions that can be obtained as (6.28). (Note that $M := D + 1$ works in Lemma 4.2 for all terms by (3.5).) Then, $\sigma^2$ is given by (6.21) (with substitutions as above). □

7. Law of large numbers

Proof of Theorem 3.6. Note first that if $R_n$ is any sequence of random variables such that
\[ \mathbb{E} R_n^2 = O(n^{-2}), \] (7.1)
then Markov’s inequality and the Borel–Cantelli lemma show that $R_n \overset{a.s.}{\to} 0$.

We begin with the unconstrained case, $D = D_\infty = (\infty, \ldots, \infty)$. We may assume, as in the proof of Theorem 3.8, that $\mu = 0$. Then (6.20) holds, and thus by the argument just given, and recalling that $\mathbb{E} \hat{U}_n = 0$ by (6.10) and (6.3),
\[ n^{-\ell} [U_n(f) - \mathbb{E} U_n(f) - \hat{U}_n] \overset{a.s.}{\to} 0. \] (7.2)

Hence, to prove (3.15), it suffices to prove $n^{-\ell} \hat{U}_n \overset{a.s.}{\to} 0$.

For simplicity, we fix $j \in [\ell]$, and define, with $f_j$ as above given by (6.1),
\[ S_{jn} = S_{jn}(f) := \sum_{k=1}^{n} f_j(X_k) \] (7.3)
and, using partial summation,
\[ \hat{U}_{jn} := \sum_{k=1}^{n} a_{j,k,n} f_j(X_k) = \sum_{k=1}^{n-1} (a_{j,k,n} - a_{j,k+1,n}) S_{jk} + a_{j,n,n} S_{jn}. \] (7.4)
The sequence $(f_j(X_k))_k$ is $m$-dependent, stationary and with $\mathbb{E} |f_j(X_k)| < \infty$. As is well known, the strong law of large numbers holds for stationary $m$-dependent sequences with finite means. (This follows by considering the subsequences $(X_{(m+1)n+q})_{n\geq 0}$, which for each fixed $q \in [m + 1]$ is an i.i.d. sequence.) Thus, by (7.3) and (6.3),
\[ S_{jn}/n \overset{a.s.}{\to} \mathbb{E} f_j(X_k) = 0. \] (7.5)
In other words, a.s. $S_{jn} = o(n)$, and thus also
\[ \max_{1 \leq k \leq n} |S_{jk}| = o(n) \quad \text{a.s.} \] (7.6)
Moreover, (6.11) implies $a_{j,k,n} - a_{j,k+1,n} = O(n^{\ell-2})$. Hence, (7.4) yields
\[ n^{-\ell} \hat{U}_{jn} = \sum_{k=1}^{n-1} O(n^{-2}) \cdot S_{jk} + O(n^{-1}) \cdot S_{jn} \] (7.7)
and thus, using (7.5),
\[ |n^{-\ell} \hat{U}_{jn}| \leq C n^{-1} \max_{k \leq n} |S_{jk}| = o(1) \quad \text{a.s.} \] (7.8)
Consequently,

\[ n^{-\ell} \hat{U}_n = \sum_{j=1}^{\ell} n^{-\ell} \hat{U}_{jn} \overset{a.s.}{\to} 0, \quad (7.9) \]

which together with (7.2) yields the desired result (3.15).

Next, for an exact constraint \( D =, \) we use Lemma 4.2. Then (4.9) together with the just shown result applied to \( g \) and \( (Y_i) \) yields

\[ n^{-b} [U_n(f; D=) - E U_n(f; D=)] = n^{-b} [U_{n-D}(g) - E U_{n-D}(g)] \overset{a.s.}{\to} 0. \quad (7.10) \]

This proves (3.17), and (3.16) follows by (3.4).

Finally, using Theorem 3.5, (3.12)–(3.14) are equivalent to (3.15)–(3.17). \( \square \)

8. The degenerate case

As is well known, even in the original symmetric and independent case studied in [17], the asymptotic variance \( \sigma^2 \) in Theorem 3.8 may vanish also in non-trivial cases. In such cases, (3.19) is still valid, but says only that the left-hand side converges to 0 in probability. In the present section, we characterize this degenerate case in Theorems 3.8 and 3.9. Note that in applications, it is frequently intuitively obvious that \( \sigma^2 > 0 \), but this is sometimes surprisingly difficult to prove. One purpose of the theorems below is to assist in showing \( \sigma^2 > 0 \); see the applications in Sections 9 and 10.

For an unconstrained \( U \)-statistic and an independent sequence \( (X_i)_{i=1}^{\infty} \) (the case \( m = 0 \) of Theorem 3.8), it is known, and not difficult to see, that \( \sigma^2 = 0 \) if and only if every projection \( f_i(X_1) \) defined by (6.1) vanishes a.s., see [24, Corollary 3.5]. (This is included in the theorem below by taking \( m = 0 \) in (iii), and it is also the correct interpretation of (vi) when \( m = 0 \).) In the \( m \)-dependent case, the situation is similar, but somewhat more complicated, as shown by the following theorem. Note that \( S_{jn}(f_j) \) defined in (3.8) below equals \( S_{jn} \); for later applications we find this change of notation convenient.

Theorem 8.1. With assumptions and notation as in Theorem 3.8, define also \( f \) by (6.1), \( \gamma_{i,j,r} \) by (6.16) and \( S_{jn} \) by (7.3). Then, the following are equivalent.

(i) \( \sigma^2 = 0. \) \( (8.1) \)

(ii) \( \text{Var} U_n = O(n^{2\ell-2}). \) \( (8.2) \)

(iii) \( \sum_{r=-m}^{m} \gamma_{i,j,r} = 0, \quad \forall i, j \in [\ell]. \) \( (8.3) \)

(iv) \( \text{Cov}[S_{mn}, S_{jn}] / n \to 0 \text{ as } n \to \infty \quad \forall i, j \in [\ell]. \) \( (8.4) \)

(v) \( \text{Var}[S_{jn}] / n \to 0 \text{ as } n \to \infty \quad \forall j \in [\ell]. \) \( (8.5) \)
(vi) For each \( j \in [\ell] \) there exists a stationary sequence \( (Z_{j,k})_{k=0}^{\infty} \) of \((m-1)\)-dependent random variables such that a.s.

\[
f_j(X_k) = Z_{j,k} - Z_{j,k-1}, \quad k \geq 1. \tag{8.6}
\]

Moreover, suppose that the sequence \( (X_k)_{k=1}^{\infty} \) is a block factor given by \((2.2)\) for some function \( h \) and i.i.d. \( \xi_i \), and that \( \sigma^2 = 0 \). Then, in \([\text{vi}]\) we may take \( Z_{j,k} \) as block factors

\[
Z_{j,k} = \varphi_j(\xi_{k+1}, \ldots, \xi_{k+m}), \tag{8.7}
\]

for some functions \( \varphi_j : S_m^m \to \mathbb{R} \). Hence, for every \( j \in [\ell] \) and \( n \geq 1 \),

\[
S_n(f_j) := \sum_{k=1}^{n} f_j(X_k) = Z_{j,n} - Z_{j,0} = \varphi_j(\xi_{n+1}, \ldots, \xi_{n+m}) - \varphi_j(\xi_1, \ldots, \xi_m), \tag{8.8}
\]

and thus \( S_n(f_j) \) is independent of \( \xi_{m+1}, \ldots, \xi_n \) for every \( j \in [\ell - 1] \) and \( n > m \).

To prove Theorem 8.1, we begin with a well known algebraic lemma; for completeness we include a proof.

