Traveling waves for 2D parabolic Allen-Cahn systems

Ramon Oliver-Bonafoux

June 18, 2021

Abstract

This paper is devoted to the study of the existence of traveling waves $w : [0, +\infty) \times \mathbb{R}^2 \to \mathbb{R}^k$ ($k \geq 2$) for the parabolic Allen-Cahn system
\[
\partial_t w - \Delta w = -\nabla_u V(w) \text{ in } [0, +\infty) \times \mathbb{R}^2,
\]
satisfying some conditions at infinity. The potential $V$ is a non-negative and smooth multi-well potential, meaning its null set is finite and contains at least two elements. We ask $w$ to propagate in one direction with positive speed $c$ and with profile $U$. The pair $(c, U)$ is then expected to solve the resulting entire elliptic system, which is supplemented with some conditions at infinity for $U$. In particular, we ask it to join at infinity (in a suitable sense) two locally minimizing 1D heteroclinics which have different energy. The $c = 0$ case (stationary problem) yields the well-known solution of Alama, Bronsard and Gui (1997) in the situation of two distinct globally minimizing 1D heteroclinics. However, to our knowledge, the non-stationary problem has not been addressed before. In this paper, we show the existence of such a pair $(c, U)$ under the suitable assumptions. In particular, our proof is limited to potentials $V$ which are a suitable small perturbation of those considered for the stationary problem. Our strategy consists on adapting a result of Alikakos and Katzourakis (2011) for curves which take values in a possibly infinite-dimensional Hilbert space and showing that it applies to our initial setting.

1 Introduction

1.1 Main goal

Consider the parabolic system of equations
\[
\partial_t w - \Delta w = -\nabla_u V(w) \text{ in } [0, +\infty) \times \mathbb{R}^2,
\]
where $V : \mathbb{R}^k \to \mathbb{R}$ is a smooth, non-negative, multi-well potential to be defined later and $w : [0, +\infty) \times \mathbb{R}^2 \to \mathbb{R}^k$, with $k \geq 2$. We seek for traveling wave solutions to (1.1). That is, we impose on $w$
\[
\forall (t, x_1, x_2) \in [0, +\infty) \times \mathbb{R}^2, \quad w(t, x_1, x_2) = \Omega(x_1 - ct, x_2),
\]
where $\Omega : \mathbb{R}^2 \to \mathbb{R}^k$ is the profile of the wave and $c > 0$ is the speed of propagation of the wave, which occurs in the $x_1$-direction. Both the profile and the speed are the unknowns of the problem. Replacing in (1.1), we find that the profile $\Omega$ and $c$ must satisfy the equation
\[
-c \partial_{x_1} \Omega - \Delta \Omega = -\nabla_u V(\Omega) \text{ in } \mathbb{R}^2.
\]

This contribution deals with the following question, which will be made precise along the paper:

**Question:** Assuming that there exist two heteroclinic connections with different energy levels, does there exist a solution $(c, \Omega)$ to (1.2) such that $\Omega$ joins the two heteroclinic connections at infinity, uniformly in $x_1$?
Heteroclinic connections are curves \( q : \mathbb{R} \to \mathbb{R}^k \) which solve the equation
\[
q'' = \nabla_u V(q) \quad \text{in } \mathbb{R}
\]
and join two different wells of \( \Sigma \) at \( \pm \infty \). Moreover, one asks that the energy (i.e., the functional associated to the previous equation) is finite. We show that, under the proper assumptions, the question we posed has an affirmative answer. Our motivation comes from two different sides:

1. A question close to the previous one has been addressed in the literature and it is by now well understood. Indeed, for a class of symmetric potentials, Alama, Bronsard and Gui in [2] showed the existence of a stationary wave (that is, a solution to (1.2) with \( c = 0 \)) in the situation such that the two heteroclinics have equal energy levels and are global minimizers. Their analysis was later extended in several papers, which in some cases obtained similar results by means of different techniques. See [11], [13], [14].

2. Under the proper assumptions, equation (1.2) can be seen as an ordinary differential equation with an unbalanced double-well potential for curves taking values in an infinite-dimensional Hilbert space. The existence of traveling-waves for such an ODE in which curves take values on \( \mathbb{R}^k \) was answered positively by Alikakos and Katzourakis in [5].

Therefore, our main contribution is to merge the two previous problems. Essentially, we do so by adapting the analysis of Alikakos and Katzourakis to the infinite-dimensional situation. The results in this paper are limited to the situations in which our problem is a small perturbation of the well understood stationary problem.

1.2 The background of the problem

We will now make our statements more precise. Firstly, recall the following standard conditions for \( V \):

\text{(H1).} \quad V \in C^3(\mathbb{R}^k) \text{ and } V \geq 0 \text{ in } \mathbb{R}^k. \text{ Moreover, } V(u) = 0 \text{ if and only if } u \in \Sigma, \quad \Sigma := \{ \sigma_1, \ldots, \sigma_l \}, \quad \text{with } l \geq 2.

\text{(H2).} \quad \text{There exist } \nu_0, R_0 > 0 \text{ such that } \forall u \in \mathbb{R}^k \setminus B(0, R_0), \quad \langle \nabla_u V(u), u \rangle \geq \nu_0 |u|^2 \text{ and } V(u) \to +\infty \text{ as } |u| \to +\infty.

\text{(H3).} \quad \text{For all } \sigma \in \Sigma, \text{ the matrix } D^2 V(\sigma) \text{ is positive definite.}

As we advanced before, one can consider the functional
\[
E(q) := \int_{\mathbb{R}} e(q(t)) dt := \int_{\mathbb{R}} \left[ \frac{1}{2} |q'(t)|^2 + V(q(t)) \right] dt, \quad q \in H^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^k).
\]

The known properties of the one-dimensional energy \( E \) are summarized in detail in the introduction of [12] and the references therein. We shall only outline the essentials in this introduction. Consider any pair of wells \( (\sigma_i, \sigma_j) \in \Sigma^2 \) and define
\[
X(\sigma_i, \sigma_j) := \left\{ q \in H^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^k) : E(q) < +\infty \text{ and } \lim_{t \to -\infty} q(t) = \sigma_i, \lim_{t \to +\infty} q(t) = \sigma_j \right\}
\]
the set of curves in \( \mathbb{R}^k \) joining \( \sigma_i \) and \( \sigma_j \). The space \( X(\sigma_i, \sigma_j) \) is a metric space when it is endowed with the \( L^2 \) and the \( H^1 \) distances since \( q - \tilde{q} \in H^1(\mathbb{R}, \mathbb{R}^k) \) whenever \( q \) and \( \tilde{q} \) belong to \( X(\sigma_i, \sigma_j) \).

\footnote{In fact, \( X(\sigma_i, \sigma_j) \) is an affine space. We refer again to [12] for more details}
If \( q \) is a critical point of the energy \( E \) in \( X(\sigma_1, \sigma_j) \), we say that \( q \) is an \textit{heteroclinic connection} when \( \sigma_1 = \sigma_j \) and that \( q \) is an \textit{heteroclinic connection} when \( \sigma_1 \neq \sigma_j \). Define as well the corresponding infimum value

\[
m_{\sigma_1, \sigma_j} := \inf \{ E(q) : q \in X(\sigma_1, \sigma_j) \}.
\]  

If \( \sigma^- \) and \( \sigma^+ \) are two distinct wells in \( \Sigma \), it turns out that \( m := m_{\sigma^-, \sigma^+} \) is not attained in general. Nevertheless, if we impose:

\[(H4).\] We have that

\[
\forall \sigma \in \Sigma \setminus \{ \sigma^-, \sigma^+ \}, \quad m < m_{\sigma^-} + m_{\sigma^+}.
\]

Then we have the following result:

\[\text{Theorem 0.1 (13). Assume that } \sigma^- \neq \sigma^+ \text{ are two elements of } \Sigma. \text{ Assume that } (H1), (H2), (H3) \text{ and } (H4) \text{ hold. Then, there exists } q \in X(\sigma^-, \sigma^+) \text{ such that } E(q) = m, \text{ where } m \text{ is as in } (1.3). \text{ Moreover, if } (q_n)_{n \in \mathbb{N}} \text{ is a minimizing sequence in } X(\sigma^-, \sigma^+), \text{ there exists a subsequence (not relabeled) and a sequence } (\tau_n)_{n \in \mathbb{N}} \text{ of real numbers such that } q_n(\cdot + \tau_n) - q \to 0 \text{ strongly in } H^1(\mathbb{R}, \mathbb{R}^k), \text{ for some } \tilde{q} \in X(\sigma^-, \sigma^+) \text{ such that } E(\tilde{q}) = m.\]

The two wells \( \sigma^- \) and \( \sigma^+ \) from Theorem 0.1 will be fixed for the rest of the paper. Theorem 0.1 shows that if we add the \textit{strict triangle’s inequality} assumption \( (H4) \), then the infimum in \( X(\sigma^-, \sigma^+) \) is attained. As a consequence, the set

\[\mathcal{F} := \{ q : q \in X(\sigma^-, \sigma^+) \text{ and } E(q) = m \}, \quad (1.4)\]

is not empty. We term the elements of \( \mathcal{F} \) as \textit{globally minimizing heteroclinics} between \( \sigma^- \) and \( \sigma^+ \). The term \textit{heteroclinics} comes from the fact that \( \sigma^- \) and \( \sigma^+ \) are different. An important fact is that, due to the translation invariance of \( E \), we have that if \( q \in \mathcal{F} \), then for all \( \tau \in \mathbb{R} \) it holds \( q(\cdot + \tau) \in \mathcal{F}. \)

Once the essentials regarding the associated one-dimensional energy \( E \) have been recalled, we now focus on the elliptic system

\[- \Delta u = \nabla u V(\mu) \text{ in } \mathbb{R}^2, \quad (1.5)\]

which can be thought as the limit \( c \to 0 \) of \( (1.2) \). Assuming the existence of two distinct globally minimizing heteroclinics up to translations, \( q_- \) and \( q_+ \), and adding a symmetry assumption on the potential, Alama, Bronsard and Gui [2] showed the existence of a solution \( \mu \) to \( (1.5) \) satisfying the conditions at infinity

\[\begin{align*}
\mu(x_1, x_2) &\to \sigma^\pm \text{ as } x_2 \to \pm \infty, \text{ uniformly in } x_1, \\
\mu(x_1, x_2) &\to q_{\pm}(x_1) \text{ as } x_1 \to \pm \infty, \text{ uniformly in } x_2.
\end{align*} \quad (1.6)\]

The symmetry assumption was later removed by Schatzman in [13]. While the existence proofs in [2] and [13] are (roughly speaking) obtained by adressing directly a functional associated to \( (1.5) \), a more general approach was carried out successfully in the more recent paper by Monteil and Santambrogio [11]. A similar procedure was carried out by Smyrnellis in [14]. Their approach follows from the key observation that \( \mu \) can be seen as a curve in the space

\[Y(q_-, q_+) := \left\{ Q : H_{\text{loc}}^1(\mathbb{R}, X(\sigma^-, \sigma^+), \| \cdot \|_{L^2(\mathbb{R}, \mathbb{R}^k)}) : \lim_{t \to \pm \infty} \| Q(t) - q_\pm \|_{H^1(\mathbb{R}, \mathbb{R}^k)} = 0 \right\}.\]

The previous leads to consider the functional

\[E_2 : Q \in Y(q_-, q_+) \to E_2(Q) := \int_\mathbb{R} \left( \frac{\| Q'(t) \|_{L^2(\mathbb{R}, \mathbb{R}^k)}^2}{2} + Y(Q(t)) \right) dt \in \mathbb{R}, \quad (1.7)\]
where $V : X(\sigma^-, \sigma^+) \to \mathbb{R}$ is the normalized energy

\[ V : q \in X(\sigma^-, \sigma^+) \to E(q) - m \in \mathbb{R}, \]

so that $V$ is a nonnegative functional in $X(\sigma^-, \sigma^+)$ with zero set equal to $\mathcal{F}$. Therefore, $V$ can be thought as a multi-well potential (modulo translations) in an infinite dimensional space. Identifying $Q$ with a function in $H^1_{\text{loc}}(\mathbb{R}^2, \mathbb{R}^k)$ in the obvious way, we rewrite from (1.7)

\[ E_2(Q) = \int_\mathbb{R} \left[ \int_\mathbb{R} \frac{\partial x_1 Q(x_1, x_2)^2}{2} dx_2 
+ \left( \int_\mathbb{R} \left( \frac{\partial x_2 Q(x_1, x_2)^2}{2} + V(Q(x_1, x_2)) \right) dx_2 - m \right] \right] dx_1, \]

so, formally, critical points of $E_2$ in $Y(q_-, q_+)$ are solutions to (1.5) satisfying the conditions at infinity (1.6). In particular, the solution found in [2] is a global minimizer of $E_2$ in $Y(q_-, q_+)$. From this point, the authors in [11] generalize the one-dimensional problem (1.3) for curves defined in infinite dimensional metric spaces. Moreover, the speed $c$ can be seen as the profile for the corresponding evolution equation. More precisely, if $q$ solves (1.8) for some speed $c > 0$ and $\mathbf{w}(t, x) := q(x - ct)$, then

\[ \partial_t \mathbf{w} - \partial_{xx} \mathbf{w} = -\nabla_a W(\mathbf{w}) \text{ in } [0, +\infty) \times \mathbb{R}. \]

The solutions found in [5] solve (1.8) for some speed $c^*$ with conditions at infinity

\[ \lim_{t \to \pm \infty} q(t) = a^\pm. \]

Moreover, the speed $c^*$ is unique, while the profile does not need to be. Their approach follows from an study of the family of functionals

\[ E_c(q) := \int_\mathbb{R} \left( \frac{|q'(t)|^2}{2} + W(q(t)) \right) e^{ct} dt, \]

where $q$ belongs to a suitable subspace in $H^1_{\text{loc}}(\mathbb{R}, \mathbb{R}^k)$ such that $\lim_{t \to \pm \infty} q(t) = a^\pm$. We formally check that critical points of $E_c$ solve (1.8). The strategy of the proof in [5] can be summarized as a constrained minimization problem of $E_c$ with $c > 0$ as a parameter. Once these problems have been shown to have a solution, one need to find the solution for the speed, say $c^*$. Finally, one needs to “remove” the constraints, which follows from showing that constrained minimizers exhibit a suitable asymptotic behavior.

### 1.3 Statement of the main results

To sum up, our approach will be based on a combination of the previous ideas to find a speed and a profile solving the equation (1.2) and connecting as $x_1 \to \pm \infty$ two locally minimizing heteroclinics with different energy levels, one of them globally minimizing. Therefore, we will adapt the result of Alikakos and Katzourakis [2] for curves taking values in an abstract Hilbert space and then deduce our result as a particular case, following the ideas from [11] and [14].

\(^2\text{which they do by a geodesic approach.}\)
1.3.1 Existence

The main assumption is as follows:

**(H5).** Assume that (H1), (H2), (H3) and (H4) hold for the potential $V$. We keep the previous notations. We assume the following:

1. It holds that $\mathcal{F}^- := \{q^- (\cdot + \tau) : \tau \in \mathbb{R}\}$ for some $q^- \in X(\sigma^-, \sigma^+)$, where $\mathcal{F}$ was defined in (1.4). We also set $m^- := m$. 

2. There exists $m^+ > m^-$ and $q^+ \in X(\sigma^-, \sigma^+)$ such that $E(q^+) = m^+$ and $q^+$ is a local minimizer of $E$ with tends to $\sigma^\pm$ at an exponential rate\(^3\). We denote $\mathcal{F}^+ := \{q^+ (\cdot + \tau) : \tau \in \mathbb{R}\}$. 

3. We have the spectral nondegeneracy assumption due to Schatzman ([13]): For all $q \in X(\sigma^-, \sigma^+)$, let $A(q)$ be the unbounded linear operator in $L^2(\mathbb{R}, \mathbb{R}^k)$ with domain $H^2(\mathbb{R}, \mathbb{R}^k)$ defined as

$$A(q) : v \rightarrow -v'' + D^2V(q)v,$$

then, it holds that for any $q \in \mathcal{F}^- \cup \mathcal{F}^+$ we have $\text{Ker}(A(q)) = \{q\}$. 

If (H5) holds, known arguments (see for example [13]), which are a consequence of the spectral assumption, give two constants $\rho_0^+ > 0$ and $\rho_0^-$ such that

\[ \forall q \in L^2_{\text{loc}}(\mathbb{R}, \mathbb{R}^k), \quad \text{dist}_{L^2(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm) \leq \rho_0^\pm \] \[ \Rightarrow \exists ! \tau^\pm(q) \in \mathbb{R} : \|q - q^\pm(\cdot + \tau^\pm(q))\|_{L^2(\mathbb{R}, \mathbb{R}^k)} = \text{dist}_{L^2(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm) \] \[ \text{and for some constant } \beta^\pm \text{ we have} \]

\[ \forall q \in X(\sigma^-, \sigma^+), \quad \text{dist}_{H^1(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm) \leq \rho_0^\pm \Rightarrow \text{dist}_{H^1(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm)^2 \leq \beta^\pm(E(q) - m^\pm). \] (1.10)

That is, we have due to (1.9) and (1.10) precise local information around $\mathcal{F}^-$ and $\mathcal{F}^+$. We will define for $r > 0$ the sets

$$\mathcal{F}^\pm_r := \{q \in L^2_{\text{loc}}(\mathbb{R}, \mathbb{R}^k) : \text{dist}_{L^2(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm) \leq r\}$$ (1.11)

so that we can assume without loss of generality that $\mathcal{F}^+_r \cap \mathcal{F}^-_r = \emptyset$. See Figure 1.1 for an explanatory design of (H5). Let us now assume that we are in a situation which is a perturbation of the balanced case:

**(H6).** Assume that (H5) holds and, moreover,

$$m^+ - m^- < b_{\text{max}}$$

where $b_{\text{max}}$ will be defined later in (1.20). Moreover, assume that

$$\{q \in X(\sigma^-, \sigma^+) : E(q) < m^+\} \subset \mathcal{F}^-_{\rho_0^-/2}$$

with $\mathcal{F}^-_{\rho_0^-/2}$ as in (1.11).

See also Figure 1.2. Essentially, (H6) requires that $m^- - m^+$ is small enough. That is, we can think about a situation which is a suitable small perturbation of the balanced case. If (H6) holds, then we are able to answer the question that we posed at the beginning in a positive way. More precisely, recall the equation of the profile:

$$-c\partial_x^2u - \Delta u = \nabla_u V(u) \text{ in } \mathbb{R}^2$$ (1.12)

\(^3\)this is a well known property for the globally minimizing heteroclinics, as long as the wells of $V$ are nondegenerate.

\(^4\)we have $\mathcal{F}^- \cup \mathcal{F}^+ \subset \psi + H^1(\mathbb{R}, \mathbb{R}^k)$, where $\psi$ is any smooth function in $X(\sigma^-, \sigma^+)$ converging exponentially fast to $\sigma^\pm$ at $\pm \infty$. Such an inclusion due to the fact that $V \in C^2(\mathbb{R}, \mathbb{R})$ and because the elements in $\mathcal{F}^- \cup \mathcal{F}^+$ tend to $\sigma^\pm$ at an exponential rate.
Figure 1.1: Situation described by (H5). The curves correspond to the traces of $q^-$ and $q^+$ as indicated. The shadowed regions correspond to the traces of the functions in $\mathcal{F}^-_{\rho_0}$ and $\mathcal{F}^+_{\rho_0}$, which are a small neighborhood of $\mathcal{F}^-$ and $\mathcal{F}^+$ respectively.

and consider the conditions at infinity

$$\exists L^- \in \mathbb{R}, \forall x_1 \leq L, \quad \Upsilon(x_1, \cdot) \in \mathcal{F}^-_{\rho_0 / 2}, \quad (1.13)$$

$$\exists \tau^+ \in \mathbb{R}, \quad \| \Upsilon(x_1, \cdot) - q^+(\cdot + \tau^+) \|_{H^1(\mathbb{R}, \mathbb{R}^k)} \to 0 \text{ as } x_1 \to +\infty \quad (1.14)$$

Then, the main result writes as follows:

**Theorem 1.** Assume that (H6) holds. Then, there exist $c^* > 0$ and $\Upsilon \in C^2(\mathbb{R}^2, \mathbb{R}^k)$ which fulfill (1.12). Moreover, $\Upsilon$ satisfies (1.13) and (1.14).

Figure 1.2: Representation of (H6). While the larger shadowed region corresponds to $\mathcal{F}^-_{\rho_0 / 2}$, the smaller one which is contained inside represents the set $\{ q \in X(\sigma^-, \sigma^+) : E(q) < m^+ \}$. Moreover, the value $m^+ - m^-$ has to be close to 0.

Notice that assumption (H6) is rather restrictive, as it only deals with perturbations of the stationary case. However, the extension to a more general case seems complicated and the possible assumptions difficult to verify in applications$^5$ contrarily to the perturbation assumption.

$^5$even in the symmetric case.
considered here. We intend to address these issues in a forthcoming work closely related to this one.

**Remark 1.1.** It can be actually shown that if \((c, \Omega)\) is the solution given by Theorem \[1\] then there exists a constant \(b > 0\) such that
\[
\lim_{x_1 \to +\infty} \|\Omega(x_1, \cdot) - q^+(\cdot + \tau^+)\|_{H^1(\mathbb{R}, \mathbb{R}^k)} e^{bx_1} = 0.
\]
That is, the convergence rate at \(+\infty\) is exponential. See Remark \[2.2\] later.

### 1.3.2 Conditions at infinity

Previously, we stated the existence of solutions which satisfy the conditions at infinity \([1.13]\) and \([1.14]\). As we can see, condition \([1.13]\) is rather weak, as it only states that \(\Omega(x_1, \cdot)\) is not far from \(\mathcal{F}^-\) in the \(L^2\) distance when \(x_1\) is small enough. We would rather like to establish a behavior of the type
\[
\exists \tau^- \in \mathbb{R}, \quad \|\Omega(x_1, \cdot) - q^-(\cdot + \tau^-)\|_{H^1(\mathbb{R}, \mathbb{R}^k)} \to 0 \text{ as } x_1 \to -\infty.
\] (1.15)

However, we failed to prove \([1.15]\) without additional assumptions. While \([1.15]\) was established in \([2]\), the infinite-dimensional does not allow to carry out the same argument in general. Nevertheless, we are able to show that \([1.13]\) holds if the speed \(c^*\) is not too large. Since it turns that the speed \(c^*\) is bounded by a quantity depending on \(m^+ - m^-\) as well as the distance between \(\mathcal{F}^-\) and \(\mathcal{F}^+\), our assumption can be written in terms of \(m^+ - m^-\). More precisely, it goes as follows:

- **(H7).** We have that assumption \([H6]\) holds and, additionally:
  \[
m^+ - m^- < \frac{(\delta_0 \mu^-)^2}{2}
\]
  where the constants \(\delta_0\) and \(\mu^-\) are defined later in \([1.18]\) and \([1.19]\) respectively.

Since assumption \([H6]\) is perturbative in nature, the bound required by assumption \([H7]\) is not too restrictive, as at worst one only needs to decrease even more the perturbation considered. The constant \(\delta_0\) essentially depends only on the distance between the sets \(\mathcal{F}^-\) and \(\mathcal{F}^+\), while \(\mu^-\) depends only on local information around \(\mathcal{F}^-\). Anyway, the result given by \([H7]\) writes as follows:

**Proposition 1.1.** Assume that \([H6]\) and \([H7]\) hold. Let \((c^*, \Omega)\) be the solution given by Theorem \[1\]. Then, \(\Omega\) satisfies the stronger condition \([1.15]\).

### 1.3.3 Properties of the speed

It is possible to show that the speed \(c^*\) is unique in some sense as well as to find some formulas to compute it. More precisely, assume that \([H5]\) holds and consider the space
\[
S := \{U \in H^1_{loc}(\mathbb{R}, L^2(\mathbb{R}, \mathbb{R}^k)) : \exists L \geq 1, \forall x_1 \geq L, \ U(x_1, \cdot) \in \mathcal{F}^+_{\rho_0^2/2} \quad \forall x_1 \leq -L, \ U(x_1, \cdot) \in \mathcal{F}^-_{\rho_0^2/2} \}.
\]

For \(U \in S\) and \(c > 0\) we define the energy
\[
E_{2,c}(U) := \int_\mathbb{R} \left( \int_\mathbb{R} \frac{\partial_x U(x_1, x_2)^2}{2} dx_2 + (E(U(x_1, \cdot)) - m^+) e^{c x_1} dx_1. \right.
\]

If \(U \in S\), we can define the translated function \(U^\tau := U(\cdot + \tau, \cdot)\) for \(\tau \in \mathbb{R}\). Then, for all \(c > 0\) we have
\[
E_{2,c}(U^\tau) = e^{-c \tau} E_{2,c}(U)
\]
which implies that
\[
\forall c > 0, \quad \inf_{U \in S} E_{2,c}(U) \in (-\infty, 0].
\]

Notice that, formally, critical points of \(E_{2,c}\) give rise to solutions of \([1.12]\). Moreover, the solutions given by Theorem \[1\] are in fact minimizers of \(E_{2,c^*}\) in \(S\) for the suitable \(c^* > 0\). That is:
Proposition 1.2. Assume that either (H6) holds. Let \((c^*, \Omega)\) be the solution given by Theorem 1. Then, \(\Omega \in S\) and
\[
E_{2,c^*}(\Omega) = 0 = \inf_{U \in S} E_{2,c^*}(U).
\]
The uniqueness result for \(c^*\) writes then as follows:

Proposition 1.3. Assume that (H6) holds. Assume that \(c^* > 0\) is such that
\[
\inf_{U \in S} E_{2,c^*}(U) = 0
\]
and that \(\bar{\Omega} \in S\) is such that \((\bar{c}^*, \bar{\Omega})\) solves (1.12) and \(E_{2,\bar{c}^*}(\bar{\Omega}) < +\infty\). Then, \(\bar{c}^* = c^*\), where \(c^*\) is the speed given by Theorem 1.

