A new analytical formula for the inverse of a square matrix

W. Astar
St. Petersburg College (SPC), P.O. Box 13489, St. Petersburg, Florida 33733-3489, USA

Abstract - A concise analytical formula is developed for the inverse of an invertible 3 x 3 matrix using a telescoping method, and is generalized to larger square matrices. The formula is confirmed using randomly generated matrices in Matlab.

Keywords: Inverse of a square matrix, Determinant of a square matrix, Leibniz determinant formula, Kronecker delta-function, discrete Heaviside step-function, gamma function, analytical formula

1. Introduction
The inverse of a square matrix can be found using a number of well-known techniques, such as Gaussian elimination, Gauss-Jordan elimination, and LU-decomposition [1], some of which are among the modules available in Mathematica®, Matlab®, Maple® and Maxima, among others [2]. The focus of this report, however, is to explore a closed-form analytical formula for the inverse of a square matrix, based on standard functions.

The product of a complex scalar a with its inverse yields unity,\[ \frac{1}{a} a = a \frac{1}{a} = 1. \] (1.1)

This relation can be extended to an invertible \( N \times N \) square matrix \( \mathbf{A} \) of such scalars,
\[
\mathbf{A} = \begin{bmatrix}
  a_{11} & a_{12} & \cdots & a_{1N} \\
  a_{21} & a_{22} & \cdots & a_{2N} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{N1} & a_{N2} & \cdots & a_{NN}
\end{bmatrix}
\] (1.2)

which in short-form notation is often expressed as
\[ \mathbf{A} \sim a_{ij} = a_{ij}, \quad \{i, j\} \in \{1, 2, 3, \ldots, N\} \times \{1, 2, 3, \ldots, N\}. \] (1.3)

with the tilde ‘∼’ denoting equivalence. A comma-delimiter is sometimes used to clarify the dependence of the matrix element \( a \) on the row index \( (i) \) and the column index \( (j) \), which is especially helpful when the indices themselves happen to be functions. Both notations will be used throughout this report. Although the matrix elements \( a_{ij} \) are generally complex for this report, they are not expressed explicitly in terms of their real and imaginary parts, and the letters \( i \) and \( j \) are reserved for the row and the column indices. For square matrices, (1.1) is generalized to
\[ \mathbf{A}^{-1} \mathbf{A} = \mathbf{AA}^{-1} = \mathbf{I} \] (1.4)

for which \( \mathbf{I} \) is the identity matrix, an \( N \times N \) matrix whose scalar analog is unity. For both
the scalar and the invertible square matrix, the products (1.1) and (1.4) are commutative. The inverse of \( A \) is found from

\[
A^{-1} = \frac{\tilde{A}}{|A|},
\]

which is the ratio of the adjugate of \( A \) to the determinant of \( A \). The adjugate of \( A \) is obtained from the transpose of the matrix of its cofactors \( C_{ij} \). A cofactor of a matrix element \( a_{ij} \) is obtained from the product of its corresponding minor \( M_{ij} \) with the sign-factor \((-1)^{i+j}\). A minor \( M_{ij} \) is found by taking the determinant of the minor-matrix \( M \),

\[
M_{ij} = |M(i, j)|, \tag{1.6}
\]

Since an \( N \times N \) matrix \( A \) possesses \( N^2 \) elements, it must also possess \( N^2 \) minors or minor-matrices. More explicitly, the minor-matrix is derived in terms of the original matrix as

\[
M_{rs}(i, j) = A_{1,\ldots,i-2,i-1,i+1,i+2,\ldots,N; 1,\ldots,j-2,j-1,j+1,j+2,\ldots,N}. \tag{1.7}
\]

It should be emphasized here that \( M \) is not indexed to \( i \) and \( j \), but to \( r \) and \( s \). However, it is a function of the indices \( i \) and \( j \), whence the nomenclature of \( M_{rs}(i, j) \), which implies that \( M_{rs} \) is a sub-matrix of \( A \), and is found from \( A \) by omitting its \( i \)-th row and \( j \)-th column. The indices of the matrix elements \( m_{rs} \) that make up a specific minor-matrix \( M_{rs} \), are found from the Cartesian product of the set of row indices with the set of column indices,

\[
\{r, s\} \in \{\{1, \ldots, i - 2, i - 1, i + 1, i + 2, \ldots, N\}\times\{1, \ldots, j - 2, j - 1, j + 1, j + 2, \ldots, N\}\}, \tag{1.8}
\]

and the 2 sets appear as arguments of \( A \) in (1.7). The convention (1.7, 1.8) is followed in subsequent sections of this report, although the index alphabet may differ.

The determinant of \( A \) may be found from the following weighted cofactor expansion using its 1st row, also known as a Laplace Expansion [3],

\[
|A| = \sum_{j=1}^{N} a_{ij} C_{ij} = \sum_{j=1}^{N} (-1)^{i+j} a_{ij} |M(1, j)|. \tag{1.9}
\]

It can also be found using any other row, or any column of the matrix \( A \). However, (1.9) is the convention to which this report will adhere. This definition may also be adapted to the minor (1.6), which is the determinant of the minor-matrix \( M \).

The inverse matrix (1.5) may also be expressed in terms of its minors as

\[
A^{-1} \sim \alpha_{ji} = \frac{(-1)^{i+j} M_{ij}}{|A|} = \frac{(-1)^{i+j} M_{ij}}{\sum_{j=1}^{N} a_{ij} (-1)^{i+j} M_{ij}}; \{i, j\}, \{j, i\} \in \{\{1, \ldots, N\} \times \{1, \ldots, N\}\}. \tag{1.10}
\]
The denominator, which represents the determinant of \( A \), is only computed once, from the sum of the minors corresponding to the elements of the 1st row \((i=1)\) of \( A \), weighted by those elements. This is perhaps the most general form of a formula for an element of the inverse of a matrix. However, (1.10) is clearly not expressed in terms of the elements of the original matrix \( A \). The kernel of the inverse matrix (1.10) is the minor (1.6), which appears in both the numerator and denominator. The minor itself is actually the determinant of a matrix (1.7). Thus, the problem to resolve, is reduced to finding a general, analytical formula for the determinant of a \((N-1) \times (N-1)\) matrix \( M \).

Apparently, the term "determinant" was first used by C.F. Gauss in 1801 [4], but the modern meaning of the term was not introduced until 1841 by A. Cayley, and the Cayley-Hamilton Theorem [5, 6], which was later generalized by Frobenius [7], can be used to find the determinant of a square matrix. However, the concept of a determinant appears to have been in use well before the 19th century, beginning with G. Leibniz (1678), and G. Cramer (1750). The latter was apparently the first to publish on the concept, and with whom is associated Cramer's Rule, which still is under active investigation [8, 9]. P.F. Sarrus, developed a graphical mnemonic for the determinant of a \(3 \times 3\) matrix, now known as the Rule of Sarrus. Although originally constrained to \(3 \times 3\) matrices, it has been recently modified, improved [10-12], and also extended to larger \(4 \times 4\) square matrices [13-16].

C.L. Dodgson (L. Carroll, 1866) [17-19] developed a method termed the Dodgson Condensation, by which the determinant is found by constructing progressively smaller matrices from the original matrix, concluding with a \(1 \times 1\) matrix that carries the determinant of the original matrix itself. There have recently been various mathematical proofs of the algorithm [20-22], and its connection to Chiò's Pivotal Condensation Method (1853) [23], among others, has also been investigated [24, 25]. Among other, recently introduced recursive methods, has been that due to Rezaifar and Rezaee [26], which has also been generalized [27], but purportedly found to be a consequence of an identity due to the 19th century mathematician Capelli [28, 29].

It appears that the most general analytical formula for the determinant of a square matrix was first proposed by Leibniz, one form of which is given by [30-32]

\[
|A| = \sum_{\sigma^{(n)} \in \sigma^{(1)}} \text{sgn}(\sigma^{(j)}) \prod_{i=1}^{N} a_{i,\sigma^{(j)}} = \sum_{\sigma^{(i)} \in S_N} \text{sgn}(\sigma^{(j)}) \prod_{i=1}^{N} a_{i,\sigma^{(j)}},
\]

(1.11)

with each set \(\sigma^{(j)}\) being identical in size to the ordered set \(J\) of all possible \(N\) column index values, but a different \((j\text{-th})\) permutation of \(J\). The sign function \(\text{sgn}(\cdot)\) yields positive (negative) unity when the set \(\sigma^{(j)}\) is obtained from an even (odd) number of permutations of \(J\). Unlike the row index \(i\), the column index \(j\) is not explicitly used as such, in the equation. Moreover, the elements of the permutated column set \(\sigma^{(j)}\) make no appearance in the formula, and this set gets larger for larger square matrices. Thus, although (1.11) is indeed a formula, it is not formulaic to the extent of an explicit dependence on the independent variables\(^1\) represented by the row and column indices of the elements \(a_{ij}\).

The aim of this report is to derive an analytical formula for any element of the

\(^1\) examples of which, are Newton's second law \(F = m \cdot a\), and Einstein's mass-energy equivalence \(E = m \cdot c^2\)
inverse of a $N \times N$ matrix in terms of the elements of that matrix, using standard functions, demonstrating explicit dependence on the row and column indices, but with nothing known \textit{a priori} about the values of the elements $a_{ij}$. No algebraic relation connecting any of the elements is assumed at the outset, unlike in [33, 34]. The report intends to explore the limitations of such an approach, and to also identify the mathematical hurdles to surmount in order to generalize it to arbitrary square matrices. It will be found that the approach is a telescoping method like the Dodgson Condensation, but is much more akin to the Leibniz formula for determinants (1.11). The method will be demonstrated for $N$ up to 5, after which it will be generalized for any $N$.

2. The $2 \times 2$ matrix $D$

The $2 \times 2$ matrix is generally given by

$$D \equiv d_{ij} = \begin{bmatrix} d_{11} & d_{12} \\ d_{21} & d_{22} \end{bmatrix}, \ {i, j} \in \{\{1, 2\} \times \{1, 2\}\} \tag{2.1}$$

and is well known to have the inverse matrix

$$D^{-1} = \begin{bmatrix} d_{22} & -d_{12} \\ -d_{21} & d_{11} \end{bmatrix} \frac{1}{d_{11}d_{22} - d_{12}d_{21}} \tag{2.2}$$

Relative to the original matrix $D$, the diagonal elements are interchanged, whereas the skew-diagonal elements are negated. It has the formulaic form of

$$D^{-1} \sim \delta_{ji} = \frac{(-1)^{i+j}d_{3-i,3-j}}{\sum_{j=1}^{N} \delta_{i,j} \delta_{i,j} (-1)^{i+j}d_{3-i,3-j}} = \frac{(-1)^{i+j}d_{3-i,3-j}}{\sum_{j=1}^{N} (-1)^{i+j}d_{1,j}d_{2,3-j}}, \ {j, i} \in \{\{1, 2\} \times \{1, 2\}\}, \tag{2.3}$$

with an expression for the determinant of $D$ found in the denominator,

$$|D| = \frac{2}{\sum_{j=1}^{2} \delta_{i,j} \delta_{i,j} (-1)^{i+j}d_{3-i,3-j}} = \frac{2}{\sum_{j=1}^{2} (-1)^{i+j}d_{1,j}d_{2,3-j}} = d_{11}d_{22} - d_{12}d_{21}. \tag{2.4}$$

The formula (2.3) reproduces the indicial change required for the diagonal elements of $D$, while maintaining the indices of the skew-diagonal elements intact. The formula also negates the skew-diagonal elements. This formula is not unique, and other, perhaps more complicated forms are possible. The \textbf{matrix element} $\delta_{ij}$, \textbf{should not be confused with the Kronecker delta-function $\delta$} used in (2.4) and in subsequent sections, which is not \textbf{italicized}.

The point of deriving the formulas in this section, serves only to illustrate an approach, which is to be adapted to the larger $N \times N$ matrices, and which are not amenable to a simple approach such as the one used here, since the inverse of an $N \times N$ matrix involves the evaluations of $(N-1) \times (N-1)$ minors, $N$ times.
3. The 3x3 matrix C

The 3 x 3 matrix is generally given by

\[ C \sim c_{kl} \sim \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix}, \quad \{k,l\} \in \{(1,2,3) \times (1,2,3)\}. \tag{3.1} \]

Unlike that of the 2 x 2 matrix D, the inverse of this matrix is not so easy to commit to memory, but is still analytical and compact, and is given by applying (1.6, 7) 9 times in (1.10) with \( A = C \), to (3.1),

\[ C^{-1} \sim \gamma_{ik} \sim \frac{\begin{bmatrix} c_{22}c_{33} - c_{23}c_{32} \\ c_{12}c_{33} - c_{13}c_{32} \\ c_{12}c_{23} - c_{13}c_{22} \end{bmatrix} - \begin{bmatrix} c_{21}c_{33} - c_{23}c_{31} \\ c_{11}c_{33} - c_{13}c_{31} \\ c_{11}c_{23} - c_{13}c_{21} \end{bmatrix}}{c_{11}\left(c_{22}c_{33} - c_{23}c_{32}\right) - c_{12}\left(c_{21}c_{33} - c_{23}c_{31}\right) + c_{13}\left(c_{21}c_{32} - c_{22}c_{31}\right)} \tag{3.2} \]

The adjugate of \( C \) is actually the transpose of the numerator of (3.2), which is represented by \( \gamma_{ki}[C] \). However, the transpose operation is omitted due to the use of \( \gamma_{ik} \) instead of \( \gamma_{ki} \) on the LHS, since an element of a transposed matrix is identical to the element of the original matrix, if its indices are interchanged. The goal is now to find a general, compact expression for any element \( \gamma_{ik} \) of the inverse of the matrix \( C \).

Up to this point, the derivation of the formula has been based on patterns observed in the indices of the matrix elements and/or its cofactors. A more systematic approach will now be developed for a 3 x 3 matrix, that can be adapted to larger square matrices. It is based on identifying the general form of the 2 x 2 minor-matrix that leads to the evaluation of all the minors required for the inverse of the matrix.

For the 1st row of \( C \) (3.1), the minor-matrices are

\[ \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix} \rightarrow \begin{bmatrix} c_{22} & c_{23} \\ c_{32} & c_{33} \end{bmatrix}, \quad \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix} \rightarrow \begin{bmatrix} c_{21} & c_{23} \\ c_{31} & c_{33} \end{bmatrix}, \quad \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix} \rightarrow \begin{bmatrix} c_{21} & c_{22} \\ c_{31} & c_{32} \end{bmatrix} \tag{3.3} \]

and using the Kronecker delta-function, defined as

\[ \delta_{s,s_{0}} = \delta_{s-s_{0}} = \delta[s-s_{0}] = \begin{cases} 1, & s = s_{0} \\ 0, & s \neq s_{0} \end{cases} \quad s_{0} \in \mathbb{Z} \tag{3.4} \]

yields the general minor-matrix, a 2 x 2 matrix corresponding to any element on the 1st row of (3.1), in accord with the scheme shown by (3.3).
\[ \mathbf{D}_c(1, l) = \mathbf{C}(2, 3; 1 + \delta_{l-1}, 2 + \delta_{l-1} + \delta_{l-2}) = \begin{bmatrix} c_{2,1+\delta_{l-1}} & c_{2,2+\delta_{l-1}+\delta_{l-2}} \\ c_{3,1+\delta_{l-1}} & c_{3,2+\delta_{l-1}+\delta_{l-2}} \end{bmatrix}, \ l \in \{1, 2, 3\}. \] (3.5)

The Kronecker delta-function \( \delta \) is not to be confused with the (italicized) element \( \delta \) of the inverse \((2.3)\) of the \(2 \times 2\) matrix. On the RHS of this expression, a \(2 \times 2\) sub-matrix is being expressed in terms of the 2nd and 3rd rows, and of the \((1+ \delta_{l-1})\)-th and the \((2+ \delta_{l-1}+ \delta_{l-2})\)-th columns, of the original \(3 \times 3\) matrix \(\mathbf{C}\) \((3.1)\), in accordance with \((1.7)\). Then for the 1st row of \(\mathbf{C}\), the 3 minors are obtained from \((3.5)\) by setting in turn the column index \(l = 1, 2\), then \(3\). Adapting this procedure for the remaining elements of \(\mathbf{C}\), yields the general \(2 \times 2\) minor-matrix for the entire matrix \(\mathbf{C}\),

\[ \mathbf{D}_c(k, l) = \mathbf{C}(1 + \delta_{k-1}, 2 + \delta_{k-1} + \delta_{k-2}; 1 + \delta_{l-1}, 2 + \delta_{l-1} + \delta_{l-2}) = \begin{bmatrix} c_{1+\delta_{k-1},1+\delta_{l-1}} & c_{1+\delta_{k-1},2+\delta_{l-1}+\delta_{l-2}} \\ c_{2+\delta_{k-1}+\delta_{l-1},1+\delta_{l-1}} & c_{2+\delta_{k-1}+\delta_{l-1}+\delta_{l-2}} \end{bmatrix}, \] \( \{k, l\} \in \{\{1, 2, 3\} \times \{1, 2, 3\}\} \). (3.6)