**Lemma 8.2.** Let \( A = (a_{ij})_{i,j=1}^{\ell} \) and \( B = (b_{ij})_{i,j=1}^{\ell} \) be symmetric real matrices such that \( A \) is positive definite and \( B \) is positive semidefinite. Then

\[
\sum_{i,j=1}^{\ell} a_{ij}b_{ij} = 0 \iff b_{ij} = 0 \quad \forall i,j \in [\ell]. \tag{8.9}
\]

**Proof.** Since \( A \) is positive definite, there exists an ON basis \((v_k)_{k=1}^{\ell} \) in \( \mathbb{R}^\ell \) consisting of eigenvectors of \( A \), in other words \( Av_k = \lambda_k v_k \); furthermore, the eigenvalues \( \lambda_k > 0 \). Write \( v_k = (v_{ki})_{i=1}^{\ell} \). We then have

\[
a_{ij} = \sum_{k=1}^{\ell} \lambda_k v_{ki}v_{kj}. \tag{8.10}
\]

Thus

\[
\sum_{i,j=1}^{\ell} a_{ij}b_{ij} = \sum_{k=1}^{\ell} \lambda_k \sum_{i,j=1}^{\ell} b_{ij}v_{ki}v_{kj} = \sum_{k=1}^{\ell} \lambda_k \langle v_k, Bv_k \rangle. \tag{8.11}
\]

Since \( B \) is positive semidefinite, all terms in the last sum are \( \geq 0 \), so the sum is 0 if and only if every term is, and thus

\[
\sum_{i,j=1}^{\ell} a_{ij}b_{ij} = 0 \iff \langle v_k, Bv_k \rangle = 0 \quad \forall k \in [\ell], \tag{8.12}
\]

By the Cauchy–Schwarz inequality for the semidefinite bilinear form \( \langle v, Bw \rangle \) (or, alternatively by using \( \langle v_k \pm v_n, B(v_k \pm v_n) \rangle \geq 0 \)) it follows that this condition implies \( \langle v_k, Bv_n \rangle = 0 \) for any \( k, n \in [\ell] \), and thus

\[
\sum_{i,j=1}^{\ell} a_{ij}b_{ij} = 0 \iff \langle v_k, Bv_n \rangle = 0 \quad \forall k,n \in [\ell]. \tag{8.13}
\]

Since \((v_k)_{k=1}^{\ell} \) is a basis, this is further equivalent to \( \langle v, Bw \rangle = 0 \) for any \( v, W \in \mathbb{R}^\ell \), and thus to \( B = 0 \). This yields \((8.9)\). \( \square \)
Proof of Theorem 8.1. The \( \ell \) polynomials \( \psi_j, j = 1, \ldots, \ell, \) of degree \( \ell - 1 \) defined by (6.12) are linearly independent (e.g., since the matrix of their coefficients in the standard basis \( \{1, x, \ldots, x^{\ell-1}\} \) is upper triangular with non-zero diagonal elements). Hence, the Gram matrix \( A = (a_{ij})_{i,j} \) with

\[
a_{ij} := \int_0^1 \psi_i(t)\psi_j(t) \, dt
\]

is positive definite.

We have by (7.3), similarly to (6.14)–(6.17),

\[
\text{Cov}(S_{in}, S_{jn}) = \sum_{k=1}^n \sum_{q=1}^n \text{Cov}[f_i(X_k), f_j(X_q)] = \sum_{r=-m}^{n-r_+} \sum_{k=1+r}^m (n - |r|) \gamma_{i,j,r}
\]

and thus, as \( n \to \infty, \)

\[
\text{Cov}(S_{in}, S_{jn})/n \to \sum_{r=-m}^m (n - |r|) \gamma_{i,j,r} =: b_{ij}.
\]

Note that (6.21) can be written

\[
\sigma^2 = \sum_{i,j=1}^\ell b_{ij}a_{ij}.
\]

The covariance matrices \( \left( \text{Cov}(S_{in}, S_{jn}) \right)_{i,j=1}^\ell \) are positive semidefinite, and thus so is the limit \( B = (b_{ij}) \) defined by (8.16). Hence Lemma 8.2 applies and yields, using (8.17) and the definition of \( b_{ij} \) in (8.16), the equivalence (i) \( \iff \) (iii).

Furthermore, (8.16) yields (iii) \( \iff \) (iv).

The implication (iv) \( \implies \) (v) is trivial, and the converse follows by the Cauchy–Schwarz inequality.

If (iii) holds, then (6.19) yields \( \text{Var} \hat{U}_n = O(n^{2\ell-2}) \), and (ii) follows by (6.20). Conversely, (ii) \( \implies \) (i) by (3.18).

Moreover, for \( m \geq 1, \) (v) \( \iff \) (vi) holds by [23, Theorem 1], recalling \( \mathbb{E}f_j(X_k) = 0 \) by (6.3). (Recall also that any stationary sequence \( (W_k)_{k=1}^\infty \) of real random variables can be extended to a doubly-infinite stationary sequence \( (W_k)_{k=-\infty}^\infty \).) The case \( m = 0 \) is trivial, since then (v) is equivalent to \( \text{Var} f_j(X_k) = 0 \) and thus \( f_j(X_k) = 0 \) a.s. by (6.3), while (vi) should be interpreted to mean that (8.6) holds for some non-random \( Z_{j,k} = z_j \).

Finally, suppose that \( (X_i)_{i=1}^\infty \) is a block factor. In this case, [23, Theorem 2] shows that \( Z_{j,k} \) can be chosen as in (8.7). (Again, the case \( m = 0 \) is trivial.) Then (8.8) is an immediate consequence of (8.6)–(8.7). \( \square \)

Remark 8.3. It follows from the proof in [23] that in (vi) we can choose \( Z_{j,k} \) such that also the random vectors \( (Z_{j,k})_{j=1}^\ell, k \geq 0, \) form a stationary \( m \)-dependent sequence. \( \square \)

Theorem 8.4. With assumptions and notation as in Theorem 3.9, define also \( g_i, i \in [b], \) as in Remark 6.2 i.e., by (6.28) in the exactly constrained case and otherwise as a sum of such terms over all \( D' \) given by (3.5). Let also (again as in Remark 6.2)
D be given by (6.7) and Y by (6.8) with $M = D + 1$. Then $\sigma^2 = 0$ if and only if for every $j \in [b]$, there exists a stationary sequence $(Z_{j,k})_{k=0}^{\infty}$ of $(m + D - 1)$-dependent random variables such that a.s.

$$g_j(Y_k) = Z_{j,k} - Z_{j,k-1}, \quad k \geq 1. \tag{8.18}$$

Moreover, if the sequence $(X_i)_i^{\infty}$ is independent and $\sigma^2 = 0$, then there exist functions $\varphi_j : S^D \to \mathbb{R}$ such that (8.18) holds with

$$Z_{j,k} = \varphi_j(X_{k+1}, \ldots, X_{k+D}), \tag{8.19}$$

and consequently a.s.

$$S_n(g_j) := \sum_{k=1}^{n} g_j(Y_k) = \varphi_j(X_{n+1}, \ldots, X_{n+D}) - \varphi_j(X_1, \ldots, X_D), \tag{8.20}$$

and thus $S_n(g_j)$ is independent of $X_{D+1}, \ldots, X_n$ for every $j \in [\ell - 1]$ and $n > D$.

**Proof.** As in the proof of Theorem 3.9 it suffices to consider $U_n(g)$ with $g$ given by Lemma 4.3 (with $M = D + 1$). The first part then is an immediate consequence of Theorem 8.1 (vi) applied to $g$ and $Y_i := (X_i, \ldots, X_{i+D})$, with appropriate substitutions $\ell \mapsto b$ and $m \mapsto m + D$.

The second part follows similarly by the last part of Theorem 8.1 with $\xi_i = X_i$; note that then $(Y_i)$ is a block factor as in (2.2), with $m$ replaced by $D$. \qed

**Remark 8.5.** Of course, under the assumptions of Theorem 8.4, also the other equivalences in Theorem 8.1 hold with the appropriate interpretations, substituting $g$ for $f$ and so on. \qed

We give an example of a constrained $U$-statistic where $\sigma^2 = 0$ in a somewhat non-trivial way.