In particular, Proposition 1.3 states that \(c^* > 0\) is the unique speed possible for minimizing solutions in \(S\). Finally, we state a result which further characterizes \(c^*\) in case (H7) holds:

Proposition 1.4. Assume that (H6) and (H7) hold. Let \((c^*, \Omega)\) be the solution given by Theorem 1. Then for any \(\tilde{U} \in S\) such that
\[
E_{2,c^*}(\tilde{U}) = 0
\]
we have that \((c^*, \tilde{U})\) solves (1.12) and
\[
c^* = \frac{m^+ - m^-}{\int_{\mathbb{R}^2} |\partial_{x_1} \tilde{U}(x_1, x_2)|^2 dx_2 dx_1}.
\]
(1.16)

In particular, the quantity \(\int_{\mathbb{R}^2} |\partial_{x_1} \tilde{U}(x_1, x_2)|^2 dx_2 dx_1\) is well-defined and constant among this class of minimizing profiles. Moreover, it holds
\[
c^* = \sup\{c > 0 : \inf_{U \in S} E_{2,c}(U) = -\infty\} = \inf\{c > 0 : \inf_{U \in S} E_{2,c}(U) = 0\}
\]
(1.17)
and we have the bound
\[
c^* \leq \sqrt{\frac{2(m^+ - m^-)}{d_0}} < \min\left\{\sqrt{\frac{2b_{\text{max}}}{d_0}}, \frac{\mu^-}{2}\right\}
\]
where \(b_{\text{max}}\), \(d_0\) and \(\mu^-\) will be defined later in (1.20), (1.18) and (1.19) respectively and the second inequality follows from the bound on \(m^+ - m^-\) given by (H6) and (H7).

Remark 1.2. Notice that the conditions at infinity imply that any \(U \in S\) is such that
\[
\int_{\mathbb{R}^2} |\partial_{x_1} U(x_1, x_2)|^2 dx_2 dx_1 > 0
\]
As it can be seen, Proposition 1.4 shows that the speed \(c^*\) is characterized by the explicit formula (1.16), which nevertheless requires knowledge on a profile \(\tilde{U}\). However, one also has the variational characterization (1.17), which does not involve any information on the profiles. Indeed, one only needs to be able to compute the infimum of the energies with \(c > 0\) as a parameter. Moreover, notice that combining (1.17) with Proposition 1.3 we obtain that if \(\bar{c} > c^*\) and \((\bar{c}, \bar{\Omega})\), with \(\bar{\Omega} \in S\), solves (1.12), then \(E_{2,\bar{c}}(\bar{\Omega}) = +\infty\), which is actually a contradiction. On the contrary, if we take \(\bar{c} < c^*\), then (1.17) implies that \(\inf_{U \in S} E_{2,\bar{c}}(U) = -\infty\), meaning that Proposition 1.3 does not apply and nothing else can be said.
1.3.4 Relevant numerical constants of the problem

We will now define some important numerical constants. In particular, this will allow to make assumptions (H6) and (H7) completely precise. Assume first that (H5) holds. Let $\rho_0^\pm$ as in (1.9) and (1.10). Recall that we chose $\rho_0^+$ and $\rho_0^-$ such that

$$\mathcal{F}_\rho^+ \cap \mathcal{F}_\rho^- = \emptyset$$

and, since those two sets (see the definition in (1.11)) are $L^2$-closed due to the local compactness of the sets $\mathcal{F}^-$ and $\mathcal{F}^+$, we have that

$$d_0 := \text{dist}_{L^2}((\rho_0^+/2, \rho_0^-/2))$$

is positive. Therefore, as we advanced before, one can see that the constant $d_0$ depends only on the distance between the two families of minimizing heteroclinics. Next, under (H5), recall the constants $\beta^\pm$ from (1.10). Set

$$\beta^\pm := \frac{1}{2}((\beta^\pm)^2 + (\beta^\pm + 1)^2) > 0$$

and, subsequently

$$\mu^- := \frac{1}{\beta^- + \beta^+} > 0$$

which is the constant appearing in (H7). Of course, the nature of the definition given in (1.19) obeys to technical considerations. But $\mu^-$ should be thought as a small constant depending only on the local behavior of the energy around $\mathcal{F}^-$. Next, assume (H5) and let for $r \in (0, \rho_0^\pm]$

$$\epsilon_r^\pm := \inf \{ E(q) : q \in X(\sigma^- , \sigma^+), \text{dist}_{L^2}(q, \mathcal{F}^\pm) \in [r, \rho_0^\pm] \}.$$ 

Known results which follow from compactness of minimizing sequences (see for instance Schatzman [13]) imply that $\epsilon_r^\pm > 0$. Moreover, we also have that for $r \in (0, \rho_0^\pm]$ there exists $\nu^\pm(r) > 0$ such that

$$\forall q \in \mathcal{F}_\rho^\pm \cap (\rho_0^+/2, \rho_0^-/2), E(q) - m^\pm \leq \nu^\pm(r) \Rightarrow \text{dist}_{H^1}(q, \mathcal{F}^\pm) \leq r.$$ 

This leads to define the constants

$$\delta_0^- := \min \left\{ \frac{1}{4} \sqrt{\frac{e^-}{\rho_0^-}} \sqrt{2(m^- - \rho_0^-/4)}, \frac{1}{4} \right\} > 0,$$

$$\tau^- := \frac{\rho_0^-}{\beta^- + 1} > 0$$

and

$$b_{\text{max}} := \frac{1}{\beta^- + 1} \min \left\{ \frac{\delta_0^2}{4}, \epsilon_0^-, m^-, \nu^-(\tau^-), \nu^-(\eta^-) \right\} > 0$$

which is the constant appearing in (H6). Again, the definition on $b_{\text{max}}$ is essentially due to technical reasons, but it must be thought as a constant which only depends on local information around $\mathcal{F}^-$. Therefore, by perturbing a balanced situation around $\mathcal{F}^+$, it is possible to guarantee that (H6) is satisfied as long as the perturbation is small enough.
1.4 Link with the asymptotic problem

The asymptotic behavior as $\varepsilon \to 0$ for families of solutions $(w_\varepsilon)_{\varepsilon > 0}$ of

$$
\partial_t w_\varepsilon - \Delta w_\varepsilon = -\varepsilon^{-2} \nabla u V(w_\varepsilon), \quad w_\varepsilon : [0, T] \times \Omega \to \mathbb{R}^k
$$

(1.21)

has been extensively studied for bounded domains $\Omega \subset \mathbb{R}^N$ and $T > 0$. Concerning the scalar case $k = 1$, Ilmanen showed in [9] that the equation above converges to Brakke’s motion by mean curvature as $\varepsilon \to 0$. Regarding the vectorial case, while analogous results are established under several additional assumptions, little is proven regarding the general picture. We refer to Bronsard and Reitich [7] as well as the more recent Laux and Simon [10] and the references therein.

A state of the art regarding the elliptic problem can be found in Bethuel [6]. We will now briefly comment on how the results obtained in this paper can be linked to the asymptotic problem introduced above. For $\varepsilon > 0$, consider

$$
w_\varepsilon(t, x_1, x_2) := \Phi_\varepsilon(x_1 - c_\varepsilon t, x_2), \quad \text{for} \quad (t, (x_1, x_2)) \in [0, +\infty) \times \mathbb{R}^2
$$

(1.22)

where for $(\tilde{x}_1, \tilde{x}_2) \in \mathbb{R}^2$

$$
\Phi_\varepsilon(\tilde{x}_1, \tilde{x}_2) := \Phi(\varepsilon^{-1} \tilde{x}_1, \varepsilon^{-1} \tilde{x}_2)
$$

(1.23)

and

$$
c_\varepsilon := \varepsilon^{-1} c.
$$

(1.24)

Combining (1.22), (1.23) and (1.24) we have that for $(t, x_1, x_2) \in [0, +\infty) \times \mathbb{R}^2$

$$
w_\varepsilon(t, x_1, x_2) = \Phi(\varepsilon^{-1} x_1 - \varepsilon^{-2} c t, \varepsilon^{-1} x_2)
$$

(1.25)

and recall that by Theorem [1] we have

$$
-c \partial_{x_1} \Phi - \Delta \Phi = -\nabla u V(\Phi) \, \text{in} \, \mathbb{R}^2
$$

(1.26)

which implies that for all $\varepsilon > 0$

$$
\partial_t w_\varepsilon - \Delta w_\varepsilon = \varepsilon^{-2} (-c \partial_{x_1} \Phi - \Delta \Phi) = -\varepsilon^{-2} \nabla u V(\Phi) \, \text{in} \, [0, +\infty) \times \mathbb{R}^2.
$$

Therefore, for any bounded domain $\Omega \subset \mathbb{R}^2$, $T > 0$ and $\varepsilon > 0$, $w_\varepsilon$ solves (1.21). That is, to sum up, $w_\varepsilon$ is a traveling wave for the re-scaled potential $V_\varepsilon := \varepsilon^{-2} V$, with profile $\Phi_\varepsilon$ as in (1.23) and with speed $c_\varepsilon$ as in (1.24). Notice that $c_\varepsilon \to +\infty$ as $\varepsilon \to 0$. Regarding the asymptotics of $(w_\varepsilon)_{\varepsilon > 0}$, let $\Omega = (-1, 1)^2 \subset \mathbb{R}^2$ for simplification and consider a time interval $[0, T]$, $T > 0$. Assume also that [H7] holds, so that by Proposition [1.1] we have

$$
\lim_{x_1 \to \pm \infty} ||\Phi(x_1, \cdot) - q^+ (\cdot + \tau^+)||_{H^1(\mathbb{R}, \mathbb{R}^k)} = 0.
$$

(1.27)

In combination with (1.25), (1.27) implies that for all $x^+ \in (0, 1)$

$$
\lim_{\varepsilon \to 0} \sup_{x_1 \in [x^+, 1]} \|w_\varepsilon(0, x_1, \cdot) - q^+(\varepsilon^{-1} (\cdot + \tau^+))\|_{L^\infty((-1, 1), \mathbb{R}^k)} = 0
$$

and for all $x^- \in (-1, 0)$

$$
\lim_{\varepsilon \to 0} \sup_{x_1 \in (-1, x^-)} \|w_\varepsilon(0, x_1, \cdot) - q^- (\varepsilon^{-1} (\cdot + \tau^-))\|_{L^\infty((-1, 1), \mathbb{R}^k)} = 0.
$$

Therefore, we find a phase transition on the line $\{(x_1, x_2) \in \mathbb{R}^2 : x_1 = 0\}$, as it happens in the elliptic case with the stationary wave. On the contrary, we find that for any $t_0 > 0$ and $\bar{x} \in (-1, 1) \setminus \{0\}$

$$
\lim_{\varepsilon \to 0} \sup_{t \in [0, T]} \sup_{x_1 \in (-1, \bar{x}) \cup (\bar{x}, 1)} \|w_\varepsilon(t, x_1, \cdot) - q^- (\varepsilon^{-1} (\cdot + \tau^-))\|_{L^\infty((-1, 1), \mathbb{R}^k)} = 0.
$$
That is, for positive time, the solutions tend to look like the globally minimizing heteroclinic at the limit \( \varepsilon \to 0 \) while this is not necessarily true for \( t = 0 \). In terms of the *interfacial density*, the previous means that an initial condition with non-constant density gives a solution with constant density for \( t > 0 \). This phenomenon is probably explained by some kind of parabolic regularization effects. To conclude this paragraph, notice that the considerations presented here are obtained by direct scaling operations. That is, they do not depend on the way \( \Pi \) is obtained. It is only required that \( \Pi \) solves \([1.26]\) with conditions \([1.27]\) and the rest follows by the simple scaling computations.

In particular, the perturbation assumption \([H6]\) is not relevant here and the same assumption would apply to profiles obtained by different means under some other type of assumptions.

### 1.5 Examples of potentials verifying the assumptions

We will now explain a rather general and elementary method for finding potentials for which the assumptions we make in this paper are satisfied. As we advanced before, the idea is to take any given wells \( \sigma^-, \sigma^+ \) in a finite set \( \Sigma \). We also assume that the strict triangle’s inequality \([H4]\) is met. Furthermore, we assume that Schatzman’s spectral assumption \([13]\) is satisfied for those heteroclinics. The idea is to make arbitrary small perturbations of \( V \) with potential \( q^- \) and that \( q^+ \) in \( X(\sigma^-, \sigma^+) \) be such that

\[
E_0(q^-) = E_0(q^+) = m_0 := \inf_{q \in X(\sigma^-, \sigma^+)} E_0(q)
\]

where, for \( q \in H_{loc}^1(\mathbb{R}, \mathbb{R}^k) \)

\[
E_0(q) := \int_\mathbb{R} \left[ \frac{|q'(t)|^2}{2} + V_0(q(t)) \right] dt.
\]

Recall that there exist \( \rho_0^\pm \) such that

\[
\forall q \in X(\sigma^-, \sigma^+), \quad \text{dist}_{H^1(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm) \leq \rho_0^\pm \Rightarrow \text{dist}_{H^1(\mathbb{R}, \mathbb{R}^k)}(q, \mathcal{F}^\pm)^2 \leq \beta^\pm(E(q) - m^\pm)
\]

where

\[
\mathcal{F}^\pm := \{ q^+(\cdot + \tau) : \tau \in \mathbb{R} \}.
\]

Then, one only needs to choose a positive cut-off function \( \chi \in C^1_c(\mathbb{R}^k) \), equal to 1 on a tubular neighbourhood of a portion the trace of \( q^+ \) (away from \( \Sigma \)). Then, one immediately finds that for all \( \delta > 0 \) it holds that

\[
E_\delta(q^+) := \int_\mathbb{R} \left[ \frac{|(q^+)'(t)|^2}{2} + (V_0(q^+(t)) + \delta \chi(q^+(t))) \right] dt = m_0 + O(\delta)
\]

and that \( q^+ \) is locally minimizing in the sense required in \([H5]\). Moreover, *Theorem 4.3 in [13]* shows that the spectral assumption (3. in \([H5]\)) is generic: That is, one can find arbitrarily small perturbations around \( q^- \) which do not modify its energy and such that the spectral assumption is verified. Under these circumstances, we have that the assumptions of Theorem 1 are satisfied with potential \( V_\delta := V_0 + \delta \chi \), provided that \( \delta > 0 \) is chosen small enough so that the perturbation assumption \([H6]\) is met. Notice that the value \( \delta_{\text{max}} \) defined in \([1.20]\) only depends on local information around \( q^- \), meaning that one needs to choose \( \chi \) with a support which does not intersect the neighbourhood of \( q^- \), which is possible. Moreover, up to decreasing the value of \( \delta \) if necessary, we can also suppose that \([H7]\) is fulfilled, so that the profile behaves with the stronger convergence at infinity given by Proposition 1.1.

**Acknowledgments**

I wish to thank my PhD advisor Fabrice Bethuel for bringing this problem into my attention and for many useful comments and remarks during the elaboration of this paper.

2 Strategy of the proofs

As we advanced in the introduction, instead of proving directly Theorem 1 and the associated propositions, we will prove a more general result which will allow us to deduce the previous ones as particular cases. In particular, we will consider an abstract setting, similar to the ones considered in [11] and especially [14]. The proof of the main abstract result (Theorem 2) will be the core of the paper. In this section, we first introduce the notations and state the abstract results (subsection 2.1). Subsequently, we show in subsection 2.2 that the results presented in the introduction are a consequence of the abstract results.

2.1 The abstract results

We will now define the abstract setting and state the main results. As we said before, this should be thought as an extension of the work by Alikakos and Katzourakis [9] to curves taking values in a more general Hilbert space and with minimum sets instead of isolated minimum points. In fact, we essentially perform an adaptation of their strategy of proof, which turns out to carry on to our setting. That is, our approach will consist on establishing existence of a pair \((c, U)\) in \((0, +\infty) \times X\) which fulfills

\[ U'' - D_\mathcal{F} \mathcal{E}(U) = -cU' \text{ in } \mathbb{R} \]  

(2.1)
and satisfies the conditions at infinity

\[ \exists T^- \leq 0 : \forall t \leq T^-, \quad U(t) \in \mathcal{F}^- \quad \text{and} \quad \exists \mathbf{v}^+(U) \in \mathcal{F}^+ : \lim_{t \to -\infty} \|U(t) - \mathbf{v}^+(U)\|_{\mathcal{H}} = 0. \tag{2.2} \]

The nature of the objects introduced before will be made precise along this paragraph. Let \( \mathcal{L} \) be a Hilbert space with inner product \( \langle \cdot, \cdot \rangle_{\mathcal{L}} \) and induced norm \( \|\cdot\|_{\mathcal{L}} \). Let \( \mathcal{H} \subset \mathcal{L} \) a Hilbert space with inner product \( \langle \cdot, \cdot \rangle_{\mathcal{H}} \). In the previous setting, \( \mathcal{L} \) will be \( L^2(\mathbb{R}, \mathbb{R}^k) \) and \( \mathcal{H} \) will be \( H^1(\mathbb{R}, \mathbb{R}^k) \), both endowed with their natural inner products. In the symmetric case, we will take the corresponding symmetric subspaces. We will take \( \mathcal{E} : \mathcal{L} \to (-\infty, +\infty] \) an unbalanced potential. In the setting of Theorem 1, \( \mathcal{E} \) will essentially coincide with \( E - m^+ \) in \( H^1(\mathbb{R}, \mathbb{R}^k) \) and with \( +\infty \) elsewhere. In the abstract setting, we just impose a set of general assumptions on \( \mathcal{E} \). Those assumptions are an adaptation of those in [5] for the infinite-dimensional setting. We will begin by fixing two sets \( \mathcal{F}_- \) and \( \mathcal{F}_+ \) in \( \mathcal{L} \). For \( r > 0 \), we define

\[ \mathcal{F}_+ := \left\{ v \in \mathcal{L} : \inf_{v \in \mathcal{F}_+} \| v - v \|_{\mathcal{L}} \leq r \right\}, \tag{2.3} \]

and

\[ \mathcal{F}_{\mathcal{H}, r} := \left\{ v \in \mathcal{H} : \inf_{v \in \mathcal{F}_+} \| v - v \|_{\mathcal{H}} \leq r \right\}, \tag{2.4} \]

that is, the closed balls in \( \mathcal{L} \) and \( \mathcal{H} \) respectively, with radius \( r > 0 \) and center \( \mathcal{F}_\pm \). The main assumption reads as follows:

(H1'). The potential \( \mathcal{E} \) is weakly lower semicontinuous in \( \mathcal{L} \). The sets \( \mathcal{F}_- \) and \( \mathcal{F}_+ \) are closed in \( \mathcal{L} \). There exists a constant \( a < 0 \) such that

\[ \forall v \in \mathcal{L}, \forall v^- \in \mathcal{F}_- \quad \mathcal{E}(v) \geq \mathcal{E}(v^-) = a \]

and each \( \mathbf{v}^+ \in \mathcal{F}_+ \) is a local minimizer satisfying \( \mathcal{E}(\mathbf{v}^+) = 0 \). Moreover, there exist two positive constants \( r_0^- \), \( r_0^+ \) such that \( \mathcal{F}_{r_0^-} \cap \mathcal{F}_{r_0^+} = \emptyset \) (see (2.3)). There also exist \( C^\pm > 1 \) such that

\[ \forall v \in \mathcal{F}_{r_0^-} \quad \left( C^\pm \right)^{-1} \text{dist}_{\mathcal{L}}(v, \mathcal{F}_\pm)^2 \leq \mathcal{E}(v) - \min\{\pm(a), 0\}. \tag{2.5} \]

Moreover, for any \( v \in \mathcal{F}_{r_0^+} \), there exists a unique \( \mathbf{v}^\pm(v) \in \mathcal{F}_{r_0^+} \) such that

\[ \| v - \mathbf{v}^\pm(v) \|_{\mathcal{L}} = \inf_{\mathbf{v}^\pm \in \mathcal{F}_\pm} \| v - \mathbf{v}^\pm \|_{\mathcal{L}}. \]

Moreover, the projection maps

\[ P^\pm : v \in \mathcal{F}_{r_0^+} \to \mathbf{v}^\pm(v) \in \mathcal{F}_\pm \]

are \( C^2 \) with respect to the \( \mathcal{L} \)-norm.

Hypothesis \([H1']\) defines \( \mathcal{E} \) as an unbalanced double well potential with respect to \( \mathcal{F}_- \) and \( \mathcal{F}_+ \) and gives local information of the minimizing sets. Compare with \([H5]\) and the remarks that follow. We have the following immediate consequence, which will be useful in the sequel:

**Lemma 2.1.** Assume that \([H1']\) holds. If we define for \( r \in (0, r_0^+] \) we define

\[ \kappa^\pm_r := \inf\{\mathcal{E}(v) : \text{dist}_{\mathcal{L}}(v, \mathcal{F}_\pm) \in [r, r_0^+]\} \tag{2.6} \]

then we have \( \kappa^\pm_r > \min\{\pm(a), 0\} \). Moreover,

\[ \forall v \in \mathcal{F}_{r_0^+} \quad \mathcal{E}(v) \geq 0. \tag{2.7} \]

\(^6\)this statement is not exact as the energy \( E \) is not defined in \( H^1(\mathbb{R}, \mathbb{R}^k) \), but on an affine space based on \( H^1(\mathbb{R}, \mathbb{R}^k) \). However, we can trivially obtain a functional defined on \( H^1(\mathbb{R}, \mathbb{R}^k) \) from \( E \). See subsection \( 2.2 \).
Proof. It follows directly from (2.5) in [H1']

We now impose the following regarding the relationship between $\mathcal{L}$ and $\mathcal{H}$:

\textbf{(H2')}. We have that \{ $v \in \mathcal{L} : E(v) < +\infty$ \} is a linear subspace of $\mathcal{L}$. Such a subspace will be denoted as $\mathcal{H}$. Moreover, $\mathcal{H}$ can be endowed with an inner product which gives rise to a norm $\|\cdot\|_{\mathcal{H}}$ which verifies $\|\cdot\|_{\mathcal{L}} \leq \|\cdot\|_{\mathcal{H}}$. Furthermore $E$ is coercive in $\mathcal{H}$ in the following weak sense: there exists a constant $C_\varepsilon$ such that

$$\forall v \in \mathcal{H}, \quad \|v\|_{\mathcal{H}} - \|v\|_{\mathcal{L}} \leq C_\varepsilon(E(v) - a)$$

Moreover, $E$ is a $C^1$ functional on $(\mathcal{H},\|\cdot\|_{\mathcal{H}})$ with differential $DE : v \in \mathcal{H} \rightarrow DE(v) \in \mathcal{H}$ and

$$\forall R > 0, \exists C_\varepsilon(R) > 0, \forall (v,w) \in \mathcal{H}^2 : \|v\|_{\mathcal{H}} \leq R, \quad |DE(v)(w)| \leq C_\varepsilon(R)\|w\|_{\mathcal{H}}.$$  

Finally, there exists an even smaller space $\mathcal{H}'$ with an inner product $(\cdot,\cdot)_{\mathcal{H}'}$ and associated norm $\|\cdot\|_{\mathcal{H}'} \geq \|\cdot\|_{\mathcal{H}}$ such that we can find a continuous correspondence

$$D_{\mathcal{H}}E : v \in (\mathcal{H}',\|\cdot\|_{\mathcal{H}'}) \rightarrow D_{\mathcal{H}}E(v) \in (\mathcal{L},\|\cdot\|_{\mathcal{L}})$$

such that

$$\forall v \in \mathcal{H}', \forall w \in \mathcal{H}, \quad D_{\mathcal{H}}E(v)(w) = D\varepsilon(v)(w),$$

where we have identified the derivative of $E$ with an element of $\mathcal{H}$ via Riesz’s Theorem.

Notice that in the context of Theorem 1 assumption (H2') is easily verified. The space $\mathcal{H}'$ will be chosen $H^2(\mathbb{R},\mathbb{R}^k)$ and (2.11) is no other than integration by parts. We now continue by imposing a compactness assumption on $\mathcal{F}^\pm$:

\textbf{(H3')}. $\mathcal{L}$-bounded subsets of $\mathcal{F}^\pm$ are compact with respect to $\mathcal{H}$-convergence\textsuperscript{7}.

Assumption (H3') readily implies the following:

\textbf{Lemma 2.2.} Assume that (H1') and (H3') hold. Then, the sets $\mathcal{F}^\pm_{r_0/2}$ defined in (2.3) are closed in $\mathcal{L}$.

Assumption (H3') is necessary in order to establish the conditions at infinity. In the main context, it is a straightforward consequence of the compactness of the minimizing sequences. Subsequently, we impose the following:

\textbf{(H4')}. Assume that (H1') holds. Fix $(v,v^\pm) \in \mathcal{F}^\pm_{r_0} \times \mathcal{F}^\pm$. There exist an associated map $P^\pm_{(v,v^\pm)} : \mathcal{L} \rightarrow \mathcal{L}$ such that

$$P^\pm_{(v,v^\pm)}(v) = v^\pm$$  

and

$$\text{dist}_{\mathcal{L}}(P^\pm_{(v,v^\pm)}(v),\mathcal{F}^\pm) = \text{dist}_{\mathcal{L}}(v,\mathcal{F}^\pm).$$

Moreover, $P^\pm_{(v,v^\pm)} : \mathcal{L} \rightarrow \mathcal{L}$ is differentiable and

$$\forall (w_1,w_2) \in \mathcal{L}^2, \quad \|D(P^\pm_{(v,v^\pm)})(w_1,w_2)\|_{\mathcal{L}} = \|w_2\|_{\mathcal{L}}$$

and

$$E(P^\pm_{(v,v^\pm)}(v)) = E(v).$$

Essentially, we impose that the projections $P^\pm$ from (H1') are, in some sense, invertible. Again, this is straightforward in the concrete setting, as the projections $P^\pm$ consist on performing a translation. We now impose an assumption for the sets $\mathcal{F}^\pm_{x_0}$:

\textsuperscript{7}hence, they are in particular compact with respect to $\mathcal{L}$-convergence
(H5'). For any \( v \in \mathcal{F}_{\mathcal{H},r_0^+} \), as defined in (2.4), there exists a unique \( v^\pm_{\mathcal{H}}(v) \in \mathcal{F}_{r_0}^\pm \) such that
\[
\|v - v^\pm_{\mathcal{H}}(v)\|_\mathcal{L} = \inf_{v^\pm \in \mathcal{F}^\pm} \|v - v^\pm\|_\mathcal{L}.
\]
Moreover, the projection maps
\[
P^\pm_{\mathcal{H}} : v \in \mathcal{F}^\pm_{\mathcal{H},r_0^+} \to v^\pm_{\mathcal{H}}(v) \in \mathcal{F}^\pm
\]
are \( C^1 \) with respect to the \( \mathcal{H} \)-norm. Moreover, if \( C^\pm > 1 \) is the constant from (H1') we have
\[
\forall v \in \mathcal{F}^\pm_{\mathcal{H},r_0^+}, \quad \|P^\pm(v) - P^\pm_{\mathcal{H}}(v)\|_\mathcal{H} \leq C^\pm \|v - P^\pm_{\mathcal{H}}(v)\|_\mathcal{H}. \tag{2.16}
\]
Furthermore, for each \( r^\pm \in (0,r_0^+ \} \) there exist constants \( \beta^\pm(r^\pm) > 0 \) such that in case that \( v \in \mathcal{F}^\pm_{r_0^+} \) satisfies
\[
\mathcal{E}(v) \leq \min\{\pm(-a),0\} + \beta^\pm(r^\pm), \tag{2.17}
\]
then \( v \in \mathcal{F}^\pm_{\mathcal{H},r^\pm} \). Finally, we have the following
\[
\forall v \in \mathcal{F}^\pm_{\mathcal{H},r_0^+}, \quad (C^\pm)^{-2}\|v - P^\pm_{\mathcal{H}}(v)\|_\mathcal{H}^2 \leq \mathcal{E}(v) - \min\{\pm(-a),0\} \leq (C^\pm)^2\|v - P^\pm_{\mathcal{H}}(v)\|_\mathcal{H}^2. \tag{2.18}
\]
Assumption (H5') is made in order to ensure the suitable local properties around \( \mathcal{F}^\pm \) in \( \mathcal{H} \).