The minor-matrix also has the more compact, alternative forms

\[ \mathbf{D}_c(k, l) = \mathbf{C}(2 - \mathbf{H}_{k-2}, 3 - \mathbf{H}_{k-3}; 2 - \mathbf{H}_{l-2}, 3 - \mathbf{H}_{l-3}), \] (3.7)

\[ \mathbf{D}_c(k, l) - d_y(k, l) = c_{i+1 - \mathbf{H}_{k-2}, j+1 - \mathbf{H}_{l-2}} - H_{2 - \mathbf{H}_{k-2}, 2 - \mathbf{H}_{l-2}} \begin{bmatrix} c_{2-H_{k-2},3-H_{l-3}} \\ c_{3-H_{k-3},3-H_{l-3}} \end{bmatrix}, \] (3.8)

\( \{i, j\} \in \{\{1, 2\} \times \{1, 2\}\}, \& \{k, l\} \in \{\{1, 2, 3\} \times \{1, 2, 3\}\}, \)

using the discrete Heaviside step-function, which, like the Kronecker delta-function whence it is derived, is another generalized function, defined as

\[ \mathbf{H}_{s-s_0} = \mathbf{H}[s-s_0] = \sum_{s=s_0}^{\infty} \delta[s-s_0] = \begin{cases} 1, & s \geq s_0 \\ 0, & s < s_0 \end{cases}, \ s_0 \in \mathbb{Z}. \] (3.9)

The \(2 \times 2\) minor-matrix \(\mathbf{D}_c\) is actually indexed to \(i\) and \(j\), as in the previous section, but its elements \(d_y\) are functions of the couple \((k, l)\), specified for the minor of the \(3 \times 3\) matrix \((3.1)\). However, since \((3.7, 3.8)\) is also a \(2 \times 2\) matrix, it should make it amenable to some of the results found in the previous section, as will be seen later. The use of Kronecker delta-functions or Heaviside step-functions in the indices of the matrix elements is a method of incorporating conditional statements in the indices themselves. For instance in \((3.6)\), a row index of \(1+\delta_{i-1}\) is interpreted as a 1, unless \(k = 1\), in which case that row index becomes a 2. Similarly, a column index of \(3-H_{l-3}\) is meant to be construed as a 3, unless \(l \geq 3\), in which case the column index is reduced to a 2. Lastly, the Kronecker delta-function and the discrete Heaviside step-function are not standard functions, and may be considered to be the discrete analogues of the Dirac delta-function, and the
continuous Heaviside step-function, which are generalized functions, or distributions \([35-38]\). However, it will be shown in §7 that these functions can be expressed in terms of standard functions over the required ranges of the indices.

There are now 2 approaches to attaining the inverse of \(C\), and they both take advantage of the conclusions reached in the previous section for the \(2 \times 2\) matrix \(D\). For the first approach, termed the surrogate matrix approach, (1.10) is implemented using the LHS of (3.8) in the form of the \(2 \times 2\) matrix \(Dc\) as the general minor-matrix for \(C\), yielding

\[
C^{-1} \sim \gamma_{ik} = \frac{(-1)^{k+l} D_c(k,l)}{|C|} = \frac{(-1)^{k+l} D_c(k,l)}{\sum_{j=1}^{3} \delta_{k,l}(-1)^{k+l} D_c(k,l)}, \quad \{l,k\} \in \{\{1,2,3\} \times \{1,2,3\}\}. \tag{3.10}
\]

The denominator is seen to carry a Laplace Expansion for \(C\). The equation clearly requires the determinant of the \(2 \times 2\) minor-matrix \(D_c\), whose general form is given by the denominator of the inverse of the \(2 \times 2\) matrix \(D\) considered in §2, specifically (2.4):

\[
|D| = \sum_{j=1}^{2} \delta_{lj}(-1)^{i+j} d_{ij} d_{3-i,3-j} = d_{11}d_{22} - d_{12}d_{21} \tag{3.11}
\]

which is another Laplace Expansion. Thus, using the surrogate matrix approach, a more explicit version of (3.10) is

\[
C^{-1} \sim \gamma_{ik} = \frac{(-1)^{k+l} \sum_{j=1}^{2} \delta_{i,j}(-1)^{i+j} \left(d_{ij} d_{3-i,3-j}\right)(k,l)}{\sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{k,l}(-1)^{i+j+k+l} c_{kl} \left(d_{ij} d_{3-i,3-j}\right)(k,l)}, \quad \{l,k\} \in \{\{1,2,3\} \times \{1,2,3\}\}. \tag{3.12}
\]

whose denominator now carries 2 nested Laplace Expansions, one for \(Dc\) (3.8), nested within another for \(C\) (3.1). After carrying out the Kronecker delta-functions where relevant, the equation simplifies to

\[
C^{-1} \sim \gamma_{ik} = \frac{\sum_{j=1}^{2} (-1)^{i+j+k+l} \left(d_{ij} d_{2,3-j}\right)(k,l)}{\sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{2+j+l} c_{ij} \left(d_{ij} d_{2,3-j}\right)(1,l)}, \quad \{l,k\} \in \{\{1,2,3\} \times \{1,2,3\}\}. \tag{3.13}
\]

As stated in §1, and based on the convention used in this report, the determinant of the matrix \(C\) is found from the sum of the minors due to the \((k = 1)\) first row of the matrix (3.1), weighted by their corresponding, signed elements \((-1)^{k+l} c_{kl}\) on that row, and is given by the denominator of (3.13),

\[
|C| = \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{i+j} c_{kl} \left(d_{ij} d_{2,3-j}\right)(k,l). \tag{3.14}
\]
To obtain a typical element $\gamma_{lk}$ of the inverse matrix $C^{-1}$, the general minor matrix $Dc$ can be found from (3.8) for the specified $\{l, k\}$, after which its elements $d_{ij}$ are substituted into either (3.12) or (3.13). It is tacitly understood that all the elements $d_{ij}$ in the numerator are functions of the indices $\{k, l\}$ due to (3.6), and are expressed as $(k, l)$ in (3.12-14).

In the second, direct approach for formulating the inverse of $C$, and which encapsulates the first approach, the general minor matrix found on the RHS of (3.7) is used instead of the surrogate matrix $Dc$. This step is more challenging because the elements now have variable indices. However, it is observable that all the indices are translated by predictable functions of either $k$ or $l$, succinctly expressed as

$$i' = i + \sum_{u=1}^{j} \delta_{k-u} = i + 1 - H_{k-i} = \kappa(i, k),$$  \hspace{1cm} (3.15)

$$j' = j + \sum_{u=1}^{j} \delta_{l-u} = j + 1 - H_{l-j} = \kappa(j, l),$$  \hspace{1cm} (3.16)

for which $\kappa$ is not to be confused with the index $k$. In the new, primed indicial system $(i', j')$, the standard mathematical operations are not satisfied, and care must be exercised,

$$1' + 1' = 2 + 2\delta_{s-1} = 2' = 2 + \delta_{s-1} + \delta_{s-2},$$

$$2' - 1' = 2 + \delta_{s-1} + \delta_{s-2} - 1 - \delta_{s-1} = 1 + \delta_{s-2},$$ \hspace{1cm} (3.17)

Eqs. (3.12) and (3.13) are still applicable, but with the elements $d$ replaced by $c$, and with the indices primed,

$$C^{-1} \approx \gamma_{lk} = \frac{\sum_{i=1}^{2} \delta_{i-1}(-1)^{i+j+k+l} c_{ij}c_{(3-i)j,(3-j)'}}{\sum_{j=1}^{2} \sum_{l=1}^{2} \delta_{k-l}(-1)^{i+j+k+l} c_{ij}c_{l(i),(3-j)'}} , \{l,k\} \in \{(1,2,3) \times (1,2,3)\}. $$  \hspace{1cm} (3.18)

Based on (3.15),

$$(3-i)' = \begin{cases} 2', & i = 1 \\ 1', & i = 2 \end{cases} = 4 - i - H_{k-4+i} = \lambda(i, k) \ \text{,} \ i \in \{1,2\}. $$  \hspace{1cm} (3.19)

However, the result is also formally obtainable from (3.15) by the discrete convolution

$$(3-i)' = i' \otimes \delta_{3-i}. $$  \hspace{1cm} (3.20)

A similar equation can be found for the corresponding column index $(3-j)'$ using (3.16), by the same logic used for (3.19). However, this equation is most easily found from (3.20), after a few simple operations,
\[ (3 - j)' = (3 - i)' \delta_{i-j} \delta_{k-l} = 4 - j - H_{i-4+j} = \lambda(j,l), \quad j \in \{1,2\}. \quad (3.21) \]

Substituting (3.15), (3.16), (3.19) and (3.21) into (3.18) yields

\[
\mathbf{C}^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2} \delta_{i-j}(-1)^{j+k+l} c_{\kappa(i,k),\kappa(j,l)} c_{\lambda(i,k),\lambda(j,l)}}{\sum_{j=1}^{3} \sum_{j=1}^{2} \delta_{i-j}(-1)^{j+k+l} c_{k,l} c_{\kappa(i,k),\kappa(j,l)} c_{\lambda(i,k),\lambda(j,l)}}, \quad \{l,k\} \in \{(1,2,3) \times (1,2,3)\} 
\]

but more explicitly,

\[
\mathbf{C}^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2} (-1)^{j+k+l} c_{i+H_{k-2+j}, j+H_{i-4+j}, i+H_{k-4+j}, j+H_{i-4+j}}}{\sum_{j=1}^{3} \sum_{j=1}^{2} (-1)^{j+k+l} c_{k,l} c_{i+H_{k-2+j}, j+H_{i-4+j}, i+H_{k-4+j}, j+H_{i-4+j}}}. \quad (3.22)
\]

The denominator, which represents the determinant, is only computed once, since it is independent of the specified indices \(\{l, k\}\) due to the extent \(\delta_{k-1}\) and the summation over \(l\). After applying all Kronecker delta-functions, a simpler expression for any element \(\gamma_{lk}\) of \(\mathbf{C}^{-1}\) is found explicitly in terms of the elements \(c_{li}\) of \(\mathbf{C}\) (3.1),

\[
\mathbf{C}^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2} (-1)^{j+k+l} c_{2-H_{k-2+j}, j+H_{i-4+j}, i+H_{k-4+j}, j+H_{i-4+j}}}{\sum_{j=1}^{3} \sum_{j=1}^{2} (-1)^{j+k+l} c_{1,l} c_{2, j+H_{i-4+j}, j+H_{i-4+j}, i+H_{k-4+j}}}. \quad (3.23)
\]

Thus, an expression alternative to (3.14) for the determinant of \(\mathbf{C}\), this time entirely in terms of its elements, is the denominator of (3.24),

\[
|\mathbf{C}| = \sum_{j=1}^{3} \sum_{j=1}^{2} (-1)^{j+k+l} c_{1,l} c_{2, j+H_{i-4+j}, j+H_{i-4+j}, i+H_{k-4+j}}. \quad (3.24)
\]

Expanding the \(j\)-summations in the numerator and denominator using (3.15) and (3.16),

\[
\mathbf{C}^{-1} \sim \gamma_{lk} = \frac{(-1)^{k+l} (c_{1-H_{i-4+j}, 1-H_{i-4+j}, 3-H_{i-4+j}, 3-H_{i-4+j}} - c_{1-H_{i-4+j}, 3-H_{i-4+j}, 3-H_{i-4+j}, 1-H_{i-4+j}})}{\sum_{j=1}^{3} (-1)^{l} c_{2,3-H_{i-4+j}, 3-H_{i-4+j}, 3-H_{i-4+j}, 1-H_{i-4+j}}}, \quad \{l,k\} \in \{(1,2,3) \times (1,2,3)\}. \quad (3.25)
\]

In §7, it is shown that (3.24) and (3.25) can be re-cast in terms of standard functions.
4. The $4 \times 4$ matrix $B$

The $4 \times 4$ matrix is generally given by

$$B = b_{mn} = \begin{bmatrix} b_{11} & b_{12} & b_{13} & b_{14} \\ b_{21} & b_{22} & b_{23} & b_{24} \\ b_{31} & b_{32} & b_{33} & b_{34} \\ b_{41} & b_{42} & b_{43} & b_{44} \end{bmatrix}, \{m,n\} \in \{\{1,2,3,4\} \times \{1,2,3,4\}\}.$$ (4.1)

The index $m$ is not to be confused with an element of the minor-matrix $M$, which is not used in this section. The inverse of this matrix is once again given by applying (1.6, 7) 16 times in (1.10) with $A = B$, to (4.1), but this time with unresolved minors,

$$B^{-1} \sim \beta_{nm} \sim \begin{bmatrix} b_{22} & b_{23} & b_{24} & b_{21} & b_{22} & b_{24} & b_{21} & b_{22} & b_{23} \\ b_{22} & b_{33} & b_{34} & -b_{31} & b_{33} & b_{34} & -b_{31} & b_{32} & b_{33} \\ b_{22} & b_{33} & b_{34} & b_{31} & b_{33} & b_{34} & b_{31} & b_{32} & b_{33} \\ b_{12} & b_{13} & b_{14} & b_{11} & b_{13} & b_{14} & b_{11} & b_{12} & b_{13} \\ b_{12} & b_{13} & b_{14} & b_{11} & b_{13} & b_{14} & b_{11} & b_{12} & b_{13} \\ b_{12} & b_{13} & b_{14} & b_{11} & b_{12} & b_{13} & b_{11} & b_{12} & b_{13} \\ b_{22} & b_{23} & b_{24} & -b_{21} & b_{23} & b_{24} & -b_{21} & b_{22} & b_{23} \\ b_{22} & b_{23} & b_{24} & b_{21} & b_{23} & b_{24} & b_{21} & b_{22} & b_{23} \\ b_{22} & b_{23} & b_{24} & b_{21} & b_{22} & b_{23} & b_{21} & b_{22} & b_{23} \end{bmatrix}. \quad (4.2)$$

The adjugate of $B$ is actually the transpose of the numerator of (4.2), which is represented by $\beta_{nm}[B]$, as was the case in the previous section for $C$. The goal is now to find a general, compact expression for any element $\beta_{nm}$ of the inverse of the matrix $B$, beginning with the general $3 \times 3$ minor-matrix, which is now derived.