**Example 8.6.** Let $(X_i)_i^{\infty}$ be an infinite i.i.d. symmetric random binary string, i.e., $S = \{0, 1\}$ and $X_i \sim \text{Be}(1/2)$ are i.i.d. Let

$$f(x, y, z) := 1\{xyz = 101\} - 1\{xyz = 011\} \tag{8.21}$$

and consider the constrained $U$-statistic

$$U_n(f; D) = \sum_{1 \leq i < i + 1 < j \leq n} f(X_i, X_{i+1}, X_j), \tag{8.22}$$

which thus has constraint $D = (1, \infty)$. (In this case, $U_n(f; D) = U_n(f; D = )$.) Note that (8.22) is a difference of two constrained subsequence counts.

Although the function (8.21) might look non-trivial and innocuous at first glance, this turns out to be a degenerate case. In fact, it is easily verified that

$$f(x, y, z) = (x - y)z, \quad x, y, z \in \{0, 1\}. \tag{8.23}$$

Hence, with $m = 0, D = 1$ and $M = D + 1 = 2$, (5.4) yields

$$\mu_D = \mu_{D=1} = E g(Y_1, Y_3) = E f(X_1, X_2, X_4) = 0 \tag{8.24}$$

while (6.28) yields

$$g_1(x, y) = E f(x, y, X_4) = E[(x - y)X_4] = \frac{1}{2}(x - y), \tag{8.25}$$

$$g_2(x, y) = E f(X_1, X_2, y) = E[(X_1 - X_2)y] = 0. \tag{8.26}$$
Thus \( g_2 \) vanishes but not \( g_1 \). Nevertheless, \( g_1(Y_k) = g_1(X_k, X_{k+1}) = \frac{1}{2}(X_k - X_{k+1}) \) is of the type in (8.18)–(8.19) (with \( Z_{1,k} := -\frac{1}{2}X_{k+1} \)). Hence, Theorem 8.2 shows that \( \sigma^2 = 0 \), and thus Theorems 3.9 and (3.8) yield \( n^{-3/2}U_n(f; D) \to 0 \).

In fact, in this example we have by (8.23), for \( n \geq 3 \),

\[
U_n(f; D) = \sum_{j=3}^{n-2} (X_1 - X_{i+1})X_j = \sum_{j=3}^{n} X_j(X_1 - X_{j-1})
\]

\[
= X_1 \sum_{j=3}^{n} X_j - n \sum_{j=3}^{n} X_{j-1}X_j. \quad (8.27)
\]

Hence, by the law of large numbers for stationary \( m \)-dependent sequences,

\[
n^{-1}U_n(f; D) \xrightarrow{a.s.} X_1 \mathbb{E}X_2 - \mathbb{E}[X_2X_3] = \frac{1}{2}X_1 - \frac{1}{4} = \frac{1}{2}(X_1 - \frac{1}{2}). \quad (8.28)
\]

As a consequence, \( n^{-1}U_n(f; D) \) has a non-degenerate limiting distribution. Note that this example differs in several respects from the degenerate cases that may occur for standard \( U \)-statistics, i.e. unconstrained \( U \)-statistics based on independent \((X_i)\). In this example, (8.28) shows that the asymptotic distribution is a linear transformation of a Bernoulli variable, and is thus neither normal, nor of the type that appears as limits of degenerate standard \( U \)-statistics. (The latter are polynomials in independent normal variables, in general infinitely many, see e.g. Theorem A.3 and, in general, [36] and [22, Chapter 11].) Moreover, the a.s. convergence to a non-degenerate limit is unheard of for standard \( U \)-statistics, where the limit is mixing.

\( \square \)

9. Constrained pattern matching in words

As said in Section 1, Flajolet, Szpankowski and Vallée [15] studied the following problem; see also Jacquet and Szpankowski [20, Chapter 5]. Consider a random string \( \Xi_n = \xi_1 \cdots \xi_n \), where the letters \( \xi_i \) are i.i.d. random elements in some finite alphabet \( \mathcal{A} \). (We may regard \( \Xi_n \) as the initial part of an infinite string \( \xi_1\xi_2 \cdots \) of i.i.d. letters.) Consider also a fixed word \( w = w_1 \cdots w_\ell \) from the same alphabet. (Thus, \( \ell \geq 1 \) denotes the length of \( w \); we keep \( w \) and \( \ell \) fixed.) Let \( N_n(w) \) be the (random) number of occurrences of \( w \) in \( \Xi_n \). More generally, for any constraint \( D = (d_1, \ldots, d_{\ell-1}) \), let \( N_n(w; D) \) be the number of constrained occurrences. This is a special case of the general setting in (3.1)–(3.2), with \( X_i = \xi_i \), and, cf. 1.1,

\[
f(x_1, \ldots, x_\ell) = 1\{x_1, \ldots, x_\ell = w\} = 1\{x_i = w_i \forall i \in [\ell]\}. \quad (9.1)
\]

Consequently,

\[
N_n(w; D) = U_n(f; D; (\xi_i)) \quad (9.2)
\]

with \( f \) given by (9.1).

Denote the distribution of the individual letters by

\[
p(x) := \mathbb{P}(\xi_1 = x), \quad x \in \mathcal{A}; \quad (9.3)
\]

We will, without loss of generality, assume \( p(x) > 0 \) for every \( x \in \mathcal{A} \). Then, (9.2) and the general results above yield the following result from [15], with \( b = b(D) \) given by (2.11). The unconstrained case (also in [13]) is a special case. Moreover, the theorem holds also for the exactly constrained case, with \( \mu_D = \prod_i p(w_i) \) and some \( \sigma^2(w; D) \); we leave the detailed statement to the reader. A formula for \( \sigma^2 \) is given
in \cite[(14)]{15}; we show explicitly that $\sigma^2 > 0$ except in trivial (non-random) cases, which seems omitted from \cite{15}.

**Theorem 9.1** (Flajolet, Szpankowski and Vallée \cite{15}). With notations as above, as $n \to \infty$,

$$
\frac{N_n(w; D) - \frac{\ell}{b} n^b}{n^{b-1/2}} \xrightarrow{d} N(0, \sigma^2)
$$

(9.4)

for some $\sigma^2 = \sigma^2(w; D) \geq 0$, with

$$
\mu_D := \prod_{d_i < \infty} d_i \cdot \prod_{i=1}^\ell p(w_i).
$$

(9.5)

Furthermore, the first two moments converge in (9.4). Moreover, if $|A| \geq 2$, then $\sigma^2 > 0$.

**Proof.** By (9.2), the convergence (9.4) is an instance of (3.21) in Theorem 3.9 together with (3.8) in Theorem 3.5. The formula (9.5) follows from (3.11) since, by (9.1) and independence,

$$
\mu := \mathbb{E} f(\xi_1, \ldots, \xi_\ell) = \mathbb{P}(\xi_1 \cdots \xi_\ell = w_1 \cdots w_\ell) = \prod_{i=1}^\ell \mathbb{P}(\xi_i = w_i).
$$

(9.6)

This argument shows also convergence (to 0) of the first moment in (9.4); convergence of the second moment follows by (3.20).