In the main setting, those are known results which follow essentially from the spectral assumption. Before introducing the last assumptions, we need some additional notation. For \( \mathcal{U} \in H^1_{\text{loc}}(\mathbb{R}, \mathcal{L}) \) and \( c > 0 \), we (formally) define
\[
\mathcal{E}_c(U) := \int_\mathbb{R} \mathcal{E}_c(U)(t)dt := \int_\mathbb{R} \left[ \frac{\|U'(t)\|_\mathcal{L}^2}{2} + \mathcal{E}(U(t)) \right] e^{ct}dt. \tag{2.19}
\]
More generally, for \( I \subset \mathbb{R} \) a non-empty interval and \( \mathcal{U} \in H^1_{\text{loc}}(I, \mathcal{L}) \), put
\[
\mathcal{E}_c(U; I) = \int_I \mathcal{E}_c(U)(t)dt. \tag{2.20}
\]
Notice that the integrals defined in (2.19) and (2.20) might not even make sense in general due to the fact that \( \mathcal{E} \) has a sign. Nevertheless, we can define the notion of local minimizer of \( \mathcal{E}_c(\cdot; I) \) as follows:

**Definition 2.1.** Assume that (H1') and (H2') hold. Let \( I \subset \mathbb{R} \) be a bounded, non-empty interval. Assume that \( \mathcal{U} \in H^1_{\text{loc}}(I, \mathcal{L}) \) is such that \( \mathcal{E}_c(U; I) \) is well-defined and finite. Assume also that there exists \( C > 0 \) such that for any \( \phi \in C^1(\text{int}(I), (\mathcal{H}, \|\cdot\|_\mathcal{H})) \) such that
\[
\max_{t \in I} \|\phi(t)\|_\mathcal{H} < C,
\]
the quantity \( \mathcal{E}_c(U + \phi; I) \) is well defined and larger than \( \mathcal{E}_c(U; I) \). Then, we say that \( \mathcal{U} \) is a local minimizer of \( \mathcal{E}_c(\cdot; I) \).

We assume the following property for local minimizers:

(H6'). Assume that (H1') and (H2') hold. There exists a map \( \mathcal{P} : \mathcal{L} \to \mathcal{L} \) such that
\[
\forall v \in \mathcal{L}, \quad \mathcal{E}(\mathcal{P}(v)) \leq \mathcal{E}(v) \quad \text{and} \quad \mathcal{E}(\mathcal{P}(v)) = \mathcal{E}(v) \Leftrightarrow \mathcal{P}(v) = v, \tag{2.21}
\]
\[
\forall (v_1, v_2) \in \mathcal{L}^2, \quad \|\mathcal{P}(v_1) - \mathcal{P}(v_2)\|_\mathcal{L} \leq \|v_1 - v_2\|_\mathcal{L}, \tag{2.22}
\]
and
\[
\mathcal{P}|_{\mathcal{F}^\pm} = \text{Id}|_{\mathcal{F}^\pm}. \tag{2.23}
\]
Let $I \subset \mathbb{R}$, possibly unbounded and non-empty. Let $c > 0$. If $W \in H^1_{\text{loc}}(I, \mathcal{L})$ is a local minimizer of $E_c(\cdot; I)$ in the sense of Definition 2.1 which, additionally, is such that for all $t \in I$, $W(t) = \mathcal{Q}(W(t))$, then $W \in \mathcal{A}(I)$ where for any open set $O \subset \mathbb{R}$, $\mathcal{A}(O)$ is defined as

$$\mathcal{A}(O) := C^2_{\text{loc}}(O, \mathcal{L}) \cap C^1_{\text{loc}}(O, (\mathcal{H}, ||\cdot||_{\mathcal{H}})) \cap C^0_{\text{loc}}(O, (\mathcal{H}', ||\cdot||_{\mathcal{H}'})$$

and $W$ solves

$$W'' - D_{\mathcal{L}}E(W) = -cW' \text{ in } I,$$

where $D_{\mathcal{L}}E$ was introduced in (2.10). Moreover if $I = (-\infty, t_0)$ for some $t_0 \in \mathbb{R}$ and there exists $v^-(W) \in \mathcal{F}^-$ such that

$$\lim_{t \to -\infty} ||W(t) - v^-(W)||_{\mathcal{F}} = 0,$$

and

$$E(W(\cdot)) = a \in L^1(\mathbb{R})$$

then

$$\lim_{t \to -\infty} ||W(t) - v^-(W)||_{\mathcal{F}} = 0.$$ 

Furthermore, if $I = (t_0, +\infty)$ with $t_0 \in \mathbb{R}$ and for some $v^+(W) \in \mathcal{F}^+$ we have

$$\lim_{t \to +\infty} ||W(t) - v^+(W)||_{\mathcal{F}} = 0,$$

as well as

$$E(W(\cdot)) \in L^1(\mathbb{R})$$

we then have

$$\sup_{t \in [t_0, +\infty)} ||W(t)||_{\mathcal{F}'} + ||W'(t)||_{\mathcal{F}} + ||W''(t)||_{\mathcal{F}} < +\infty.$$ 

In the context of Theorem 1 (H6) is a consequence of classical elliptic regularity results as well as properties on the energy functional. Before stating the abstract result, we introduce the following constants (assuming that all the previous assumptions hold) which obviously coincide with those introduced in subsection 1.3.4.

$$\eta_0^- := \min \left\{ \sqrt{e^{-\frac{r_0}{4}} \frac{2(\kappa^{-}_{r_0}/4 - a)}{\frac{r_0}{4}}} \right\} > 0,$$

$$\hat{r}^- := \frac{r_0^-}{C^- + 1} > 0$$

$$\varepsilon_0^- := \frac{1}{(C^-)^2(C^- + 1)} \min \left\{ \frac{(\eta_0^-)^2}{4} - a, \beta^-(\hat{r}^-), \beta^-(\eta_0^-) \right\} > 0,$$

$$C^\pm := \frac{1}{2} (C^\pm)^2( (C^\pm)^2 + (C^\pm + 1)^2 ) > 0,$$

$$\gamma^- := \frac{1}{C^- + C^-} > 0$$

and

$$d_0 := \text{dist}_{\mathcal{F}'}(\mathcal{F}^+, \mathcal{F}^-) > 0,$$

where the constants $C^-, \beta^-(\hat{r}^-), \beta^-(\eta_0^-)$ are those from (H5) and $\kappa_r^\pm$ for $r > 0$ are defined in (2.6). The fact that $d_0 > 0$ follows from Lemma 2.2 and (H1'). We can finally state the following assumption:
Assume that \((H1')\) and \((H2')\) hold. Moreover, assume that

\[-a < \varepsilon_0^2\]

and

\[
\{ v \in \mathcal{H} : E(v) < 0 \} \subset \mathcal{F}^-_{r_0^2/2}.
\]  \(2.37\)

Assumption \((H7')\) is essentially the abstract version of \((H6)\). Let us next define the space

\[
X := \{ U \in H^1_{\text{loc}}(\mathbb{R}, \mathcal{L}) : \exists T \geq 1, \forall t \geq T, \text{dist}_L(U(t), \mathcal{F}^+) \leq \frac{r_0^2}{2}, \forall t \leq -T, \text{dist}_L(U(t), \mathcal{F}^-) \leq \frac{r_0^2}{2} \}. \]  \(2.38\)

The precise statement is as follows:

**Theorem 2.** Assume that \((H3')\), \((H4')\), \((H5')\), \((H6')\) and \((H7')\) hold. Then, there exists \(c^* > 0\) and \(U \in \mathcal{A}(\mathbb{R}) \cap Z, \mathcal{A}(\mathbb{R})\) as in \((2.24)\), such that \((c^*, U)\) solves \((2.1)\) with conditions at infinity \((2.2)\) and \(U\) is a global minimizer of \(E_c\) in \(X\) (that is, \(E_c(U) = 0\). See Remark 2.1). Moreover, \(c^*\) is unique in the following sense: if \(c^*>0\) is such that \(\inf_{U \in Z} E_c(U) = 0\) and there exists \(U \in \mathcal{A}(\mathbb{R}) \cap X\) such that \((c^*, U)\) solves \((2.1)\) and \(E_c(U) < +\infty\), then \(c^* = c^*\).

**Remark 2.1.** Recall the definition of the constrained set \(X\) in \((2.38)\). Notice that for any \(U \in X\) and \(\tau \in \mathbb{R}\), we have \(U(\cdot + \tau) \in Z\) and for any \(c > 0\) it holds \(E_c(U(\cdot + \tau)) = e^{c\tau}E_c(U)\). Such a thing implies

\[\forall c > 0, \inf_{U \in X} E_c(U) \in \{-\infty, 0\}.\]

Moreover, we see that in case \(c > 0\) is such that \(\inf_{U \in X} E_c(U) = 0\) one can find plenty of examples of minimizing sequences in \(X\) which cannot ever reasonably produce a global minimizer. Indeed, consider any function \(\tilde{U} \in X\) such that \(E_c(\tilde{U}) > 0\) and then take the minimizing sequence \((\tilde{U}(\cdot + n))_{n \in \mathbb{N}}\).

**Remark 2.2.** It can be shown that the rate of convergence of \(U\) to \(v^+(U)\) is exponential. This is exactly Lemma 3.12.

**Remark 2.3.** A more general statement can be given about the uniqueness of the speed, which in particular works for non-minimizing solutions. See Proposition 3.3.

Theorem 2 will be shown to contain Theorem 1 as well as Propositions 1.2 and 1.3. Notice that, as we pointed out before, the conditions at infinity \((2.2)\) are rather weak, since we do not have convergence to an element of \(\mathcal{F}^-\) as \(t \to -\infty\). It is however clear that the conditions at infinity \((2.2)\) are enough to ensure that the solution given by Theorem 2 is not constant. In any case, we can impose an additional assumption in order to obtain stronger conditions at \(-\infty\) on the solution:

**\((H8')\).** Hypothesis \((H7')\) is fulfilled and, additionally:

\[-a < \left(\frac{d_0\gamma^-}{2}\right)^2, \]  \(2.39\)

where \(d_0\) and \(\gamma^-\) were defined in \((2.36)\) and \((2.35)\) respectively.

We can show the following:
Proposition 2.1. Assume that \((H2'), (H3'), (H4'), (H5'), (H6'), (H7') and (H8')\) hold. Then, if \((c^*, U)\) is the solution given by Theorem 2, the function \(U\) satisfies in addition

\[
\lim_{t \to -\infty} \|U(t) - v^-(U)\|_{\mathcal{H}} = 0
\]

for some \(v^-(U) \in \mathcal{F}^-.\)

Proposition 2.1 will be shown to yield Proposition 1.1. Finally, we have:

Proposition 2.2. Assume that \((H2'), (H3'), (H4'), (H5'), (H6'), (H7') and (H8')\) hold. Let \((c^*, U)\) be the solution given by Theorem 2. Then, if \(\tilde{U} \in \mathcal{A}(\mathbb{R}) \cap X\) is such that

\[
E_{c^*}(\tilde{U}) = 0
\]

then we have that \((c^*, \tilde{U})\) solves (2.1) and

\[
c^* = \frac{-a}{\int_{\mathbb{R}} \|\tilde{U}'(t)\|^2_{L^2} dt}.
\]

In particular, the quantity \(\int_{\mathbb{R}} \|\tilde{U}'(t)\|^2_{L^2} dt\) is finite. Moreover, we have

\[
c^* = \sup\{c > 0 : \inf_{U \in X} E_c(U) = -\infty\} = \inf\{c > 0 : \inf_{U \in X} E_c(U) = 0\}
\]

as well as the bound

\[
c^* \leq \frac{\sqrt{-2a}}{d_0} < \min \left\{ \frac{\sqrt{2\varepsilon^-}}{d_0}, \frac{\gamma^-}{2} \right\}
\]

with \(\varepsilon^-\) as in (2.32), \(d_0\) as in (2.36) and \(\gamma^-\) as in (2.35). The second inequality follows from the bounds on \(-a\) given by \((H7')\) and \((H8')\).

Proposition 2.2 corresponds to Proposition 1.3.

2.2 Proving the link between the main setting and the abstract setting

We will essentially show that the abstract results stated before contain the main results considered in the introduction. Such a fact will be guaranteed by the following Lemma:

Lemma 2.3. Assume that \((H5)\) holds. Set

\[
\mathcal{L} := L^2(\mathbb{R}, \mathbb{R}^k), \quad \mathcal{H} := H^1(\mathbb{R}, \mathbb{R}^k), \quad \mathcal{H}' := H^2(\mathbb{R}, \mathbb{R}^k),
\]

and

\[
\forall v \in \mathcal{L}, \quad \mathcal{E}(v) := \begin{cases} E(\psi + v) - m^+ & \text{if } v \in \mathcal{H}, \\ +\infty & \text{otherwise}, \end{cases}
\]

where \(m^+\) was introduced in \((H5)\) and the function \(\psi\) is any smooth function in \(X(\sigma^-, \sigma^+)\) converging to \(\sigma^\pm\) at \(\pm\infty\) at an exponential rate and such that \(\psi' \in H^2(\mathbb{R}, \mathbb{R}^k)\). Under this choice, assumptions \((H1') (H2') (H3') (H4') (H5') and (H6')\) hold. Moreover, we have:

- If \((H6)\) holds, then \((H7)\) holds.
- If \((H7)\) holds, then \((H8)\) holds.
Proof. The fact that the functional
\[ v \in \mathcal{H} \rightarrow E(\psi + v) \]
is well defined and, moreover, is a \( C^1 \) functional on \((\mathcal{H}, \|\cdot\|_{\mathcal{H}})\) is proven in \([12]\). We obviously have \( \mathcal{F}^\pm = \mathcal{F}^\pm - \psi \). We now pass to prove that the assumptions are satisfied.

**Assumption \((H1')\) is satisfied:**
The fact that \( \mathcal{E} \) is weakly lower semicontinuous in \( \mathcal{L} \) was already proven in \([14]\). Nevertheless, we recall the proof for the convenience of the reader. Let \( v \in \mathcal{L} \) and \((v_n)_{n \in \mathbb{N}}\) a sequence in \( \mathcal{L} \) such that \( v_n \rightharpoonup v \). If \( \liminf_{n \rightarrow +\infty} \mathcal{E}(v_n) = +\infty \), there is nothing to prove. Assume then that \( \liminf_{n \rightarrow +\infty} \mathcal{E}(v_n) < +\infty \). Then, up to an extraction, we can suppose that \((\mathcal{E}(v_n))_{n \in \mathbb{N}}\) is bounded. According to \((2.45)\), such a fact implies that \((v_n)_{n \in \mathbb{N}}\) is contained in \( \mathcal{H} \) and \((E(\psi + v_n))_{n \in \mathbb{N}}\) is bounded. Now, classical compactness results (see, for example, \([12]\) for the details) give that
\[ v_n' + \psi' \rightarrow v' + \psi' \]
weakly in \( \mathcal{L} \) and \( v_n + \psi \rightarrow v + \psi \) locally uniformly
which readily implies
\[ E(\psi + v) \leq \liminf_{n \rightarrow +\infty} \mathcal{E}(v_n), \]
due to Fatou’s Lemma and weak lower semicontinuity of the norm in a Hilbert space.

For the rest, set \( \tau_{\pm}^0 := \rho_{0}^\pm \). We already invoked Lemma 2.1 in \([13]\) in Schatzmann so that \((1.9)\)
and \((1.10)\). That is, we have that if
\[ \inf_{\tau \in \mathbb{R}} \|v + \psi - q^\pm(\cdot + \tau)\|_{\mathcal{L}} \leq \tau_{\pm}^0 \]
there a unique \( \tau(v) \in \mathbb{R} \) which attains the infimum in \((2.46)\). Moreover, the correspondence \( v \rightarrow \tau(v) \) defined on the subset of \( \mathcal{L} \) composed of functions that verify \((2.46)\) is of class \( C^2 \).

Therefore, the applications
\[ P^\pm : v \in \mathcal{F}_{\rho_{0}^+/2} \rightarrow q^\pm(\cdot + \tau(v)) - \psi \in \mathcal{F}^\pm, \]
satisfy the properties required.

**Assumption \((H2')\) is satisfied:**
By \((2.44)\), we have that \( \mathcal{H}' \subset \mathcal{H} \subset \mathcal{L} \) and the associated norms verify
\[ \|\cdot\|_{\mathcal{L}} \leq \|\cdot\|_{\mathcal{H}} \leq \|\cdot\|_{\mathcal{H}'} \]
As we pointed out before, \( \mathcal{E} \) restricted to \((\mathcal{H}, \|\cdot\|_{\mathcal{H}})\) is a \( C^1 \) functional. Inequality \((2.8)\) is straightforward. Moreover, as shown in \([12]\), we have that the differential is given by
\[ \forall v \in \mathcal{H}, \quad D\mathcal{E}(v) : w \in \mathcal{H} \rightarrow \int_{\mathbb{R}} \left(\langle \psi' + v', w' \rangle + \langle \nabla V(\psi + v), w \rangle \right) \in \mathbb{R}. \]
We now show that \((2.9)\) holds. For that purpose, let \( R > 0, v \in \mathcal{H} \) such that \( \|v\|_{\mathcal{H}} \leq R \) and \( v \in \mathcal{H} \).
We have that
\[ |D\mathcal{E}(v)(w)| \leq \|v' + v\|_{\mathcal{L}} \|w\|_{\mathcal{L}} + \int_{\mathbb{R}} \langle D^2 V(h)v, w \rangle, \]
where for each \( t \in \mathbb{R} \), \( h(t) \) lies on the segment joining \( v(t) + \psi(t) \) and \( \psi(t) \). Since \( \|v\|_{L^\infty(\mathbb{R}, \mathbb{R}^k)} \leq R \) and \( D^2 V \) is continuous, we have
\[ C_0(R) := \max\{|D^2 V(u)| : u \in \mathbb{R}^k, |u| \leq R + \|\psi\|_{L^\infty(\mathbb{R}, \mathbb{R}^k)}\} < +\infty, \]
which, plugging into \((2.48)\) gives
\[ |D\mathcal{E}(v)(w)| \leq (\|v'\|_{\mathcal{L}} + R) \|w\|_{\mathcal{L}} + C_0(R) R \|w\|_{\mathcal{L}}, \]
so that by taking $C_\mathcal{L}(R) := \|\psi\|_\mathcal{L} + R + C_0(R) R$, (2.48) has been established. Let now $v \in \mathcal{H}$, since $\psi$ is smooth with good behavior at infinity we can integrate by parts to get

$$
\forall w \in \mathcal{H}, \quad D\mathcal{E}(v)(w) = \int_{\mathbb{R}} \left( - (\psi'' + v'') + \nabla V(\psi + v), w \right) = (D\mathcal{L}\mathcal{E}(v), w)_\mathcal{L},
$$

where we have set

$$
D\mathcal{L}\mathcal{E} : v \in (\mathcal{H}, \|\cdot\|_\mathcal{H}) \to -(\psi'' + v'') + \nabla V(\psi + v) \in (\mathcal{L}, \|\cdot\|_\mathcal{L}),
$$

which, by standard arguments, can be shown to be continuous. Notice that (2.11) in (H2') is exactly (2.49) above, which concludes this part of the proof.

**Assumption [H3]** is satisfied:

Let $(v_n^-)_n \in \mathbb{N}$ be a $\mathcal{L}$-bounded sequence in $\mathcal{F}^-$. We want to show the existence of a subsequence of $(v_n^-)_n \in \mathbb{N}$ strongly convergent in $\mathcal{H}$. Since

$$
\mathcal{F}^- = \mathcal{F} - \psi = \{ q^-(\cdot + \tau) - \psi : \tau \in \mathbb{R} \},
$$

we have that $(v_n^-)_n \in \mathbb{N} = (q^- (\cdot + \tau_n) - \psi)_n \in \mathbb{N}$ with $(\tau_n)_n \in \mathbb{N}$ a bounded sequence of real numbers. Since such a sequence is bounded in $\mathcal{L}$, we know that, up to an extraction, there exists $\tilde{v} \in \mathcal{L}$ such that $q^- (\cdot + \tau_n) - \psi \rightharpoonup \tilde{v}$ weakly in $\mathcal{L}$. Due to the weak lower semicontinuity of $\mathcal{E}$, we have that

$$
\mathcal{E}(\tilde{v}) \leq \liminf_{n \to +\infty} \mathcal{E}(q^- (\cdot + \tau_n) - \psi) = a,
$$

which, by minimality, implies that $\mathcal{E}(v) = 0$, that is, $\tilde{v} \in \mathcal{F}^-$. We can then write $\tilde{v} = q^- (\cdot + \tau) - \psi$ for some $\tau \in \mathbb{R}$. Now, notice that, by Theorem 0.1 there exists a sequence $(\tau_n)_n \in \mathbb{N}$ of real numbers such that, up to an extraction

$$
q^- (\cdot + \tau_n + \tau'_n) - q^- \to 0 \text{ strongly in } \mathcal{H},
$$

which necessarily implies that

$$
\tau_n + \tau'_n \to 0
$$

and, since $(\tau_n)_n \in \mathbb{N}$ is bounded, we have that $(\tau'_n)_n \in \mathbb{N}$ is a bounded sequence as well. Therefore, we can assume, up to an extraction, that $\tau'_n \to \tau$. Combining this information with (2.50), we obtain

$$
q^- (\cdot + \tau_n) - q^- (\cdot - \tau - \tau) \to 0 \text{ strongly in } \mathcal{H},
$$

which establishes the claim.

We need to show the same for $\mathcal{F}^+$. The argument is identical to the one above, except for the fact that Theorem 0.1 is replaced by 3. in assumption [H5] and we use that the elements in $\mathcal{F}^+$ are local minimizers (instead of global ones), which does not require any modification of the reasoning.