For the 1st row, the corresponding $3 \times 3$ minor-matrices (4.3), found on the next page, yield the general $3 \times 3$ minor-matrix $C_B$, valid for the 1st row and any $n$-th column

$$C_B(1,n) = B(2,3,4; 1+\delta_{n-1},2+\delta_{n-1}+\delta_{n-2},2+\delta_{n-1}+\delta_{n-2}+\delta_{n-3}) = \begin{bmatrix} b_{2,1+\delta_{n-1}} & b_{2,2+\delta_{n-1}+\delta_{n-2}} & b_{2,3+\delta_{n-1}+\delta_{n-2}+\delta_{n-3}} \\ b_{3,1+\delta_{n-1}} & b_{3,2+\delta_{n-1}+\delta_{n-2}} & b_{3,3+\delta_{n-1}+\delta_{n-2}+\delta_{n-3}} \\ b_{4,1+\delta_{n-1}} & b_{4,2+\delta_{n-1}+\delta_{n-2}} & b_{4,3+\delta_{n-1}+\delta_{n-2}+\delta_{n-3}} \end{bmatrix}.$$ (4.4)
which always involves the 2nd, 3rd, and 4th rows of (4.1). When \( n = 1 \), the minor-matrix only involves the 2nd, 3rd, and 4th columns, for \( n = 2 \), the 1st, 3rd, and 4th columns, and lastly, for \( n = 3 \), the 1st, 2nd, and 4th columns. Carrying out this process for the remaining 12 elements of (4.1) yields the general minor matrix \( C_B \) for the matrix \( B \):

\[
C_B(m,n) = B(1 + \delta_{m-1}, 2 + \delta_{m-1} + \delta_{m-2}, 3 + \delta_{m-1} + \delta_{m-2} + \delta_{m-3} + \delta_{n-3} ; 1 + \delta_{n-1}, 2 + \delta_{n-1} + \delta_{n-2}, 3 + \delta_{n-2} + \delta_{n-3} + \delta_{n-3})
\]

(4.5)

or in long-form as

\[
C_B(m,n) \sim c_{i'j'}(m,n) \sim
\begin{bmatrix}
  b_{1+\delta_{m-1},1+\delta_{m-1}} & b_{1+\delta_{m-1},2+\delta_{m-1}+\delta_{m-2}} & b_{1+\delta_{m-1},3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3}} \\
  b_{2+\delta_{m-1}+\delta_{m-2},1+\delta_{m-1}+\delta_{m-2}} & b_{2+\delta_{m-1}+\delta_{m-2},2+\delta_{m-1}+\delta_{m-2}+\delta_{m-3}} & b_{2+\delta_{m-1}+\delta_{m-2},3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3}} \\
  b_{3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3},1+\delta_{m-1}+\delta_{m-2}} & b_{3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3},2+\delta_{m-1}+\delta_{m-2}+\delta_{m-3}} & b_{3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3},3+\delta_{m-1}+\delta_{m-2}+\delta_{m-3}}
\end{bmatrix},
\]

\[\{k,l\} \in \{(1,2,3) \times \{1,2,3\}\}, \ \{m,n\} \in \{(1,2,3,4) \times \{1,2,3,4\}\}.
\]

(4.6)

Since \( C_B \) is a 3 \times 3 matrix like that analyzed in the previous section, its elements \( c \) are indexed using \( k \) and \( l \), although these elements are still functions of \((m, n)\), as evidenced by the RHS of (4.6). Consequently, a representative element of \( C_B \) is expressed as \( c_{i'j'}(m,n) \), as in (4.6). Unlike the indices of the elements of the RHS of (4.5), or (4.6), the elements \( c_{i'j'} \) of \( C_B \) are always indexed beginning with \( \{k, l\} = \{1, 1\} \), and are limited to a maximum of \( \{3, 3\} \). The 2 expressions can be simplified to the more compact forms

\[
C_B(m,n) = B(2 - H_{m-2}, 3 - H_{m-3}, 4 - H_{m-4} ; 2 - H_{n-2}, 3 - H_{n-3}, 4 - H_{n-4}),
\]

(4.7)

\[
C_B(m,n) \sim c_{i'j'}(m,n) = b_{k+1-H_{m-1}}, l+1-H_{n-1} \sim
\begin{bmatrix}
  b_{2-H_{m-2},2-H_{m-2}} & b_{2-H_{m-2},3-H_{m-3}} & b_{2-H_{m-2},4-H_{m-4}} \\
  b_{3-H_{m-3},2-H_{m-2}} & b_{3-H_{m-3},3-H_{m-3}} & b_{3-H_{m-3},4-H_{m-4}} \\
  b_{4-H_{m-4},2-H_{m-2}} & b_{4-H_{m-4},3-H_{m-3}} & b_{4-H_{m-4},4-H_{m-4}}
\end{bmatrix}
\]

(4.8)
Then for any given pair \( \{m, n\} \), the corresponding minor-matrix \( \mathbf{C}_B \) can be found. It is possible to telescope to a 2 \( \times \) 2 matrix \( \mathbf{D}_C \) that serves as the minor-matrix, to the minor-matrix \( \mathbf{C}_B \) itself, in short-form,

\[
\mathbf{D}_C(k,l) = \mathbf{C}_B(1 + \delta_{k-1}, 2 + \delta_{k-2}; 1 + \delta_{j-1}, 2 + \delta_{j-2}),
\]

and in long-form,

\[
\mathbf{D}_C(k,l) \sim d_{ij}(k,l) = c_{i+1-H_{i-1}, j+1-H_{j-1}} = \begin{bmatrix}
c_{2-H_{i-2}, 2-H_{j-2}} & c_{2-H_{i-3}, 3-H_{j-3}} \\
c_{3-H_{i-3}, 2-H_{j-2}} & c_{3-H_{i-4}, 3-H_{j-4}}
\end{bmatrix},
\]

\( \{i, j\} \in \{(1, 2) \times (1, 2)\}, & \{k, l\} \in \{(1, 2, 3) \times (1, 2, 3)\}. \)

As for the previous section, there are 2 approaches to attaining the inverse of \( \mathbf{B} \), and they both take advantage of the conclusions reached in the previous section for the matrix \( \mathbf{C}_B \).

For the first, surrogate matrix approach, the inverse matrix is found by substituting (4.7) into (1.10) with \( \mathbf{A} = \mathbf{B} \),

\[
\mathbf{B}^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \mathbf{C}_B(m,n)}{\mathbf{B}}, \quad \{m,n\} \in \{(1,2,3,4) \times (1,2,3,4)\}. \]

(4.11)

The determinant of a 3 \( \times \) 3 matrix \( \mathbf{C}_B \) was already found in \( \S 3 \), and is found from (3.12),

\[
|\mathbf{C}_B| = \sum_{l=1}^{3} \delta_{k-l}c_{kl}(-1)^{k+l}|\mathbf{D}_C(k,l)| = \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{j-l}(-1)^{i+j+k+l}c_{ij}(m,n)(d_{ij}d_{3-i-j})(k,l),
\]

(4.12)

In one form, the inverse (4.11) may then be re-cast using the LHS of (4.12),

\[
\mathbf{B}^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \mathbf{C}_B(m,n)}{\mathbf{B}}, \quad \sum_{l=1}^{3} \delta_{k-l}(-1)^{k+l+m+n}c_{kl}|\mathbf{D}_C(k,l)|
\]

\[
\sum_{n=1}^{4} \sum_{l=1}^{3} \delta_{j-l}(-1)^{j+k+l+m+n}b_{mn}c_{kl}|\mathbf{D}_C(k,l)|
\]

(4.13)

which is an expression of the inverse of \( \mathbf{B} \) in terms of the determinant of the 2 \( \times \) 2 matrix \( \mathbf{D}_C \). Alternatively, substituting the RHS of (4.12) into (4.11), \( \mathbf{B}^{-1} \) is more explicitly

\[
\mathbf{B}^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{i-j}(-1)^{i+j+k+l}c_{ij}(m,n) \cdot (d_{ij}d_{3-i-j})(k,l)}{\sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{i-j}(-1)^{i+j+k+l+m+n}b_{mn}c_{kl}(m,n) \cdot (d_{ij}d_{3-i-j})(k,l)},
\]

\( \{n,m\} \in \{(1,2,3,4) \times (1,2,3,4)\}. \)
For the above equation, it should be clarified that the elements $c$ of the surrogate minor-matrix $C_B$ are indexed to $(k, l)$, but are functions of the indices $m$ and $n$ of the original $4 \times 4$ matrix $B$ (4.1), and are thus represented as $c_{ij}(m, n)$, in accordance with (4.8). Furthermore, the elements $d$ of the surrogate $2 \times 2$ matrix $D_C$ are indexed to $(i, j)$ but are functions of the indices $k$ and $l$ of the minor-matrix $C_B$, and so are represented as $d_{ij}(k, l)$, in accordance with (4.10). The indices of a matrix element are always expressed as subscripts in this report. The denominator, which is the determinant of $B$, is effectively 3 nested Laplace Expansions. On the other hand, the numerator, which is the determinant of the minor-matrix $C_B$, is comprised of 2 nested Laplace Expansions. Applying the various Kronecker delta-functions yields the simplified expression, 

\[
\begin{align*}
B^{-1} \sim \beta_{nm} &= \frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l} c_{1,l}(m, n) \cdot (d_{1,j} d_{2,3-j})(1, 1)}{ \sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l+n} b_{1,n} \cdot c_{1,j}(1, n) \cdot (d_{1,j} d_{2,3-j})(1, 1) }, \\
{n, m} &\in \{(1,2,3,4) \times \{1,2,3,4\}\}, 
\end{align*}
\]

which, from the denominator, yields the determinant

\[
|B| = -\sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l+n} b_{1,n} \cdot c_{1,l}(1, n) \cdot (d_{1,j} d_{2,3-j})(1, 1). 
\]

In the second, direct approach for formulating the inverse of $B$, the elements $d$ of the surrogate matrix $D_C$ are replaced by the elements $b$ of the original matrix $B$. This is possible since the matrix $D_C$ is obtained from the matrix $C_B$, which in turn, is obtained from the original matrix $B$. Similarly, the elements $c$ are also replaced by $b$’s. As in the previous section, this approach is significantly more challenging, since both $C_B$ and $D_C$ are variable in indices, as is evident from (4.8) and (4.10). After taking the 1st step, in which both elements $c$ and $d$ are replaced by $b$ in (4.14),

\[
\begin{align*}
B^{-1} \sim \beta_{nm} &= \frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{l-1} \delta_{k-1} (-1)^{j+k+l} b_{k,l}(m, n) \cdot (b_{r,j} b_{3-i,j';3-j})(k, l)}{ \sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{l-1} \delta_{k-1} \delta_{m-1} (-1)^{j+k+l+m+n} b_{m,n} \cdot b_{k,l}(m, n) \cdot (b_{r,j} b_{3-i,j'})(k, l) }, \\
{n, m} &\in \{(1,2,3,4) \times \{1,2,3,4\}\}. 
\end{align*}
\]

A new convention is adopted for the indices of the elements $b$ that replace both $c$ and $d$ in (4.14): The elements $b$ retain the indices of the elements being replaced, but they are primed a number of times dependent on the number of telescoping steps associated with the matrix whose element is being replaced by $b$. After replacing the elements $c$ with $b$ in (4.14), its indices now carry single primes since the replaced elements $c$ are obtained from $C_B$, which is found from the original matrix $B$ after a single telescoping step.
Following the approach used for (3.14, 15), they have the following expressions

\[ k' = k + 1 - H_{m-k-1} = \kappa(k, m), \quad (4.18) \]
\[ l' = l + 1 - H_{n-l-1} = \kappa(l, n). \quad (4.19) \]

which are obtained from the LHS of (4.8). The index \( k \) should not be confused with the function \( \kappa \), which is Greek. Upon replacing the elements \( d \) in (4.14) with \( b \), its indices acquire double-primes, since the replaced elements \( d \) are obtained from \( D_c \), which is in turn found from the original matrix \( B \), after two telescoping steps. There results a total of 4 double-primed indices, which have to be resolved. However, all the double-prime indices may be obtainable through simple operations on just one of the indices. The row index \( i'' \) can be considered first:

\[
(i'' + 1 - H_{m-i-1})' = \begin{cases} 
(2 - H_{k-1})', & i = 1 \\
2'H_{k-2} + 1'H_{k-3}, & i = 1 \\
3'H_{k-3} + 2'H_{k-4}, & i = 2 \\
(3 - H_{k-1})', & i = 2
\end{cases}
\]

which can be summarized as

\[
i'' = (i + 1 - H_{m-i-1}) H_{k-i-1} + (i + 2 - H_{m-i-2}) H_{l-k}, \quad i \in \{1, 2\}, \quad k \in \{1, 2, 3\}, \quad m \in \{1, 2, 3, 4\}. \quad (4.20)
\]

It can be simplified to the compact expression

\[
i'' = \sum_{u=1}^{2} (i + u - H_{m-i-u}) H_{(1)''(i-u-k+2)} = \lambda(i, k, m) \quad (4.22)
\]

with the same indicial conditions as the ones in (4.21). For the double-primed column index \( j'' \) in (4.17), it may be obtained after simple operations on (4.21) and/or (4.22),

\[
j'' = i'' \delta_{i-j} \delta_{k-l} \delta_{m-n} \quad (4.23)
\]

with the result

\[
j'' = (j + 1 - H_{n-j-1}) H_{j-i-1} + (j + 2 - H_{n-j-2}) H_{l-j} = \sum_{u=1}^{2} (j + u - H_{n-j-u}) H_{(1)''(j-l-u+2)} = \lambda(j, l, n), \quad j \in \{1, 2\}, \quad l \in \{1, 2, 3\}, \quad n \in \{1, 2, 3, 4\}. \quad (4.24)
\]

As for \( (3 - i)'' \), it is obtainable from (4.22) by the discrete convolution

\[
(3 - i)'' = i'' \otimes \delta_{3-j}, \quad (4.25)
\]
which performs a reflection in \( i \), followed by a shift of 3 units. It yields the compact expression

\[
(3 - i)^* = (4 - i - H_{m-3+i})H_{k-4+i} + (5 - i - H_{m-5+i})H_{3-i-k} = \sum_{u=4}^{5} (u - i - H_{m-u+i})H_{(-1)^u(k+u-i-8)} = \mu(i, k, m),
\]

\[
i \in \{1, 2\}, \ k \in \{1, 2, 3\}, \ m \in \{1, 2, 3, 4\}. \tag{4.26}
\]

The corresponding column index may be obtained from the following simple operations on (4.26) above:

\[
(3 - j)^* = (3 - i)^* \delta_{i-j} \delta_{k-l} \delta_{m-n}
\]

\[
\text{with the implication that} \ i \ \text{is to be replaced by} \ j, \ k \ \text{by} \ l, \ \text{and} \ m \ \text{by} \ n. \ \text{The result of these operations yields the expression}
\]

\[
(3 - j)^* = (4 - j - H_{m-4+j})H_{l-4+j} + (5 - j - H_{m-5+j})H_{3-j-l} = \sum_{u=4}^{5} (u - j - H_{n-u+j})H_{(-1)^u(l+u-j-8)} = \mu(j, l, n),
\]

\[
j \in \{1, 2\}, \ l \in \{1, 2, 3\}, \ n \in \{1, 2, 3, 4\}. \tag{4.28}
\]

After substituting (4.18), (4.19), (4.22), (4.24), (4.26) and (4.28) into (4.17),

\[
\mathbf{B}^{-1} \simeq \beta_{nm} = \frac{(-1)^{m+n} \sum_{j=1}^{2} \delta_{i-j} \delta_{k-l} (-1)^{i+j+k+l} b_{k(l,m), \kappa(l,n)} \cdot b_{\lambda(i,k,m), \lambda(j,l,n)} \cdot b_{\mu(i,k,m), \mu(j,l,n)}}{\sum_{n=1}^{4} \sum_{j=1}^{3} \delta_{i-j} \delta_{k-l} \delta_{m-n} (-1)^{i+j+k+l+m+n} b_{n(l,m), \kappa(l,n)} \cdot b_{\lambda(i,k,m), \lambda(j,l,n)} \cdot b_{\mu(i,k,m), \mu(j,l,n)}, \quad \{n, m\} \in \{(1, 2, 3, 4) \times (1, 2, 3, 4)\}. \tag{4.29}
\]

which is now explicitly in terms of the elements of the original matrix \( \mathbf{B} \). After enforcing the various Kronecker delta-functions,

\[
\mathbf{B}^{-1} \simeq \beta_{nm} = \frac{(-1)^{m+n} \sum_{j=1}^{2} (-1)^{2s+j+l} b_{k(1,m), \kappa(1,n)} \cdot b_{\lambda(1,l,m), \lambda(1,l,n)} \cdot b_{\mu(1,l,m), \mu(1,l,n)}}{\sum_{n=1}^{4} \sum_{j=1}^{2} (-1)^{2s+j+l+m+n} b_{n(1,m), \kappa(1,n)} \cdot b_{\lambda(1,l,m), \lambda(1,l,n)} \cdot b_{\mu(1,l,m), \mu(1,l,n)}, \quad \{n, m\} \in \{(1, 2, 3, 4) \times (1, 2, 3, 4)\}. \tag{4.30}
\]

which yields the simplified indicial functions
\[ \kappa(1,m) = 2 - H_{m-2} \]  
\[ \kappa(1,1) = 2 - H_{-1} = 2 \]  
\[ \lambda(1,1,m) = (i + 1 - H_{m-1})H_{-1} + (3 - H_{m-3})H_0 = 3 - H_{m-3}, \]  
\[ \lambda(1,1,1) = 3 \]  
\[ \mu(1,1,m) = (4 - i - H_{m-4+i})H_2 + (4 - H_{m-4})H_1 = 4 - H_{m-4}, \]  
\[ \mu(1,1,1) = 4 - H_3 = 4 \]

since the Heaviside step-function vanishes for negative arguments, according to its definition (3.9). Eqs. (4.33) and (4.35) are actually reduced beginning with the outermost Heaviside step-functions, and since their arguments are found to be negative, they are neglected along with any parenthesized expression with which they are multiplied, since they are always finite. Finally, an expression for the inverse is found explicitly in terms of the elements of the original matrix \( B \):

\[
B^{-1} \sim \beta_{nm} = -\frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l} b_{2-H_{m-2}, \kappa(l,n)} \cdot b_{2-H_{m-3}, \lambda(j,l,n)} \cdot b_{4-H_{m-4}, \mu(j,l,n)} \cdot \sum_{n=1}^{2} \sum_{l=1}^{2} \sum_{j=1}^{2} (-1)^{j+l+n} b_{1,n} \cdot b_{2, \kappa(l,n)} \cdot b_{3, \lambda(j,l,n)} \cdot b_{4, \mu(j,l,n)}}{4} \right),
\]

\[
\{n,m\} \in \{\{1,2,3,4\} \times \{1,2,3,4\}\},
\]

with the determinant given by the denominator

\[
|B| = \sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l+n} b_{1,n} \cdot b_{2, \kappa(l,n)} \cdot b_{3, \lambda(j,l,n)} \cdot b_{4, \mu(j,l,n)} \]  
\[ \kappa(l,n) = l + 1 - H_{n-l+1}, \]  
\[ \lambda(j,l,n) = \sum_{u=1}^{2} \left( j + u - H_{n-j-u} \right)H_{(1)\epsilon(j-l-u+2)} \]  
\[ \mu(j,l,n) = \sum_{u=4}^{5} \left( u - j - H_{n-u+j} \right)H_{(1)\epsilon(i+u-j-8)} \]  