Finally, assume $|A| \geq 2$ and suppose that $\sigma^2 = 0$. Then Theorem 8.4 says that (8.20) holds, and thus, for each $n > D$, the sum $S_n(g_j)$ is independent of $\xi_{D+1}, \ldots, \xi_n$. We consider only $j = 1$. Choose $a \in A$ with $a \neq w_1$. Consider first an exact constraint $D=\ldots$. Then $g_{D=}$ is given by (4.18). Since $f(x_1, \ldots, x_\ell) = 0$ whenever $x_1 = a$, it follows from (4.18) that $g(y_1, \ldots, y_b) = 0$ whenever $y_1 = (y_{1k})_{k=1}^M$ has $y_11 = a$. hence, (6.1) shows that

$$
g_1(y_1) = -\mu_D = -\mu, \quad \text{if } y_11 = a.
$$

(9.7)

Consequently, on the event $\xi_1 = \cdots = \xi_n = a$, we have, recalling (4.8) and $M = D+1$, $g_1(Y_k) = g_1(\xi_k, \ldots, \xi_{k+D}) = -\mu$ for every $k \in [n]$. Thus,

$$
S_n(g_1) = -n\mu \quad \text{if } \xi_1 = \cdots = \xi_n = a.
$$

(9.8)

On the other hand, as noted above, the assumption $\sigma^2 = 0$ implies that $S_n(g_1)$ is independent of $\xi_{D+1}, \ldots, \xi_n$. Consequently, (9.8) implies

$$
S_n(g_1) = -n\mu \quad \text{if } \xi_1 = \cdots = \xi_D = a,
$$

(9.9)

regardless of $\xi_{D+1}, \ldots, \xi_{n+D}$. This is easily shown to lead to contradiction. For example, we have, by (6.8),

$$
\mathbb{E} g_1(Y_k) = \mathbb{E} g_1(\xi_k, \ldots, \xi_{k+D}) = 0,
$$

(9.10)

and thus, conditioning on $\xi_1, \ldots, \xi_D$,

$$
\mathbb{E}(S_n(g_1) \mid \xi_1 = \cdots = \xi_D = a) = \sum_{k=1}^n \mathbb{E}(g_1(\xi_k, \ldots, \xi_{k+D}) \mid \xi_1 = \cdots = \xi_D = a)
$$

$$
= O(1),
$$

(9.11)
since all terms with \( k > D \) are unaffected by the conditioning and thus vanish by (9.10); this contradicts (9.9) for large \( n \), since \( \mu > 0 \). This contradiction shows that \( \sigma^2 > 0 \) for an exact constraint \( D = \).

Alternatively, instead of using the expectation as in (9.11), one might easily show that if \( n > D + \ell \), then \( \xi_{D+1}, \ldots, \xi_n \) can be chosen such that (9.9) does not hold.

For a constraint \( D \), \( g = g_D \) is given by a sum (4.23) of exactly constrained cases \( D' = \). Hence, by summing (9.7) for these \( D' = \), it follows that (9.7) holds also for \( g_D \) (with \( \mu \) replaced by \( \mu_D \)). This leads to a contradiction exactly as above.

\[ \Box \]

Theorem 9.1 shows that, except in trivial cases, the asymptotic variance \( \sigma^2 > 0 \) for a subgraph count \( N_n(w; D) \), and thus (9.4) yields a non-degenerate limit, and thus really shows asymptotic normality. By the same proof, see also Remark 8.10.

Theorem 9.1 extends to linear combinations of different subsequence counts (in the same random string \( \Xi_n \)), but in this case, it may happen that \( \sigma^2 = 0 \), and then (9.4) has a degenerate limit and thus yields only convergence in probability to 0. (We consider only linear combinations with coefficients not depending on \( n \).) One such degenerate example with constrained subsequence counts is discussed in Example 8.6.

There are also degenerate examples in the unconstrained case. In fact, the general theory of degenerate (in this sense) \( U \)-statistics based on independent \((X_i)_i\) is well understood; for symmetric \( U \)-statistics this case was characterized by [17] and studied in detail by [36]; and their results were extended to the asymmetric case relevant here in [22, Chapter 11.2]. In Appendix A we apply these general results to string matching and give a rather detailed treatment of the degenerate cases of linear combinations of unconstrained subsequence counts. See also [12] for further algebraic aspects of both non-degenerate and degenerate cases.

**Problem 9.2.** Appendix A considers only the unconstrained case. Example 8.6 shows that for linear combinations of constrained pattern counts, there are further possibilities to have \( \sigma^2 = 0 \). It would be interesting to extend the results in Appendix A and characterize these cases, and also to obtain limit theorems for such cases, extending Theorem A.4 (in particular the case \( k = 2 \)); note again that the limit in Example 8.6 is of a different type than the ones occurring in unconstrained cases (Theorem A.4). We leave this as open problems.

### 10. Constrained pattern matching in permutations

Consider now random permutations. As usual, we generate a random permutation \( \pi = \pi^{(n)} \in \mathfrak{S}_n \) by taking a sequence \((X_i)_i\) of i.i.d. random variables with a uniform distribution \( X_i \sim U(0, 1) \), and then replacing the values \( X_1, \ldots, X_n \), in increasing order, by \( 1, \ldots, n \). Then, the number \( N_n(\tau) \) of occurrences of a fixed permutation \( \tau = \tau_1 \cdots \tau_\ell \) in \( \pi \) is given by the \( U \)-statistic \( U_n(f) \) defined by (4.1) with

\[ f(x_1, \ldots, x_\ell) := \prod_{1 \leq i < j \leq \ell} \mathbf{1}_{\{x_i < x_j \iff \tau_i < \tau_j\}}. \]  

(10.1)

Similarly, for any constraint \( D = (d_1, \ldots, d_{\ell-1}) \), we have for the number of constrained occurrences of \( \tau \), with the same \( f \) given by (10.1),

\[ N_n(\tau; D) = U_n(f; D). \]  

(10.2)

Hence, Theorems 5.8 and 5.9 yield the following result showing asymptotic normality of the number of (constrained) occurrences. As said in the introduction, the unconstrained case was shown by Bóna [2], the case \( d_1 = \cdots = d_{\ell-1} = 1 \) by Bóna [4]
and the general vincular case by Hofer [19]; we extend it to general constrained cases. The fact that $\sigma^2 > 0$ was shown in [19] (in vincular cases); we give a shorter proof based on Theorem [8.4]. Again, the theorem holds also for the exactly constrained case, with $\mu_{D^n} = 1/\ell!$ and some $\sigma^2(\tau; D^n)$.

**Theorem 10.1** (largely Bóna [2] [4] and Hofer [19]). For any fixed permutation $\tau \in S_\ell$ and constraint $D = (d_1, \ldots, d_{\ell-1})$, as $n \to \infty$,

$$
\frac{N_n(\tau; D) - \mu_nD^n n^b}{n^{b-1/2}} \xrightarrow{d} N(0, \sigma^2)
$$

(10.3)

for some $\sigma^2 = \sigma^2(\tau; D) \geq 0$ and

$$
\mu_D := \frac{1}{\ell!} \prod_{d_j < \infty} d_j.
$$

(10.4)

Furthermore, the first two moments converge in (9.4).

Moreover, if $\ell \geq 2$, then $\sigma^2 > 0$.

**Proof.** This is similar to the proof of Theorem [9.1]. By [10.2], the convergence [10.3] is an instance of [3.21] together with [3.8]. The formula [10.4] follows from [3.11] since $\mu := \mathbb{E} f(X_1, \ldots, X_\ell)$ by (10.1) is the probability that $X_1, \ldots, X_\ell$ have the same order as $\tau_1, \ldots, \tau_\ell$, i.e., $1/\ell!$. This yields also convergence of the first moment in (9.4); convergence of the second moment follows by [3.20].

Finally, suppose that $\ell \geq 2$ but $\sigma^2 = 0$. Then Theorem [8.4] says that [8.20] holds, and thus, for each $j$ and each $n > D$, the sum $S_n(g_j)$ is independent of $X_{D+1}, \ldots, X_n$; we want to show that this leads to a contradiction. We choose again $j = 1$, but we now consider two cases separately.