**Assumption [H4]** is satisfied:

Notice that since the results are local in nature and [H1'] implies that locally the situation does not change between $\mathcal{F}^-$ and $\mathcal{F}^+$, we can treat both cases together. Let $(v, \mathbf{v}^\pm) \in \mathcal{F}^\pm_{\tilde{\alpha}}$. Let $\tau(v)$ be given by the projection map defined in (2.47). We have that $\mathbf{v}^\pm = q^\pm (\cdot + \tau) - \psi$ for some $\tau \in \mathbb{R}$. Define

$$
\hat{P}^\pm_{(v, \mathbf{v}^\pm)} : w \in \mathcal{L} \to w (\cdot - \tau(v) + \tau) - \psi + \psi (\cdot - \tau(v) + \tau) \in \mathcal{L}.
$$

Clearly, using the definition of the projection in (2.47) and $\tau(v)$

$$
\|\hat{P}^\pm_{(v, \mathbf{v}^\pm)}(v) - \mathbf{v}^\pm\|_\mathcal{L} = \|v (\cdot - \tau(v) + \tau) - (q^\pm (\cdot + \tau) - \psi (\cdot - \tau(v) + \tau))\|_\mathcal{L}
$$

$$
= \|v - (q^\pm (\cdot + \tau) - \psi)\|_\mathcal{L} \leq \inf_{\tau \in \mathbb{R}} \|v - (q^\pm (\cdot + \tilde{\tau}) - \psi)\|_\mathcal{L},
$$

20
meaning that
\[ \hat{P}_{(v,v^\pm)}^\pm(v) = v^\pm \]
and
\[ \text{dist}_{\mathcal{L}}(\hat{P}_{(v,v^\pm)}^\pm, \mathcal{F}^\pm) = \text{dist}_{\mathcal{L}}(v, \mathcal{F}^\pm) \]
which are (2.12) and (2.13) respectively. Next, notice that for \((w_1, w_2) \in \mathcal{L}^2 \) and \( h \in \mathbb{R} \) we have
\[ \hat{P}_{(v,v^\pm)}^\pm(w_1 + hw_2) = \hat{P}_{(v,v^\pm)}^\pm(w_1) + hw_2(\cdot - \tau(v) + \tau) \]
so that \( \hat{P}_{(v,v^\pm)}^\pm \) is differentiable and
\[ \forall (w_1, w_2) \in \mathcal{L}^2, \; D(\hat{P}_{(v,v^\pm)}^\pm)(w_1, w_2) = w_2(\cdot - \tau(v) + \tau) \]
so that
\[ \forall (w_1, w_2) \in \mathcal{L}^2, \; \|D(\hat{P}_{(v,v^\pm)}^\pm)(w_1, w_2)\|_{\mathcal{L}} = \|w_2\|_{\mathcal{L}}, \]
which is (2.14). Finally, notice that \( v \in \mathcal{H} \) if and only if \( \hat{P}_{(v,v^\pm)}^\pm \in \mathcal{H} \). Assuming that \( v \in \mathcal{H} \) we have
\[ \mathcal{E}(\hat{P}_{(v,v^\pm)}^\pm(v)) = \mathcal{E}(v(\cdot - \tau(v) + \tau) - \psi(\cdot - \tau(v) + \tau)) \]
\[ = E(v(\cdot - \tau(v) + \tau) + \psi(\cdot - \tau(v) + \tau)) = E(\psi + v) = \mathcal{E}(v) \]
and if \( v \in \mathcal{L} \setminus \mathcal{H} \), we have \( \mathcal{E}(\hat{P}_{(v,v^\pm)}^\pm(v)) = +\infty = \mathcal{E}(v) \). Therefore, (2.15) holds. We have then showed that (H4\textsuperscript{*}) holds.
Assumption (H5\textsuperscript{*}) is satisfied:
Lemma 2.1 in Schatzmann states that for \( v \in \mathcal{H}_{r_0^\pm} \) the problem
\[ \inf_{\tau \in \mathbb{R}} \|v + \psi - q^\pm(\cdot + \tau)\|_{\mathcal{H}} \]
has a unique solution \( \tau_{\mathcal{H}}(v) \in \mathbb{R} \) and the projection map
\[ P_{\mathcal{H}}^\pm : v \in \mathcal{H}_{r_0^\pm} \to q^\pm(\cdot + \tau_{\mathcal{H}}(v)) \in \mathcal{F}^\pm \]
is \( C^1 \) with respect to the \( \mathcal{H} \)-norm. Next, we have that (2.16) is Corollary 2.3 in [13]. Finally, the fact that (2.17) implies (2.18) for the constants \( C^\pm \) (up to possibly increasing) is a consequence of the compactness of the minimizing sequences. See for example Corollary 3.2 in [13].
Assumption (H6\textsuperscript{*}) is satisfied:
We show the existence of the map \( \Psi \). We follow Lemma 3.3 in [13]. Let \( R_0 > 0 \) be the constant from (H2). For \( R \geq R_0 \) define in \( \mathbb{R}^k \)
\[ f_R(u) := \begin{cases} u & \text{if } |u| \leq R, \\ R \frac{u}{|u|} & \text{otherwise,} \end{cases} \]
where \( R_0 \) is the constant from (H2) For \( u \in \mathbb{R}^k \) such that \( |u| \leq R \), we have \( f_R(u) = u \). Assume that \( u \in \mathbb{R}^k \) is such that \( |u| > R \). In that case, there exists \( \xi \in \left( \frac{R}{|u|}, 1 \right) \) such that
\[ V(u) = V(f_R(u)) + \langle \nabla_u V(\xi u), u - f_R(u) \rangle = V(f_R(u)) + \frac{1}{\xi} \left( 1 - \frac{R}{|u|} \right) \langle \nabla_u V(\xi u), \xi u \rangle \]
which, by (H2) implies
\[ \forall R \geq R_0, \forall u \in \mathbb{R}^k : |u| > R, \; V(u) \geq V(f_R(u)) + \frac{1}{\xi} \left( 1 - \frac{R}{|u|} \right) v_0 |\xi u|^2 > V(f_R(u)). \quad (2.51) \]
In particular, we have shown
\[ \forall R \geq R_0, \forall u \in \mathbb{R}^k, \; V(u) \geq V(f_R(u)). \] (2.52)

Next, let \( J \subset \mathbb{R} \) be a compact interval and \( v \in H^1(J, \mathbb{R}^k) \). For \( R \geq R_0 \), consider the function \( v_R := f_R \circ v \). Since we clearly have that for all \( u \in \mathbb{R}^k, |f_R(u)| \leq |u| \), it holds that \( v_R \in L^2(J, \mathbb{R}^k) \). Next, we have that \( f_R \) is the projection onto the closed ball of center 0 and radius \( R \), so that it is a contraction. As a consequence, we have
\[ \forall R \geq R_0, \forall u \in \mathbb{R}^k, \; |Df_R(u)| \leq |u|. \] (2.53)

Therefore, applying the chain rule we obtain
\[ \text{for a. e. } t \in J, \; |v_R'(t)| \leq |v'(t)|, \]
which means that \( v_R \in H^1(J, \mathbb{R}^k) \) and, combining with (2.52) we obtain
\[ E(v_R; J) \leq E(v; J) \] (2.54)
and, by (2.51) the equality above holds if and only if \( v_R = v \). Let now
\[ R_{\text{max}} := 2 \max \{ R_0, \| q^- \|_{L^\infty(\mathbb{R}, \mathbb{R}^k)}, \| q^+ \|_{L^\infty(\mathbb{R}, \mathbb{R}^k)} \}. \]
Consider now the application
\[ \mathfrak{P} : v \in \mathcal{L} \to f_{R_{\text{max}}} \circ (v + \psi) - \psi \in \mathcal{L} \] (2.55)
which is well-defined due to the previous considerations. Moreover, the choice of \( R_{\text{max}} \) implies that \( \mathfrak{P} \) equals the identity on \( \{ q^- (\cdot + \tau) - \psi : \tau \in \mathbb{R} \} \) and \( \{ q^+ (\cdot + \tau) - \psi : \tau \in \mathbb{R} \} \), which is exactly (2.23). Inequality (2.54) gives (2.21). Finally, using (2.53) we have that
\[ \forall (v_1, v_2) \in \mathcal{L}^2, \; \| \mathfrak{P}(v_1) - \mathfrak{P}(v_2) \|_{\mathcal{L}}^2 = \int_{\mathbb{R}} |f_{R_{\text{max}}} \circ (v_1 + \psi) - f_{R_{\text{max}}} \circ (v_2 + \psi)|^2 \]
\[ \leq \int_{\mathbb{R}} \sup_{u \in \mathbb{R}^k} |Df_{R_{\text{max}}}(u)|^2 |v_1 - v_2|^2 \]
\[ \leq \int_{\mathbb{R}} |v_1 - v_2|^2 = \| v_1 - v_2 \|_{\mathcal{L}}^2, \]
which is (2.22). Therefore, our map \( \mathfrak{P} \) satisfies the required properties. Next, let \( \mathbf{W} \) be a local minimizer of \( E_c \). We show that \( \mathbf{W} \) satisfies the desired regularity properties, that is, \( \mathbf{W} \in \mathcal{A}(I) \) with \( \mathcal{A}(I) \) as in (2.24). Write \( \mathbf{W} := \mathbf{W} + \psi \), so that, by classical elliptic regularity arguments, we have that, with the obvious identifications, \( \mathbf{W} \) solves
\[ - c \partial_{x_1} \mathbf{W} - \Delta \mathbf{W} = \nabla_u V(\mathbf{W}) \text{ in } I \times \mathbb{R} \] (2.56)
and for all \( \alpha \in (0, 1) \) we have \( \mathbf{W} \in \mathcal{C}^{1,0}_{\text{loc}}(\mathbb{R}^2, \mathbb{R}^k) \). Moreover, we assume that for all \( t \in I \), \( \mathbf{W}(t) = \mathfrak{P}(\mathbf{W}) \). The definition of \( \mathfrak{P} \) in (2.55) implies that
\[ \forall (x_1, x_2) \in I \times \mathbb{R}, \; \mathbf{W}(x_1, x_2) = f_{R_{\text{max}}} (\mathbf{W}(x_1, x_2)) \]
so that
\[ \| \mathbf{W} \|_{L^\infty(I \times \mathbb{R}, \mathbb{R}^k)} \leq R_{\text{max}}. \] (2.57)
We now fix a compact interval \( I_C \subset I \) so that \( \mathbf{W} \in H^1(I_C, L^2(\mathbb{R}, \mathbb{R}^k)) \). Performing again the proper identifications, we have that (2.56) writes in terms of \( U \) as
\[ - c \partial_{x_1} \mathbf{W} - \Delta \mathbf{W} = \nabla_u V(\mathbf{W}) + \psi'' \text{ in } I \times \mathbb{R}. \] (2.58)
We will show that $W \in H^3(I_C \times \mathbb{R}, \mathbb{R}^k)$ by using a bootstrap argument. Notice that we have that $\psi'' \in H^1(\mathbb{R}, \mathbb{R}^k)$ by assumption and

$$\forall (x_1, x_2) \in I_C \times \mathbb{R}, \quad |\nabla u(V(\mathbf{w}(x_1, x_2)))| = |(D^2\mathbf{w}(h^+(x_1, x_2)), \mathbf{w}(x_1, x_2) + (\psi(x_2) - \sigma^\pm))|,$$

where, for all $(x_1, x_2) \in I_C \times \mathbb{R}$, $h^+(x_1, x_2)$ lies on the segment joining $\mathbf{w}(x_1, x_2)$ and $\sigma^\pm$. Since $I_C$ is compact, we have that $\mathbf{w} \in L^2(I_C \times \mathbb{R}, \mathbb{R}^k)$. For the same reason, and since $\psi - \sigma^\pm \in L^2([0, +\infty))$ and $\psi - \sigma^- \in \mathbb{L}^2((-\infty, 0])$, we have that the inequality above along with the uniform bound (2.57) gives (since $D^2V$ is continuous) that $\nabla_uV(\mathbf{w}(\cdot)) \in L^2(I_C \times \mathbb{R}, \mathbb{R}^k)$. Using (2.58) and $L^2$ elliptic regularity, we obtain that $\mathbf{w} \in H^2(I_C \times \mathbb{R}, \mathbb{R}^k)$. Next, notice that

$$\text{for a. e. } (x_1, x_2) \in I_C \times \mathbb{R}, \forall i \in \{1, 2\}, \quad |\partial_{x_i}(\nabla u(V(\mathbf{w}(x_1, x_2))))| = |(D^2V(\mathbf{w}(x_1, x_2)), \partial_{x_i}\mathbf{w}(x_1, x_2))|$$

and since $\mathbf{w} = \mathbf{w} + \psi$ and $I_C$ is bounded, arguing as before we obtain that $\nabla_u(\mathbf{w}(\cdot)) \in H^1(I_C \times \mathbb{R}, \mathbb{R}^k)$. Using again classical elliptic regularity results, we obtain that $\mathbf{w} \in H^3(I_C \times \mathbb{R}, \mathbb{R}^k)$ as we wanted to show. With the obvious identifications and using the Sobolev embeddings such a thing implies that

$$\mathbf{w} \in C^2(I_C, L^2(\mathbb{R}, \mathbb{R}^k)) \cap C^1(I_C, H^1(\mathbb{R}, \mathbb{R}^k)) \cap C^0(I_C, H^2(\mathbb{R}, \mathbb{R}^k))$$

and since $I_C$ is an arbitrary compact interval contained in $I$, we have that $\mathbf{w} \in \mathcal{A}(I)$. Subsequently, assume that $I = (-\infty, 0]$ for some $x_0 \in \mathbb{R}$ and that there exists $\tau^- \in \mathbb{R}$ such that

$$\lim_{x_1 \to -\infty} \int_{\mathbb{R}} |\mathbf{w}(x_1, x_2) - q^-(x_2 + \tau^-)|^2 dx_2 = 0 \quad (2.59)$$

as well as

$$\int_{-\infty}^{x_0} \int_{\mathbb{R}} (E(\mathbf{w}(x_1, x_2)) - m^-) dx_2 dx_1 < +\infty, \quad (2.60)$$

which are (2.25) and (2.26) respectively. Our goal is to show that, under the previous assumptions, (2.27) holds. Since $q^-$ is a minimizer of the energy, it verifies

$$(q^-(\cdot + \tau^-))'' = \nabla_uV(q(\cdot + \tau^-)) \text{ in } \mathbb{R}$$

which in combination with (2.59) implies

$$\forall (x_1, x_2) \in (-\infty, 0) \times \mathbb{R}, \quad -\Delta g(x_1, x_2) - c\partial_{x_1} g(x_1, x_2)$$

$$= \nabla_uV(\mathbf{w}(x_1, x_2)) - \nabla_uV(q^-(x_2 + \tau^-)), \quad (2.61)$$

where

$$g : (x_1, x_2) \in (-\infty, 0) \times \mathbb{R} \to \mathbf{w}(x_1, x_2) - q^-(x_2 + \tau^-) \in \mathbb{R}^k.$$ 

Notice that by expanding we get

$$\forall (x_1, x_2) \in (-\infty, 0) \times \mathbb{R}, \quad \nabla u(\mathbf{w}(x_1, x_2)) - \nabla u(V(q^-(x_2 + \tau^-)))$$

$$= (D^2V(h(x_1, x_2)), g(x_1, x_2)) \quad (2.62)$$

where, for each $(x_1, x_2) \in (-\infty, 0) \times \mathbb{R}$, $h(x_1, x_2)$ lies on the segment joining $\mathbf{w}(x_1, x_2)$ and $q^-(x_2 + \tau^-)$. Recall the bound (2.57) on $\mathbf{w}$. We also have $\|q^-(\cdot)\|_{L^\infty(\mathbb{R}, \mathbb{R}^k)} < +\infty$ because $q^- \in X(\sigma^-, \sigma^+)$. Therefore, since $\nabla uV$ is continuous, we obtain from (2.62)

$$\forall (x_1, x_2) \in (-\infty, 0) \times \mathbb{R}, \quad |\nabla uV(\mathbf{w}(x_1, x_2)) - \nabla uV(q^-(x_2 + \tau^-))| \leq C_V|g(x_1, x_2)| \quad (2.63)$$

for a constant $C_V > 0$. Decreasing the value of $x_0$ if necessary, (2.59) implies that

$$\forall x_1 \leq x_0, \quad \mathbf{w}(x_1, \cdot) \in \mathcal{F}_{\rho_0}^-$$
and
\[ \lim_{x_1 \to -\infty} \left| \int_\mathbb{R} [\mathbf{W}(x_1, x_2) - q^-(x_2 + \tau^-)]^2 dx_2 - \text{dist}_{L^2(\mathbb{R}, \mathbb{R}^k)}(\mathbf{W}(x_1, \cdot), \mathcal{F}^-) \right| = 0. \]

Therefore, using (1.9) and (1.10) and decreasing the value of \( x_0 \) if necessary, we can show that
\[ \forall x_1 \leq x_0, \quad \int_\mathbb{R} [\mathbf{W}(x_1, x_2) - q^-(x_2 + \tau^-)]^2 dx_2 \leq 2\beta^- \int_\mathbb{R} (\mathbf{E}(\mathbf{W}(x_1, x_2)) - m^-) dx_2, \]
which in combination with (2.59) gives exactly (2.27) and concludes this part of the proof. Subsequently, we have shown that assumption (H6') holds.

Therefore, the purpose of this subsection has been achieved.

If Proposition 2.2 holds, then Proposition 1.4 holds.

If Proposition 2.1 holds, then Proposition 1.1 holds.

If Theorem 2 holds, then Theorem 1 as well as Propositions 1.2, 1.3 hold.

Once Lemma 2.3 has been proven, it is clear that the abstract results are sufficient to deduce the original results. Indeed:

\[ \forall x_1 \leq x_0, \quad \int_\mathbb{R} [\mathbf{W}(x_1, x_2) - q^-(x_2 + \tau^-)]^2 dx_2 \leq 2\beta^- \int_\mathbb{R} (\mathbf{E}(\mathbf{W}(x_1, x_2)) - m^-) dx_2, \]
which in combination with (2.60) implies that \( g \in L^2((\mathbb{R}, x_0) \times \mathbb{R}, \mathbb{R}^k) \). As a consequence, combining equation (2.61), (2.63) and standard \( L^2 \) regularity estimates we obtain that \( g \in H^2((\mathbb{R}, x_0) \times \mathbb{R}, \mathbb{R}^k) \). In particular
\[ \int_{-\infty}^{x_0} (|\partial_{x_2} g(x_1, x_2)|^2 + |\partial_{x_1 x_2} g(x_1, x_2)|^2) dx_2 dx_1 < +\infty \]
which implies that the function
\[ x_1 \in (-\infty, x_0] \to \int_\mathbb{R} |\partial_{x_2} g(x_1, x_2)|^2 dx_2 \in \mathbb{R} \]

belongs to \( H^1((-\infty, x_0]) \). Therefore
\[ \lim_{x_1 \to -\infty} \int_\mathbb{R} |\partial_{x_2} g(x_1, x_2)|^2 dx_2 = 0 \]
which in combination with (2.59) gives exactly (2.27) and concludes this part of the proof. Subsequently, assume that for some \( x_0 \in \mathbb{R} \) we have \( \Gamma = [x_0, +\infty) \) and for some \( \tau^+ \in \mathbb{R} \)
\[ \lim_{x_1 \to +\infty} \int_\mathbb{R} (|\mathbf{W}(x_1, x_2) - q^+(x_2 + \tau^+)|^2 + |\partial_{x_2} \mathbf{W}(x_1, x_2) - q^+(x_2 + \tau^+)|^2) dx_2 = 0, \]
which is (2.28). Assume moreover that
\[ \int_{x_0}^{+\infty} \int_\mathbb{R} (\mathbf{E}(\mathbf{W}(x_1, x_2)) - m^+) dx_2 dx_1 < +\infty \]
which is (2.29). Using the bound (2.57) and classical Schauder regularity, equation (2.56) implies that for all \( \alpha \in (0, 1), \mathbf{W} \in C^{2,\alpha}((x_0, +\infty) \times \mathbb{R}, \mathbb{R}^k) \). This implies that we are under the assumptions of Lemma 2.1 in Fusco [8] and, therefore, it holds that
\[ \forall (x_1, x_2) \in [x_0, +\infty) \times \mathbb{R}, \forall (i, j) \in \mathbb{N}^2 : j + k \leq 2, \]
\[ |\partial_{x_1}^i \partial_{x_2}^j \mathbf{W}(x_1, x_2) - q^+(x_2 + \tau^+)| \leq K_1^+ e^{-K_3^+ |x_2|}, \]
for some constants \( K_1^+ > 0 \) and \( K_2^+ > 0 \). As a consequence, we have
\[ \forall x_1 \in [x_0, +\infty), \forall (j, k) \in \mathbb{N}^2 : i + j \leq 2, \quad \int_\mathbb{R} |\partial_{x_1}^i \partial_{x_2}^j \mathbf{W}(x_1, x_2) - q^+(x_2 + \tau^+)|^2 dx_2 \leq K_3^+ \]
for some \( K_3^+ \). Therefore, we have
\[ \forall (i, j) \in \mathbb{N}^2 : i + j \leq 2, \quad \sup_{x_1 \in [x_0, +\infty)} \int_\mathbb{R} |\partial_{x_1}^i \partial_{x_2}^j \mathbf{W}(x_1, x_2)|^2 dx_2 < +\infty \]
which is exactly (2.30). Therefore, we have shown that assumption (H6') holds.

Assumption (H6') implies (H7'). Immediate.

Assumption (H7') implies (H8'). Immediate. \( \square \)
3 Proof of the abstract results

As pointed out several times, the proofs of the abstract results consist, for a large part, on taking the results from [5] and adapting them for curves taking values in a more general Hilbert space, which introduces an extra difficulty as one needs to deal with two different norms (which should be thought as $L^2$ and $H^1$ for simplification). In fact, we follow more closely subsection 2.6 in the book [4], which slightly modifies the argument in [5]. We will also rely on some arguments provided in [14], when an analogous abstract approach is taken for the stationary problem. An additional difficulty comes from the fact that, due to the requirements of our original problem, we are not joining two isolated minimum points, but two isolated minimum sets, which leads to a non-straightforward modification of the argument even for the finite-dimensional case. However, this difficulty is successfully circumvented if the precise knowledge of some type of projections mappings (namely assumptions (H1), (H4), and (H5)) is available. Along this section, the hypothesis needed in each result are specified in the statement of all the intermediate results since, most of the times, only a smaller set of assumptions needs to be made. We will now briefly sketch the scheme of the proof of Theorem 2. Recall that, according to Remark 2.1, direct minimization of $E_c$ in $X$ cannot yield solutions to the problem, the reason being the action of the group of translations. The spaces $X_T$, which were introduced in [5] (also in Alikakos and Fusco [3] for the equal-depth case) and will be precisely presented in (3.1), are defined in order to overcome this source of degeneracy (they are no longer invariant by the action of the group of translations). See the design in Figure 3.1. As a consequence the corresponding minimization problem has a solution for all $c > 0$ and $T \geq 1$. See Lemma 3.6 later on. In general, minimizers in $X_T$ solve the equation on a proper subset of $\mathbb{R}$ (see Lemma 3.7), meaning that they are not solutions of the original problem. However, such constrained minimizers yield solutions to (2.1) in the case they do not saturate the constraints. Therefore, the goal will be to show the existence of the speed $c^*$ such that, for some $T \geq 1$, there exists a constrained minimizer in $X_T$ which does not saturate the constraints. For that purpose, a careful analysis of the behavior of the constrained minimizers is needed. The precise result is Corollary 3.1. It is at this point when the assumption (H7) is needed. The reason is that one needs a uniform bound (independent on $T$ and $c$) on the distance between the times in which the constrained minimizers enter $F^{\pm}_r$. Assumption (H7) provides this control as the perturbation is chosen small enough so that the energy density of the constrained minimizers is positive in the interval lying between the two times mentioned before. If one does not have the positivity of the energy density, there could exist compensations which would not allow to find the uniform bound. Therefore, removal of this assumption would require additional arguments which, according to the work in [5] and [4], would lead to introduce some convexity assumption on the level sets of $E$. While this assumption was easily verified for the finite-dimensional situation, we believe it to be too restrictive to be applied to the original problem. We try illustrate this issues in a related work in preparation. In any case, after the previous step has been completed, one needs to find the speed $c^*$ as, until this point, the speed $c > 0$ has been only considered as a parameter of the problem without any special role. For that purpose, one introduces a suitable set capturing relevant variational information on the energies $E_c$. The set is $C$, as in (3.85) and one shows (Lemma 3.10) that it is open, bounded, non-empty and that its positive limit points give rise to entire minimizing solutions of the equations (since one can find corresponding constrained minimizers which do not saturate the constraints). The speed $c^*$ is then defined as the supremum of $C$, which is in fact the unique positive limit point of the set, as shown in Corollary 3.3. At this point, the process of the proof of Theorem 2 is completed. Later on, one analyzes the asymptotic behavior of the constrained solutions, which gives Lemmas 3.12 and 3.13. Those results imply, as particular cases, Proposition 2.1. They are also used for proving the Proposition 2.2 which gives more precise information on the speed $c^*$. At this point, the proofs of all the abstract results will be completed.
Figure 3.1: One-dimensional representation of $X_T$. The blue line represents a function $U$ belonging to $X_T$. The red lines contain the points which are at distance smaller than $r_0^+/2$ from $\mathcal{F}^\pm$.

3.1 Preliminaries

Let $r_0^-$ and $r_0^+$ be the constants introduced in subsection 2.1 and $\mathcal{F}_{r_0^+/2}^\pm$ be the corresponding closed balls as in (2.3). Assume that (H1') holds. For $T \geq 1$, we define the sets

$$X_T^- := \left\{ U \in H^1_{loc}(\mathbb{R}, \mathcal{L}) : \forall t \leq -T, U(t) \in \mathcal{F}_{r_0^-/2}^- \right\},$$

$$X_T^+ := \left\{ U \in H^1_{loc}(\mathbb{R}, \mathcal{L}) : \forall t \geq T, U(t) \in \mathcal{F}_{r_0^+/2}^+ \right\},$$

where the constant . Subsequently, we set

$$X_T := X_T^- \cap X_T^+.$$  \hspace{1cm} (3.1)

Recall the space $X$ introduced in (2.38). Notice that $X = \bigcup_{T \geq 1} X_T$.

We have the following preliminary properties on the spaces $X_T$:

**Lemma 3.1.** Assume that (H1') holds. Let $c > 0$ and $T \geq 1$. For any $U \in X_T$, we have that

$$\forall t \geq T, \quad E(U(t)) \geq 0.$$  \hspace{1cm} (3.2)

Moreover, the quantity $E_c(U)$ as introduced in (2.19) is well defined in $(-\infty, +\infty]$.

**Proof.** Let $U \in X_T$. Notice that for $t \geq T$, we have that $U(t) \in \mathcal{F}_{r_0^+/2}^+$. Therefore, (3.2) follows directly from (2.7) in Lemma 2.1. As a consequence, (3.2) follows.

Let now $E^+(U) \geq 0$ and $E^-(U) \geq 0$ be, respectively, the positive and the negative part of $E(U)$, so that $E(U) = E^+(U) - E^-(U)$. Therefore, $E^-(U)$ is null on $[T, +\infty)$. That is

$$\int_{-\infty}^{+\infty} E^-(U(t))e^{ct} \, dt = \int_{-\infty}^{T} E^-(U(t))e^{ct} \, dt \leq \frac{a}{c} e^{CT} < +\infty,$$

where $a$ is the minimum value from (H1'). Therefore, the negative part of the energy density $E_c(U)$ (see (2.19)) belongs to $L^1(\mathbb{R})$, which establishes the result. \hfill $\square$

We now establish convergence properties at $+\infty$ for functions in $X_T$: 

Lemma 3.2. Assume that (H1') and (H5') hold. Let \( c > 0 \) and \( T \geq 1 \). Take \( U \in X_T \) such that \( E_c(U) < +\infty \). Then,

\[
\lim_{t \to +\infty} E(U(t)) = 0 \tag{3.3}
\]

and

\[
\lim_{t \to +\infty} \| U(t) - v^+(U) \|_H = 0 \tag{3.4}
\]

for some \( v^+(U) \in \mathcal{F}^+ \).