The arguments of these functions are specified by the summations in (4.37), along with the column index \( n \).
5. The 5×5 matrix A
The 5 × 5 matrix is generally given by

\[
A = \begin{bmatrix}
    a_{11} & a_{12} & a_{13} & a_{14} & a_{15} \\
    a_{21} & a_{22} & a_{23} & a_{24} & a_{25} \\
    a_{31} & a_{32} & a_{33} & a_{34} & a_{35} \\
    a_{41} & a_{42} & a_{43} & a_{44} & a_{45} \\
    a_{51} & a_{52} & a_{53} & a_{54} & a_{55}
\end{bmatrix}, \quad \{p, q\} \in \{(1,2,3,4,5) \times \{1,2,3,4,5\}\}.
\] (5.1)

The expression for the inverse of this matrix is even larger than that (4.2) of the 4×4 B matrix (4.1), and is only provided here for completeness:

\[
A^{-1} = \begin{bmatrix}
    a_{22} & a_{23} & a_{24} & a_{25} & a_{26} \\
    a_{32} & a_{33} & a_{34} & a_{35} & a_{36} \\
    a_{42} & a_{43} & a_{44} & a_{45} & a_{46} \\
    a_{52} & a_{53} & a_{54} & a_{55} & a_{56} \\
    a_{62} & a_{63} & a_{64} & a_{65} & a_{66}
\end{bmatrix}, \quad \{p, q\} \in \{(1,2,3,4,5) \times \{1,2,3,4,5\}\}.
\] (5.2)

The general minor-matrices of the 3×3 and 4×4 matrices (3.1) and (4.1) were respectively found to be (3.6) and (4.5), reproduced here as

\[
C(1 + \delta_{k-1}, 2 + \delta_{k-1} + \delta_{k-2} ; 1 + \delta_{l-1}, 2 + \delta_{l-1} + \delta_{l-2}), \quad \{k, l\} \in \{(1,2,3) \times \{1,2,3\}\},
\] (5.3)

\[
B(1 + \delta_{m-1}, 2 + \delta_{m-1} + \delta_{m-2}, 3 + \delta_{m-1} + \delta_{m-2} + \delta_{m-3} ; 1 + \delta_{n-1}, 2 + \delta_{n-1} + \delta_{n-2}, 3 + \delta_{n-1} + \delta_{n-2} + \delta_{n-3}), \quad \{m, n\} \in \{(1,2,3,4) \times \{1,2,3,4\}\}.
\] (5.4)
The matrix version for each, can be found from the Cartesian product of the set of row indices, with the set of column indices, defined by the semi-colon delimiter ‘;’. For the $5 \times 5$ matrix (5.1) then, the following $4 \times 4$ minor-matrix expression may be deduced by a process of induction,

$$
\begin{pmatrix}
1 + \delta_{p-1},2 + \delta_{q-1},3 + \delta_{p-1} + \delta_{q-1},4 + \delta_{p-1} + \delta_{q-2} + \delta_{q-1} + \delta_{q-2} + \delta_{p-2} + \delta_{p-2} + \delta_{p-3} + \delta_{q-3} + \delta_{q-3} + \delta_{q-4} + \delta_{q-4} + \delta_{p-3} + \delta_{p-3}; \\
1 + \delta_{p-1},2 + \delta_{q-1},3 + \delta_{p-1} + \delta_{q-1},4 + \delta_{p-1} + \delta_{q-2} + \delta_{q-1} + \delta_{q-2} + \delta_{p-2} + \delta_{p-2} + \delta_{p-3} + \delta_{q-3} + \delta_{q-3} + \delta_{q-4} + \delta_{q-4} + \delta_{p-3} + \delta_{p-3} \\
\end{pmatrix},
$$

$$
\{p, q\} \in \{(1, 2, 3, 4, 5) \times (1, 2, 3, 4, 5)\}
$$

(5.5)

It was also found that the general minor-matrices of the $3 \times 3$ and $4 \times 4$ matrices (3.1) and (4.1) had the more compact forms of (3.7) and (4.7), reproduced here as

$$
\begin{pmatrix}
C \left( 2 - H_{k-2}, 3 - H_{k-3} ; 2 - H_{l-2}, 3 - H_{l-3} \right), \{k, l\} \in \{(1, 2, 3) \times (1, 2, 3)\}, \\
B \left( 2 - H_{m-2}, 3 - H_{m-3}, 4 - H_{m-4} ; 2 - H_{n-2}, 3 - H_{n-3}, 4 - H_{n-4} \right), \{m, n\} \in \{(1, 2, 3, 4) \times (1, 2, 3, 4)\},
\end{pmatrix}
$$

(5.6)

(5.7)

which have been re-expressed using the equivalence of

$$
\sum_{u=1}^{p} (1 + \delta_{s-u}) = P + 1 - H_{s-P-1} , \ P \in \mathbb{Z}.
$$

(5.8)

This alternative form which exclusively uses the Heaviside step-function, is more compact and more amenable to the standard matrix format. Once again, based on (5.6) and (5.7), it is not difficult to see that for the $5 \times 5$ matrix (5.1), its minor-matrix must be

$$
\begin{pmatrix}
A \left( 2 - H_{p-2}, 3 - H_{p-3}, 4 - H_{p-4}, 5 - H_{p-5} ; 2 - H_{q-2}, 3 - H_{q-3}, 4 - H_{q-4}, 5 - H_{q-5} \right), \\
\{p, q\} \in \{(1, 2, 3, 4, 5) \times (1, 2, 3, 4, 5)\},
\end{pmatrix}
$$

(5.9)

and which can also be expressed in matrix form as

$$
\begin{pmatrix}
A_{m+1-H_{p,n}, n+1-H_{q,n}} \\
\end{pmatrix}
$$

$$
\begin{pmatrix}
a_{2-H_{p-2},2-H_{q-2}} & a_{2-H_{p-2},3-H_{q-2}} & a_{2-H_{p-2},4-H_{q-2}} & a_{2-H_{p-2},5-H_{q-2}} \\
a_{3-H_{p-2},2-H_{q-2}} & a_{3-H_{p-2},3-H_{q-2}} & a_{3-H_{p-2},4-H_{q-2}} & a_{3-H_{p-2},5-H_{q-2}} \\
a_{4-H_{p-2},2-H_{q-2}} & a_{4-H_{p-2},3-H_{q-2}} & a_{4-H_{p-2},4-H_{q-2}} & a_{4-H_{p-2},5-H_{q-2}} \\
a_{5-H_{p-2},2-H_{q-2}} & a_{5-H_{p-2},3-H_{q-2}} & a_{5-H_{p-2},4-H_{q-2}} & a_{5-H_{p-2},5-H_{q-2}} \\
\end{pmatrix},
$$

(5.10)

$$
\{m, n\} \in \{(1, 2, 3, 4) \times (1, 2, 3, 4)\}, \{p, q\} \in \{(1, 2, 3, 4, 5) \times (1, 2, 3, 4, 5)\}.
$$
Using the surrogate matrix approach, the following closed-form expressions were found for the inverses of the $2 \times 2$, $3 \times 3$ and $4 \times 4$ matrices, respectively given by (2.3), and (3.12), and (4.14),

$$D^{-1} \sim \frac{(-1)^{i+j} d_{i,j}}{\sum_{j=1}^{N} \delta_{i,j}(-1)^{i+j} d_{i,j}d_{j,j}}, \quad \{j,i\} \in \{(1,2) \times \{1,2\}\}, \quad (5.11)$$

$$C^{-1} \sim \gamma_{jk} = \frac{(-1)^{k+l} \sum_{l=1}^{N} \delta_{l,k}(-1)^{i+j+k+l} c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}{\sum_{l=1}^{N} \sum_{j=1}^{N} \sum_{i=1}^{N} \delta_{i,j} \delta_{j,k} \delta_{k,m} (-1)^{i+j+k+l+m+n} b_{mn} \cdot c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}, \quad \{l,k\} \in \{(1,2,3) \times \{1,2,3\}\} \quad (5.12)$$

$$B^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \sum_{m=1}^{N} \sum_{n=1}^{N} \sum_{l=1}^{N} \delta_{i,m} \delta_{j,n} \delta_{k,l} \delta_{l,p} (-1)^{i+j+k+l+m+n+p+q} a_{pq} \cdot b_{mn} \cdot c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}{\sum_{q=1}^{5} \sum_{n=1}^{N} \sum_{l=1}^{N} \sum_{i=1}^{N} \delta_{i,n} \delta_{j,l} \delta_{k,p} (-1)^{i+j+k+l+m+n+p+q} a_{pq} \cdot b_{mn} \cdot c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}, \quad \{n,m\} \in \{(1,2,3,4) \times \{1,2,3,4\}\} \quad (5.13)$$

The expressions can be significantly simplified by enforcing the Kronecker delta-functions within each summand. However, they are retained to establish the trend that should lead to the desired expression for the inverse of $A$. It is now observable that, when expressed as a quotient, the inverse of a $N \times N$ matrix is comprised of $(N-2)$ summations in the numerator, and $(N-1)$ summations in the denominator, the outermost of which depends on the column index of the $N \times N$ matrix. The numerator of the inverse of a $N \times N$ matrix is of the form of the denominator of the inverse of the $N-1 \times N-1$ matrix. The denominator of the inverse matrix, which is its determinant, is the sum of its numerator evaluated for its first row over the $N$ columns, but weighted by the signed elements of the first row of the matrix. By induction for the $5 \times 5$ matrix $A$ (5.1), its inverse should be a rational expression with 3 summations in its numerator, and 4 summations in its denominator. Furthermore, its numerator should be of the same form as the denominator of the $4 \times 4$ matrix $B$, signed according to $(-1)^{p+q}$, whereas its denominator should be its numerator summed over all $(q=5)$ five columns of $A$, but evaluated for its $(p=1)$ first row, and weighted by that row's signed elements, $(-1)^{p+q} a_{iq}$. Consequently, the inverse of $A$ (5.1) has the form

$$A^{-1} \sim \alpha_{qp} = \frac{(-1)^{p+q} \sum_{m=1}^{N} \sum_{l=1}^{N} \sum_{j=1}^{N} \delta_{i,m} \delta_{j,n} \delta_{k,l} (-1)^{i+j+k+l+m+n+p+q} a_{pq} \cdot b_{mn} \cdot c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}{\sum_{q=1}^{5} \sum_{n=1}^{N} \sum_{l=1}^{N} \sum_{i=1}^{N} \delta_{i,n} \delta_{j,l} \delta_{k,p} (-1)^{i+j+k+l+m+n+p+q} a_{pq} \cdot b_{mn} \cdot c_{kl}(m,n) \cdot (d_{i,j}d_{j,j})(k,l)}, \quad \{n,m\} \in \{(1,2,3,4,5) \times \{1,2,3,4,5\}\} \quad (5.14)$$
In this expression, the elements \( b, c, \) and \( d \) are respectively obtained from the surrogate matrices \( B_A, C_B, \) and \( D_C. \) The matrix \( B_A \sim b_{mn}(p, q) \) is a \( 4 \times 4 \) matrix that serves as a surrogate for the minor-matrix of \( A, \) and is a direct function of the indices \( (p, q) \) of the matrix \( A. \) The matrix \( C_B \sim c_{kl}(m, n) \) is a \( 3 \times 3 \) matrix that is used as the surrogate for the minor-matrix of the resultant matrix \( B_A, \) is a direct function of its indices \( (m, n), \) but is also indirectly a function of \( (p, q). \) Lastly, \( D_C \sim d_{ij}(k, l) \) is a \( 2 \times 2 \) matrix that is used as the surrogate for the minor-matrix of the matrix \( C_B. \) They are all given by

\[
    B_A = A \left( 2 - H_{p-2}, 3 - H_{p-3}, 4 - H_{p-4}, 5 - \delta_{p-5} \right) \left( 2 - H_{q-2}, 3 - H_{q-3}, 4 - H_{q-4}, 5 - \delta_{q-5} \right),
    \{ p, q \} \in \left\{ \{1, 2, 3, 4\} \times \{1, 2, 3, 4\} \right\}.
\]

(5.15)

\[
    C_B = B_A \left( 2 - H_{m-2}, 3 - H_{m-3}, 4 - H_{m-4} \right) \left( 2 - H_{n-2}, 3 - H_{n-3}, 4 - H_{n-4} \right),
    \{ m, n \} \in \left\{ \{1, 2, 3\} \times \{1, 2, 3\} \right\}.
\]

(5.16)

\[
    D_C = C_B \left( 2 - H_{k-2}, 3 - H_{k-3}; 2 - H_{l-2}, 3 - H_{l-3} \right),
    \{ m, n \} \in \left\{ \{1, 2, 3\} \times \{1, 2, 3\} \right\}.
\]

(5.17)

More explicitly in terms of the elements of the original matrices themselves, the following expressions for the inverse matrices were found:

\[
    D^{-1} \sim -\left( -1 \right)^{j+i} d_{3-i,3-j}, \quad \{ j, i \} \in \left\{ \{1, 2\} \times \{1, 2\} \right\},
\]

(5.18)

\[
    C^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2} \delta_{l-1} \left( -1 \right)^{i+j+k+l} c_{\mu(l,k),\mu(j,l)} c_{\lambda(l,k),\lambda(j,l)}}{\sum_{i=1}^{2} \sum_{j=1}^{2} \delta_{i-1} \delta_{k-1} \left( -1 \right)^{i+j+k+l} c_{\mu(i,k),\mu(j,l)} c_{\lambda(i,k),\lambda(j,l)}}, \{ l, k \} \in \left\{ \{1, 2, 3\} \times \{1, 2, 3\} \right\}
\]

(5.19)

\[
    B^{-1} \sim \beta_{nm} = \frac{\left( -1 \right)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{n-1} \delta_{k-1} \left( -1 \right)^{i+j+k+l} b_{\mu(l,m),\mu(l,n)} b_{\nu(i,j,l),\nu(i,j,l)} b_{\lambda(i,k,m),\lambda(i,j,l,n)}}{\sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} \delta_{n-1} \delta_{k-1} \delta_{m-1} \left( -1 \right)^{i+j+k+l+m+n} b_{mn} b_{\mu(l,m),\mu(l,n)} b_{\nu(i,j,l),\nu(i,j,l,n)} b_{\lambda(i,k,m),\lambda(i,j,l,n)}}, \{ n, m \} \in \left\{ \{1, 2, 3, 4\} \times \{1, 2, 3, 4\} \right\}.
\]

(5.20)

By similar reasoning, a more explicit expression for \( A \) can be found, in which all the elements in (5.14) are replaced by \( a \)'s, but with all indices primed where required.
As previously explained, an index is primed depending on the number of telescoping steps required to attain its corresponding matrix element, which is being replaced by a. For instance, the indices \( i \) and \( j \) are primed thrice since 3 telescoping steps are required to derive the 2 x 2 matrix \( D_{C}(5.17) \) from the original 5 x 5 matrix \( A(1.5) \). The indices can be simplified as follows, beginning with

\[
m' = m + 1 - H_{p-m-1} = \kappa(m, p),
\]

\[
n' = m' \delta_{m-n} \delta_{p-q} = n + 1 - H_{q-n-1} = \kappa(n, q).
\]

For the double-primed row index \( k'' \),

\[
k'' = (k + 1 - H_{p-k-1})' \quad (2H_{m-2} + 1'H_{m-2}, k = 1)
\]

\[
= (k + 2 - H_{p-k-2})' \quad (3H_{m-2} + 2'H_{m-2}, k = 2)
\]

which can be summarized as

\[
k'' = (k + 1 - H_{p-k-1})' H_{m-k-1} + (k + 2 - H_{p-k-2})' H_{k-m}, \quad k \in \{1, 2, 3\}, \quad m \in \{1, \ldots, 4\}, \quad p \in \{1, \ldots, 5\}.
\]