**Case 1:** $d_1 < \infty$. Recall the notation in (4.11)–(4.14), and note that in this case

$$
\ell_1 > 1, \quad t_{11} = 0, \quad t_{12} = d_1, \quad v_1 = 0.
$$

(10.5)

Assume for definiteness that $\tau_1 > \tau_2$. (Otherwise, we may exchange $<$ and $>$ in the argument below.) Then (10.1) implies that

$$
f(x_1, \ldots, x_\ell) = 0 \quad \text{if} \quad x_1 < x_2.
$$

(10.6)

Consider first the exact constraint $D^\ell$. Then $g_{D^n}$ is given by (4.18). Hence, (10.6) and (10.3) imply that

$$
g_{D^n}(y_1, \ldots, y_{b^n}) = 0 \quad \text{if} \quad y_1 = (y_{1,k})_{k=1}^M \text{ with } y_{1,1} < y_{1,1+d_1}.
$$

(10.7)

In particular,

$$
g_{D^n}(y_1, \ldots, y_{b^n}) = 0 \quad \text{if} \quad y_{1,1} < y_{1,2} < \cdots < y_{1,M}.
$$

(10.8)

By (4.23), the same holds for the constraint $D$. Hence, (6.1) shows that, for $g = g_D$,

$$
g_1(y_1) = -\mu_D \quad \text{if} \quad y_{1,1} < y_{1,2} < \cdots < y_{1,M}.
$$

(10.9)

Consequently, on the event $X_1 < \cdots < X_{n+D}$, we have, recalling (4.8) and $M = D+1$, $g_1(Y_k) = g_1(X_k, \ldots, X_{k+D}) = -\mu_D$ for every $k \in [n]$, and thus

$$
S_n(g_1) = -n\mu_D \quad \text{if} \quad X_1 < \cdots < X_{n+D}.
$$

(10.10)

On the other hand, as noted above, the assumption $\sigma^2 = 0$ implies that $S_n(g_1)$ is independent of $X_{D+1}, \ldots, X_n$. Consequently, (10.10) implies that a.s.

$$
S_n(g_1) = -n\mu_D \quad \text{if} \quad X_1 < \cdots < X_D < X_{n+1} < \cdots < X_{n+D}.
$$

(10.11)
However, in analogy with (9.10)–(9.11), we have \( \mathbb{E} g_1(Y_k) = 0 \) by (6.3), and thus
\[
\mathbb{E}(S_n(g_1) \mid X_1 < \cdots < X_D < X_{n+1} < \cdots < X_{n+D})
= \sum_{k=1}^n \mathbb{E}(g_1(X_k, \ldots, X_{k+D}) \mid X_1 < \cdots < X_D < X_{n+1} < \cdots < X_{n+D})
= O(1),
\]
(10.12)
since all terms with \( D < k \leq n - D \) are unaffected by the conditioning and thus vanish. But (10.12) contradicts (10.11) for large \( n \), since \( \mu_D > 0 \). This contradiction shows that \( \sigma^2 > 0 \) when \( \ell \geq 2 \) and \( d_1 < \infty \).

Case 2: \( d_1 = \infty \). In this case, \( \ell_1 = 1 \). Consider again first \( \mathcal{D} = \). Since \( (X_i) \) are i.i.d., then (11.18) and (11.1) yield, choosing \( j_i := (D + 1)i \), say,
\[
g_1(y_i) = \mathbb{E} \left[ g(y_{11}, Y_{j_2}, \ldots, Y_{j_b}) - \mu \right] = \mathbb{E} \left[ f(y_{11}, X_2, \ldots, X_\ell) - \mu \right] = f_1(y_{11}).
\]
(10.13)
(With \( \mu = 1/\ell! \)) Thus, recalling (11.8),
\[
S_n(g_1) = \sum_{k=1}^n g_1(Y_k) = \sum_{k=1}^n f_1(X_k).
\]
(10.14)
By Theorem 8.4 the assumption \( \sigma^2 = 0 \) thus implies that the final sum in (10.14) is independent of \( X_{D+1} \), for any \( n \geq D + 1 \). Since \( (X_i) \) are independent, this is possible only if \( f_1(X_{D+1}) = c \) a.s. for some constant \( c \), i.e., if \( f_1(x) = c \) a.e. \( x \in (0, 1) \).

However, by (10.1), \( f(x, X_2, \ldots, X_\ell) = 1 \) if and only if \( \tau_1 - 1 \) prescribed \( X_j \) are in \( (0, x) \) and in a specific order, and the remaining \( \ell - \tau_1 \) ones are in \( (x, 1) \) and in a specific order. Hence, (6.1) yields
\[
f_1(x) = \frac{1}{(\tau_1 - 1)! \ell \! - \! \tau_1)!} x^{\tau_1 - 1} (1 - x)^{\ell - \tau_1} - \mu.
\]
(10.15)
Since \( \ell \geq 2 \), \( f_1(x) \) is a non-constant polynomial in \( x \).

This is a contradiction, and shows that \( \sigma^2 > 0 \) also when \( d_1 = \infty \). \( \square \)

Remark 10.2. Although, \( \sigma^2 > 0 \) for each pattern count \( N_n(\tau; D) \) with \( \ell > 1 \), non-trivial linear combinations might have \( \sigma^2 = 0 \), and thus variance of lower order, even in the unconstrained case. (Similarly to the case of patterns in strings in Section 9 and Appendix A.) In fact, for the unconstrained case, it is shown in [20] that for permutations \( \tau \) of a given length \( \ell \), the \( \ell! \) counts \( N_n(\tau) \) converge jointly, after normalization as above, to a multivariate normal distribution of dimension only \( (\ell - 1)^2 \), meaning that there is a linear space of dimension \( \ell! - (\ell - 1)^2 \) of linear combinations that have \( \sigma^2 = 0 \). This is further analyzed in [11], where the spaces of linear combinations of \( N_n(\tau) \) having variance \( O(n^{2\ell - r}) \) are characterized for each \( r = 1, \ldots, \ell - 1 \), using the representation theory of the symmetric group. In particular, the highest degeneracy, with variance \( \Theta(n^\ell) \), is obtained for the sign statistic \( U_n(\text{sgn}) \), where \( \text{sgn}(x_1, \ldots, x_\ell) \) is the sign of the permutation defined by the order of \( (x_1, \ldots, x_n) \); in other words, \( U_n(\text{sgn}) \) is the sum of the signs of the \( \ell \) subsequences of length \( \ell \) of a random permutation \( \pi^{(n)} \in \mathfrak{S}_n \). For \( \ell = 3 \), the asymptotic distribution of \( n^{-(\ell+1)/2} U_n(\text{sgn}) \) is of the type in [A.19], see [13] and [20, Remark 2.7]. For larger \( \ell \), the asymptotic distribution can be obtained by the methods in Appendix A be expressed as a polynomial of degree \( \ell - 1 \) in infinitely many independent normal variables, as in [A.17]; however, we do not know any concrete such representation.
We expect that, in analogy with Example 8.6, for linear combinations of constrained pattern counts, there are further possibilities to have $\sigma^2 = 0$. We have not pursued this, and we leave it as an open problem to characterize these cases with $\sigma^2 = 0$; moreover, it would also be interesting to extend the results of [11] characterizing cases with higher degeneracies to constrained cases. □

11. Further comments

We discuss here briefly some possible extensions of the present work. We have not pursued them, and they are left as open problems.

11.1. Moment convergence. Theorems 3.8 and 3.9 include convergence of the first (trivially) and second moments in (3.19) and (3.21). In the unconstrained case with independent $X_i$, it was shown in [24, Theorem 3.15] that convergence of all moments up to order $p$ holds provided $E|f(X_1, \ldots, X_\ell)|^p < \infty$. We expect that this extends as follows to the $m$-dependent case, and thus to constrained cases.