Proof. First, notice that the fact that \( U \) has finite energy implies

\[
\int_T^{+\infty} \| U(t) \|_2^2 dt \leq E_c(U) - \int_{-\infty}^T \| U(t) \|_2^2 e^{ct} dt \leq E_c(U) - \frac{a}{c} e^{cT} < +\infty. \tag{3.5}
\]

Due to inequality (3.2) in Lemma 3.1 assuming by contradiction that (3.3) does not hold is equivalent to the existence of an increasing sequence \( (t_n)_{n \in \mathbb{N}} \) in \([T, +\infty)\) and \( l > 0 \) such that

\[
\forall n \in \mathbb{N}, \ E(U(t_n)) \geq l.
\]

Up to an extraction, we can assume that for all \( n \in \mathbb{N} \) we have \( t_{n+1} \geq t_n + 1 \). We have that

\[
\int_{t_n}^{t_{n+1}} E(U(t)) e^{ct} dt \geq \sum_{n \in \mathbb{N}} \int_{t_n}^{t_{n+1}} E(U(t)) e^{ct} dt \geq \sum_{n \in \mathbb{N}} \frac{e^{ct_{n+1}} - e^{ct_n}}{c} \geq \sum_{n \in \mathbb{N}} \frac{(e-1)e^{cT}}{c} = +\infty,
\]

which contradicts (3.5). Therefore, we have shown that (3.3) holds. Such a fact implies

\[
\lim_{t \to +\infty} \text{dist}_H(U(t), \mathcal{F}^+) = 0 \tag{3.6}
\]

by (H5'). We now prove that (3.4) holds. For that purpose, notice that

\[
\int_T^{+\infty} \| U'(t) \|_2^2 dt \leq \int_T^{+\infty} \| U'(t) \|_2^2 e^{ct} dt \leq E_c(U) - \frac{a}{c} e^{cT} < +\infty
\]

which means that \( U \) has a limit at \( +\infty \) as a curve in \( L^2 \). Combining this fact with (3.6) we obtain that there exists \( v^+(U) \in \mathcal{F}^+ \) such that (3.4) holds.

Remark 3.1. Notice that the exponential weight in the energy \( E_c \) implies that we can only say that if \( U \in X_T \) is such that \( E_c(U) \), then \( E(U) \) does not get to \( +\infty \) faster than \( e^{ct} \) at the limit \( t \to -\infty \). That is, almost nothing can be said for generic finite energy solutions regarding their behavior at \( -\infty \).

Lemma 3.1 shows that for any \( T \geq 1 \) and \( c > 0 \), \( E_c \) is well defined as an extended functional on \( X_T \), at least if sufficient hypothesis are made. This result will be often used implicitly along this section. We define the corresponding infimum value

\[
m_{c,T} := \inf_{U \in X_T} E_c(U) \tag{3.7}
\]

We have the following preliminary result:

Lemma 3.3. Assume that (H1') and (H2') hold. Fix \( \hat{v} \in \mathcal{F}^+ \). Let \( c > 0 \) and \( T \geq 1 \). For all \( T \geq 1 \) the function

\[
\Psi(t) := \begin{cases} \hat{v}^- & \text{if } t \leq -1, \\ \frac{1-t}{T} \hat{v}^- + \frac{t+1}{T} \hat{v}^+ & \text{if } -1 \leq t \leq 1, \\ \hat{v}^+ & \text{if } t \geq 1, \end{cases} \tag{3.8}
\]
belongs to $X_T$. Moreover, for all $c > 0$
\[ E_c(\Psi) < +\infty. \] (3.9)
Furthermore, we have
\[ -\infty < m_{c,T} < +\infty. \] (3.10)

Proof. It is clear that $\Psi \in X_T$. We now show that (3.9) holds. Notice first that
\[ \int_{-\infty}^{1} e_c(\Psi) = \int_{-\infty}^{1} a e^{ct} dt = \frac{a}{c} e^{c}, \]
where $a$ is the minimum value from [H1']. Subsequently, we have
\[ \int_{1}^{+\infty} e_c(\Psi) = 0 \]
and
\[ \int_{-1}^{1} e_c(\Psi) = \int_{-1}^{1} \left[ \frac{\|\hat{v}^+ - \hat{v}^-\|^2}{2} + E\left(\frac{1-t}{2} \hat{v}^- + \frac{t+1}{2} \hat{v}^+\right) \right] e^{ct} dt \]
\[ \leq \left[ \frac{\|\hat{v}^+ - \hat{v}^-\|^2}{4} + 2 \max_{t \in [-1,1]} E\left(\frac{1-t}{2} \hat{v}^- + \frac{t+1}{2} \hat{v}^+\right) \right] e^{c} - e^{-c} \]
and we have
\[ \max_{t \in [-1,1]} E\left(\frac{1-t}{2} \hat{v}^- + \frac{t+1}{2} \hat{v}^+\right) < +\infty, \]
by [H2']. Therefore, we have obtained $E_c(\Psi) < +\infty$, which readily implies that $m_{c,T} < +\infty$ and
\[ m_{c,T} < +\infty. \]
In order to establish (3.10), we still need to show that $m_{c,T} > -\infty$. For that purpose, let $U \in X_T$. By (3.2) in Lemma 3.1, we have
\[ \int_{T}^{+\infty} e_c(U) \geq 0. \]
We also have
\[ \int_{-\infty}^{T} e_c(U) \geq \int_{-\infty}^{T} a e^{ct} dt = \frac{a}{c} e^{cT}. \]
That is
\[ \forall U \in X_T, \quad E_c(U) \geq \frac{a}{c} e^{cT} > -\infty, \]
which means that $m_{c,T} > -\infty$. \qed

The next goal will be to show that, under the proper assumptions, we have that for any $c > 0$ and $T \geq 1$, the infimum values defined in (3.7) are attained. Such a fact is not hard to prove since the constraints that define the spaces $X_T$ allow to restore compactness. It relies on some properties that will be proven in the next subsection.

3.2 Two (semi-)continuity results

We now provide some results which address continuity and semicontinuity properties of the energies $E_c$ in the spaces $X_T$. Such properties will allow us to show that the infimum values defined in (3.7) are attained under the proper assumptions. They will be also be useful in a more advanced stage of the proof, when the constrains will be removed. For now, we essentially adapt some results from [5] to our setting.

Our first result is essentially Lemma 26 in [5]:
Lemma 3.4. Assume that (H1') holds. Fix $T \geq 1$ and $U \in X_T$. Consider the set

$$A_{T,U} := \{c > 0 : E_c(U) < +\infty\}.$$

Then, if $c \in A_{T,U}$, then $(0, c] \subset A_{T,U}$. Moreover, the correspondence

$$c \in A_{T,U} \to E_c(U) \in \mathbb{R}$$

is continuous.

Proof. Let $c \in A_{T,U}$. On the one hand, inequality (3.2) in Lemma 3.1 gives

$$0 \leq \int_T^{+\infty} e_c(U(t)) dt \leq E_c(U) - \int_{-\infty}^T \mathcal{E}^{-}(U(t))e^c dt \leq E_c(U) - ae^{cT} < +\infty,$$

which implies that a.e. in $(T, +\infty)$

$$0 \leq e_c(U(\cdot)) \in L^1((T, +\infty)).$$

Therefore, if $c' \leq c$ we have that a.e. in $(T, +\infty)$

$$0 \leq e_c(U(\cdot)) \leq e_{c'}(U(\cdot)) \in L^1(T, +\infty). \quad (3.11)$$

On the other hand,

$$\int_{-\infty}^T |e_c(U(t))| dt \leq E_c(U) + 2ae^{cT} < +\infty$$

because $e_c(U(\cdot))$ is nonnegative a.e. in $[T, +\infty)$. The previous inequality shows

$$|e_c(U(\cdot))| \in L^1((-\infty, T)),$$

and we have that a.e. in $(-\infty, T)$

$$|e_{c'}(U(\cdot))| \leq |e_c(U(\cdot))| \in L^1((-\infty, T)). \quad (3.12)$$

Combining (3.11) and (3.12), we obtain that $|e_c(U(\cdot))| \in L^1(\mathbb{R})$, meaning that $c' \in A_{T,U}$. Hence, we have $(0, c] \subset A_{T,U}$ as we wanted to show.

Consider now a sequence $(c_n)_{n \in \mathbb{N}}$ in $A_{T,U}$ such that $c_n \to c_\infty \in A_{T,U}$. The sequence $(c_n)_{n \in \mathbb{N}}$ is convergent (so in particular it is bounded), meaning that in case it does not attain its sup we must have $c_\infty = \sup_{n \in \mathbb{N}} c_n$. Therefore, we can set

$$\hat{c} := \begin{cases} c_\infty & \text{if } c_\infty = \sup_{n \in \mathbb{N}} c_n, \\ \max_{n \in \mathbb{N}} c_n & \text{otherwise}, \end{cases}$$

and we obviously have $\hat{c} \in A_{T,U}$. As a consequence, (3.11) and (3.12) imply that a.e. in $\mathbb{R}$

$$\forall n \in \mathbb{N}, \quad |e_{c_n}(U(\cdot))| \leq |e_{c}(U(\cdot))| \in L^1(\mathbb{R}).$$

Since we also have $e_{c_n}(U(\cdot)) \to e_{c_\infty}(U(\cdot))$ pointwise a.e. in $\mathbb{R}$, the Dominated Convergence Theorem gives the result.

We now show a lower semicontinuity result, which in particular will imply the existence of the constrained solutions:
Lemma 3.5. Assume that \((H1')\), \((H3')\) and \((H4')\) hold. Let \(T \geq 1\) be fixed. Let \((U_n^i)_{n \in \mathbb{N}}\) be a sequence in \(X_T\) and \((c_n)_{n \in \mathbb{N}}\) a convergent sequence of positive real numbers such that
\[
\sup_{n \in \mathbb{N}} E_{c_n}(U_n^i) < +\infty.
\]
Then, there exists a sequence \((U_n)\) in \(X_T\) and \(U_\infty \in X_T\) such that up to extracting a subsequence in \((U_n, c_n)_{n \in \mathbb{N}}\) it holds
\[
\forall n \in \mathbb{N}, \quad E_{c_n}(U_n) = E_{c_n}(U_n^i), \quad (3.13)
\]
\[
\forall t \in \mathbb{R}, \quad U_n(t) \rightharpoonup U_\infty(t) \quad \text{weakly in } \mathcal{L} \quad (3.14)
\]
\[
U_n' e^{c_n t} \rightharpoonup U'_\infty e^{c_\infty t} \quad \text{weakly in } L^2(\mathbb{R}, \mathcal{L}) \quad (3.15)
\]
and
\[
E_{c_\infty}(U_\infty) \leq \liminf_{n \to \infty} E_{c_n}(U_n), \quad (3.16)
\]
where \(c_\infty := \lim_{n \to \infty} c_n\).

Proof. Denote \(M := \sup_{n \in \mathbb{N}} E_{c_n}(U_n^i)\), which is finite by \((3.5)\). Fix any \(v^+ \in \mathcal{F}^+\) and for all \(n \in \mathbb{N}\) set \(v_n := U_n^i(T) \in \mathcal{F}^+\). Define
\[
U_n : t \in \mathbb{R} \to \hat{P}_{(v_n, v^+)}(U_n^i(t)),
\]
where \(\hat{P}_{v^+}\) was the differentiable operator introduced in \((H4')\). We apply the properties summarized in \((H4')\) Notice that for all \(n \in \mathbb{N}\) we have \(U_n \in X_T\) due to \((2.13)\). The energy equality \((3.13)\) follows from \((2.14)\) and \((2.15)\). Moreover, \((2.12)\) implies that
\[
\forall t \geq T, \quad P^+(U_n(t)) = P^+\left(\hat{P}_{(v_n, v^+)}(U_n^i(t))\right) = P^+\left(\hat{P}_{(v_n, v^+)}(v_n)\right) = v^+,
\]
which in particular means
\[
\forall n \in \mathbb{N}, \forall t \geq T \quad ||U_n(t) - v^+||_{\mathcal{L}} \leq \frac{r_0^+}{2}. \quad (3.17)
\]
Notice now that \(E(U(\cdot))\) is nonnegative in \([T, +\infty)\) as \(U \in X_T\) by \((3.2)\) in Lemma 3.1, therefore
\[
\forall n \in \mathbb{N}, \quad \int_{\mathbb{R}} \|U_n'(t)e^{c_n t}\|_{\mathcal{L}} dt \leq M - \int_{\mathbb{R}} E(U_n(t)) e^{c_n t} dt \leq M - \int_{-\infty}^{T} E(U_n(t)) e^{c_n t} dt \leq M - \frac{a}{c} e^{cT} < +\infty. \quad (3.18)
\]
That is, we have that \((U_n'e^{c_n t/2})_{n \in \mathbb{N}}\) is uniformly bounded in \(L^2(\mathbb{R}, \mathcal{L})\). Therefore, there exists \(\hat{U} \in L^2(\mathbb{R}, \mathcal{L})\) such that
\[
U_n'e^{c_n t/2} \rightharpoonup \hat{U} \quad \text{weakly in } L^2(\mathbb{R}, \mathcal{L}) \quad (3.19)
\]
up to subsequences. Such a thing implies
\[
\int_{\mathbb{R}} \|\hat{U}(t)\|^2_{\mathcal{L}} dt \leq \liminf_{n \to \infty} \int_{\mathbb{R}} \|U_n'(t)e^{c_n t}\|^2_{\mathcal{L}} dt. \quad (3.20)
\]
Now, notice that by \((3.17)\) we have that \((U_n(T))_{n \in \mathbb{N}}\) is bounded in \(\mathcal{L}\). Therefore, up to an extraction there exists \(v_\infty \in \mathcal{L}\) such that
\[
U_n(T) \rightharpoonup v_\infty \quad \text{in } \mathcal{L}. \quad (3.21)
\]
As in \([14]\), we point out that
\[
\forall t \in \mathbb{R}, \forall n \in \mathbb{N}, \quad U_n(t) = U_n(T) + \int_{T}^{t} U_n'(s) ds.
\]
Now, notice that for all \( t \in \mathbb{R} \) we have \( 1_{(0,t)}e^{-ct_{Id}/2} \to 1_{(0,t)}e^{-c_{Id}/2} \) in \( L^\infty(\mathbb{R}) \), where \( 1 \) states for the indicator function of a set. Therefore, we obtain by (3.19) and (3.21)

\[
\forall t \in \mathbb{R}, \quad U_n(t) \to U_\infty(t) := v_\infty + \int_T^t U(s)e^{-c_{Id}/2}ds,
\]

which gives (3.14). Moreover, we have that \( U_\infty \in H^1_{\text{loc}}(\mathbb{R}, \mathcal{L}) \) and \( U'_\infty = \bar{U}e^{-c_{Id}/2} \), meaning by (3.19) that (3.15) also holds.

Recall now that \( \mathcal{E} \) is lower semicontinuous on \( \mathcal{L} \) by [H1'] so that (3.14) gives

\[
\forall t \in \mathbb{R}, \quad \mathcal{E}(U_\infty(t)) \leq \liminf_{n \to \infty} \mathcal{E}(U_n(t)). \tag{3.22}
\]

We need to show that \( U_\infty \in X_T \) and to establish the inequality (3.16).

- We begin by showing that \( U_\infty \in X_T \). We need to show that for all \( t \in [T, +\infty) \), it holds \( U_\infty(t) \in \mathcal{F}^+_{r_0^t/2} \) and similarly for \( (-\infty, -T] \). Fix \( t \in [T, +\infty) \). We have that \( U_n(t) \in \mathcal{F}^+_{r_0^t/2} \), so we can define the sequence \( (v_n^+(t))_{n \in \mathbb{N}} \) in \( \mathcal{F}^+ \) as \( v_n^+(t) := P^+(U_n(t)) \). We show that such a sequence is bounded. Indeed, we have

\[
\forall n \in \mathbb{N}, \quad \|v_n^+(t)\|_{\mathcal{L}} \leq \frac{r_0^t}{2} + \|u_n(t)\|_{\mathcal{L}}
\]

and \( (U_n(t))_{\mathcal{L}} \) converges weakly in \( \mathcal{L} \), so in particular it is bounded. Therefore, up to an extraction we can assume that \( v_n^+(t) \rightharpoonup v_\infty^+(t) \in \mathcal{L} \) and by [H3'] we have \( v_\infty^+(t) \in \mathcal{F}^\pm \).

Using now the convergence properties we get the inequality

\[
\|U_\infty(t) - v_\infty^+(t)\|_{\mathcal{L}} \leq \liminf_{n \to \infty} \|U_n(t) - v_n^+(t)\|_{\mathcal{L}} \leq \frac{r_0^t}{2},
\]

so that \( U_n(t) \in \mathcal{F}^+_{r_0^t/2} \). An identical argument shows that for all \( t \in (-\infty, -T] \) we have \( U_n(t) \in \mathcal{F}^-_{r_0^t/2} \). Therefore, we have shown that \( U_\infty \in X_T \).

- Next, we prove (3.16). We have

\[
\sup_{n \in \mathbb{N}} \int_\mathbb{R} \mathcal{E}(U_n(t))e^{ct}dt \leq M - \sup_{n \in \mathbb{N}} \int_\mathbb{R} \frac{\|U'_n(t)\|_{\mathcal{L}}^2}{2} e^{ct}dt < +\infty,
\]

by (3.18). Hence, we can apply Fatou’s Lemma to \( (t \in \mathbb{R} \to \mathcal{E}(U_n(t))e^{ct})_{n \in \mathbb{N}} \) (a sequence of functions uniformly bounded below by a) to show

\[
\int_\mathbb{R} \liminf_{n \to +\infty} \mathcal{E}(U_n(t))e^{ct}dt \leq \liminf_{n \to +\infty} \int_\mathbb{R} \mathcal{E}(U_n(t))e^{ct}dt,
\]

which, combined with (3.22) implies

\[
\int_\mathbb{R} \mathcal{E}(U_\infty(t))e^{ct}dt \leq \liminf_{n \to +\infty} \int_\mathbb{R} \mathcal{E}(U_n(t))e^{ct}dt. \tag{3.23}
\]

Combining (3.20) and (3.23) we get

\[
\mathcal{E}(U_\infty) \leq \liminf_{n \to +\infty} \int_\mathbb{R} \frac{\|U'_n(t)\|_{\mathcal{L}}^2}{2} e^{ct}dt + \liminf_{n \to +\infty} \int_\mathbb{R} \mathcal{E}(U_n(t))e^{ct}dt,
\]

which, by superadditivity of the limit inferior gives (3.16).
3.3 Existence of an infimum for \( E_c \) in \( X_T \)

The goal now is to show that, for \( T \geq 1 \) and \( c > 0 \) fixed, the infimum \( m_{c,T} \) as defined in (3.7) is attained by a function in \( X_T \). This will actually follow easily from Lemma 3.5.

**Lemma 3.6.** Assume that \([H1'], [H2'], [H3']\) and \([H4']\) hold. Let \( c > 0 \), \( T \geq 1 \) and \( m_{c,T} \) be as in \((3.7)\). Then, \( m_{c,T} \) is attained for some \( U_{c,T} \in X_T \).

**Proof.** By (3.10) in Lemma 3.3, we have that there exists a minimizing sequence \((U_n)_{n \in \mathbb{N}}\). We apply Lemma 3.5 to \((U_n)_{n \in \mathbb{N}}\) and the sequence of speeds constantly equal to \( c \). We obtain a function \( U_{c,T} \in X_T \) such that

\[
E_c(U_{c,T}) = \lim_{n \to \infty} E_c(U_n) = m_{c,T},
\]

due to (3.16). Therefore, \( m_{c,T} \) is attained by \( U_{c,T} \in X_T \). □

Subsequently, we show that assumptions \([H6']\) implies that the constrained minimizers are solutions of the equation in a certain set containing \((-T,T)\), with the proper regularity.

**Lemma 3.7.** Assume that \([H6']\) holds. Let \( c > 0 \), \( T \geq 1 \) and \( m_{c,T} \) be as in \((3.7)\). Let \( U_{c,T} \in X_T \) be such that \( E_c(U_{c,T}) = m_{c,T} \). Then, \( U_{c,T} \in A((-T,T)) \) as in (2.24) and

\[
U''_{c,T} - D_x E(U_{c,T}) = -cU'_{c,T} \text{ in } (-T,T).
\]

Moreover, if \( t \geq T \) is such that

\[
\text{dist}_x(U_{c,T}(t), \mathcal{F}^+) < \frac{r_0}{2},
\]

then, there exists \( \delta^+(t) > 0 \) such that \( U_{c,T} \in A((t - \delta^+(t), t + \delta^+(t))) \) and

\[
U''_{c,T} - D_x E(U_{c,T}) = -cU'_{c,T} \text{ in } (t - \delta^+(t), t + \delta^+(t)).
\]

Similarly, if \( t \leq -T \) is such that

\[
\text{dist}_x(U_{c,T}(t), \mathcal{F}^-) < \frac{r_0}{2},
\]

then, there exists \( \delta^-(t) > 0 \) such that \( U_{c,T} \in A((t - \delta^-(t), t + \delta^-(t))) \) and

\[
U''_{c,T} - D_x E(U_{c,T}) = -cU'_{c,T} \text{ in } (t - \delta^-(t), t + \delta^-(t)).
\]

**Proof.** We first show that

\[
\forall t \in \mathbb{R}, \quad \mathcal{P}(U_{c,T}(t)) = U_{c,T}(t),
\]

where \( \mathcal{P} \) is the map from \([H6']\) We claim that the function

\[
U_{c,T}^\mathcal{P} : t \in \mathbb{R} \to \mathcal{P}(U_{c,T}(t))
\]

belongs to \( X_T \). Indeed, this follows from (2.22) and (2.23). Property (2.21) implies that

\[
\forall t \in \mathbb{R}, \quad E(U_{c,T}^\mathcal{P}(t)) \leq E(U_{c,T}(t)).
\]

Take now \( t \in \mathbb{R} \) and \( s \in \mathbb{R} \setminus \{t\} \). Property (2.22) implies that

\[
\left\| \frac{U_{c,T}^\mathcal{P}(t) - U_{c,T}^\mathcal{P}(s)}{t - s} \right\|_{\mathcal{P}} \leq \left\| \frac{U_{c,T}(t) - U_{c,T}(s)}{t - s} \right\|_{\mathcal{P}},
\]

which, by Lebesgue’s differentiation Theorem implies that

\[
\text{for a.e. } t \in \mathbb{R}, \quad \| (U_{c,T}^\mathcal{P})'(t) \|_{\mathcal{P}} \leq \| U'_{c,T}(t) \|_{\mathcal{P}}.
\]

(3.30)
By contradiction, assume now that there exists \( t \in \mathbb{R} \) such that \( U_{c,T}(t) \neq \mathcal{P}(U_{c,T}(t)) = U_{c,T}^{\mathcal{P}}(t) \). Property (2.22) implies that \( \mathcal{P} \) is a \( \mathcal{L} \)-continuous map. Therefore, since \( U_{c,T} \) is also \( \mathcal{L} \)-continuous, we must have that for some non-empty interval \( I_t \ni t \), it holds

\[
\forall s \in I_t, \quad U_{c,T}(s) \neq \mathcal{P}(U_{c,T}(s)) = U_{c,T}^{\mathcal{P}}(s),
\]

so that, using (2.21) we get

\[
\forall s \in I_t, \quad \mathcal{E}(U_{c,T}^{\mathcal{P}}(s)) < \mathcal{E}(U_{c,T}(s))
\]

so that, combining with (3.29) and (3.30) we obtain

\[
E_c(U_{c,T}^{\mathcal{P}}) < E_c(U_{c,T}) = m_{c,T},
\]

which contradicts the definition of \( m_{c,T} \) since \( U_{c,T}^{\mathcal{P}} \in X_T \). Therefore, we have shown that (3.28) holds. Next, notice that

\[
\left[\begin{array}{l}
\mathcal{E}(U_{c,T};[-T, T]) \\
\mathcal{E}(U_{c,T};[-T, T]) = \mathcal{E}(U_{c,T} + \phi)
\end{array}\right]
\]

and for any \( \phi \in C^1_c((-T, T), (\mathcal{M}, \|\|_{\mathcal{M}})) \) we have \( U_{c,T} + \phi \in X_T \), so that \( E_c(U_{c,T}) \leq E_c(U_{c,T} + \phi) \). Therefore, the restriction of \( U_{c,T} \) in \((-T, T)\) is a local minimizer of \( E_c(\cdot, [-T, T]) \) in the sense of Definition 2.1. Since \( U_{c,T} \) also verifies (3.28), we can apply the regularity assumption (H6'). Therefore, \( U_{c,T} \in \mathcal{A}((-T, T)) \) and (3.24) holds. Assume now that there exists \( t \geq T \) such that (3.25) holds. Then, there exists \( v^+(t) \in \mathcal{F}^+ \) such that

\[
\|U_{c,T}(t) - v^+(t)\|_{\mathcal{L}} < \frac{r_0^+}{2}
\]

which, since \( U_{c,T} \) is \( \mathcal{L} \)-continuous, implies that there exists \( \delta^+(t) > 0 \) such that

\[
\forall s \in (t - \delta^+(t), t + \delta^+(t)), \quad \|U_{c,T}(s) - v^+(t)\|_{\mathcal{L}} < \frac{r_0^+}{2} - d^+(t)
\]

where

\[
d^+(t) := \frac{1}{2} \left( \frac{r_0^+}{2} - \|U_{c,T}(t) - v^+(t)\|_{\mathcal{L}} \right) > 0.
\]

Therefore, if \( \phi \in C^1_c((-T, T), (\mathcal{M}, \|\|_{\mathcal{M}})) \) is such that

\[
\max_{t \in [t - \delta^+(t), t + \delta^+(t)]} \|\phi(t)\|_{\mathcal{M}} \leq \frac{d^+(t)}{2}
\]

we have that

\[
\forall s \in (t - \delta^+(t), t + \delta^+(t)), \quad \|U_{c,T}(s) + \phi(s) - v^+(t)\|_{\mathcal{L}} < \frac{r_0^+}{2} - \frac{d^+(t)}{2}
\]

so that \( U_{c,T} + \phi \in X_T \). Meaning that \( E_c(U_{c,T}) \leq E_c(U_{c,T} + \phi) \). Since \( \phi \) is supported on \([t - \delta^+(t), t + \delta^+(t)]\), the previous implies that

\[
E_c(U_{c,T};[t - \delta^+(t), t + \delta^+(t)]) \leq E_c(U_{c,T} + \phi; [t - \delta^+(t), t + \delta^+(t)]),
\]

so that \( U_{c,T} \) is a local minimizer of \( E_c(\cdot; [t - \delta^+(t), t + \delta^+(t)]) \) in the sense of Definition 2.1. Since (3.28) also holds, we can apply (H6') and obtain that \( U_{c,T} \in \mathcal{A}((t - \delta^+(t), t + \delta^+(t))) \) and equation (3.26) holds. If \( t \leq -T \) is such that (3.27) holds, the same reasoning shows that for some \( \delta^-(t) > 0 \), \( U_{c,T} \in \mathcal{A}((t - \delta^-(t), t + \delta^-(t))) \) and (3.25) holds, which concludes the proof of the result. 

\[\square\]
3.4 The comparison result

The goal of this subsection is to obtain relevant information on the behavior of the constrained minimizers. Such information is contained in Corollary 3.1 and it will allow us to remove the constraints later on. In order to carry on these arguments, assumption \((H7')\) will become necessary.