It can be simplified to the compact expression

\[
k'' = \sum_{u=1}^{2} (k + u - H_{p-k-u})' H_{(m-u+2)} = \lambda(k, m, p), \quad k \in \{1, 2, 3\}, \quad m \in \{1, \ldots, 4\}, \quad p \in \{1, \ldots, 5\}.
\]

Applying the following operations on the double-primed row index \( k'' \) yields the double-primed column index \( l'' \):

\[
l'' = k'' \delta_{m-n} \delta_{p-q} = \sum_{u=1}^{2} (l + u - H_{q-l-u})' H_{(m-u+2)} = \lambda(l, n, q), \quad l \in \{1, 2, 3\}, \quad n \in \{1, \ldots, 4\}, \quad q \in \{1, \ldots, 5\}.
\]

As for
\[ i^n = (i + 1 - H_{k-1}) = \begin{cases} (2 - H_{k-1})^i, i = 1 \\ (3 - H_{k-1})^i, i = 2 \end{cases} \]

\[ = \begin{cases} (2H_{k-1} + 1H_{k-2}, i = 1 \\ (3H_{k-2} + 2H_{k-3}, i = 2 \end{cases} \]

\[ = \begin{cases} (2H_{k-1} + 1H_{k-2})H_{k-2} + (3H_{k-2} + 2H_{k-3})H_{k-3}, i = 1 \\ (3H_{k-2} + 2H_{k-3} + 3H_{k-3} + 4H_{k-4})H_{k-4}, i = 2 \end{cases} \]

\[ = \begin{cases} (2H_{k-1} + 1H_{k-2})H_{k-2} + (3H_{k-2} + 2H_{k-3})H_{k-3}, i = 1 \\ (3H_{k-2} + 2H_{k-3} + 3H_{k-3} + 4H_{k-4})H_{k-4}, i = 2 \end{cases} \]

\[ \text{which can be generalized for any value of } i \text{ being 1 or 2 as} \]

\[ i^n = (i + 1 - H_{p-1})H_{m-1} + (i + 2 - H_{p-1})H_{m-2} + (i + 3 - H_{p-1})H_{m-3} \]

\[ = \begin{cases} \sum_{u=1}^{2} \sum_{v=0}^{1} (i + u + v - H_{p-1})H_{m-1} = \mu(i, k, m, p). \end{cases} \]

\[ \text{The corresponding column index is obtainable from the above results as follows} \]

\[ j^n = i^n \delta_{-j} \delta_{k-l} \delta_{m-n} \delta_{p-q} \]

\[ \text{which involves the replacement in } i^n (5.30), \text{ of } i \text{ with } j, k \text{ with } m, \text{ with } n, \text{ and } p \text{ with } q, \text{ with the result,} \]

\[ j^n = \sum_{u=1}^{2} \sum_{v=0}^{1} (j + u + v - H_{q-1})H_{-1} = \mu(j, l, n, q) \]

\[ \text{As for} \]

\[ (3-i)^n = i^n \otimes \delta_{3-i} = \sum_{u=1}^{2} \sum_{v=0}^{1} (i + u + v + 3 - H_{p-i-1})H_{-1} = \nu(i, k, m, p) \]

\[ \text{and is obtained by discrete convolution on (5.30), as explained in the previous section.} \]

\[ \text{The function } \nu(\bullet) \text{ should not be confused with the summation index } \nu \text{ on the LHS. Lastly,} \]

\[ \text{the corresponding column index is obtained from (5.32) after a few simple operations,} \]

\[ (3-j)^n = (3-i)^n \delta_{3-j} \delta_{k-l} \delta_{m-n} \delta_{p-q} = \nu(j, l, n, q) \]

\[ \text{Consequently,} \]
\[
A^{-1} \sim \alpha_{qp} = \frac{(-1)^{p+q} \sum_{n=1}^{4} \sum_{l=1}^{3} \delta_{l,2} \delta_{n,1} \delta_{y,1} (-1)^{j+k+l+m+n} \alpha_{k(m,p),k(n,q)} \cdot a_{l(k,m,p),l(l,n,q)} \cdot a_{q(l,m,p),l(l,n,q)} \cdot a_{s(l,m,p),s(l,n,q)} \cdot a_{v(l,m,p),v(l,n,q)}}{\sum_{q=1}^{5} \sum_{n=1}^{4} \sum_{l=1}^{3} \delta_{l,2} \delta_{n,1} \delta_{y,1} (-1)^{j+k+l+m+n} \alpha_{q(m,p),q(n,q)} \cdot a_{l(k,m,p),l(l,n,q)} \cdot a_{q(l,m,p),l(l,n,q)} \cdot a_{s(l,m,p),s(l,n,q)} \cdot a_{v(l,m,p),v(l,n,q)}} .
\]

(5.35)

After enforcing the various Kronecker delta-functions, the expression simplifies to

\[
A^{-1} \sim \alpha_{qp} = \frac{(-1)^{p+q} \sum_{n=1}^{3} \sum_{l=1}^{2} (-1)^{j+k+l+m+n} \alpha_{k(l,p),k(n,q)} \cdot a_{o(l,1,p),o(l,1,n)} \cdot a_{o(l,1,1,p),o(l,1,1,n)} \cdot a_{o(l,1,1,1,p),o(l,1,1,1,n)}}{\sum_{q=1}^{4} \sum_{n=1}^{3} \sum_{l=1}^{2} (-1)^{j+k+l+m+n} \alpha_{q(l,1),q(n,q)} \cdot a_{o(l,1,1),o(l,1,1,n)} \cdot a_{o(l,1,1,1),o(l,1,1,1,n)} \cdot a_{o(l,1,1,1,1),o(l,1,1,1,1,n)}} ,
\]

(5.36)

where

\[
\kappa(1, p) = 2 - H_{p-2} ,
\]

(5.37)

\[
\kappa(1, 1) = 2 - H_{1} = 2 ,
\]

(5.38)

\[
\lambda(1, 1, p) = \left(2 - H_{p-2}\right)H_{1} + \left(3 - H_{p-3}\right)H_{0} = 3 - H_{p-3}
\]

(5.39)

\[
\lambda(1, 1, 1) = 3 ,
\]

(5.40)

\[
\mu(1, 1, 1, p) = \left(2 - H_{p-2}\right)H_{1} + \left(3 - H_{p-3}\right)H_{0} = \left(3 - H_{p-3}\right)H_{2} + \left(4 - H_{p-4}\right)H_{1} ,
\]

(5.41)

\[
\mu(1, 1, 1, 1) = 4 ,
\]

(5.42)

\[
\nu(1, 1, 1, p) = \left(4 - i - H_{p-4}\right)H_{1} + \left(5 - i - H_{p-5}\right)H_{1} = 5 - H_{p-5}
\]

(5.43)

\[
\nu(1, 1, 1, 1) = 5 .
\]

(5.44)

and finally,

\[
A^{-1} \sim \alpha_{qp} = \frac{(-1)^{p+q} \sum_{n=1}^{4} \sum_{l=1}^{2} (-1)^{j+k+l+m+n} \alpha_{2-H_{p-2}, k(n,q)} \cdot a_{3-H_{p-3}, \lambda(l,n,q)} \cdot a_{4-H_{p-4}, \mu(j,l,n,q)} \cdot a_{5-H_{p-5}, \nu(j,l,n,q)}}{\sum_{q=1}^{5} \sum_{n=1}^{4} \sum_{l=1}^{3} (-1)^{j+k+l+m+n} \alpha_{q(k,n),q(n,q)} \cdot a_{2-l, k(n,q)} \cdot a_{3-l, \lambda(l,n,q)} \cdot a_{4-l, \mu(j,l,n,q)} \cdot a_{5-l, \nu(j,l,n,q)}} .
\]

(5.45)
where $\kappa(n,q), \lambda(l,n,q), \mu(j,l,n,q)$, and $\nu(j,l,n,q)$ are respectively given by (5.23), (5.27), (5.32) and (5.34). The determinant is found in the denominator of (5.45),

$$ |A| = \sum_{q=1}^{5} \sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+n+q} a_{1,q} \cdot a_{2,\kappa(n,q)} \cdot a_{3,\lambda(l,n,q)} \cdot a_{4,\mu(j,l,n,q)} \cdot a_{5,\nu(j,l,n,q)} $$

No mathematical proof is proffered for the conjecture (5.45) at this juncture. However, in order to validate (5.45), one hundred-thousand, $5 \times 5$ matrices were generated in Matlab, using the randn(5)-function, which produced $5 \times 5$ matrices comprised of pseudo-random elements selected from the standard normal distribution. The inverse of an $r$-th matrix was found using (5.45), as well as by using Matlab's inv-function, represented by $\zeta_{pq}$. Subsequently, the mean-square error (MSE) $\varepsilon_r$ for each $r$-th matrix was found as

$$ \varepsilon_r = \frac{1}{5^2} \sum_{p=1}^{5} \sum_{q=1}^{5} \left[ \beta_{qp} - \zeta_{pq} \right]^2, \ r \in \{1,2,3,\cdots,9998,9999,10^5\}. \ (5.47) $$

A histogram, of 10 times the base-10-logarithm of each $r$-th MSE, was then generated using the Matlab hist- or histogram-function. In order to avoid zero MSE values that would yield infinite outcomes under the logarithm, the MSE vector $\varepsilon_r$ was initialized to constants of the order of $10^{-100}$. The result is found in fig. 1.

![Histogram](image)

Fig. 1. A histogram of the normalized distribution of $10\log_{10}\varepsilon_r$ (5.47) for the inverse of one hundred-thousand $5 \times 5$ random matrices. The inset shows a typical histogram generated by the Matlab randn-function.

The minimum MSE was found to be $4.1 \times 10^{-34}$ (-334 in fig. 1), while the maximum MSE for a generated matrix was no more than $3 \times 10^{-12}$. The mode MSE is seen to be of the order of $10^{-32}$ (-320 in fig. 1). The non-zero MSE is attributed to the different
computational methods used in the 2 approaches, but is quite small regardless, validating (5.45) for the inverse of a randomly generated 5 x 5 matrix. The majority of the MSE is observed to be < $10^{-20}$ (-200 in fig. 1), and the distribution exhibits a non-negative skewness. The MSE distribution would not be expected to be Gaussian, since the determinant of a square matrix comprised of i.i.d. Gaussian random variables, upon which (5.45) is based, would not be Gaussian in general. Therefore, the MSE (5.47) is even less likely to be Gaussian.

It is known that if at least one row (or column) of a square matrix is comprised entirely of zeros, the determinant resolves to zero, and the associated matrix would not be invertible. However, the determinant also resolves to zero when this is not the case, for some inversion techniques on sparse, but invertible square matrices, such as the following matrices,

\[
\begin{bmatrix}
0 & 0 & 0 & x & 0 \\
0 & x & 0 & 0 & 0 \\
x & 0 & 0 & 0 & 0 \\
0 & 0 & x & 0 & 0 \\
0 & 0 & 0 & 0 & x
\end{bmatrix},
\begin{bmatrix}
x & 0 & 0 & 0 & 0 \\
0 & x & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & x \\
0 & 0 & x & 0 & 0 \\
0 & 0 & 0 & x & 0
\end{bmatrix},
\begin{bmatrix}
0 & x & 0 & 0 & 0 \\
x & 0 & 0 & 0 & 0 \\
0 & 0 & x & 0 & 0 \\
0 & 0 & 0 & 0 & x \\
0 & 0 & 0 & x & 0
\end{bmatrix}
\] (5.48)

Preliminary work indicates that the technique reported herein is immune to such cases. As exemplified by (5.48), an invertible $N \times N$ matrix need not support more than $N$ non-zero elements $x$ to remain invertible, or equivalently, it can support as many as $(N^2-N)$ appropriately located zeros and still be invertible. There are no restrictions on the value of $x$ as long as the matrix remains invertible. Such matrices as shown in (5.48) carry many interior zero-elements, which can be problematic for certain determinant techniques such as Dodgson Condensation [8, 18, 19], and the recursive technique due to Razaifar and Rezaee [26]. The problem is usually alleviated by some additional (pre-) processing on the matrix in question [8, 27]. In order to establish the viability of the technique (5.45) proposed in this report for invertible sparse matrices, the ones shown in (5.48) were used as test cases. There was no disagreement between (5.46) and Matlab's det-function, for any of the 3 matrices. Furthermore, (5.45) produced identical results to Matlab's inv-function, for all 3 matrices. Although this evaluation by no means exhausts the set of all possible invertible, maximally sparse 5 x 5 matrices, the technique is at least valid for the test cases (5.48). A more rigorous evaluation is perhaps required, but the results reported here are a good, preliminary step.
6. Generalization to a N x N matrix A

Based on the previous results, it can be surmised that, given a general \(N \times N\) square matrix \(A\),

\[
A = \begin{bmatrix}
    a_{11} & a_{12} & \cdots & a_{1N} \\
    a_{21} & a_{22} & \cdots & a_{2N} \\
    \vdots & \vdots & \ddots & \vdots \\
    a_{N1} & a_{N2} & \cdots & a_{NN}
\end{bmatrix}
\]

(6.1)

which is indexed to \(\{r_0, s_0\}\), and with an inverse of the form of

\[
A^{-1} \sim \alpha_{r_1,s_1}
\]

its general \((N-1) \times (N-1)\) minor-matrix \(M\) should be expected to have the form of

\[
M_{i_0,j_0}(r_0,s_0) = A \left(1 + \delta_{i_0-1,2} + \delta_{j_0-2,2} + \cdots, N-1 + \sum_{x=1}^{N-1} \delta_{i_0-x,2} + 1 + \delta_{j_0-1,2} + 2 + \delta_{j_0-2,2} + \cdots, N-1 + \sum_{y=1}^{N-1} \delta_{j_0-y} \right),
\]

\(\{r_1,s_1\} \in \{(1, \cdots, N) \times (1, \cdots, N)\}, \{r_0,s_0\} \in \{(1, \cdots, N) \times (1, \cdots, N)\}\), \(N \geq 2\) & \(N \in \mathbb{Z}\).

(6.3)

The matrix \(M\) is a function of the indices \(\{r_0, s_0\}\) of the original matrix \(A\), but \(M\) itself is actually indexed to \(\{r_1, s_1\}\). Eq. (6.3) may be re-stated concisely as

\[
M(r_0,s_0) = A \left(\bigcup_{\sigma=1}^{N-1} \left[\left(\sigma + \sum_{x=1}^{N-1} \delta_{i_0-x}\right) \cup \left(\tau + \sum_{y=1}^{N-1} \delta_{j_0-y}\right)\right]\right),
\]

(6.4)
where is general,
\[
\bigcup_{\xi=1}^{N-1} \left\{ \xi + \sum_{w=1}^{N} \delta_{t-w} \right\} = \left\{ 1 + \delta_{t-1}, 2 + \delta_{t-2}, \cdots, N - 1 + \sum_{w=1}^{N-1} \delta_{t-w} \right\}, \quad \{t, w, \xi\} \in \left\{ \{r_0, x, \sigma\}, \{s_0, y, \tau\} \right\}.
\]
(6.5)

However, the braces would be discarded due to their redundancy, if (6.5) is utilized as an argument of the minor-matrix expression (6.3). For instance, applying this conclusion to a 2 x 2 matrix \( D \) for which \( N = 2 \), the general minor-matrix (6.4) is reduced to
\[
D \left\{ 1 + \delta_{t-1}, 1 + \delta_{t-1} \right\} = d_{t-1}, \{r_0, s_0\} \in \left\{ \{1,2\} \times \{1,2\} \right\}
\]
(6.6)

and the minor-matrix trivially reduces to the elements of the matrix \( D \) itself, for a given \( (r_0, s_0) = (i, j) \). The expression yields the correct result for \( N = 2 \), and also reproduces (3.6) and (4.5), respectively for \( N = 3 \), and 4.