Conjecture 11.1. If [A] is strengthened to $E|f(X_{i_1}, \ldots, X_{i_\ell})|^p < \infty$, for some $p \geq 2$, then all moments up to order $p$ converge in (3.19) and (3.21).

11.2. Functional limit theorems. In the unconstrained case with independent $X_i$, [24, Theorem 3.2] gives a functional limit theorem. It seems likely that this might be extended to a more general functional limit theorem for $m$-dependent and constrained $U$-statistics, corresponding to Theorems 3.8 and 3.9.

11.3. Mixing and Markov input. We have in this paper studied $U$-statistics based on a sequence $(X_i)$ that is allowed to be dependent, but only under the rather strong assumption of $m$-dependence (partly motivated by our application to constrained $U$-statistics). It would be interesting to extend the results to weaker assumptions on $(X_i)$, for example that it is stationary with some type of mixing property. (See e.g. [7] for various mixing conditions and central limit theorems under some of them.) Alternatively (or possibly as a special case of mixing conditions), it would be interesting to consider $(X_i)$ that form a stationary Markov chain (under suitable assumptions).

In particular, it seems interesting to study constrained $U$-statistics under such assumptions, since the mixing or Markov assumptions typically imply strong dependence for sets of variables $X_i$ with small gaps between the indices, but not if the gaps are large.

Markov models are popular models for random strings. Substring counts, i.e., the completely constrained case of subsequence counts (see Remark 1.1) have been treated for Markov sources by e.g. [34], [29] and [20].

A related model for random strings is a probabilistic dynamic source, see e.g. [20, Section 1.1]. For substring counts, asymptotic normality has been shown by [6]. For (unconstrained or constrained) subsequence counts, asymptotic results on mean and variance are special cases of [5] and [20, Theorem 5.6.1]; we are not aware of any results on asymptotic normality in this setting.

11.4. Generalized $U$-statistics. Generalized $U$-statistics (also called multi-sample $U$-statistics) are defined similarly to (3.1), but are based on two (for simplicity) sequences $(X_i)_{i=1}^{n_1}$ and $(Y_j)_{j=1}^{n_2}$ of random variables, with the sum in (3.1) replaced by a sum over all $i_1 < \cdots < i_{\ell_1} \leq n_1$ and $j_1 < \cdots < j_{\ell_2} \leq n_2$, and $f$ now a function of $\ell_1 + \ell_2$ variables. Limit theorems, including asymptotic normality, under suitable
Appendix A. Linear combinations for unconstrained subsequence counts

As promised in Section 9, we consider here unconstrained subsequence counts in a random string $\Xi_n$ with i.i.d. letters, normalized as in Theorem 9.1, and study further the case of linear combinations of such normalized counts (with coefficients not depending on $n$); in particular, we study in some detail such linear combinations that are degenerate in the sense that the asymptotic variance $\sigma^2 = 0$.

The results are based on the orthogonal decomposition introduced in the symmetric case by Hoeffding [18], see also Rubin and Vitale [36]; this is extended to the asymmetric case in [22, Chapter 11.2], but the treatment there uses a rather heavy formalism, and we therefore give here a direct treatment in the present special case. (This case is somewhat simpler than the general case since we only have to consider finite-dimensional vector spaces below, but otherwise the general case is similar.) See also [12], which contains a much deeper algebraic study of the asymptotic variance $\sigma^2(f)$ and the vector spaces below, and in particular a spectral decomposition that refines (A.9).

Fix $A$ and the random string $(\xi_i)_{i=1}^{\infty}$. Assume, as in Section 9, that $p(x) > 0$ for every $x \in A$. Let $A := |A|$, the number of different letters.

We fix also $\ell \geq 1$ and consider all unconstrained subsequence counts $N_n(w)$ with $|w| = \ell$. There are $A^\ell$ such words $w$, and it follows from (9.2) and (9.1) that the linear combinations of these counts are precisely the asymmetric $U$-statistics (3.1) for all $f : A^\ell \to \mathbb{R}$, by the relation

$$\sum_{w \in A^\ell} f(w)N_n(w) = U_n(f). \quad (A.1)$$

Note that Theorem 3.8 applies to every $U_n(f)$ and thus (3.18) and (3.19) hold for some $\sigma^2 = \sigma^2(f) \geq 0$. (As said above, this case of Theorem 3.8 with i.i.d. $X_i$, i.e., the case $m = 0$, is treated also in [22, Corollary 11.20] and [24].)

Let $V$ be the linear space of all functions $f : A^\ell \to \mathbb{R}$. Thus $\dim V = A^\ell$. Similarly, let $W$ be the linear space of all functions $h : A \to \mathbb{R}$, i.e., all functions of a single letter; thus $\dim W = A$. Then $V$ can be identified with the tensor product $W^\otimes \ell$, with the identification

$$h_1 \otimes \cdots \otimes h_\ell(x_1, \ldots, x_\ell) = \prod_{i=1}^{\ell} h_i(x_i). \quad (A.2)$$

We regard $V$ as a (finite-dimensional) Hilbert space with inner product

$$\langle f, g \rangle_V := \mathbb{E}[f(\Xi_n)g(\Xi_n)], \quad (A.3)$$

and, similarly, $W$ as a Hilbert space with inner product

$$\langle h, k \rangle_W := \mathbb{E}[h(\xi_1)k(\xi_1)]. \quad (A.4)$$

Let $W_0$ be the subspace of $W$ defined by

$$W_0 := \{1\}^\perp = \{h \in W : \langle h, 1 \rangle_W = 0\} = \{h \in W : \mathbb{E} h(\xi_1) = 0\}. \quad (A.5)$$

Thus, $\dim W_0 = A - 1$. 
For a subset $B \subseteq A$, let $V_B$ be the subspace of $V$ spanned by all functions $h_1 \otimes \cdots \otimes h_\ell$ as in \((A.2)\) such that $h_i \in W_0$ if $i \in B$, and $h_i = 1$ if $i \notin B$. In other words, if we for a given $B$ define $W'_i := W_0$ when $i \in B$ and $W'_i = \mathbb{R}$ when $i \notin B$, then
\[
V_B = W'_1 \otimes \cdots \otimes W'_\ell \cong W_0^{\otimes |B|}.
\] (A.6)

It is easily seen that these $2^A$ subspaces of $V$ are orthogonal, and that we have an orthogonal decomposition
\[
V = \bigoplus_{B \subseteq A} V_B. \tag{A.7}
\]

Furthermore, for $k = 0, \ldots, \ell$, define
\[
V_k := \bigoplus_{|B| = k} V_B. \tag{A.8}
\]

Thus, we have also an orthogonal decomposition (as in \([18]\) and \([36]\))
\[
V = \bigoplus_{k=0}^\ell V_k. \tag{A.9}
\]

Note that, by \((A.6)\) and \((A.8)\),
\[
\dim V_B = (A - 1)^{|B|}, \quad \dim V_k = \binom{\ell}{k} (A - 1)^k. \tag{A.10}
\]

Let $\Pi_B$ and $\Pi_k = \sum_{|B| = k} \Pi_B$ be the orthogonal projections of $V$ onto $V_B$ and $V_k$. Then, for any $f \in V$, we may consider its components $\Pi_k f \in V_k$.

First, $V_0$ is the 1-dimensional space of constant functions in $V$. Trivially, if $f \in V_0$, then $U_n(f)$ is non-random, so $\text{Var} U_n(f) = 0$ for every $n$, and $\sigma^2(f) = 0$. More interesting is that for any $f \in V$, we have
\[
\Pi_0 f = \mathbb{E} f(\xi_1, \ldots, \xi_\ell) = \mu. \tag{A.11}
\]

Next, it is easy to see that taking $B = \{i\}$ yields the projection $f_i$ defined by \((6.1)\), except that $\Pi_{\{i\}} f$ is defined as a function on $A^\ell$; to be precise,
\[
\Pi_{\{i\}} f(x_1, \ldots, x_\ell) = f_i(x_i). \tag{A.12}
\]

Recalling \((A.1)\), this leads to the following characterization of degenerate linear combinations of unconstrained subsequence counts.