We begin by introducing some constants. For \(0 < r \leq r_0^\pm\), recall the definition of \(\kappa_r^\pm\) introduced in (2.6). Lemma 2.1. We define

\[
\eta_0^+ := \min \left\{ \sqrt{e^{-1} \frac{r_0^+}{4} \sqrt{2 \kappa_r^+/4}, \frac{r_0^+}{4}} \right\} > 0,
\]

(3.31)

\[
\hat{t}^+ := \frac{r_0^+}{C^+ + 1} > 0,
\]

(3.32)

\[
\varepsilon_0^+ := \frac{1}{(C^+)^2(C^+ + 1)} \min \left\{ \left( \frac{\eta_0^+}{2}, \kappa_0^+, \beta^+(\hat{t}^+), \beta^+(\eta_0^+) \right) \right\} > 0,
\]

(3.33)

where the constants \(C^\pm, \beta^+(\hat{t}^\pm), \beta(\eta_0^\pm)\) were introduced in \((H5')\). Recall that in (2.31), (2.32), (2.33) we introduced the analogous constants

\[
\eta_0^- := \min \left\{ \sqrt{e^{-1} \frac{r_0^-}{4} \sqrt{2 \kappa_r^-/4}, \frac{r_0^-}{4}} \right\} > 0,
\]

(3.34)

\[
\hat{t}^- := \frac{r_0^-}{C^- + 1} > 0
\]

(3.35)

and

\[
\varepsilon_0^- := \frac{1}{(C^-)^2(C^- + 1)} \min \left\{ \left( \frac{\eta_0^-}{2}, \kappa_0^-, \beta^-(\hat{t}^-), \beta^-(\eta_0^-) \right) \right\} > 0.
\]

(3.36)

For any \(U \in X_T\), define

\[
t^-(U, \varepsilon_0^-) := \sup \left\{ t \in \mathbb{R} : \mathcal{E}(U(t)) \leq a + \varepsilon_0^- \text{ and } \text{dist}_\mathcal{F}(U(t), \mathcal{F}^-) \leq \frac{r_0^-}{2} \right\}
\]

(3.37)

and

\[
t^+(U, \varepsilon_0^+) := \inf \left\{ t \in \mathbb{R} : \mathcal{E}(U(t)) \leq \varepsilon_0^+ \text{ and } \text{dist}_\mathcal{F}(U(t), \mathcal{F}^+) \leq \frac{r_0^+}{2} \right\}.
\]

(3.38)

We have the following technical property:

**Lemma 3.8.** Assume that \((H1')\) and \((H5')\) hold. Let \(\hat{t}^\pm > 0\) be as in \((3.32), (3.33)\) and \(\varepsilon_0^\pm\) be as in \((3.33), (3.36)\). Then, if \(v \in \mathcal{F}^\pm\) is such that

\[
\mathcal{E}(v) \leq \min \{ \pm(-a), 0 \} + \beta^+(\hat{t}^\pm),
\]

(3.39)

then

\[
\forall \lambda \in [0, 1], \quad \mathcal{E}(\lambda v + (1 - \lambda)P^\pm(v)) \leq \min \{ \pm(-a), 0 \} + C^\pm(\mathcal{E}(v) - \min \{ \pm(-a), 0 \}).
\]

(3.40)

In particular, if

\[
\mathcal{E}(u) \leq \min \{ \pm(-a), 0 \} + \varepsilon_0^+,
\]

(3.41)

then

\[
\forall \lambda \in [0, 1], \quad \mathcal{E}(\lambda v + (1 - \lambda)P^\pm(v)) \leq \min \{ \pm(-a), 0 \} + C^\pm \varepsilon_0^+.
\]

(3.42)

The constants \(\varepsilon_0^\pm, C^\pm\) where defined in \((3.36), (3.33)\) and \((2.34)\) respectively. \(P^\pm(u)\) is the projection introduced in \((H1')\).
Proof. Assume that (3.39) holds for \( v \in \mathcal{F}_0^\pm \). Then, invoking (H5') we have that \( v \in \mathcal{F}_0^\pm \), so in particular the projection \( P_{\mathcal{F}}(u) \) is well defined. Fix \( \lambda \in [0,1] \). Since \( v \in \mathcal{F}_0^\pm \), the projection \( P^\pm(v) \) is well defined by (H1'). Using (2.16) we obtain
\[
\|\lambda v + (1-\lambda)P^\pm(v) - P^\pm(v)\|_{\mathcal{F}} = \lambda\|v - P^\pm(v)\|_{\mathcal{F}} \leq (C^\pm + 1)\|v - P^\pm_{\mathcal{F}}(v)\|_{\mathcal{F}} \leq (C^\pm + 1)\hat{r}^\pm
\]
so that \( \lambda v + (1-\lambda)P^\pm(v) \in \mathcal{F}_0^\pm \) by the definition of \( \hat{r}^\pm \) in (3.32), (3.35). Using now again (2.16) along with the estimate (2.18) in (H5') we get
\[
\|P^\pm(v) - P^\pm_{\mathcal{F}}(v)\|_{\mathcal{F}}^2 \leq (C^\pm)^2(\mathcal{E}(v) - \min\{\pm(-a), 0\})
\]
which, plugging into (3.43), gives
\[
\|\lambda v + (1-\lambda)P^\pm(v) - P^\pm_{\mathcal{F}}(v)\|_{\mathcal{F}}^2 \leq \frac{1}{2}((C^\pm)^2 + (C^\pm + 1)^2)(\mathcal{E}(v) - \min\{\pm(-a), 0\}),
\]
that, using again (2.18), implies exactly (3.40). Assuming now that (3.41) holds, we have by (3.36), (3.33) that in particular (3.39) holds. Therefore, (3.42) follows from (3.40).

Next, we have the following property:

Lemma 3.9. Assume that (H5') and (H7') hold. Let \( c > 0 \) and \( T \geq 1 \). Assume that \( U \in X_T \) is such that \( E_c(U) \leq 0 \). Then the quantities \( t^-(U, \varepsilon_0^-) \) and \( t^+(U, \varepsilon_0^+) \) defined in (3.37) and (3.38), respectively, are well defined as real numbers. Moreover, it holds that
\[
\mathcal{E}(U(t^-(U, \varepsilon_0^-))) \leq a + \varepsilon_0^- , \quad \text{dist}_{\mathcal{F}}(U(t^-(U, \varepsilon_0^-)), \mathcal{F}^-) \leq \frac{r_0^-}{2}
\]
and
\[
\mathcal{E}(U(t^+(U, \varepsilon_0^+))) \leq \varepsilon_0^+ , \quad \text{dist}_{\mathcal{F}}(U(t^+(U, \varepsilon_0^+)), \mathcal{F}^+) \leq \frac{r_0^+}{2}.
\]

Proof. Using that \( E_c(U) \leq 0 \) and the fact that \( \{ t \in \mathbb{R} : \mathcal{E}(U(t)) > 0 \} \) is nonempty since \( U \in X_T \), we must have that
\[
\{ t \in \mathbb{R} : \mathcal{E}(U(t)) < 0 \} \neq \emptyset
\]
and if \( v \in \mathcal{L} \) is such that \( \mathcal{E}(v) < 0 \), then we have \( \text{dist}_{\mathcal{F}}(v, \mathcal{F}^-) \leq r_0^-/2 \) by (2.37) in (H7') and \( \mathcal{E}(v) < a + \varepsilon_0^- \) since we assume \( a + \varepsilon_0^- > 0 \). Therefore, \( t^-(U, \varepsilon_0^-) \) is well defined, as we have shown that
\[
\{ t \in \mathbb{R} : \mathcal{E}(U(t)) \leq a + \varepsilon_0^- \quad \text{and} \quad \text{dist}_{\mathcal{F}}(U(t), \mathcal{F}^-) \leq \frac{r_0^-}{2} \} \neq \emptyset
\]
and such set is bounded above by \( T \), because \( \mathcal{F}^- \cap \mathcal{F}^+ = \emptyset \). Using Lemma 3.2 we have that \( t^+(U, \varepsilon_0^+) \) is well defined. Finally, inequalities (3.44) and (3.45) follow because \( t \in \mathbb{R} \rightarrow \mathcal{E}(U(t)) \in \mathbb{R} \) is lower semicontinuous by (H1') and \( t \rightarrow \text{dist}_{\mathcal{F}}(U(t), \mathcal{F}^+) \) is continuous whenever \( U(t) \in \mathcal{F}_0^\pm \) by (H1') (recall that \( t \in \mathbb{R} \rightarrow U(t) \in \mathcal{L} \) is continuous because \( U \in H^1_{loc}(\mathbb{R}, \mathcal{L}) \)).

The main work is done by the following result:

Proposition 3.1. Assume that (H5') and (H7') hold. Let \( c > 0 \) and \( T \geq 1 \). Consider \( U \in X_T \) with \( E_c(U) \leq 0 \). Let \( t^\pm := t^\pm(U, \varepsilon_0^\pm, r_0^\pm) \) be as in (3.37) and (3.38). Then, \( t^\pm \) are well defined by Lemma 3.9. Moreover, if there exists \( t^- < t^- \) such that
\[
r_0^- \geq \text{dist}_{\mathcal{F}}(U(t^-), \mathcal{F}^-) \geq \frac{r_0^-}{2}
\]
(3.46)
then, we can find \( \tilde{U}^- \in X_T \) such that
\[
\forall t \leq t^-, \quad \text{dist}_\lambda(\tilde{U}^-(t), \mathcal{F}^-) < \frac{r^-_0}{2},
\]
and
\[
E_c(\tilde{U}^-) < E_c(U).
\]

Analogously, if there exists \( \tilde{t}^+ > t^+ \) such that
\[
r^+_0 \geq \text{dist}_\lambda(U(\tilde{t}^+), \mathcal{F}^+) \geq \frac{r^+_0}{2},
\]
then we can find \( \tilde{U}^+ \in X_T \) such that
\[
\forall t \geq t^+, \quad \text{dist}_\lambda(\tilde{U}^+(t), \mathcal{F}^+) < \frac{r^+_0}{2},
\]
and
\[
E_c(\tilde{U}^+) < E_c(U).
\]

Furthermore, we have that
\[
0 < t^+ - t^- \leq T^*(c),
\]
where
\[
T^*(c) := \frac{1}{c} \ln \left( \frac{-a}{\alpha_*} + 1 \right),
\]
with \( \alpha_* > 0 \) a constant which is independent from \( c, T \) and \( U \).

**Proof.** We begin by proving the first part of the result for \( \mathcal{F}^- \). Recall that Lemma 3.9 gives

\[
E(U(t^-)) \leq a + \varepsilon^-_0.
\]

and \( U(t^-) \in \mathcal{F}^-_{r^-_0/2} \). Since \( a + \varepsilon^-_0 \leq \beta(\eta^-_0) \) by the definition of \( \varepsilon^-_0 \), \( \beta \) in (3.36), we have by \( (H5') \) that

\[
\text{dist}_\lambda(U(t^-), \mathcal{F}^-) \leq \eta^-_0.
\]

Assume that there exists \( \tilde{t}^- < t^- \) such that (3.46) is satisfied. Moreover, we assume, as we can, that

\[
\tilde{t}^- := \max \left\{ t \leq t^- : \text{dist}_\lambda(U(t), \mathcal{F}^-) \geq \frac{r^-_0}{2} \right\}
\]

(the sup can be replaced by a max by continuity).

\[
t^-_0 := \inf \{ t \in \left[ \tilde{t}^-, t^- \right] : E(U(t)) \leq a + \varepsilon^-_0 \text{ and } \text{dist}_\lambda(U(t)) \leq \eta^-_0 \}.
\]

Let \( v^- := P^-(U(t^-_0)) \in \mathcal{F}^- \), with \( P^- \) as in \( (H1') \). Notice that due to (3.56), we have

\[
\forall t \in [t^-_0, t^-], \quad \text{dist}(U(t), \mathcal{F}^-) < \frac{r^-_0}{2}.
\]

The proof now bifurcates according to two possible cases:

- \( t^-_0 \leq \tilde{t}^- + 1 \). In that case, set

\[
\tilde{U}^-(t) := \begin{cases} 
  v^- & \text{if } t \leq t^-_0 - 1, \\
  (t^-_0 - t)v^- + (t - t^-_0 + 1)U(t^-_0) & \text{if } t^-_0 - 1 \leq t \leq t^-_0, \\
  U(t) & \text{if } t \geq t^-_0.
\end{cases}
\]
which belongs to \( X_T \). Due to the definition of \( \tilde{U}^- \) and \([3.58]\), we have that \( \tilde{U}^- \) satisfies \([3.47]\). It remains to check \([3.48]\). We have

\[
\int_{t_0}^{\bar{t}_0} e_c(\tilde{U}^-(t))dt \leq \int_{t_0}^{\bar{t}_0} \left[ \frac{\|U(t_0) - v^-\|^2}{2} + \mathcal{E}(\tilde{U}^-(t)) \right] e^r dt. \tag{3.59}
\]

Fix \( t \in [t_0 - 1, \bar{t}_0] \). Choosing \( \lambda = t - t_0 + 1 \in [0, 1] \) and applying \([3.42]\) in Lemma 3.8 and \([3.54]\), we have that

\[
\mathcal{E}(\tilde{U}^-(t)) \leq a + C^- \varepsilon_0.
\]

The previous fact combined with \([3.55]\), \([3.54]\) and \([3.59]\), gives

\[
\int_{t_0}^{\bar{t}_0} e_c(\tilde{U}^-(t))dt \leq \left( \frac{(\eta_0)^2}{2} + C^- \varepsilon_0 \right) e^{c\bar{t}_0} + a(e^{c\bar{t}_0} - e^{c(t_0 - 1)}).
\]

The continuity of \( U \) and \([3.46]\) implies that there exists \( \tilde{t}_2 \in (\tilde{t}^-, \bar{t}_0^-) \) such that

\[
\text{dist}(U(\tilde{t}_2), \mathcal{F}^-) = \frac{r_0^-}{4} \quad \text{and} \quad \forall t \in [\tilde{t}^-, \tilde{t}_2], \quad \text{dist}(U(t), \mathcal{F}^-) \geq \frac{r_0^-}{4}.
\]

Using \([3.61]\), we get

\[
\int_{\tilde{t}^-}^{\tilde{t}_2} \|U'(t)\|_{\mathcal{F}^-} e^r dt \geq \frac{r_0^- e^{c\tilde{t}_2^-}}{4}
\]

and \([3.61]\) also implies

\[
\forall t \in [\tilde{t}^-, \tilde{t}_2], \quad \mathcal{E}(U(t)) \geq \kappa^- r_0^- / 4.
\]

Inequalities \([3.62]\) and \([3.63]\) along with the definition of \( \eta_0^- \) in \([3.34]\) and Young’s inequality give

\[
\int_{\tilde{t}^-}^{\tilde{t}_2} e_c(U(t))dt \geq \frac{r_0^- e^{c\bar{t}_0^-}}{4} \sqrt{2(\kappa^- r_0^- / 4 - a)} + a(e^{c\tilde{t}_2^-} - e^{c\tilde{t}^-})
\]

\[
= e(\eta_0^-)^2 e^{c\tilde{t}_2^-} + a e^{c\tilde{t}_2^-} - e^{c\tilde{t}^-},
\]

which gets to, using also that \( \tilde{t}^- \geq t_0^- - 1, \)

\[
\int_{-\infty}^{t_0^-} e_c(U(t))dt = \int_{(\tilde{t}^-, t_0^-)(\tilde{t}_2)]} e_c(U(t))dt + \int_{\tilde{t}^-}^{\tilde{t}_2} e_c(U(t))dt \geq e(\eta_0^-)^2 e^{c\tilde{t}_2^-} + a e^{c\tilde{t}_0^-} + a \frac{e^{c\tilde{t}_0^-}}{c}.
\]

Using now \([3.60]\) we get

\[
\int_{-\infty}^{t_0^-} e_c(\tilde{U}^-(t))dt = \int_{-\infty}^{t_0^- - 1} e_c(\tilde{U}^-(t))dt + \int_{t_0^- - 1}^{t_0^-} e_c(\tilde{U}^-(t))dt \leq \left( \frac{(\eta_0^-)^2}{2} + C^- \varepsilon_0^- \right) e^{c\tilde{t}_0^-} + a e^{c\tilde{t}_0^-} / c.
\]

Therefore, subtracting \([3.65]\) from \([3.64]\) we get

\[
\int_{-\infty}^{t_0^-} e_c(U(t))dt - \int_{-\infty}^{t_0^-} e_c(\tilde{U}^-(t))dt \geq \left( \frac{(\eta_0^-)^2}{2} + C^- \varepsilon_0^- \right) e^{c\tilde{t}_0^-},
\]

37
which is positive because (3.36) implies

\[ C^- \varepsilon^0_0 \leq \frac{(r_0^2)^2}{4}. \]

Since \( \bar{U}^- \) and \( U \) coincide in \( [t_0^-, +\infty) \), the proof of the first case is concluded.

- \( t_0^- > \bar{t} + 1 \). In such a case, set

\[ \bar{U}^-(t) := \begin{cases} \vspace{-0.2cm} \\ v^- & \text{if } t \leq \bar{t}, \\ (t - \bar{t}^-)U(t_0^-) + (\bar{t}^- + 1 - t)v^- & \text{if } \bar{t}^- \leq t \leq \bar{t}^- + 1, \\ U(t_0^-) & \text{if } \bar{t}^- + 1 \leq t \leq t_0^-, \\ U(t) & \text{if } t_0^- \leq t, \end{cases} \]

which clearly belongs to \( X_T \) and for all \( t \leq t^- \), \( U(t) \in \bar{\mathcal{F}}^-_{r^0/2} \) by (3.58). We have that \( \bar{U}^- \) is constant in \( [\bar{t}^- + 1, t_0^-] \), therefore

\[ \int_{t_0^-}^{t_0^- + 1} \mathbf{e}_c(\bar{U}^-(t))dt \leq (a + \varepsilon^-_0) \frac{e^{t_0^-} - e^{\bar{t}^- + 1}}{c} \]

and, due to the definitions of \( \varepsilon^-_0 \) in (3.36) and \( t_0^- \) in (3.57)

\[ \int_{t^-}^{t_0^-} \mathbf{e}_c(U(t))dt \geq \min\{a + \varepsilon_0, \kappa_0\} \frac{e^{t_0^-} - e^{t^- + 1}}{c} \geq \int_{t^-}^{t_0^-} \mathbf{e}_c(\bar{U}^-(t))dt, \]

because \( \varepsilon^-_0 + a > 0 \) by (H7) and \( t_0^- \geq \bar{t}^- + 1 \) by assumption. Hence

\[ \int_{\bar{t}^- + 1}^{t^- + \infty} \mathbf{e}_c(\bar{U}(t))dt \leq \int_{\bar{t}^- + 1}^{t^- + \infty} \mathbf{e}_c(U(t))dt. \]

Arguing as in the first case scenario, we can prove that

\[ \int_{-\infty}^{\bar{t}^- + 1} \mathbf{e}_c(\bar{U}(t))dt < \int_{-\infty}^{\bar{t}^- + 1} \mathbf{e}_c(U(t))dt, \]

which concludes the proof of the second case.

To sum up, we have shown that if (3.46) is satisfied, then there exists \( \bar{U}^- \) such that (3.47) and (3.48) hold, as we wanted.

Assume now that there exists \( \bar{t}^+ > t^+ \) such that (3.49) holds. As before, Lemma 3.9 and the definition of \( \varepsilon^+_0 \), (3.33), imply that \( t^+ := t^+(U, \varepsilon^+_0) \) is such that

\[ \text{dist}_\mathcal{F}(U(t^+), \mathcal{F}^+) \leq r^+_0 \]

and

\[ \mathcal{E}(U(t^+)) \leq \varepsilon^+_0. \]

We claim that we can assume without loss of generality that

\[ \forall t \in [t^+, +\infty), \quad \mathcal{E}(U(t)) \geq 0. \]

Indeed, if we can find \( t_0^+ \in (t^+, +\infty) \) such that \( \mathcal{E}(U(t)) < 0 \), then by (H7) we have have that \( \mathcal{E}(U(t_0^+)) \leq a + \varepsilon^+_0 \) and by (2.37) in (H7) we also have that \( \text{dist}_\mathcal{F}(U(t_0^+), \mathcal{F}^-) \leq r^-_0/2 \). Therefore, we have by the definitions (3.37) and (3.38) that \( t^- \geq t_0^+ \) and \( t^+ > t^- \), a contradiction since we assume \( t_0^+ > t^+ \).
For the positive case, the proof is simpler as it suffices to define \( v^+ := P^+(U(t^+)) \) and

\[
U^+(t) := \begin{cases} v^+ & \text{if } t \geq t^+ + 1 \\ (t - t^+)v^+ + (t^+ + 1 - t)U(t^+) & \text{if } t^+ + 1 \geq t \geq t^+, \\ U(t) & \text{if } t \geq t^+, 
\end{cases}
\]

which is such that \( U \in X_T. \) Moreover, it holds that for all \( t \geq t^+, \) we have \( \bar{U}^+(t) \in \mathcal{F}^{+}_{r_0^2/2}. \) Therefore, the requirements \((3.50)\) and \((3.51)\) hold for \( \bar{U}^+. \) It remains to check that \((3.51)\) is also fulfilled. We have that

\[
\int_{t^+}^{t+1} e_c(\bar{U}^+(t))dt = \int_{t^+}^{t+1} \left[ \frac{\|U(t) - v^+\|_{X^*}^2}{2} + \mathcal{E}(\bar{U}^+(t)) \right] e^{ct}dt. \tag{3.69}
\]

Using \((3.42)\) in Lemma \((3.8)\) and \((3.67),\) we get

\[
\int_{t^+}^{t+1} e_c(\bar{U}^+(t))dt \leq C^+ \varepsilon_0^+ e^{c(t^+ + 1)}. \tag{3.70}
\]

Using now \((3.66),\) we get

\[
\int_{t^+}^{t+1} \frac{\|U(t) - v^+\|_{X^*}^2}{2} e^{ct}dt \leq \frac{(\eta_0^+)^2}{2} e^{c(t^+ + 1)}. \tag{3.71}
\]

Plugging \((3.70)\) and \((3.71)\) into \((3.69),\) we get

\[
\int_{t^+}^{t+1} e_c(\bar{U}^+(t))dt \leq \left( \frac{(\eta_0^+)^2}{2} + C^+ \varepsilon_0^+ \right) e^{ct^+ + 1}. \tag{3.72}
\]

Since for all \( t \geq t^+ + 1 \) we have \( \bar{U}^+(t) = v^+, \) we obtain from \((3.72)\)

\[
\int_{t^+}^{t+\infty} e_c(\bar{U}^+(t))dt \leq \left( \frac{(\eta_0^+)^2}{2} + C^+ \varepsilon_0^+ \right) e^{ct^+ + 1}. \tag{3.73}
\]

Next, notice that by continuity we can find \( \hat{t}_2^+ \in (t^+, \hat{t}^+) \) such that

\[
\text{dist}(U(\hat{t}_2^+), \mathcal{F}^+) = \frac{r_0^+}{4} \text{ and } \forall t \in [\hat{t}^+, \hat{t}_2^+], \quad \frac{r_0^+}{2} \geq \text{dist}_{\mathcal{F}}(U(t), \mathcal{F}^+) \geq \frac{r_0^+}{4}. \tag{3.74}
\]

Therefore, using \((3.49)\) and \((3.74),\) we obtain

\[
\int_{\hat{t}_2^+}^{t^+} \|U(t)\|_{X^*} e^{ct}dt \geq \frac{r_0^+}{4} e^{ct^+ + 1} e^{-1} \tag{3.75}
\]

and \((3.74),\) \((2.5)\) in \( [H1'] \) imply

\[
\forall t \in [\hat{t}^+, \hat{t}_2^+], \quad \mathcal{E}(U(t)) \geq \kappa^+_0 / 4. \tag{3.76}
\]

Inequalities \((3.75),\) \((3.76)\) yield by Young’s inequality

\[
\int_{\hat{t}_2^+}^{t^+} e_c(U(t))dt \geq \frac{r_0^+}{4} e^{ct^+ + 1} e^{-1} \sqrt{2\kappa^+_0 / r_0^2} = (\eta_0^+)^2 e^{ct^+ + 1},
\]

where the last equality is due to the definition of \( \eta_0^+ \) in \((3.31).\) Combining with \((3.68),\) we get

\[
\int_{t^+}^{t+\infty} e_c(U(t))dt \geq (\eta_0^+)^2 e^{ct^+ + 1}.
\]
The definition of $\varepsilon_0^\pm$ in (3.33) and (3.73) imply then that
\[
\int_{t^+}^{+\infty} e_c(U(t))dt > \int_{t^+}^{+\infty} e_c(\tilde{U}(t))dt,
\]
which establishes (3.51).