Using the equivalence,
\[
\xi + \sum_{w=1}^{N} \delta_{t-w} = \sum_{w=1}^{N} (w + \delta_{t-w}) = \xi + 1 - H_{t-\xi-1}
\]
(6.7)
an alternative version of the general minor-matrix (6.3) is found to be
\[
M(r_0, s_0) = A \left( \bigcup_{\sigma=2}^{N} (\sigma - H_{0-\sigma}); \bigcup_{\tau=2}^{N} (\tau - H_{0-\tau}) \right), \{r_0, s_0\} \in \left\{ \{1,\ldots,N\} \times \{1,\ldots,N\} \right\}.
\]
(6.8)
or in long form, as
\[
M(r_0, s_0) = A \left( 2 - H_{0-2}, 3 - H_{0-3}, \cdots, N - H_{0-N}; 2 - H_{0-2}, 3 - H_{0-3}, \cdots, N - H_{0-N} \right), \{r_0, s_0\} \in \left\{ \{1,\ldots,N\} \times \{1,\ldots,N\} \right\}, N \geq 2.
\]
(6.9)
The matrix version is given by
\[
M(r_0, s_0) \sim a_{r_0+l-H_{r_0+l-2},s_0+l-H_{s_0+l-2}} \sim \begin{bmatrix}
  a_{2-H_{2-2}}, a_{2-H_{2-3}}, \cdots, a_{2-H_{2-N}} \\
  a_{3-H_{3-2}}, a_{3-H_{3-3}}, \cdots, a_{3-H_{3-N}} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{N-H_{N-2}}, a_{N-H_{N-3}}, \cdots, a_{N-H_{N-N}}
\end{bmatrix}, \{r_1, s_1\} \in \left\{ \{1,\ldots,N-1\} \times \{1,\ldots,N-1\} \right\}, \{r_0, s_0\} \in \left\{ \{1,\ldots,N\} \times \{1,\ldots,N\} \right\}.
\]
(6.10)
At this juncture, it seems that the matrix indices are unnecessarily over-subscripted. However, it will be seen later that using these indices simplify the ultimate general expressions for the inverse of A. In order to use the telescoping method, a new indexing system is adopted, since the alphabet set is easily exhausted. Beginning with the primary minor-matrix $M^{(N-1)}_{r_1,s_1}(r_0,s_0)$, whose determinants are the entries of the numerator of the inverse of $A$ (6.2),

$$M^{(N-1)}_{r_1,s_1} = A \left( \bigcup_{r_1=2}^{N} \left( \sigma_{r_1} - H_{r_1-r_1} \right); \bigcup_{s_1=2}^{N} \left( \tau_{s_1} - H_{s_1-s_1} \right) \right), \{r_1,s_1\} \in \{(1,\ldots,N-1)\times\{1,\ldots,N-1\}\},$$

$$M^{(N-2)}_{r_2,s_2} = M^{(N-1)}_{r_1,s_1} \left( \bigcup_{r_2=2}^{N-1} \left( \sigma_{r_2} - H_{r_2-r_2} \right); \bigcup_{s_2=2}^{N-1} \left( \tau_{s_2} - H_{s_2-s_2} \right) \right), \{r_2,s_2\} \in \{(1,\ldots,N-2)\times\{1,\ldots,N-2\}\},$$

$$\cdot \cdot \cdot$$

$$M^{(3)}_{r_3,s_3} = M^{(4)}_{r_4,s_4} \left( \bigcup_{r_3=2}^{N-3} \left( \sigma_{r_3} - H_{r_3-r_3} \right); \bigcup_{s_3=2}^{N-3} \left( \tau_{s_3} - H_{s_3-s_3} \right) \right), \{r_3,s_3\} \in \{(1,2,3)\times\{1,2,3\}\},$$

$$M^{(2)}_{r_2,s_2} = \begin{cases} M^{(3)}_{r_3,s_3} \left( \bigcup_{r_2=2}^{N-2} \left( \sigma_{r_2} - H_{r_2-r_2} \right); \bigcup_{s_2=2}^{N-2} \left( \tau_{s_2} - H_{s_2-s_2} \right) \right), \{r_2,s_2\} \in \{(1,2)\times\{1,2\}\}, & N \geq 4 \\
A \left( 2-H_{r_2-2} - 3H_{r_2-3}; 2-H_{r_2-2} - 3-H_{r_2-3} \right), \{r_2,s_2\} \in \{(1,2)\times\{1,2\}\}, & \text{if } N = 3 \end{cases}$$

The LHS matrix is termed the parent minor-matrix. By convention, the dimensions of the matrix $A$ is stated as $N \times N = N^2$, and in the above progression, the superscript of a minor-matrix $M$ indicates the square-root of its dimension. The index subscript indicates the number of telescoping steps used to attain the corresponding minor-matrix $M$. For instance, if $A$ were a 3 x 3 matrix, the couple $(r_{N-2},s_{N-2})=(r_1,s_1)$ in which the indices are both subscripted with a 1 implies that its corresponding 2 x 2 minor-matrix $M_{r_2,s_2}^{(2)} = M_{r_1,s_1}^{(3)}$ is obtained after 1 telescoping step from $A$. In general, and with one exception, the index subscript is obtained by negating the superscript and adding the square-root of the dimensions of $A$.

Once all the minor-matrices are found by telescoping, they are processed in the formula for the inverse of matrix $A$ (6.1)\(^2\)

$$A^{-1}(r_0,s_0) = \sum_{r_1\in[1,\ldots,N]} \sum_{s_1\in[1,\ldots,N]} \sum_{r_2\in[1,\ldots,N]} \sum_{s_2\in[1,\ldots,N]} \cdots \sum_{r_{N-1}\in[1,\ldots,N]} \sum_{s_{N-1}\in[1,\ldots,N]} \sigma_{r_{N-1}} \cdots \sigma_{r_1} \tau_{s_{N-1}} \cdots \tau_{s_1} \cdot (-1)^{\sum_{i=1}^{N-1} r_i} \cdot \cdots \cdot (-1)^{\sum_{i=1}^{N-1} s_i} \cdot m_{(r_0,s_0)}^{(r_{N-1},s_{N-1})} \cdots m_{(r_0,s_{N-1})}^{(r_{N-1},s_0)} \cdot m_{(r_0,s_0)}^{(r_{N-2},s_{N-2})} \cdots m_{(r_0,s_{N-2})}^{(r_{N-2},s_0)} \cdot m_{(r_0,s_0)}^{(r_{N-3},s_{N-3})} \cdots m_{(r_0,s_{N-3})}^{(r_{N-3},s_0)} \cdot m_{(r_0,s_0)}^{(r_2,s_2)} \cdots m_{(r_0,s_2)}^{(r_2,s_0)} \cdot m_{(r_0,s_0)}^{(r_1,s_1)} \cdots m_{(r_0,s_1)}^{(r_1,s_0)} \cdot m_{(r_0,s_0)}^{(r_0,s_0)} \cdots m_{(r_0,s_0)}^{(r_0,s_0)}$$

with the implication that there are $(N-2)$ summations in the numerator, and $(N-1)$ summations in the denominator, as evidenced by the respective upper bounds of the

\(^2\) may have to magnify for a clearer view
summations. Moreover, a Kronecker delta-function is associated with each summation, and a -1, is raised to the sum of all the row and column indices of all the minors involved in telescoping toward the 2 x 2 minor-matrix \( M_{N_2,N_2}^{(2)} \). Eq. (6.12) also shows the functional dependence of each matrix element, and it can be re-expressed more concisely as

\[
A^{-1} \sim \alpha_{s_0,r_0} = \frac{(-1)^{\delta_{N_2,N_2}} \prod_{\rho=2}^{N_2} \sum_{\lambda=1}^{\rho} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} m_{\lambda}^{(\rho)} \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)}{\prod_{\rho=2}^{N_2} \sum_{\lambda=1}^{\rho} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} \left( \delta_{\rho-\lambda} a_{\rho \lambda} + H_{N-\rho-3} m_{\lambda}^{(\rho)} \right) \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)},
\]

\[\{s_0, r_0\} \in \{(1, \ldots, N) \times (1, \ldots, N)\}, \quad N \geq 3. \quad (6.13)\]

where the functional dependence of the various matrix elements is as follows:

\[
m_{\lambda}^{(\rho)} \sim m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right), \quad (6.14)
\]

\[
m_{\lambda}^{(2)} \sim m_{\lambda}^{(2)} \left( r_{\rho-3}, s_{\rho-3} \right), \quad (6.15)
\]

An application of (6.16) is now illustrated using the 4 x 4 matrix \( B \) examined in §4, with a specific aim of reproducing (4.15) and (4.16). In this case, \( N = 4 \), so

\[
B^{-1} \sim \beta_{s_0,r_0} = \frac{(-1)^{\delta_{N_2,N_2}} \prod_{\rho=2}^{N_2} \sum_{\lambda=1}^{\rho} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right) \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)}{\prod_{\rho=2}^{N_2} \sum_{\lambda=1}^{\rho} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} \left( \delta_{\rho-\lambda} b_{\rho \lambda} + H_{N-\rho-3} m_{\lambda}^{(\rho)} \right) \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)},
\]

\[\{s_0, r_0\} \in \{1, 2, 3, 4\} \times \{1, 2, 3, 4\}. \quad (6.16)\]

After expanding the products,

\[
B^{-1} \sim \beta_{s_0,r_0} = \frac{(-1)^{\delta_{N_2,N_2}} \sum_{s_{\lambda-1} \rho=2}^{N_2} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right) \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)}{\sum_{s_{\lambda-1} \rho=2}^{N_2} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right) \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)},
\]

\[\{s_0, r_0\} \in \{1, 2, 3, 4\} \times \{1, 2, 3, 4\}. \quad (6.16)\]

and simplifying

\[
B^{-1} \sim \beta_{s_0,r_0} = \frac{(-1)^{\delta_{N_2,N_2}} \sum_{s_{\lambda-1} \rho=2}^{N_2} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right) \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)}{\sum_{s_{\lambda-1} \rho=2}^{N_2} \delta_{\rho-\lambda-1} \cdot (-1)^{\delta_{\rho-\lambda-1}} b_{\rho \lambda} \cdot m_{\lambda}^{(\rho)} \left( r_{\rho-1}, s_{\rho-1} \right) \cdot \left( H_{\rho-3} + \delta_{\rho-2} m_{\lambda}^{(2)} \right)},
\]

\[\{s_0, r_0\} \in \{1, 2, 3, 4\} \times \{1, 2, 3, 4\}. \quad (6.16)\]
Eq. (4.15) is reproduced after enforcing the various Kronecker delta-functions in (6.18),

\[
\mathbf{B}^{-1} \sim \beta_{\delta, \epsilon} = \sum_{n=1}^{3} \sum_{l=1}^{2} \sum_{j=1}^{2} \left( -1 \right)^{l+j} \gamma^{3} \delta_{m, s} \cdot m_{l,s}^{(3)} (r_{0}, s_{0}) \cdot \left( m_{l,s}^{(2)} m_{2,3-s,2}^{(2)} \right) (1, s_{1})
\]

(6.19)

and making the element re-assignment of \( \{ m^{(3)}, m^{(2)} \} \) to \( \{ c, d \} \), and of the indices \( \{ r_{0}, s_{0} \} \) to \( \{ m, n \} \), \( \{ r_{1}, s_{1} \} \) to \( \{ k, l \} \), and \( \{ r_{2}, s_{2} \} \) to \( \{ i, j \} \),

\[
\mathbf{B}^{-1} \sim \beta_{nm} = \sum_{n=1}^{3} \sum_{l=1}^{2} \sum_{j=1}^{2} \left( -1 \right)^{l+j} \gamma^{3} \delta_{m, s} \cdot m_{l,s}^{(3)} (r_{0}, s_{0}) \cdot \left( m_{l,s}^{(2)} m_{2,3-s,2}^{(2)} \right) (1, s_{1})
\]

(6.20)

\( \{ n, m \} \in \{(1, 2, 3, 4) \times (1, 2, 3, 4)\} \).

It is not difficult to demonstrate the reverse, i.e. obtaining (6.16) from (6.20).

In the second approach, which is an extension of the above, telescoping approach, all the matrix elements \( m \) are replaced with the elements of the original matrix \( \mathbf{A} \) (6.1), with their corresponding indices primed a number of times identical with the number of telescoping steps required to find them,

\[
\mathbf{A}^{-1} \sim \alpha_{\delta, \epsilon} = \sum_{\delta=1}^{N} \sum_{\epsilon=1}^{N} \sum_{n=1}^{3} \sum_{l=1}^{2} \sum_{j=1}^{2} \delta_{\delta, \epsilon} \cdot \delta_{\delta, \epsilon} \cdot \delta_{\delta, \epsilon} \cdot \delta_{\delta, \epsilon} \cdot \delta_{\delta, \epsilon} \cdot \delta_{\delta, \epsilon} \cdot \left( -1 \right)^{l+j} \gamma^{3} \delta_{m, s} \cdot m_{l,s}^{(3)} (r_{0}, s_{0}) \cdot \left( m_{l,s}^{(2)} m_{2,3-s,2}^{(2)} \right) (1, s_{1})
\]

(6.21)

or as

\[
\mathbf{A}^{-1} \sim \alpha_{\delta, \epsilon} = \prod_{\rho=2}^{N} \sum_{i=1}^{N} \delta_{\delta, \epsilon} \cdot \left( -1 \right)^{l+j} \gamma^{3} \delta_{m, s} \cdot m_{l,s}^{(3)} (r_{0}, s_{0}) \cdot \left( m_{l,s}^{(2)} m_{2,3-s,2}^{(2)} \right) (1, s_{1})
\]

(6.22)

The functional dependence of the elements \( a \) have been suppressed in (6.21) and (6.22) for compactness. In both cases, the number of times an index is primed is expressed as a parenthesized superscript on that index. For instance, for \( \rho = 2 \), \( a_{\rho, \rho, \rho, \rho, \rho, \rho, \rho, \rho, \rho, \rho}^{(N-2)} \).

There are actually 4 indices to generalize, \( s_{N, p}^{(N-2)}, s_{N, p, p}^{(N-2)}, s_{N, p, p}^{(N-2)}, \) and \( (3-s_{N, p})^{(N-2)} \). However, and as in the previous sections, only one of them need be generalized, and the
rest can be obtained from it by simple operations. In this section, \( r^{(N-p)}_K \) is chosen as the one to first generalize. To ensure the most compact expressions, the following identity

\[
q + 1 - H_{p-q-1} = q + H_{q-p}, \quad p, q \in \mathbb{Z}
\]  

(6.23)

will be used. The progression of primed row indices now follows that covered in the previous section, with

\[
r^{(k)}_1 = r_1 + H_{q_{-q_0}},
\]

(6.24)

\[
r^{(k)}_2 = (r_2 + H_{q_{-q_0}}) H_{(-1)^{r_1} (q_{-q_0} - 1 + u_0)} + (r_2 + 1 + H_{q_{-q_0}}) H_{(-1)^{r_1} (q_{-q_0} - u_0)},
\]

(6.25)

\[
r^{(k)}_3 = \sum_{a=0}^1 (r_3 + u + H_{q_{-q_0}} H_{(-1)^{r_1} (q_{-q_0} - 1 + u_0)} + \sum_{k=0}^1 \binom{r_3 + 1 + u + H_{q_{-q_0}} H_{(-1)^{r_1} (q_{-q_0} - u_0)}}{(9.24)}
\]

(6.26)

or in general,

\[
r^{(k)}_K = \sum_{u_{-1}=0}^{H_{q_{-q_0}}} \sum_{u_2=0}^{H_{q_{-q_0}}} r_K + \sum_{k=1}^{K-1} u_k H_{r_K - r_0 + \sum_{k=1}^{K-1} u_k} \prod_{k=1}^{K-1} H_{(-1)^{u_k} (r_K - r_0 - 1 + 2u_k - \sum_{k=1}^{K-1} u_k)},
\]

(6.28)

Throughout this report, and for compactness reasons, the arguments of the Kronecker delta-function and the Heaviside step-function were displayed as subscripts, instead of parenthesized arguments as would be the case for a standard function. However, the arguments have grown relatively large, and for the sake of clarity, they are now displayed parenthesized. In (6.28), and for \( K = 4 \), the set \( \{ u_1, u_2, u_3 \} \) corresponds bijectively to the set \( \{ u, v, w \} \) used in the progression (6.25-27). The above expression is true for \( K \geq 2 \), but fails for \( K = 1 \) (6.24). Therefore, (6.28) must be combined with (6.24), in the event that \( K = 1 \). However, (6.28) can also be modified to extend its validity to \( K \geq 1 \), as

\[
r^{(K)}_K = \sum_{u_{-1}=0}^{H_{q_{-q_0}}} \sum_{u_2=0}^{H_{q_{-q_0}}} \sum_{u_3=0}^{H_{q_{-q_0}}} \sum_{K=1}^{H_{q_{-q_0}}} \sum_{u_0=0}^{K-H_{q_{-q_0}}} \sum_{u_0=0}^{K-H_{q_{-q_0}}} u_0 H_{r_K - r_0 + \sum_{k=1}^{K-H_{q_{-q_0}}} u_k} \prod_{k=1}^{K-H_{q_{-q_0}}} H_{(-1)^{u_k} (r_K - r_0 - 1 + 2u_k - \sum_{k=1}^{K-H_{q_{-q_0}}} u_k)},
\]