**Theorem A.1.** With notations and assumptions as above, if $f : A^\ell \to \mathbb{R}$, then the following are equivalent.

(i) $\sigma^2(f) = 0$.

(ii) $f_i = 0$ for every $i = 1, \ldots, \ell$.

(iii) $\Pi_{\{i\}} f = 0$.

**Proof.** The equivalence $[\text{(i)}] \iff [\text{(ii)}]$ is a special case of Theorem 8.1, as said above, this special case is also given in \([24, \text{Corollary 3.5}]\).

The equivalence $[\text{(ii)}] \iff [\text{(iii)}]$ follows by \((A.8)\) and \((A.12)\), which give
\[
\Pi_1 f = 0 \iff \Pi_{\{i\}} f = 0 \forall i \iff f_i = 0 \forall i. \tag{A.13}
\]

$\Box$
where $Z$.

**Theorem A.4.** Let $\xi_i.i.d.$ sequence, independent of $(\xi_i)$ also be reduced to the symmetric case in [36] by the following trick. Let $(\xi_i)$ similar to the symmetric case in [17]; cf. also (in the more complicated case) the cases $k \geq 1$ in (4.1) and $k = 2$ in (6.9). We omit the details.

**Proof.** This is easily seen using the expansion (4.3) without the constraint $\xi_i$. Moreover, if $f \in V_{\geq k}$, then $\mathbb{E} U_n(f)^{2} = O(n^{2k-k})$. Furthermore, if $f \in V_{\geq k} \setminus V_{\geq k+1}$, then $\mathbb{E} U_n(f)^{2} = \Theta(n^{2k-k})$.

**Corollary A.2.** The $A^\ell$ different unconstrained subsequence counts $N_n(w)$ with $w \in A^\ell$ converge jointly, after normalization as in (9.4), to a centered multivariate normal distribution in $\mathbb{R}^{A^\ell}$ whose support is a subspace of dimension $\ell(A - 1)$.

**Proof.** By Remark 3.10 we have joint convergence in Theorem 9.1 to some centered multivariate normal distribution in $V = \mathbb{R}^{A^\ell}$. Let $L$ be the support of this distribution; then $L$ is a subspace of $V$. Let $f \in V$. Then, by Theorems 9.1 and A.1

$$f \perp L \iff \sum_{w \in A^\ell} f(w) \frac{N_n(w) - \mathbb{E} N_n(w)}{n^{\ell-1/2}} \xrightarrow{d} 0 \iff \sigma^2(f) = 0 \iff \Pi_1 f = 0 \iff f \perp V_1.$$  

(A.15)

Hence $L = V_1$, and the result follows by (A.10).

What happens in the degenerate case when $\Pi_1 f = 0$ and thus $\sigma^2(f) = 0$? For symmetric $U$-statistics, this was considered by Hoeffding [17] (variance) and Rubin and Vitale [36] (asymptotic distribution), see also Dynkin and Mandelbaum [9]. Their results extend to the present asymmetric situation as follows. We make a final definition of a special subspace of $V$: let

$$V_{\geq k} := \bigoplus_{i=k}^\ell V_i = \{ f \in V : \Pi_i f = 0 \text{ for } i = 0, \ldots, k-1 \}.$$  

(A.16)

In particular, $V_{\geq 1}$ consists of all $f$ with $\mathbb{E} f(\xi_n) = 0$. Note also that $f_s$ in (6.2) by (A.11) and (A.14) equals $f - \Pi_0 f - \Pi_1 f \in V_{\geq 2}$.

**Lemma A.3.** Let $0 \leq k \leq \ell$. If $f \in V_{\geq k}$, then $\mathbb{E} U_n(f)^2 = O(n^{2k-k})$. Moreover, if $f \in V_{\geq k} \setminus V_{\geq k+1}$, then $\mathbb{E} U_n(f)^2 = \Theta(n^{2k-k})$.

**Proof.** This is easily seen using the expansion (4.3) without the constraint $D$, and similar to the symmetric case in [17]; cf. also (in the more complicated $m$-dependent case) the cases $k = 1$ in (4.1) and $k = 2$ in (6.9). We omit the details.

We can now state a general limit theorem that also include degenerate cases.

**Theorem A.4.** Let $k \geq 1$ and suppose that $f \in V_{\geq k}$. Then

$$n^{k/2-\ell} U_n(f) \xrightarrow{d} Z,$$  

(A.17)

where $Z$ is some polynomial of degree $k$ in independent normal variables (possibly infinitely many). Moreover, $Z$ is not degenerate unless $f \in V_{\geq k+1}$.

**Proof.** This follows by [22, Theorem 11.19]. As noted in [22, Remark 11.21], it can also be reduced to the symmetric case in [36] by the following trick. Let $(\eta_1)_{i=1}^\infty$ be an i.i.d. sequence, independent of $(\xi_i)_{i=1}^\infty$, with $\eta_i \sim U(0, 1)$; then

$$U_n(f; (\xi_i)) \xrightarrow{d} \sum_{i_1, \ldots, i_\ell \in n} f(\xi_{i_1}, \ldots, \xi_{i_\ell}) \mathbf{1}_{\{\eta_{i_1} < \cdots < \eta_{i_\ell}\}},$$  

(A.18)
where \( \sum^* \) denotes summation over all distinct \( i_1, \ldots, i_\ell \in [n] \), and the sum in (A.18) can be regarded as a symmetric \( U \)-statistic based on \( (\xi_i, \eta_i)_i^\infty \). The result (A.17) then follows by [36]. □

**Remark A.5.** The case \( k = 1 \) in Theorem A.4 is just a combination of Theorem 9.1 (in the unconstrained case) and Theorem A.1; then \( Z \) is simply a normal variable. When \( k = 2 \), there is a canonical representation (where the number of terms is finite or infinite)

\[
Z = \frac{1}{2(\ell - 2)!} \sum_i \lambda_i (\zeta_i^2 - 1),
\]

where \( \zeta_i \) are i.i.d. \( \text{N}(0,1) \) random variables and \( \lambda_i \) are the non-zero eigenvalues (counted with multiplicity) of a compact self-adjoint integral operator on \( L^2(A \times [0,1], \nu \times dt) \), where \( \nu := L(\xi_1) \) is the distribution of a single letter and \( dt \) is Lebesgue measure; the kernel \( K \) of this integral operator can be constructed from \( f \) by applying [22, Corollary 11.5(iii)] to the symmetric \( U \)-statistic in (A.18). We omit the details, but note that in the particular case \( k = \ell = 2 \), this kernel \( K \) is given by

\[
K((x,t),(y,u)) = f(x,y)1\{t < u\} + f(y,x)1\{t > u\},
\]

and thus the integral operator is

\[
h \mapsto Th(x,t) := \mathbb{E} \int_0^t f(\xi_1, x)h(\xi_1, u) du + \mathbb{E} \int_1^t f(x, \xi_1)h(\xi_1, u) du.
\]

When \( k \geq 3 \), the limit \( Z \) can be represented as a multiple stochastic integral [22, Theorem 11.19], but we do not know any canonical representation of it. See also [36] and [9]. □

We give two simple examples of limits in degenerate cases; in both cases \( k = 2 \). The second example shows that although the space \( V \) has finite dimension, the representation (A.19) might require infinitely many terms. (Note that the operator \( T \) in (A.21) acts in an infinite-dimensional space.)