We now show the last part of the proof: we show that (3.52) holds with the constant $T_*(c)$ defined in (3.53). The argument is the same as in [4, Lemma 2.10]. Assume by contradiction that there exists $t \in (t^-, +\infty)$ such that $\mathcal{E}(U(t)) < 0$. Then, arguing as above we must have $t < t^-$ by the definition of $t^-$ in (3.37), a contradiction. Therefore, we can write
\[
\mathbf{E}_c(U) = \frac{1}{2} \int_{\mathbb{R}} \|U(t)\|^2 e^{ct} dt - \int_{-\infty}^{t^-} \mathcal{E}(U(t)) e^{ct} dt + \int_{t^-}^{t^+} \mathcal{E}^+(U(t)) e^{ct} dt,
\]
where $\mathcal{E}^-$ and $\mathcal{E}^+$ stand for the positive and the negative part of $\mathcal{E}$, respectively. We have that
\[
\int_{-\infty}^{t^-} \mathcal{E}^-(U(t)) e^{ct} dt \leq \frac{-a}{c} e^{ct^-}.
\]
Set $\alpha_* := \min\{\varepsilon_0^+, \varepsilon_0^- + a\} > 0$, which is independent on $U$, $c$ and $T$. Notice that for all $t \in (t^-, t^+)$ we have that $\mathcal{E}(U(t)) \geq \alpha_*$. Indeed, if $\mathcal{E}(U(t)) < \alpha_*$, then by the definition of $t^-$ and $t^+$ in (3.37) and (3.38) we get
\[
\text{dist}_{\mathscr{F}}(U(t), \mathscr{F}^+) \geq \frac{r_0^+}{2},
\]
which implies that
\[
\mathcal{E}(U(t)) \geq \min\{\kappa_0^+, \kappa_0^- / 2, \kappa_0^- / 2 + a\} \geq \alpha_*,
\]
by (3.36) and (3.33), a contradiction. Therefore,
\[
\int_{t^-}^{t^+} \mathcal{E}^+(U(t)) e^{ct} dt \geq \int_{t^-}^{t^+} \mathcal{E}^+(U(t)) e^{ct} dt \geq \frac{\alpha_*}{c} \left( e^{ct^+} - e^{ct^-} \right).
\]
Plugging (3.78) and (3.79) into (3.77) and using that $\mathbf{E}_c(U) \leq 0$, we obtain
\[
0 \geq \frac{a}{c} e^{ct^-} + \frac{\alpha_*}{c} \left( e^{ct^+} - e^{ct^-} \right) \geq \left( \frac{a}{c} + \frac{\alpha_*}{c} \left( e^{c(t^+-t^-)} - 1 \right) \right) e^{ct^-},
\]
that is,
\[
0 \geq - \left( \frac{-a}{\alpha_*} + 1 \right) + e^{c(t^+-t^-)},
\]
which implies
\[
0 < t^+ - t^- \leq \frac{1}{c} \ln \left( \frac{-a}{\alpha_*} + 1 \right) = T_*(c),
\]
which is exactly (3.52) according to the definition (3.53).

See Figure 3.2. The importance of Proposition 3.1 is summarized by the following result, which gives important information on the behavior of the constrained minimizers:

**Corollary 3.1.** Assume that (H3'), (H4'), (H5') and (H7') hold. Let $c > 0$ and $T \geq 1$. Let $U_{c,T}$ be an associated minimizer of $\mathbf{E}_c$ in $X_T$ given by Lemma 3.6. Then, if $t^\pm := t^+(U_{c,T}, \varepsilon_0^\pm)$ are as in (3.37), (3.38) it holds that
\[
\forall t \leq t^-, \text{ dist}_{\mathscr{F}}(U_{c,T}(t), \mathscr{F}^-) < \frac{r_0^-}{2}.
\]
Figure 3.2: As it has been shown, the proof of Proposition 3.1 consists on showing that if the function $U$ gets too far from $\mathcal{F}^\pm$ after getting too close, then we can find a suitable competitor with strictly less energy. Above, we see a design for the positive case (the competitor $\tilde{U}^+$ is represented in blue). The second and third picture correspond to the two possible scenarios for the negative case (the competitor $\tilde{U}^-$ is represented in blue).
and
\[ \forall t \geq t^+, \quad \text{dist}_{\mathcal{F}}(U_{c,T}(t), \mathcal{F}^+) < \frac{\epsilon_0}{2}, \]  
\text{ (3.81)}

Moreover, we have
\[ \forall t \geq t^-, \quad \mathcal{E}(U_{c,T}(t)) \geq 0. \]  
\text{ (3.82)}

Finally, we have that if \( E_c(U_{c,T}) \leq 0 \), then
\[ 0 < t^+ - t^- \leq T^*(c), \]  
\text{ (3.83)}

where \( T^*(c) \) is as in (3.53). In particular, the function
\[ c \in (0, +\infty) \to T^*(c) \]
is continuous.

**Proof.** If we assume by contradiction that (3.81) does not hold, then we necessarily have that there exists \( \tilde{t}^- < t^- \) such that (3.46) hold. Proposition 3.1 implies then the existence of \( \tilde{U} \in X_T \) such that \( E_c(\tilde{U}) < E_c(U_{c,T}) = m_{c,T} \), a contradiction. Therefore, (3.81) holds. Similarly, we can show that (3.80) also holds. Finally, in order to establish (3.82), we argue as in the proof Proposition 3.1. Indeed, due to the definition of \( t^- \), we have that for \( t \geq t^- \) it holds that either
\[ E(U_{c,T}(t)) \geq a + \varepsilon^- > 0 \]  
(which is \( (H7') \)) or
\[ \text{dist}_{\mathcal{F}}(U_{c,T}(t), \mathcal{F}^-) \geq \frac{\epsilon_0}{2} \]
which by (2.37) in \( (H7') \) implies that \( E(U_{c,T}(t)) \geq 0 \). Therefore, (3.82) holds and the proof is concluded. \( \square \)

Moreover, Lemma 3.7 applies to \( V_{c,T} \) as follows:

**Corollary 3.2.** Assume that \( (H3'), (H4'), (H5') \) and \( (H7') \) hold. Let \( c > 0 \) and \( T \geq 1 \). Let \( U_{c,T} \) be an associated minimizer of \( E_c \) in \( X_T \) given by Lemma 3.6. Then, if \( t^\pm := t^\pm(U_{c,T}, \varepsilon_0^\pm) \) are as in (3.37), (3.38) it holds that there exists \( \delta_{c,T} > 0 \) such that the set
\[ S_{c,T} := (-\infty, t^- + \delta_{c,T}) \cup (-T, T) \cup (t^+ - \delta_{c,T}, +\infty) \]
is such that \( U_{c,T} \in A(S_{c,T}) \) (see (2.24)) and
\[ U_{c,T}'' - D_{\mathcal{F}}E(U_{c,T}) = -cU_{c,T}' \text{ in } S_{c,T}. \]  
\text{ (3.84)}

**Proof.** It is straightforward, combining Lemma 3.7 with the informations given by Corollary 3.1. \( \square \)

That is, constrained solutions are picewise solutions and, in particular, they solve the equation for times with large absolute value.

### 3.5 Existence of the unconstrained solutions

We now establish the existence of the unconstrained solutions making use of the previous comparison results. As in [4] and [5], we define the set
\[ \mathcal{C} := \{ c > 0 : \exists T \geq 1 \text{ and } U \in X_T \text{ such that } E_c(U) < 0 \}. \]  
\text{ (3.85)}

We first prove some important properties for \( \mathcal{C} \) which are the same to Lemma 2.12 in [4] and Lemma 27 in [5]:

42
Lemma 3.10. Assume that (H3'), (H4') and (H5') hold. Let \( C \) be the set defined in (3.85). Then, \( C \) is open and non-empty. Moreover, if we assume that (H7') holds, then \( C \) is also bounded with
\[
\sup C \leq \frac{\sqrt{-2a}}{d_0},
\]
where \( d_0 \) was defined in (2.36).

Proof. Firstly, we show that \( C \neq \emptyset \). For that purpose, consider the function \( \Psi \) introduced in (3.8).
Consider the function
\[
f : c \in (0, +\infty) \rightarrow e^{-c} \left( \frac{a}{c} + e^{2c} \int_{-1}^{1} \left( \frac{2}{\gamma} + E(\Psi(t)) \right) dt \right) \in \mathbb{R},
\]
which is well defined by Lemma 3.3. We have that for all \( c > 0 \)
\[
E_c(\Psi) = -\frac{a}{c} e^{-c} + \int_{-1}^{1} \left( \frac{2}{\gamma} + E(\Psi(t)) \right) e^{2c} dt \leq f(c)
\]
and \( f \) is a continuous function such that \( \lim_{c \to 0} f(c) = -\infty \) because \( a < 0 \). Moreover, we have that for all \( c > 0 \),
\[
f'(c) = -e^{-c} a + e^{2c} \int_{-1}^{1} \left( \frac{2}{\gamma} + E(\Psi(t)) \right) dt > 0
\]
and \( \lim_{c \to +\infty} f(c) = +\infty \). Therefore, there exists a unique \( c_0 > 0 \) such that \( f(c_0) = 0 \) and for all \( c < c_0 \) we have \( E_c(\Psi) < 0 \) by (3.87). Therefore, \( (0, c_0) \subset C \), meaning that \( C \neq \emptyset \) as we wanted to show.

We next prove that \( C \) is open. Let \( c \in C \), we have that \( E_c(U_{c,T}) < 0 \), where \( U_{c,T} \) is a minimizer of \( E_c \) in \( X_T \) given by Lemma 3.6. Let \( v_{c,T}^+ \) be the limit at \( +\infty \) of \( U_{c,T} \) according to the \( \mathcal{H} \)-norm (see Lemma 3.2). For any \( t \geq T \), define
\[
U_{c,T}^t(s) := \begin{cases} U_{c,T}(s) & \text{if } s \leq t, \\ (1 + t - s)U_{c,T}(t) + (s - t)v_{c,T}^+ & \text{if } t \leq s \leq t + 1, \\ v_{c,T}^+ & \text{if } t + 1 \leq s. \end{cases}
\]
Clearly, we have that for all \( t \geq T \), \( U_{c,T}^t \in X_T \) and \( E_c(U_{c,T}^t) < +\infty \). We will show that for \( t \geq T \) large enough, we have \( E_c(U_{c,T}^t) < 0 \). Let \( \hat{r}^+ \) be as in (3.32). By Lemma 3.2, we have that there exists \( T_r \geq T \) such that
\[
\forall t \geq T_r, \quad E(U_{c,T}(t)) \leq \beta^+(\hat{r}^+),
\]
where \( \beta^+(\hat{r}^+) \) was introduced in (H5'). Due to (3.88) we can use (3.40) in Lemma 3.8 meaning that for a constant \( b_1 > 0 \) independent on \( t \) we have
\[
\forall s \geq t, \quad |E(U_{c,T}(s)) - E(U_{c,T}^t(s))| \leq b_1 E(U_{c,T}(s)).
\]
Similarly, using (H5') we find a constant \( b_2 > 0 \) independent on \( t \) such that
\[
\forall s \geq t, \quad ||U_{c,T}(s)||_{\mathcal{H}}^2 - ||U_{c,T}^t(s)||_{\mathcal{H}}^2 \leq b_2 (||U_{c,T}^t(s)||_{\mathcal{H}}^2 + E(U_{c,T}(s))).
\]
Combining (3.89) and (3.90), we obtain for some constant \( b_3 > 0 \) independent on \( t \)
\[
\forall t \geq T, \quad |E_c(U_{c,T}) - E_c(U_{c,T}^t)| \leq b_3 \int_t^{+\infty} e_c(U_{c,T}(s))ds
\]
and since the right-hand side in the expression above tends to 0 as \( t \to +\infty \) and we assume \( E_c(U_{c,T}) < 0 \), we have that \( E_c(U_{c,T}^t) < 0 \) if we take \( t \geq T \) large enough. Since \( U_{c,T}^t \) is constant in \([t + 1, +\infty)\), we have that for all \( \tilde{c} > 0 \), \( E_{\tilde{c}}(U_{c,T}) < +\infty \). Therefore, by Lemma 3.4 we have that
\[
\tilde{c} \in (0, +\infty) \to E_{\tilde{c}}(U_{c,T}^t) \in \mathbb{R}
\]
is well defined and continuous. Therefore, we can find some $\delta > 0$ such that for all $c \in (c - \delta, c + \delta)$, $E_c(U_{c,T}) < 0$. As a consequence, we have that $(c - \delta, c + \delta) \subseteq C$, which shows that $C$ is open.

We now assume that $[H7']$ holds and we use it to establish the bound (3.86). In particular, we can apply Proposition 3.1. Let $c > 0$ and $T \geq 1$ be such that $E_c(U_{c,T}) < 0$ with $U_{c,T} \in X_T$ a minimizing solution given by Lemma 3.6. Let $t^\pm := t^\pm(U_{c,T}, \varepsilon_0^\pm)$ be as in (3.37), (3.38). Inequality (3.83) in Proposition 3.1 implies that $t^- < t^+$. Recall the definition of $d_0$ in (2.36) and the fact that $U_{c,T}(t^\pm) \in \mathcal{F}^\pm_{t^0/2}$. Those facts imply

$$d_0 \leq \|U_{c,T}(t^+) - U_{c,T}(t^-)\|_X. \quad (3.91)$$

Since $[H7']$ holds, we can use (3.82) in Corollary 3.1 to obtain

$$\|U_{c,T}(t^+) - U_{c,T}(t^-)\|^2 \leq 2 \int_{\mathbb{R}} \frac{\|U'_{c,T}(t)\|^2}{2} e^{ct} dt \left( \frac{e^{-ct} - e^{-ct^+}}{c} \right) \leq 2 \left( E_c(U_{c,T}) - \frac{a}{c} e^{ct^-} \right) \left( \frac{e^{-ct} - e^{-ct^+}}{c} \right).$$

Using now that $E_c(U_{c,T}) \leq 0$, the fact that $t^- < t^+$ and (3.91), the inequality above becomes

$$d_0^2 \leq -2a - \frac{e^{c(t^- - t^+)}}{c^2} \leq -\frac{2a}{c^2},$$

so that (3.86) follows.

We now have all the ingredients to establish the existence of the unconstrained solutions:

**Proposition 3.2.** Assume that $[H3'], [H4'], [H5'], [H6']$ and $[H7']$ hold. Let $c \in \partial(C) \cap (0, +\infty)$, where $\partial(C)$ stands for the boundary of the set $C$ defined in (3.85). Then, there exists $T \geq 1$ such that $m_{c,T} = 0$ (and in (3.7)) and $\bar{U} \in X_T$ an associated minimizer of $E_{T}$ in $X_T$ which does not saturate the constraints, i.e.

$$\forall t \geq \bar{T}, \ dist_{\mathcal{F}}(\bar{U}(t), \mathcal{F}^+) < \frac{r_0^+}{2} \quad (3.92)$$

and

$$\forall t \leq -\bar{T}, \ dist_{\mathcal{F}}(\bar{U}(t), \mathcal{F}^-) < \frac{r_0^-}{2}. \quad (3.93)$$

Moreover, $\bar{U} \in A(\mathbb{R})$ and the pair $(c, \bar{U})$ solves (2.1).

**Remark 3.2.** Notice that Lemma 3.10 implies that (under the necessary assumptions) the set $C$ is bounded, meaning that the set $\partial(C) \cap (0, +\infty)$. Such a fact, in combination with Proposition 3.2 shows the existence of the unconstrained solutions.

**Proof of Proposition 3.2.** By Lemma 3.10 we have that $C \neq \emptyset$ is open, which implies that $\partial(C) \subseteq \mathbb{R} \setminus C$. Therefore, we have $\bar{c} \notin C$. Recall that due to the definition of $C$ in (3.85), we have that

$$\forall T \geq 1, \ m_{c,T} \geq 0. \quad (3.94)$$

The definition of the boundary allows to consider a sequence $(c_n)_{n \in \mathbb{N}}$ contained in $C$ such that $c_n \to \bar{c}$. Then, for each $n \in \mathbb{N}$ there exists $T_n \geq 1$ such that $E_{c_n}(U_{c_n,T_n}) < 0$, where, for each $n \in \mathbb{N}$, $U_{c_n,T_n}$ is a minimizer of $E_{c_n}$ in $X_{T_n}$. For each $n \in \mathbb{N}$, set $t_n^\pm := t^\pm(U_{c_n,T_n}, \varepsilon_0^\pm)$ as in (3.37), (3.38). Using (3.83) in Corollary 3.1 we have that that

$$\forall n \in \mathbb{N}, \ 0 < t_n^+ - t_n^- \leq T_*(c_n),$$

44
and the function
\[ c \in (0, +\infty) \to T_*(c) \in (0, +\infty) \]
is continuous. Since the sequence \((c_n)_{n \in \mathbb{N}}\) is bounded, we have that
\[ T_* := \max \left\{ 1, \sup_{n \in \mathbb{N}} T_*(c_n) \right\} < +\infty \]
and
\[ \forall n \in \mathbb{N}, \ 0 < t^+_n - t^-_n \leq T_*, \quad (3.95) \]
so that we have a bound on \((t^+_n - t^-_n)_{n \in \mathbb{N}}\). Moreover, \((3.80)\) and \((3.81)\) in Corollary 3.1 imply
\[ \forall n \in \mathbb{N}, \forall t \geq t^+_n, \ 0 < \text{dist}_n(U_{cn,T_n}(t), \mathcal{E}^+) < \frac{r_0^+}{2} \quad (3.96) \]
and
\[ \forall n \in \mathbb{N}, \forall t \leq t^-_n, \ 0 < \text{dist}_n(U_{cn,T_n}(t), \mathcal{E}^-) < \frac{r_0^-}{2} \quad (3.97) \]
For each \(n \in \mathbb{N}\), define the function \(U_{cn,T_n}^{t^n} := U_{cn,T_n}(-t^+_n)\). Then, \((3.95)\) implies that \((3.96)\) and \((3.97)\) write as
\[ \forall n \in \mathbb{N}, \forall t \geq 0, \ 0 < \text{dist}_n(U_{cn,T_n}(t), \mathcal{E}^+) < \frac{r_0^+}{2} \]
and
\[ \forall n \in \mathbb{N}, \forall t \leq -T_*, \ 0 < \text{dist}_n(U_{cn,T_n}(t), \mathcal{E}^-) < \frac{r_0^-}{2} \]
so that for all \(n \in \mathbb{N}\) we have \(U_{cn,T_n}^{t^n} \in X_{T_*}\). Moreover, a computation shows
\[ \forall n \in \mathbb{N}, \ E_{cn}(U_{cn,T_n}^{t^n}) = e^{-c_n t^+_n} E_{cn}(U_{cn,T_n}) < 0. \]
Therefore, if we apply Lemma 3.5 with sequence of speeds \((c_n)_{n \in \mathbb{N}}\) and the sequence \((U_{cn,T_n}^{t^n})_{n \in \mathbb{N}}\) in \(X_{T_*}\), we obtain \(\bar{U} \in X_{T_*}\) such that
\[ E_{\mathcal{E}}(\bar{U}) \leq \liminf_{n \to \infty} E_{cn}(U_{cn,T_n}^{t^n}) \leq 0, \]
which in combination with \((3.94)\) implies that \(m_{T_*} = 0\). Therefore, we have \(E_{\mathcal{E}}(\bar{U}) = 0\), so that \(\bar{U}\) is a minimizer of \(E_{\mathcal{E}}\) in \(X_{T_*}\). Set \(t^\pm : = t^\pm(\hat{U}, \varepsilon_0)\) as in \((3.37), (3.38)\). Invoking \((3.94)\) and Corollary 3.2 we obtain that for all \(T \geq 1\) such that \(m_{T,T} = 0\) and \(\bar{U} \in X_T\), we have \(\bar{U} \in A(S_{c,T})\) with
\[ S_{c,T} := (-\infty, t^*_+ + \delta_*(T)) \cup (-T, T) \cup (t^*_+ - \delta_*(T), +\infty) \quad (3.98) \]
for some \(\delta_*(T) > 0\) and
\[ \bar{U}'' - D_{\mathcal{E}}(\bar{U}) = -\varepsilon \bar{U}' \quad \text{in} \quad S_{c,T}. \]
Moreover, using \((3.80)\) and \((3.81)\) in Corollary 3.1 we obtain as before that
\[ \forall t \geq t^+_*, \ 0 < \text{dist}_n(\bar{U}(t), \mathcal{E}^+) < \frac{r_0^+}{2} \quad (3.99) \]
and
\[ \forall t \leq -T_*, \ 0 < \text{dist}_n(\bar{U}(t), \mathcal{E}^-) < \frac{r_0^-}{2} \quad (3.100) \]
Therefore, if we set \(T = \max\{1, t^+_*, -T_*\}\), then \((3.99)\) and \((3.100)\) imply that \(\bar{U} \in X_T\) and that \((3.92), (3.93)\) hold. Moreover, we have that \(E_{\mathcal{E}}(\bar{U}) = 0\), so that \(\bar{U}\) is a minimizer of \(E_{\mathcal{E}}\) in \(X_T\) by \((3.94)\). Therefore, we obtain that \(\bar{U} \in A(S_{c,T})\) and
\[ \bar{U}'' - D_{\mathcal{E}}(\bar{U}) = -\varepsilon \bar{U}' \quad \text{in} \quad S_{c,T}, \]
with \(S_{c,T}\) as in \((3.98)\). The choice of \(T\) implies that \(S_{c,T} = \mathbb{R}\). Therefore, \(\bar{U} \in A(\mathbb{R})\) and \((1, \bar{U})\) solves \((2.1)\), which finishes the proof. \qed
Notice that our Proposition 3.2 follows very similar lines than the analogous results in [4] and [5].

3.6 Uniqueness of the speed

The precise statement of the uniqueness result is as follows:

**Proposition 3.3.** Assume that (H6') holds. Let \( X \) be the set defined in (2.38). Let \((c_1, c_2) \in (0, +\infty)^2\) be such that there exist \(U_1\) and \(U_2\) in \(X \cap \mathcal{A}(\mathbb{R})\) such that \((c_1, U_1)\) and \((c_2, U_2)\) solve (2.1) and for each \(i \in \{1, 2\} \), \(E_{c_i}(U_i) < +\infty\). Assume moreover that

\[
\forall i \in \{1, 2\}, \forall j \in \{1, 2\} \setminus \{i\}, \quad E_{c_i}(U_j) \geq 0.
\]

Then, we have \(c_1 = c_2\).

**Proof.** We prove the result by contradiction. Hence, we can assume without loss of generality that \(c_1 < c_2\). A direct computation shows that for every \((c, U) \in (0, +\infty) \times (X \cap \mathcal{A}(\mathbb{R}))\) a solution to (2.1), we have

\[
\forall t \in \mathbb{R}, \quad \frac{\|U'(t)\|^2}{2} + E(U(t)) = e^{-ct} \left( \frac{ct}{c} \left( E(U(t)) - \frac{\|U'(t)\|^2}{2} \right) \right).
\]

Replacing \((c_2, U_2)\) in (3.102) and multiplying for each \(t \in \mathbb{R}\) by \(e^{ct}\), computations show that

\[
\forall t_1 < t_2, \quad c_1 E_{c_1}(U_2; (t_1, t_2)) = (c_1 - c_2) \int_{t_1}^{t_2} \|U'_2(t)\|^2 e^{ct} dt
\]

\[
+ \left[ e^{ct_1} \left( E(U_2(t)) - \frac{\|U'_2(t)\|^2}{2} \right) \right]_{t_1}^{t_2}.
\]

Notice now that the definition of \(X\) in (2.38) implies that

\[
X = \bigcup_{T \geq 1} X_T,
\]

which means that there exists \(T \geq 1\) such that \(U_2 \in X_T\). Combining then Lemma 3.1 and the fact that \(E_{c_2}(U_2) < +\infty\), we get that \(E_{c_2}(U_2(\cdot)) \in L^1(\mathbb{R})\). Therefore, we can find two sequences \((t_n^+)_n \in \mathbb{N}\) and \((t_n^-)_n \in \mathbb{N}\) such that \(t_n^+ \to +\infty\) and

\[
\lim_{n \to \infty} E_{c_2}(U_2(t_n^+)) = 0.
\]

Since we have \(c_1 < c_2\), it holds

\[
\forall t \in \mathbb{R}, \quad e^{ct} \left| E(U_2(t)) - \frac{\|U'_2(t)\|^2}{2} \right| \leq |E_{c_2}(U_2(t))|
\]

which in combination with (3.104) implies

\[
\lim_{n \to \infty} e^{ct_n^+} \left( E(U_2(t_n^+)) - \frac{\|U'_2(t_n^+)\|^2}{2} \right) = 0.
\]

Therefore, if we replace for each \(n \in \mathbb{N}\) in (3.103) with \(a = t_n^-\) and \(b = t_n^+\), we can then pass to the limit (3.105) and obtain

\[
c_1 E_{c_1}(U_2) = (c_1 - c_2) \int_{\mathbb{R}} \|U'_2(t)\|^2 e^{ct} dt < 0
\]

because we assume \(c_1 < c_2\). However, by (3.101) we have \(E_{c_1}(U_2) \geq 0\), which is a contradiction. \(\square\)
Remark 3.3. Again, the proof of Proposition 3.3 is essentially the same as the given in [4] and [5]. Our hypothesis are slightly weaker, since we only assume that the solutions have finite energies and (3.101), while in [4] and [5] it is assumed that the solutions are global minimizers of the corresponding energy functionals. Notice also that (H7') is not needed for proving Proposition 3.3, which holds in a more general setting.

Proposition 3.3 along with Proposition 3.2 allows to show that the set $C$ defined in (3.85) is in fact an open interval:

Corollary 3.3. Assume that (H3'), (H4'), (H5'), (H6') and (H7') hold. Let

$$c(C) := \sup C.$$  

Then, we have $C = (0, c(C))$.