(6.29)
with the understanding that the expression begins with the \( u_1 \)-summation, even for \( K = 1 \). Summations and products are rendered redundant when the upper and lower bounds are identical, which occurs for \( K = 1 \), since \( H_{K=2} = 1 \) only when \( K \geq 2 \), by definition. For the Heaviside step-function under the product symbol, its argument reduces to just \( \delta_{K-1} - 1 \) for \( K = 1 \), which then yields \( \delta_{K-1} - 1 = 0 \). Consequently, the corresponding Heaviside step-function reduces to unity, since its argument vanishes. Thus, (6.29) is reduced to (6.24) for \( K = 1 \). Ultimately, whether (6.28) in combination with (6.24) is used instead of (6.29), which is valid for \( K \geq 1 \), is a matter of preference. Eqs. (6.28) and (6.29) also reveal the functional dependence of a \( K \)-th row index \( r_K \) primed \( K \)-times, which involves all row indices up to and including the \( K \)-th row index itself,

\[
r^{(K)}_K \sim r^{(K)}_K (r_1, r_2, \ldots, r_{K-1}, r_K).
\]  

(6.30)

In order to obtain a similar relation for the column index, the following operation is carried out on (6.29),

\[
s^{(K)}_K = i^{(K)}_K \cdot \prod_{k=0}^{K} \delta_{t_k - s_k}.
\]  

(6.31)

which entails the replacement of all the row indices with their corresponding column indices, yielding the expression from (6.29),

\[
s^{(K)}_K = \sum_{u_{K-1} = 0}^{H_{K-1}} \cdots \sum_{u_1 = 0, u_1 = 0}^{H_{1-2}} s_K + \sum_{k=1}^{K-H_{K-2}} u_k + H \left( s_K - s_0 + \sum_{k=1}^{K-H_{K-2}} u_k \right) \prod_{k=1}^{K-H_{K-2}} H \left[ (-1)^{s_k} (\delta_{K-1} + s_K - s_{K-1} + 2u_K - \sum_{j=1}^{K-H_{K-2}} u_j) \right],
\]

\( K \in \{1, 2, 3, \ldots, N - 3, N - 2\}, \quad N \geq 3, \)  

(6.32)

and with an analogous functional relation to (6.30), also obtained from (6.31). The row index \((3 - r_K)^{(K)}\) can be obtained by convolution from (6.29), as follows,

\[
(3 - r_K)^{(K)} = r^{(K)}_K \otimes \delta_{3-r_K}
\]  

(6.33)

with the result,

\[
(3 - r_K)^{(K)} = \sum_{u_{K-1} = 0}^{H_{K-1}} \cdots \sum_{u_1 = 0, u_1 = 0}^{H_{1-2}} \left[ 3 - r_K + \sum_{k=1}^{K-H_{K-2}} u_k + H \left( 3 - r_K - s_0 + \sum_{k=1}^{K-H_{K-2}} u_k \right) \prod_{k=1}^{K-H_{K-2}} H \left[ (-1)^{s_k} (\delta_{K-1} - r_K - s_{K-1} + 2u_K - \sum_{j=1}^{K-H_{K-2}} u_j) \right] \right],
\]

\( K \in \{1, 2, 3, \ldots, N - 3, N - 2\}, \quad N \geq 3. \)

(6.34)

The functional dependence of (6.34) is identical to that of (6.30). Lastly,

\[
(3 - s_K)^{(K)} = (3 - r_K)^{(K)} \cdot \prod_{k=0}^{K} \delta_{t_k - s_k}
\]  

(6.35)
with the result,

\[
(3-s_k)^{(K)} = \sum_{k_{1}} \sum_{k_{2}} \sum_{k_{3}} \left[ 3-s_k + \sum_{i=1}^{K-H_{k-2}} u_i + H \left( 3-s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \right] \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} - s_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right],
\]

where

\[
K \in \{1,2,3,\ldots,N-3,N-2\}, \quad N \geq 3.
\]

(6.36)

The functional dependence of \((3-s_k)^{(K)}\) is identical to that of (6.32).

To summarize, the following expressions have been derived for the 2nd approach, with the inverse matrix having the form of

\[
A^{-1} \alpha_{s_k} = \frac{(-1)^{k+4} \prod_{p=1}^{K} \sum_{s_k=0}^{H_{k-1}} \sum_{u_2=0}^{H_{k-2}} \sum_{u_3=0}^{H_{k-3}} \sum_{u_4=0}^{H_{k-4}} \sum_{u_5=0}^{H_{k-5}} \left( \delta_{s_k} + s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right]}{\prod_{p=2}^{K} \sum_{s_k=0}^{H_{k-1}} \sum_{u_2=0}^{H_{k-2}} \sum_{u_3=0}^{H_{k-3}} \sum_{u_4=0}^{H_{k-4}} \sum_{u_5=0}^{H_{k-5}} \left( \delta_{s_k} + s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right]}
\]

(6.37)

with the element arguments fully restored, and with the following indicial functions, all being valid over \(K \in \{1,2,3,\ldots,N-3,N-2\}\, and for \(N \geq 3\),

\[
r_k^{(K)} = \sum_{k_{1}} \sum_{k_{2}} \sum_{k_{3}} \sum_{k_{4}} \sum_{k_{5}} \left[ r_k + \sum_{i=1}^{K-H_{k-2}} u_i + H \left( r_k - r_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \right] \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right],
\]

(6.38)

\[
s_k^{(K)} = \sum_{k_{1}} \sum_{k_{2}} \sum_{k_{3}} \sum_{k_{4}} \sum_{k_{5}} \left[ s_k + \sum_{i=1}^{K-H_{k-2}} u_i + H \left( s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \right] \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + s_k - s_0 + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right],
\]

(6.39)

\[
(3-r_k)^{(K)} = \sum_{k_{1}} \sum_{k_{2}} \sum_{k_{3}} \sum_{k_{4}} \sum_{k_{5}} \left[ 3-r_k + \sum_{i=1}^{K-H_{k-2}} u_i + H \left( 3-r_k - r_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \right] \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right],
\]

(6.40)

\[
(3-s_k)^{(K)} = \sum_{k_{1}} \sum_{k_{2}} \sum_{k_{3}} \sum_{k_{4}} \sum_{k_{5}} \left[ 3-s_k + \sum_{i=1}^{K-H_{k-2}} u_i + H \left( 3-s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \right] \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} - s_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right],
\]

(6.41)

Alternatively, (6.39-41) can be found using (6.31), (6.33), and (6.35), after finding (6.38).

An application will now be demonstrated of (6.37-41), for \(N = 4\), for which \(A = B\). The desired target is (4.17) and (4.30), along with (4.18, 19, 22, 24, 26, 28). Then

\[
A^{-1} \alpha_{s_k} = \frac{(-1)^{k+4} \prod_{p=1}^{K} \sum_{s_k=0}^{H_{k-1}} \sum_{u_2=0}^{H_{k-2}} \sum_{u_3=0}^{H_{k-3}} \sum_{u_4=0}^{H_{k-4}} \sum_{u_5=0}^{H_{k-5}} \left( \delta_{s_k} + s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right]}{\prod_{p=2}^{K} \sum_{s_k=0}^{H_{k-1}} \sum_{u_2=0}^{H_{k-2}} \sum_{u_3=0}^{H_{k-3}} \sum_{u_4=0}^{H_{k-4}} \sum_{u_5=0}^{H_{k-5}} \left( \delta_{s_k} + s_k - s_0 + \sum_{i=1}^{K-H_{k-2}} u_i \right) \prod_{k=1}^{K-H_{k-2}} H \left[ (-1)^{a} \delta_{k-1} + r_k - r_k + 2 + 2u_k - \sum_{r=0}^{K-H_{k-2}} u_r \right]}
\]

(6.42)
and expanding the product symbol,

\[
A^{-1} \sim \alpha_{\mu, \nu} = \frac{(-1)^{k+r} \sum_{\eta=1}^{3} \delta_{\eta} \cdot (-1)^{k+r} a_{\eta, \mu} (r, s, r, s)}{\sum_{\delta_{\eta=1}^{3} \cdot (-1)^{k+r} a_{\eta, \mu} (r, s, r, s)} \cdot (-1)^{k+r} \cdot \delta_{\eta} \cdot a_{\eta, \mu} (r, s, r, s)} \cdot \left(r, s, \right) \tag{6.43}
\]

and simplifying further,

\[
A^{-1} \sim \alpha_{\mu, \nu} = \frac{(-1)^{k+r} \sum_{\eta=1}^{3} \delta_{\eta} \cdot (-1)^{k+r} \cdot \delta_{\eta} \cdot \delta_{\eta} \cdot (-1)^{k+r} a_{\eta, \mu} (r, s, r, s) \cdot \delta_{\eta} \cdot a_{\eta, \mu} (r, s, r, s)}{\sum_{\delta_{\eta=1}^{3} \cdot (-1)^{k+r} \cdot \delta_{\eta} \cdot \delta_{\eta} \cdot (-1)^{k+r} a_{\eta, \mu} (r, s, r, s) \cdot \delta_{\eta} \cdot a_{\eta, \mu} (r, s, r, s)} \cdot (-1)^{k+r} \cdot \delta_{\eta} \cdot a_{\eta, \mu} (r, s, r, s)} \cdot \left(r, s, \right) \tag{6.44}
\]

which indeed reproduces (4.17), with the bijective assignment of variables to be identified later. Then for the primed indices,

\[
r' = r^{(1)} = \sum_{\eta=0}^{1} r + \sum_{k=1}^{1} u_{k} + H \left(r_{1} - r_{0} + \sum_{k=1}^{1} u_{k}\right) \prod_{k=1}^{1} \left(-1\right)^{k} \left(1 + r_{k} - r_{k-1} + 2 u_{k} - \sum_{k=1}^{1} u_{k}\right) = r_{1} + H_{s=0}, \tag{6.45}
\]

\[
s' = s^{(1)} = r^{(1)} \cdot \prod_{k=0}^{1} \delta_{\eta=0} = s_{1} + H_{s=0}, \tag{6.46}
\]

\[
r' = r^{(2)} = \sum_{\eta=0}^{1} r_{\eta} + \sum_{k=1}^{1} u_{k} + H \left(r_{2} - r_{0} + \sum_{k=1}^{1} u_{k}\right) \prod_{k=2}^{1} \left(-1\right)^{k} \left(2 u_{k} - \sum_{k=1}^{1} u_{k}\right) = \sum_{\eta=0}^{1} \left(r_{1} + u_{1} + H_{s=0}\right) H_{s=0} \tag{6.47}
\]

\[
s' = s^{(2)} = r^{(2)} \cdot \prod_{k=0}^{1} \delta_{\eta=0} = \sum_{\eta=0}^{1} \left(s_{2} + u_{1} + H_{s=0}\right) H_{s=0} \tag{6.48}
\]

\[
(3 - r_{2})^{(2)} = r^{(2)} \otimes \delta_{3-r_{2}} = \sum_{u_{1}=0}^{1} \left(3 - r_{2} + u_{1} + H_{3-r_{2}+u_{1}-2}\right) H_{3-r_{2}+u_{1}-2} \tag{6.49}
\]

\[
(3 - s_{2})^{(2)} = (3 - s_{2})^{(2)} \cdot \prod_{k=0}^{1} \delta_{s=0} = \sum_{u_{1}=0}^{1} \left(3 - s_{2} + u_{1} + H_{3-s_{2}+u_{1}-2}\right) H_{3-s_{2}+u_{1}-2} \tag{6.50}
\]
The arguments of the Heaviside step-functions have been relocated to the subscript of these functions, for compactness. At this juncture, (6.45-50) bear little resemblance to (4.18, 19, 22, 24, 26, 28). After using (6.23), in reverse however, as

\[ q + H_{q-p} = q + 1 - H_{p-q-1}, \quad p, q \in \mathbb{Z} \]  

there results:

\[ r'_1 = r_1 + H_{n_q-n_0} = r_1 + 1 - H_{n_0-n_1} = \kappa(r_1, r_0), \quad (6.52) \]

\[ s'_1 = r'_1 \prod_{k=0}^{1} \delta_{q_k-q_0} = s_1 + 1 - H_{n_0-n_1} = \kappa(s_1, s_0), \quad (6.53) \]

\[ r'_2 = \sum_{n_2=0}^{1} (r_2 + u_1 + 1 - H_{n_2+n_0+n_1}) H_{(-1)^0(n_3-n_2-u_0)} \xrightarrow{u=u_1+1} \sum_{n_2=0}^{2} (r_2 + u - H_{n_2+n_0+n_2}) H_{(-1)^1(n_3-n_2-u_2)} = \lambda(r_2, r_1, r_0) \quad (6.54) \]

\[ s'_2 = r'_2 \prod_{k=0}^{1} \delta_{n_k-n_0} = \sum_{u=1}^{2} (s_2 + u - H_{n_0-n_2-u}) H_{(-1)^1(n_3-n_2-u_2)} = \lambda(s_2, s_1, s_0), \quad (6.55) \]

\[ (3-r_v) = r'_2 \otimes \delta_{n_v} = \sum_{u=1}^{2} (3 - r_2 + u - H_{n_2+n_0+n-3}) H_{(-1)^0(n_3-n_2-u_0)} \xrightarrow{v=v_2+3} \sum_{v=4}^{5} (v - r_2 - H_{n_0+n_2+v}) H_{(-1)^3(n_3+n_2+v_2)} = \mu(r_2, r_1, r_0) \quad (6.56) \]

\[ (3-s_v) = (3-s_2) \cdot \prod_{k=0}^{2} \delta_{n_k-n_v} \sum_{v=4}^{5} (v - s_2 - H_{n_0+n_2+v}) H_{(-1)^3(n_3+n_2+v_2)} = \mu(s_2, s_1, s_0). \quad (6.57) \]

Substituting (6.52-57) into (6.44) yields, after enforcing the various Kronecker delta-functions,

\[ A^{-1} \sim \alpha_{n_q,n_0} = \sum_{n_3=0}^{2} \sum_{n_1=0}^{1} \sum_{n_2=0}^{2} \frac{(-1)^{n_2+n_0} \cdot a_{k(1,0),k(0,0),n_2,n_0}}{(a_{k(1,0),k(0,0),n_2,n_0})} (r_0, s_0) (a_{k(1,0),k(0,0),n_2,n_0}) (1, s_1) 
\]

\[ \sum_{n_3=0}^{2} \sum_{n_1=0}^{1} \sum_{n_2=0}^{2} (a_{n_1,n_2,n_0}) (r_0, s_0) (a_{n_1,n_2,n_0}) (1, s_1) \quad (6.58) \]

which reproduces (4.30), after the bijective assignment of \{A, a, \alpha\} to \{B, b, \beta\}, and of the indices \{(r_0, s_0), (r_1, s_1), (r_2, s_2)\} to \{(m, n), (k, l), (i, j)\}.
7. Generalized functions in terms of standard functions

This report makes extensive use of the Kronecker delta-function, and the Heaviside step-function. As stated in previous sections, they are not standard functions, but they may be considered to be the discrete analogues of the Dirac delta-function $\delta(\bullet)$, and the continuous Heaviside step-function $H(\bullet)$, which are distributions, or generalized functions [39]. Historically however, it appears that the Kronecker delta-function was the only one to have been introduced with a mathematical foundation. The Dirac delta-function and the Heaviside step-function were not rigorously understood till the development of the theory of distributions by L. Schwartz [40, 41].