**Example A.6.** Let \( \Xi_n \) be a symmetric binary string, i.e., \( A = \{0,1\} \) and \( p(0) = p(1) = 1/2 \). Consider

\[
N_n(00) + N_n(11) - N_n(01) - N_n(10) = U_n(f),
\]

with

\[
f(x,y) := 1\{xy = 00\} + 1\{xy = 11\} - 1\{xy = 01\} - 1\{xy = 10\}
= (1\{x = 1\} - 1\{x = 0\})(1\{y = 1\} - 1\{y = 0\}).
\]

For convenience, we change notation and consider instead the letters \( \hat{\xi}_i := 2\xi_i - 1 \in \{\pm 1\} \); then \( f \) corresponds to

\[
\hat{f}(\hat{x}, \hat{y}) := \hat{x}\hat{y}.
\]

Thus

\[
U_n(\hat{f}; (\hat{\xi}_i)) = U_n(\hat{f}; (\hat{\xi}_i)) = \sum_{1 \leq i < j \leq n} \hat{\xi}_i \hat{\xi}_j = \frac{1}{2} \left( \left( \sum_{i=1}^n \hat{\xi}_i \right)^2 - \sum_{i=1}^n \hat{\xi}_i^2 \right)
= \frac{1}{2} \left( \sum_{i=1}^n \hat{\xi}_i \right)^2 - \frac{n}{2}.
\]

By the central limit theorem, \( n^{-1/2} \sum_{i=1}^{n} \hat{\xi}_i \xrightarrow{d} \zeta \sim \mathcal{N}(0,1) \), and thus (A.25) implies

\[
n^{-1} U_n(f) \xrightarrow{d} \frac{1}{2}(\zeta^2 - 1).
\]  

(A.26)

This is an example of (A.17), with \( k = \ell = 2 \) and limit given by (A.19), in this case with a single term in the sum and \( \lambda_1 = 1 \).

Note that in this example, the function \( f \) is symmetric, so (A.22) is an example of a symmetric \( U \)-statistic and thus the result (A.26) is also an example of the limit result in [30].

**Example A.7.** Let \( \mathcal{A} = \{a, b, c, d\} \), with \( \xi \), having the symmetric distribution \( p(x) = 1/4 \) for each \( x \in \mathcal{A} \). Consider

\[
N_n(ac) - N_n(ad) - N_n(bc) + N_n(bd) = U_n(f),
\]

with, writing \( \mathbf{1}_y(x) := 1\{x = y\} \),

\[
f(x, y) := (\mathbf{1}_a(x) - \mathbf{1}_b(x))(\mathbf{1}_c(x) - \mathbf{1}_d(x))
\]

(A.28)

Then, \( \Pi_0 f = \Pi_1 f = 0 \) by symmetry, so \( f \in \mathcal{V}_{[2]} = \mathcal{V}_2 \) (since \( \ell = 2 \)).

Consider the integral operator \( T \) on \( L^2(\mathcal{A} \times [0,1]) \) defined by (A.21). Let \( h \) be an eigenfunction with eigenvalue \( \lambda \neq 0 \), and write \( h_x(t) := h(x, t) \). The eigenvalue equation \( Th = \lambda h \) then is equivalent to, using (A.21) and (A.28),

\[
\lambda h_a(t) = \frac{1}{4} \int_0^1 (h_c(u) - h_d(u)) \, du,
\]

(A.29)

\[
\lambda h_b(t) = \frac{1}{4} \int_0^1 (-h_c(u) + h_d(u)) \, du,
\]

(A.30)

\[
\lambda h_c(t) = \frac{1}{4} \int_0^1 (h_a(u) - h_b(u)) \, du,
\]

(A.31)

\[
\lambda h_d(t) = \frac{1}{4} \int_0^1 (-h_a(u) + h_b(u)) \, du.
\]

(A.32)

These equations hold a.e., but we can redefine \( h_x(t) \) by these equations so that they hold for every \( t \in [0,1] \). Moreover, although originally we assume only \( h_x \in L^2[0,1] \), it follows from (A.29)–(A.32) that the functions \( h_x(t) \) are continuous in \( t \), and then by induction that they are infinitely differentiable on \( [0,1] \). Note also that (A.29) and (A.30) yield \( h_b(t) = -h_a(t) \), and similarly \( h_d(t) = -h_c(t) \). Hence, we may reduce the system to

\[
\lambda h_a(t) = \frac{1}{2} \int_t^1 h_c(u) \, du,
\]

(A.33)

\[
\lambda h_c(t) = \frac{1}{2} \int_0^t h_a(u) \, du.
\]

(A.34)

By differentiation, for \( t \in (0,1) \),

\[
h'_a(t) = -\frac{1}{2\lambda} h_c(t),
\]

(A.35)

\[
h'_c(t) = \frac{1}{2\lambda} h_a(t).
\]

(A.36)

Hence, with \( \omega := 1/(2\lambda) \),

\[
h''_c(t) = -\omega^2 h_c(t).
\]

(A.37)
Furthermore, (A.34) yields \( h_c(0) = 0 \), and thus (A.37) has the solution (up to a constant factor that we may ignore)

\[ h_c(t) = \sin \omega t = \sin \frac{t}{2\lambda}, \quad (A.38) \]

By (A.36), we then obtain

\[ h_a(t) = \cos \omega t = \cos \frac{t}{2\lambda}, \quad (A.39) \]

However, (A.33) also yields \( h_a(1) = 0 \) and thus we must have \( \cos(1/2\lambda) = 0 \); hence

\[ \lambda = \frac{1}{(2N + 1)\pi}, \quad N \in \mathbb{Z}. \quad (A.40) \]

Conversely, for every \( \lambda \) of the form (A.40), the argument can be reversed to find an eigenfunction \( h \) with eigenvalue \( \lambda \). It follows also that all these eigenvalues are simple.

Consequently, Theorem A.4 and (A.19) yield

\[ n^{-1} U_n(f) \xrightarrow{d} \frac{1}{2\pi} \sum_{N=-\infty}^{\infty} \frac{1}{2N + 1} (\zeta_N^2 - 1) = \frac{1}{2\pi} \sum_{N=0}^{\infty} \frac{1}{2N + 1} (\zeta_N^2 - \zeta_{N-1}^2) \quad (A.41) \]

where, as above, \( \zeta_N \) are i.i.d. and \( \mathcal{N}(0,1) \). A simple calculation, using the product formula for cosine \([10, \S 12], [30, 4.22.2]\), shows that the moment generating function of the limit distribution \( Z \) in (A.41) is

\[ E e^{sZ} = \frac{1}{\cos^{1/2}(s/2)}, \quad |\text{Re } s| < \pi. \quad (A.42) \]

It can be shown that \( Z \overset{d}{=} \frac{1}{2} \int_0^1 B_1(t) dB_2(t) \) if \( B_1(t) \) and \( B_2(t) \) are two independent standard Brownian motions; this is, for example, a consequence of (A.42) and the calculation, using [8] or [35, page 445] for the final equality,

\[ E e^{s \int_0^1 B_1(t) dB_2(t)} = E E[e^{s \int_0^1 B_1(t) dB_2(t) | B_1}] = E e^{\frac{1}{2} \int_0^1 B_1(t)^2 dt} = \cos^{-1/2}(s), \quad |\text{Re } s| < \pi/2. \quad (A.43) \]

We omit the details, but note that this representation of the limit \( Z \) is related to the special form (A.28) of \( f \); we may, intuitively at least, interpret \( B_1 \) and \( B_2 \) as limits (by Donsker’s theorem) of partial sums of \( \xi_i - 1_a(\xi_i) \) and \( 1_c(\xi_i) - 1_d(\xi_i) \).

In fact, in this example it is possible to give a rigorous proof of \( n^{-1} U_n(f) \xrightarrow{d} Z \) by this approach; again we omit the details. \( \square \)