Proof. The statement of the result is equivalent to show that

$$\partial C \cap (0, +\infty) = \{c(C)\}$$

The quantity $c(C)$ is well defined in $(0, +\infty)$ because $C$ is non-empty and bounded by Lemma 3.10. Therefore, we have $c(C) \in \partial C \cap (0, +\infty)$ because $C$ is open, so it does not contain its limit points. By Proposition 3.2, we find $U^C \in X$ such that $(c(C), U^C)$ solves (2.1). Let now $\tau \in \partial C \cap (0, +\infty)$. If we show that $\tau = c(C)$, the proof will be finished. Applying Proposition 3.2 with $\tau$, we find $U \in X$ such that $(\tau, U)$ solves (2.1). Proposition 3.2, along with the fact that $\tau$ and $c(C)$ do not belong to $C$, also implies that

$$\inf_{U \in X} E_\tau(U) = E_\tau(U) = 0 = E_{c(C)}(U^C) = \inf_{U \in X} E_{c(C)}(U)$$

so that

$$E_{c(C)}(U) \geq 0$$

meaning that we can apply Proposition 3.3 to $(c(C), U^C)$, $(\tau, U)$. As a consequence, we have $\tau = c(C)$, which concludes the proof. \hfill $\square$

3.7 Proof of Theorem 2 completed

Proposition 3.2 along with Corollary 3.3 implies the existence of $(c^*, U) \in (0, +\infty) \times X_{T^*}$ a solution to (2.1) with $c^* = c(C)$. In particular, we have that

$$\forall t \leq -T^*, \quad \text{dist}_{\mathcal{F}}(U(t), \mathcal{F}^-) \leq \frac{r_0}{2}$$

and Lemma 3.2 implies the existence of some $v_+^* \in \mathcal{F}^+$ such that

$$\lim_{t \to +\infty} \|U(t) - v_+^*\|_{\mathcal{F}} = 0,$$

which shows that $U$ fulfills the weak conditions at infinity (2.2). The statement regarding the uniqueness of the speed $c^*$ follows from Proposition 3.3. Thus, the proof of Theorem 2 is completed. \hfill $\square$

3.8 Asymptotic behavior of the constrained solutions

The goal of this subsection is to analyze in some deep the behavior of the constrained solutions near $\pm \infty$. In particular, we will produce the results which will provide the proof of Propositions 2.1 and 2.2. We have the following preliminary result, which follows from a direct computation:
Lemma 3.11. Assume that \([H6']\) holds. Let \(c > 0\), \(t_1 < t_2\) and \(U \in \mathcal{A}(t_1, t_2)\) such that
\[
U'' - D_x E(U) = -cU' \quad \text{in} \quad (t_1, t_2).
\]
Then, we have the formula
\[
\forall t \in (t_1, t_2), \quad \frac{d}{dt} \left( E(U(t)) - \frac{\|U'(t)\|^2}{2} \right) = c\|U'(t)\|^2. \tag{3.106}
\]

Following the ideas from [4], we show that constrained solutions converge to \(+\infty\) at an exponential rate. We define the constant
\[
\gamma^+ := \frac{1}{e(C^+ + C^+)} > 0, \tag{3.107}
\]
where \(C^+\) was defined in (2.34). The result writes as follows:

Lemma 3.12. Assume that \([H3'], [H4'], [H5'], [H6'], [H7']\) hold. Let \(c > 0\) and \(T \geq 1\). Let \(U_{c,T} \in X_T\) be a constrained solution given by Lemma 3.6. Then, it holds that for some \(v^+_{c,T} \in \mathcal{F}^+\)
\[
\lim_{t \to +\infty} \|U_{c,T}(t) - v^+_{c,T}\|_{\mathcal{F}^+} e^{\frac{\gamma^+}{2} t} = 0 \tag{3.108}
\]
\[
\lim_{t \to +\infty} \|U'_{c,T}(t)\|_{\mathcal{F}} e^{\frac{\gamma^+}{2} t} = 0 \tag{3.109}
\]
and
\[
\lim_{t \to +\infty} E(U_{c,T}(t)) e^{\frac{\gamma^+}{2} t} = 0, \tag{3.110}
\]
where \(\gamma^+\) was defined in (3.107).

Proof. Let \(t^+ := t^+(U_{c,T}, \varepsilon_0^+)\) be as is (3.38). We have that (3.81) in Corollary 3.1 implies in particular that
\[
\forall t \geq t^+, \quad E(U_{c,T}(t)) \geq 0. \tag{3.111}
\]
Fix \(t \geq t^+\) and define \(v^+(t) := P^+(U_{c,T}(t))\). Consider the function
\[
\hat{U}^+_t(s) := \begin{cases} U_{c,T}(s) & \text{if } s \leq t, \\ (s - t)v^+(t) + (t + 1 - s)U_{c,T}(t) & \text{if } t \leq s \leq t + 1, \\ v^+(t) & \text{if } t \geq t + 1, \end{cases}
\]
which clearly belongs to \(X_T\). Therefore, we have
\[
E_c(U_{c,T}) \leq E_c(\hat{U}^+_t)
\]
and, equivalently
\[
\int_t^{+\infty} e_c(U_{c,T}(s))ds \leq \int_t^{t+1} \left( \frac{\|U_{c,T}(t) - v^+(t)\|^2}{2} + E(\hat{U}^+_t(s)) \right) e^{\gamma^+ s}ds.
\]
The expression above becomes, after using (3.40) in Lemma 3.8 and the definition of \(\varepsilon_0^+\),
\[
\int_t^{+\infty} e_c(U_{c,T}(s))ds \leq \left( \frac{\|U_{c,T}(t) - v^+(t)\|^2}{2} + C^+ E(U_{c,T}(t)) \right) e^{ct} e, \tag{3.112}
\]
where we used that \(U_{c,T}(t) \in \mathcal{F}^+_0\), which holds by (3.81) in Corollary 3.1 since \(U_{c,T}\) is a minimizer of \(E_c\) in \(X_T\). Using (2.5) in (H1') we get from (3.112)
\[
\int_t^{+\infty} e_c(U_{c,T}(s))ds \leq (C^+ + C^+) e E(U_{c,T}(t)) e^{ct}, \tag{3.113}
\]
48
which, by the definition of $\gamma^+$ in (3.107), implies
\[ \int_{t}^{+\infty} \mathcal{E}(U_{c,T}(s))e^{cs}ds \leq \frac{1}{\gamma^+} \mathcal{E}(U_{c,T}(t)e^{ct}). \]  
(3.114)

Define now the function
\[ \theta^+_{c,T}(t) := \int_{t}^{+\infty} \mathcal{E}(U_{c,T}(s))e^{cs}ds. \]  
(3.115)
and notice that (3.113), (3.114) and the definition of $\gamma^+$ in (3.107) imply
\[ \forall t \geq t^+, \ (\theta^+_{c,T})'(t) = -\mathcal{E}(U_{c,T}(t))e^{ct} \leq -\gamma^+\theta_{c,T}(t). \]
Therefore, using also (3.111) we can write
\[ e^{\gamma^+(t-t^+)} \leq \frac{\theta^+_{c,T}(t)}{\theta^+_{c,T}(t^+)}. \]
which by rearranging gives
\[ \theta^+_{c,T}(t) \leq \theta^+_{c,T}(t^+)e^{-\gamma^+(t-t^+)} \]
and we immediately check that this inequality also holds if we drop the assumption $\theta^+_{c,T}(t) > 0$.

Therefore, using also (3.111) we can write
\[ \forall t \geq t^+, \ 0 \leq \theta^+_{c,T}(t) \leq \theta^+_{c,T}(t^+)e^{-\gamma^+(t-t^+)}. \]  
(3.116)

Now, notice that by (3.4) in Lemma 3.2, we have that (2.28) in [H6')] (with $I = (t^+, +\infty)$) is satisfied. We also have that $\mathcal{E}(U_{c,T}(\cdot)) \in L^1((-\infty, t^+))$, which is (2.29) in [H6']). Moreover, $U_{c,T}$ is a local minimizer of $E_c(\cdot; [t^+ , +\infty))$ in the sense of Definition 2.1. In particular, Corollary 3.2 gives
\[ U''_{c,T} - D_x\mathcal{E}(U_{c,T}) = -eU'_{c,T} \text{ in } (t^+, +\infty). \]  
(3.117)
Therefore, the last part of [H6')] applies. Therefore, (2.30) in [H6')] and equation (3.117) imply that
\[ \sup_{t \in (t^+, +\infty)} |(\mathcal{E}(U_{c,T}(t)))'| = \sup_{t \in (t^+, +\infty)} |(D_x\mathcal{E}(U_{c,T}(t)), U'_{c,T}(t))_X| \]
\[ = \sup_{t \in (t^+, +\infty)} |e\|U'_{c,T}(t)\|_X^2 + (U''_{c,T}(t), U'_{c,T}(t))_X| < +\infty. \]

Notice also that (3.3) implies that there exists a constant $L_1 > 0$ such that
\[ \max_{t \in (t^+, +\infty)} \mathcal{E}(U_{c,T}(t)) \leq L. \]

Therefore, the function
\[ t \in [t^+, +\infty) \rightarrow \mathcal{E}(U_{c,T}(t)) \]
is Lipschitz in $[t^+ + 1, +\infty)$. Let $L := \|\mathcal{E}(U_{c,T}(\cdot))\|_{W^{1,\infty}(t^+ + 1, +\infty)}$. There exists $t_0^+ \geq t^+ + 1$ such that
\[ \forall t \geq t_0^+, \ [t - \mathcal{E}(U_{c,T}(t))/(2L), t] \subset [t^+ + 1, t]. \]
Moreover, for any $s \in [t - \mathcal{E}(U_{c,T}(t))/(2L), t]$ we have that
\[ \mathcal{E}(U_{c,T}(s)) \geq \mathcal{E}(U_{c,T}(t)) - L|s - t| \geq \frac{\mathcal{E}(U_{c,T}(t))}{2}, \]
49
Recall that \( t \) and applying now (3.112) we obtain
\[ \text{fix } t \geq t_{a} \text{ for some constant } M > 0 \text{ such that } \frac{\|u_{c,T}(t)\|^2_{L^2}}{2} \leq \frac{\|u_{c,T}(t_{a})\|^2_{L^2}}{2} - \mathcal{E}(u_{c,T}(t)) = c \int_{t}^{t_{a}} \mathcal{E}(u_{c,T}(s))ds \]
from which (3.110) follows. The limit (3.108) is then readily established by using (2.18) in (H5').

It remains then to show (3.109). For that purpose, let \( t^{+} < t_{1} \leq t_{2} < +\infty \). By (3.117), Lemma 3.11 implies that (3.106) holds for \( U_{c,T} \) in \((t_{1}, t_{2})\). Integrating this identity on \((t_{1}, t_{2})\), we get
\[ \mathcal{E}(u_{c,T}(t_{2})) - \mathcal{E}(u_{c,T}(t_{1})) + \frac{\|u'_{c,T}(t_{1})\|^2_{L^2}}{2} - \frac{\|u'_{c,T}(t_{2})\|^2_{L^2}}{2} = c \int_{t_{1}}^{t_{2}} \mathcal{E}(u_{c,T}(s))ds \]
Recall that \( t \in (t^{+}, +\infty) \rightarrow e^{ct}\|u'_{c,T}(t)\|^2_{L^2} \) belongs to \( L^{2}((t^{+}, +\infty)) \), so in particular there exists a sequence \((t_{n})_{n\in\mathbb{N}}\) in \((t^{+}, +\infty)\) and tending to \(+\infty\) such that \( \|u'_{c,T}(t_{n})\|^2_{L^2} \rightarrow 0 \) as \( n \rightarrow \infty \). If we fix \( t > t^{+} \) and \( n \in \mathbb{N} \) large enough, apply (3.118) with \( t_{1} = t \) and \( t_{2} = t_{n} \) and finally pass to the limit \( n \rightarrow \infty \), we get
\[ \forall t \geq t^{+}, \frac{\|u'_{c,T}(t)\|^2_{L^2}}{2} - \mathcal{E}(u_{c,T}(t)) = c \int_{t}^{+\infty} \mathcal{E}(u_{c,T}(s))ds \]
Therefore, using (3.111)
\[ \forall t > t^{+}, \frac{\|u'_{c,T}(t)\|^2_{L^2}}{2} \leq \mathcal{E}(u_{c,T}(t)) + e^{-ct}c \int_{t}^{+\infty} \mathcal{E}(u_{c,T}(s))ds \]
and applying now (3.112) we obtain
\[ \forall t > t^{+}, \|u'_{c,T}(t)\|^2_{L^2} \leq M \mathcal{E}(u_{c,T}(t)) \]
for some constant \( M > 0 \). The previous inequality and (3.110) imply (3.109). \[\square\]

We now show that constrained solutions tend to an element of \( \mathcal{F}^{-} \) at \(-\infty\) provided that the speed \( c \) is not too large.

**Lemma 3.13.** Assume that (H3'), (H4'), (H5'), (H6') and (H7') hold. Let \( c > 0 \) and \( T \geq 1 \). Assume moreover that \( c < \gamma^{+} \), where \( \gamma^{+} \) is defined in (2.35). Let \( U_{c,T} \) be a constrained solution given by Lemma 3.6. Then, it holds that for some \( v_{c,T} \in \mathcal{F}^{+} \)
\[ \lim_{t \rightarrow -\infty} \|U_{c,T}(t) - v_{c,T}\|^2_{\mathcal{F}} = 0 \]
\[ \lim_{t \rightarrow -\infty} \|U'_{c,T}(t)\|^2_{L^2} = 0 \]
and
\[ \lim_{t \rightarrow -\infty} \mathcal{E}(U_{c,T}(t)) = a. \]

**Proof.** This proof mostly mimics that of Lemma 3.12 with some minor changes. Let \( t^{-} := t^{-}(U_{c,T}, \bar{c}_{0}) \) be as in (3.37). By applying (3.80) in Corollary 3.1 we obtain that for all \( t \leq t^{-} \), \( U_{c,T}(t) \in \mathcal{F}^{-}_{0} / 2 \). For all \( t \leq t^{-} \), define \( v^{-}(t) := 2^{-}(U_{c,T}(t)) \). Consider the function
\[ \tilde{v}_{c}^{-}(s) := \begin{cases} v^{-}(t) & \text{if } s \leq t - 1, \\ (t - s)v^{-}(t) + (s - t + 1)U_{c,T}(t) & \text{if } t - 1 \leq s \leq t, \\ U_{c,T}(s) & \text{if } t \leq s, \end{cases} \]

\[50\]
which belongs to $X_T$. Therefore, 
\[ E_c(U_{c,T}) \leq E_c(\tilde{U}) \]
and, equivalently
\[ \int_{-\infty}^t e_c(U_{c,T}(s)) ds \leq \frac{a}{c} e^{\frac{at}{c}} + \int_{t-1}^t \left( \frac{||U_{c,T}(t) - V^-(t)||_2^2}{2} + (E(\tilde{U}^-(s)) - a) \right) e^{cs} ds. \quad (3.122) \]

Using Lemma 3.8 and (2.5) in (H') (3.122) becomes
\[ \int_{-\infty}^t e_c(U_{c,T}(s)) ds \leq \frac{a}{c} e^{\frac{at}{c}} + (C^- + C^-)(E(U_{c,T}(t)) - a)e^{ct}, \]
which gives
\[ \int_{-\infty}^t (E(U_{c,T}(s)) - a)e^{cs} ds \leq \frac{1}{\gamma^-} (E(U_{c,T}(t)) - a)e^{ct}, \quad (3.123) \]
where $\gamma^-$ was defined in (2.35). Define the function
\[ \theta^-_{c,T}: t \in (-\infty, t^-) \rightarrow \int_{-\infty}^t (E(U_{c,T}(s)) - a)e^{cs} ds \in \mathbb{R}. \quad (3.124) \]

We claim that $t \in (-\infty, t^-] \rightarrow E(U_{c,T}(t)) \in \mathbb{R}$ is bounded. Indeed, assume the opposite by contradiction. Then, $\inf_{t \in (-\infty, t^-]} E(U_{c,T}(t))$ is attained because $U_{c,T}$ is continuous as a curve in $\mathcal{H}$. Consider then any $t \in (-\infty, t^-]$ such that $E(U_{c,T}(t)) = \inf_{t \in (-\infty, t^-]} E(U_{c,T}(t))$. Define
\[ \hat{U}(s) := \begin{cases} U_{c,T}(t) & \text{if } s \leq t, \\ U_{c,T}(s) & \text{if } s \geq t, \end{cases} \]
which belongs to $X_T$. Since $t \rightarrow (-\infty, t^-] \rightarrow E(U_{c,T}(t))$ is unbounded, we have
\[ \int_{-\infty}^t E(\hat{U}(s))e^{cs} ds < \int_{-\infty}^t E(U_{c,T}(s))e^{cs} ds \]
and $\hat{U}' = 0$ in $(-\infty, t^-]$, which implies that $E_c(\hat{U}) < E_c(U_{c,T})$, a contradiction because $U_{c,T}$ minimizes $E_c(\cdot)$ in $X_T$. Hence, the claim has been established, which implies that
\[ \lim_{t \rightarrow -\infty} (E(U_{c,T}(t)) - a)e^{ct} = 0. \]

As a consequence, the function $\theta^-_{c,T}$ defined in (3.124) verifies
\[ (\theta^-_{c,T})'(t) = (E(U_{c,T}(t)) - a)e^{ct} \]
which, by (3.123) implies
\[ \forall t \leq t^-, \quad \gamma^- \theta^-_{c,T}(t) \leq (\theta^-_{c,T})'(t). \]

Fix now $t \in (-\infty, t^-)$ and assume that $\theta^-_{c,T}(t) > 0$. The previous inequality is equivalent to
\[ \forall t \leq t^-, \quad \gamma^- \leq (\ln(\theta^-_{c,T}(t)))'. \]
which, by integrating in $[t, t^-]$ becomes
\[ \gamma^- (t^- - t) \leq \ln(\theta^-_{c,T}(t^-)) - \ln(\theta^-_{c,T}(t)), \]
hence
\[ e^{\gamma^- (t^- - t)} \leq \frac{\theta^-_{c,T}(t^-)}{\theta^-_{c,T}(t)}, \]

51
that is
\[ \theta_{c,T}^+(t)e^{-r(t-t^-)} \leq \theta_{c,T}^-(t^-), \]
which clearly also holds if we drop the assumption \( \theta_{c,T}^+(t) > 0 \), as \( \theta_{c,T}^- \) is a nonnegative function. Thus, we have shown that
\[ \forall t \leq t^-, \; \theta_{c,T}^+(t) \leq \theta_{c,T}^-(t^-)e^{-r(t-t^-)}. \] (3.125)

Notice that (3.84) in Corollary 3.2 implies that \( U_{c,T} \) solves
\[ U''_{c,T} - D\mathcal{L}U_{c,T} = -eU'_{c,T} \text{ in } (-\infty, t^-). \]

Therefore, the function
\[ f_{c,T} : t \in (-\infty, t^-) \rightarrow e^{ct}\left(\mathcal{L}(U_{c,T}(t)) - a - \frac{\|U'_{c,T}(t)\|^2_{\mathcal{L}}}{2}\right), \]
is \( C^1 \) and we clearly have that \( f_{c,T} \in L^1((-\infty, t^-]) \). By (3.106) in Lemma 3.11, we have
\[ \forall t \in (-\infty, t^-), \; f'_{c,T}(t) = cf_{c,T}(t) + ce^{ct}\|U'_{c,T}(t)\|^2_{\mathcal{L}} \geq 0, \] (3.126)
and we also have \( f'_{c,T} \in L^1((-\infty, t^-]) \). Therefore, it holds that
\[ \lim_{t \rightarrow -\infty} f_{c,T}(t) = 0. \] (3.127)

Fix \( t_1 < t_2 \leq t^- \). Integrating (3.126) in \([t_1, t_2]\) we get
\[ f_{c,T}(t_2) \geq f_{c,T}(t_1) \]
which in combination with (3.127) gives
\[ \forall t < t^- , \; f_{c,T}(t) \geq 0 \]
and, equivalently
\[ \forall t < t^- , \; \|U'_{c,T}(t)\|^2_{\mathcal{L}} \leq 2(\mathcal{L}(U_{c,T}(t)) - a). \] (3.128)

Now, we have that using (3.125) we get for any fixed \( t \leq t^- - 1 \) and \( i \in \mathbb{N} \)
\[ \int_{t-i}^{t-i-1} (\mathcal{L}(U_{c,T}(s)) - a)ds \leq e^{-c(t-i-1)} \int_{t-i-1}^{t-i} (\mathcal{L}(U_{c,T}(s)) - a)e^{cs}ds \leq e^{-c(t-i-1)}\theta_{c,T}^-(t^-)e^{-r(t^- - i + 1)} = e^{c(1-t^-)}\theta_{c,T}^-(t^-)e^{(c-r)(t^- - i)}e^{(c-r)i} \]

and, since we assume that \( c < r^- \), we have that
\[ \sum_{i \in \mathbb{N}} e^{(c-r)i} = \frac{1}{1 - e^{c-r}}, \]
which gives for some \( M > 1 \) independent on \( t \)
\[ \forall t \leq t^- - 1, \; \int_{-\infty}^{t} (\mathcal{L}(U_{c,T}(s)) - a)ds \leq Me^{(c-r)(t^- - t)}. \] (3.129)

We can now use (3.128) to obtain
\[ \forall t \leq t^- - 1, \; \int_{-\infty}^{t} \|U'_{c,T}(s)\|^2_{\mathcal{L}}ds \leq 2Me^{(c-r)(t^- - t)}. \] (3.130)
Since \( c < \gamma^- \), in particular inequality (3.130) implies the existence of some \( \tilde{v}^- \in \mathcal{L} \) such that
\[
\lim_{t \to -\infty} \| U_{c,T}(t) - \tilde{v}^- \|_{\mathcal{L}} = 0. \tag{3.131}
\]
Moreover, we have that (3.129) implies in particular that
\[
(\mathcal{E}(U_{c,T}(\cdot)) - a) \in L^1((-\infty, t^- - 1]), \tag{3.132}
\]
therefore there exists a sequence \((t_n)_{n \in \mathbb{N}}\) tending to \(-\infty\) such that
\[
\lim_{n \to \infty} \mathcal{E}(U_{c,T}(t_n)) - a = 0,
\]
which, by \([H5']\) means that
\[
\lim_{n \to \infty} \text{dist}_{\mathcal{H}}(U_{c,T}(t_n), \mathcal{F}^-) = 0
\]
and by (3.131) such a fact implies that \( \tilde{v}^- = v_{c,T}^- \in \mathcal{F}^- \). Therefore, (3.131) is exactly (2.25) in \([H6']\) and (3.132) is exactly (2.26) in \([H6']\). Therefore, \([H6']\) applies for \( I = (-\infty, t^- - 1) \).

3.9 Proof of Proposition 2.1 completed

Assume first that \([H7']\) holds. Let \((c^*, U)\) be the solution to (2.1) with conditions at infinity (2.2) given by Proposition 3.2. Since we took \( c^* = \sup C \) with \( C \) as in (3.85), inequality (3.86) in Lemma 3.10 implies that
\[ c^* \leq \sqrt{-2a/d_0} \]
which by (2.39) in \([H8']\) implies that
\[ c^* < \gamma^- \]
so that we can apply Lemma 3.13 to \( U \), as it is a minimizer of \( E_{c^*} \) in \( X_{T^*} \) for some \( T^* \geq 1 \). Therefore, (2.40) holds for \( U \).

3.10 Proof of Proposition 2.2 completed

Since we assume that \([H8']\) holds and \( \tilde{U} \) is such that \( \tilde{U} \in X_T \) for some \( T \geq 1 \) and \( E_{c^*}(\tilde{U}) = 0 \), then by Proposition 3.2 we can apply Lemma 3.13 to \( U \). We can also apply Lemma 3.12. Hence we have that
\[
\lim_{t \to \pm\infty} \| U'(t) \|_{\mathcal{L}} = 0, \tag{3.133}
\]
\[
\lim_{t \to \mp\infty} E(U(t)) = 0 \tag{3.134}
\]
and
\[
\lim_{t \to -\infty} E(U(t)) = a. \tag{3.135}
\]
Taking the scalar product in \( \mathcal{L} \) between equation (2.1) and \( U' \), we obtain
\[
\forall t \in \mathbb{R}, \quad \langle U''(t), U'(t) \rangle_{\mathcal{L}} - \langle D_{\mathcal{L}} \mathcal{E}(U(t)), U'(t) \rangle_{\mathcal{L}} = -c \| U'(t) \|^2_{\mathcal{L}}
\]
so that
\[
\forall t \in \mathbb{R}, \quad \langle U''(t), U'(t) \rangle_{\mathcal{L}} - \langle \mathcal{E}(U(t)) \rangle' = -c^* \| U'(t) \|^2_{\mathcal{L}}.
\]
Fix \( T > 0 \). Integrating above in \([-T, T]\) we obtain
\[
\int_{-T}^{T} \langle U''(t), U'(t) \rangle_{\mathcal{L}} dt - \mathcal{E}(U(T)) + \mathcal{E}(U(-T)) = -c^* \int_{-T}^{T} \| U'(t) \|^2_{\mathcal{L}} dt. \tag{3.136}
\]
Integrating by parts we obtain
\[ \int_{-T}^{T} \langle U''(t), U'(t) \rangle \, dt = \| U'(T) \|_{L}^{2} - \| U'(-T) \|_{L}^{2} - \int_{-T}^{T} \langle U'(t), U''(t) \rangle \, dt, \]
which means
\[ \int_{-T}^{T} \langle U''(t), U'(t) \rangle \, dt = \frac{1}{2} (\| U'(T) \|_{L}^{2} - \| U'(-T) \|_{L}^{2}). \]
Plugging into (3.136) we obtain
\[ \frac{1}{2} (\| U'(T) \|_{L}^{2} - \| U'(-T) \|_{L}^{2} - \mathcal{E}(U(T)) + \mathcal{E}(U(-T)) = -c^* \int_{-T}^{T} \| U'(t) \|_{L}^{2} \, dt. \]
Using (3.133), (3.134) and (3.135), we can pass to the limit as \( T \to -\infty \) and we get that \( U' \in L^{2}(\mathbb{R}, L^{2}) \)
and
\[ a = -c^* \int_{\mathbb{R}} \| U'(t) \|_{L}^{2} \, dt, \]
which shows (2.41). We now show that (2.42) holds. Inspecting again the proof of Theorem 2, we have that \( c^* \) is equal to \( c(C) \) as in Corollary 3.3. Take \( c < c^* \), then by Corollary 3.3 we have that \( c \in C \). The definitions of \( C \) in (3.85) implies then that
\[ \exists T \geq 1, \inf_{U \in \mathcal{X}_{T}} E_{c}(U) < 0 \]
which, by considering \( \tilde{U} \in \mathcal{X}_{T} \) such that \( E_{c}(\tilde{U}) < 0 \) and then the sequence \( (\tilde{U}(\cdot + n))_{n \in \mathbb{N}} \) which is contained in \( \mathcal{X} \), implies that \( \inf_{U \in \mathcal{X}} E_{c}(U) = -\infty \). If we now take \( c > c^* \), we have again by Corollary 3.3 that
\[ \forall T \geq 1, \inf_{U \in \mathcal{X}_{T}} E_{c}(U) \geq 0 \]
which means
\[ \inf_{U \in \mathcal{X}} E_{c}(U) = 0. \]
Therefore, (2.42) follows. Finally, we have that (2.43) is exactly (3.86) in Lemma 3.10.