In one-dimensional Euclidean real space $R$, $\delta$ is a linear functional, from the space of distributions $S'(R)$ on a test function $f$ from the Schwartz Space $S(R)$, that results in the assignment of a specific value to that function [42-45],

$$\langle f, \delta_{x-\xi} \rangle = \int_{R} f(x) \delta(x - \xi) \, dx = f(\xi), \quad x, \xi \in R$$  \hspace{1cm} (7.1)

and where, by a definition adapted from one due to P.A.M. Dirac [46],

$$\delta(x - \xi) = \begin{cases} \infty, & x = \xi \\ 0, & x \neq \xi \end{cases}$$  \hspace{1cm} (7.2)

The Dirac delta-function may also be viewed as a generalized function, which is an extension of the concept of a conventional function [47]. Many functions are capable of identical behavior in the limit, an instance of which is the scaled Gaussian function [39]

$$\delta(x - \xi) = \lim_{\lambda \to \infty} \left( \frac{\lambda}{4\pi} \right)^{1/2} \exp \left( -\frac{\lambda}{4} (x - \xi)^2 \right), \quad \xi, \lambda \in R.$$  \hspace{1cm} (7.3)

Then Kronecker delta-function, due to L. Kronecker, is a function that maps to the set $\{0, 1\}$, the Cartesian product of a set of integers with itself, taking the value of zero everywhere, except on the diagonal subset of that product for which it is identical with unity [48]. It is demonstrated on a test function $g$ as follows

$$g[r] \delta[r-n] = g[n], \quad n \in Z$$  \hspace{1cm} (7.4)

with the Kronecker delta-function defined as

$$\delta[r-n] = \delta_{r-n} = \begin{cases} 1, & r = n \\ 0, & r \neq n \end{cases}$$  \hspace{1cm} (7.5)

Like the Dirac delta-function, the Kronecker delta-function is also a generalized function, an instance of which is the discrete analogue of (7.3), the discrete Gaussian function [49],

$$\delta[r-n] = \lim_{\kappa \to \infty} \frac{\kappa}{\pi^{1/2}} \exp \left( -\kappa^2 [r-n]^2 \right), \quad n, \kappa \in Z.$$  \hspace{1cm} (7.6)
Similarly and in one-dimensional Euclidean real space $\mathbb{R}$, $H$ is a linear functional, from the space of distributions $S'(\mathbb{R})$, on a test function $f$ from the Schwartz Space $S(\mathbb{R})$, that maps that function to its integral over a sub-space of the real-number axis [50],

$$\langle f, H_{x-\xi} \rangle = \int_{\mathbb{R}} f(x) H(x-\xi) \, dx = \int_{\xi}^{\infty} f(x) \, dx, \quad x, \xi \in \mathbb{R} \quad (7.7)$$

and where, by a definition due to O. Heaviside [51 - 53],

$$H(x-\xi) = \begin{cases} 0, & x < \xi \\ 1/2, & x = \xi \\ 1, & x > \xi \end{cases} \quad (7.8)$$

but it can also be construed as the distributional derivative of the delta-function (7.2),

$$\langle f', H_{x-\xi} \rangle = \int_{\mathbb{R}} f'(x) H(x-\xi) \, dx = -\int_{\mathbb{R}} f(x) H'(x-\xi) \, dx = -f(\xi) \quad (7.9)$$

by integration-by-parts, which due to (7.1), leads to the conclusion that

$$H'(x-\xi) = \delta(x-\xi). \quad (7.10)$$

Many functions are capable of identical behavior in the limit, an instance of which is the scaled complementary error-function [54], the integral of the scaled Gaussian (7.3),

$$H(x-\xi) = \frac{1}{2} \lim_{\xi \to \infty} \text{erfc}(-\lambda(x-\xi)), \quad \xi, \lambda \in \mathbb{R}. \quad (7.11)$$

The discrete Heaviside step-function is the discrete analogue of (7.8), whence it is adapted,

$$H[r-n] = \begin{cases} 0, & r < n \\ 1/2, & r = n \\ 1, & r > n \end{cases} \quad (7.12)$$

In this case, however, since the function's domain is the set of integers, the inequality $r > n$ effectively implies that $r \geq n + 1$, whereas $r < n$, implies that $r \leq n - 1$. Consequently, the function exhibits ramp-like behavior over the sub-domain $\{n-1, 0, n+1\}$. This is not the case for the continuous Heaviside step-function defined over the set of real numbers $\mathbb{R}$, for which its variable $x$ can be infinitesimally smaller or larger than the constant $\xi$ as required by (7.8), which renders the function step-like for all practical purposes. The discrete Heaviside step-function must thus be re-defined as

$$H[r-n] = H_{r-n} = \begin{cases} 0, & r < n \\ 1, & r \geq n \end{cases}, \quad n \in \mathbb{Z} \quad (7.13)$$
which ensures a step-like change over the sub-domain \(\{n-1, 0, n+1\}\). Thus (7.13) is the definition of the discrete Heaviside step-function used in this report.

The connection between the Kronecker delta-function (7.5) and the discrete Heaviside step-function (7.13), can be found from the discrete analogue of (7.10), using the forward difference scheme [55]

\[
\delta[r - n] = \lim_{\Delta \to 1} \frac{H[r - n + \Delta] - H[r - n]}{\Delta} = H[r - n + 1] - H[r - n] \tag{7.14}
\]

with an identical result, using the backward difference scheme. Moreover, the Heaviside step-function is obtained from the Dirac delta-function by integration from (7.10), followed by (7.1), as

\[
\int_{-\infty}^{x} \delta(z - \xi) \, dz = \int_{-\infty}^{x} H(x - z) \delta(z - \xi) \, dz = H(x - \xi) \tag{7.16}
\]

whose discrete analogue yields, using (7.5),

\[
H[r - n] = \sum_{k=-\infty}^{r} \delta[k - n] - \sum_{k=n}^{\infty} \delta[r - s]. \tag{7.17}
\]

The middle equality uses (7.5), which is only non-zero when \((k-n)\) is allowed to assume a value of 0, or equivalently \(k=n\), in accord with the requirements of (7.13).

It is not difficult to implement the Kronecker delta-function and the discrete Heaviside step-function in a computer program [56, 57]. Although dedicated function modules can be created for that purpose, it is unnecessary for the smaller matrices, since the implementation may be efficiently carried out with logical operations. This is best illustrated with an example. In §4, it was found that the general expression for the minor-matrix of a 4 x 4 matrix \(B\) is given by (4.5), reproduced here

\[
C_B(m,n) = B(1 + \delta_{m-1}, 2 + \delta_{m-2}, 3 + \delta_{m-3}; 1 + \delta_{n-1}, 2 + \delta_{n-2}, 3 + \delta_{n-3}) \tag{7.18}
\]

In Matlab for instance, after initializing the elements of \(C\) to zeros, (7.18) is encoded as

\[
C = B([1+(m==1), 2+(m==1)+(m==2), 3+(m==1)+(m==2)+(m==3)], ... [1+(n==1), 2+(n==1)+(n==2), 3+(n==1)+(n==2)+(n==3)]) \tag{7.19}
\]

Alternatively, (7.18) was found to have the more compact expression given by (4.7),

\[
C_B(m,n) = B(2 - H_{m-2}, 3 - H_{m-3}, 4 - H_{m-4}; 2 - H_{n-2}, 3 - H_{n-3}, 4 - H_{n-4}) \tag{7.20}
\]

which unlike (7.18), is exclusively in terms of Heaviside step-functions. In Matlab then,

\[
C = B([2-(m>=2), 3-(m>=3), 4-(m>=4)], [2-(n>=2), 3-(n>=3), 4-(n>=4)]) \tag{7.21}
\]
Although clearly not required for computer programming implementations, a goal of this report is the expression of the inverse of a matrix using standard functions, which has yet to be demonstrated, and which is now the focus of the remainder of this section. The following section only applies to expressions which are explicitly in terms of the elements of the original matrices themselves.

One method of converting the generalized functions to real standard functions, is to first limit the domain of the functions to the set of values required by the summations or the indices, for a given formula. The validity of this conversion outside the constrained domain is not relevant to this report, and will thus not be explored. The conversion may be achieved using the gamma function for strictly for positive integral arguments, which makes it synonymous with the factorial function

\[
\Gamma(\eta + 1) = 1 \cdot 2 \cdot 3 \cdot \cdots (\eta - 2) \cdot (\eta - 1) \cdot \eta = \eta!, \quad \eta \in \mathbb{Z}^+.
\] (7.22)

The gamma function also has the peculiar, useful property that \( \Gamma(1) = \Gamma(2) = 1 \), whereas it is infinite for all negative integers, as well as zero. The conversion is illustrated beginning with the simplest case, that of the inverse of the 2x2 matrix,

\[
\mathbf{D}^{-1} \sim \frac{(-1)^{i+j} d_{1+\delta_{i,j+1}+\delta_{j+1}+1}}{\sum_{j=1}^{2} \delta_{i+1} d_{i,j} (-1)^{i+j} d_{1+\delta_{i+1}+1+\delta_{j+1}+1}}, \quad \{i, j, \{j, i\} \in \{\{1, 2\} \times \{1, 2\}\}.
\] (7.23)

Using the relation

\[
\delta_{z-1} = \frac{((-1)^{\Gamma(z+2)} - (-1)^{\Gamma(z+1)})}{2}
\] (7.24)

which need be valid only for the range of indices \( i \) and \( j \) required by (7.23),

\[
\mathbf{D}^{-1} \sim \frac{(-1)^{i+j} d_{1+\left((-1)^{\Gamma(z+2)} - (-1)^{\Gamma(z+1)}\right)\delta_{i+1}}}{\sum_{j=1}^{2} \left((-1)^{i} d_{1,j} d_{2,1+\left((-1)^{\Gamma(z+2)} - (-1)^{\Gamma(z+1)}\right)\delta_{j+1}}\right)/2}, \quad \{i, j, \{j, i\} \in \{\{1, 2\} \times \{1, 2\}\}.
\] (7.25)

A compact expression may be obtained by applying to (7.23), the relation

\[
\sum_{u=1}^{P} (1 + \delta_{z-u}) = P + 1 - H_{z-P-1}, \quad P \in \mathbb{Z}^+
\] (7.26)

with \( P = 1 \), which from (7.23) yields the alternative

\[
\mathbf{D}^{-1} \sim \frac{(-1)^{i+j} d_{2+\left(2-H_{z-2}\right)} \cdot \left(2-H_{z-2}\right)}{\sum_{j=1}^{2} \left((-1)^{i} d_{1,j} d_{2,2-\left(2-H_{z-2}\right)}\right)}, \quad \{i, j, \{j, i\} \in \{\{1, 2\} \times \{1, 2\}\}.
\] (7.27)
and after using
\[ H_{2,-2} = \left(1 + (-1)^{z+1}\right)/2 \] (7.28)

(7.27) is simplified to
\[ D^{-1} \approx -\frac{(-1)^{ij} d_{3-(-1)^{f^{(i)}}} d_{3-(-1)^{j}}}{2}, \quad \{i, j\} \in \{(1, 2) \times \{1, 2\}\}. \] (7.29)

The formula for the inverse of a 2 x 2 matrix is actually trivial, and was given by (2.3). The above formula however, which is clearly less efficient than (2.3), or even (7.28), merely illustrates the conversion to standard functions, using the simplest of examples.

A more complicated case is that of the inverse of the 3 x 3 matrix \( C \) (3.26),
\[ C^{-1} \approx \gamma_{ik} = \frac{(-1)^{ik} \left(c_{2-H_{2,3},2-H_{2,3},3-H_{2,3}} - c_{2-H_{2,3},3-H_{2,3},2-H_{2,3}}\right)}{3}, \quad \{i, k\} \in \{(1, 2, 3) \times \{1, 2, 3\}\}, \] (7.30)
or using (7.26),
\[ C^{-1} \approx \gamma_{ik} = \frac{(-1)^{ik} \left(c_{2-H_{2,3},2-H_{2,3},3-H_{2,3}} - c_{2-H_{2,3},3-H_{2,3},2-H_{2,3}}\right)}{3}, \quad \{i, k\} \in \{(1, 2, 3) \times \{1, 2, 3\}\} \] (7.31)

Using (7.28), along with
\[ H_{3,-3} = \left(1 + (-1)^{F^{(2)}}\right)/2 \] (7.32)
yields the alternative to (7.31) using standard functions, after a simplification:
\[ C^{-1} \approx \gamma_{ik} = \frac{\sum_{j=0}^{1} (-1)^{jk+j} \frac{c_{5-(-1)^{f^{(i)}}}}{2} \frac{c_{3-(-1)^{f^{(i+j)}}}}{2} \frac{c_{3-(-1)^{f^{(j)}}}}{2}}{\sum_{j=0}^{2} \sum_{l=1}^{3} (-1)^{j+l} c_{il} \frac{c_{3-2j-(-1)^{f^{(i+j)}}}}{2} \frac{c_{5-2j-(-1)^{f^{(i+j)}}}}{2}}, \quad \{i, k\} \in \{(1, 2, 3) \times \{1, 2, 3\}\}; \] (7.33)

It is an analytical formula for any element \( \gamma_{ik} \) in the inverse of a 3 x 3 matrix \( C \), explicitly in terms of the elements of \( C \), and entirely in terms of standard functions. Beyond a 3 x 3 matrix, it is difficult to make an equivalent, similarly compact statement about the inverse

40
of a matrix, as the indicial functions become relatively large and cumbersome. This is demonstrated by the next example.

For a $4 \times 4$ matrix $B$, its inverse was found to have the form of (4.37)

$$B^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l} b_{2-H_{n-j-l},\kappa(l,n)} \cdot b_{3-H_{n-j-l},\lambda(j,l,n)} \cdot b_{4-H_{n-j-l},\mu(j,l,n)}}{\sum_{n=1}^{4} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l+l+n} b_{1,n} \cdot b_{2-j+k(l,n)} \cdot b_{3-j+l,l,n} \cdot b_{4-j+l,n}}$$,

(7.34)

with the expression for the determinant of the $4 \times 4$ matrix $B$ found in the denominator. In terms of the gamma function,

$$M - H_{m-M} = M - \frac{1}{2} \left(1 - (-1)^{\Gamma[(m-M-5\Gamma(M-1)+8)(3-2\Gamma(M-1))]\Gamma(M-1)}\right), \ m \in \{1, 2, 3, 4\}, M \in \{2, 3, 4\}$$,

(7.35)

$$\kappa(l,n) = l + 1 - H_{n-l-1} = l + 1 - \frac{1}{2} \left(1 - (-1)^{\Gamma[(n-l-5\Gamma(l)+7)(3-2\Gamma(l))]\Gamma(l)}\right), \ l \in \{1, 2, 3\}, n \in \{1, 2, 3, 4\}$$,

(7.36)

$$\lambda(j,l,n) = \sum_{u=1}^{2} (j + u - H_{n-j-u}) H_{(l-u+2),(-1)^{l-j-u+2}} = \frac{1}{4} \sum_{u=0}^{1} \left(1 + 2(j + u) + (-1)^{\Gamma[6(j-1) + 2(j-3)(u-u+1)]} \right)(1 + (-1)^{u+\Gamma(l-j+2)})$$,

(7.37)

$$\mu(j,l,n) = \sum_{u=1}^{3} (u - j - H_{n-u-1}) H_{(-1)^{l-u+j+8},(l+u+j-8)} = \frac{1}{4} \sum_{u=0}^{1} \left(7 + 2(u - j) - (-1)^{\Gamma[6(j-1) + 2(j-3)(u-u+1)]} \right)(1 + (-1)^{u+\Gamma(l-j+1)})$$,

(7.38)

These equations may also be re-expressed in terms of trigonometric functions using Euler's Identity, that $(-1) = \exp(i\pi)$, but the resultant expressions are even more cumbersome.

The preceding discussion was concerned with the use of standard functions, *in lieu* of discrete generalized functions. Although the gamma function is a standard function, it is not an elementary function [59]. It is however still possible to express the discrete generalized functions in terms of elementary functions, but it would lead to even more complicated expressions. Whether these formulations are useful in any way, is a matter for subsequent discovery.
8. Summary and Conclusions

A telescoping method has been developed for the inverse of a square \((N \times N)\) matrix \(A\), based on a general expression of its \((N-1 \times N-1)\), primary minor-matrix. Another, \((N-2 \times N-2)\) minor-matrix is then extracted from the \((N-1 \times N-1)\) minor-matrix, and the process is continued until a \(2 \times 2\) minor-matrix is attained. This process is illustrated mathematically beginning with the primary minor-matrix \(M_{r_1,s_1}^{(N-1)}(r_0,s_0)\), whose determinants are the entries of the numerator of the inverse of \(A\) (6.2),

\[
M_{r_1,s_1}^{(N-1)} = A \left( \bigcup_{\sigma_{r_1}=1}^{N} (\sigma_1 - H_{r_1,s_1}); \bigcup_{\tau_{r_1}=1}^{N} (\tau_1 - H_{r_1,s_1}) \right), \{r_1,s_1\} \in \{(1,\ldots,N-1) \times \{1,\ldots,N-1\}\},
\]

\[
M_{r_2,s_2}^{(N-2)} = M_{r_1,s_1}^{(N-1)} \left( \bigcup_{\sigma_{r_2}=2}^{N-1} (\sigma_2 - H_{r_2,s_2}); \bigcup_{\tau_{r_2}=2}^{N-1} (\tau_2 - H_{r_2,s_2}) \right), \{r_2,s_2\} \in \{(1,\ldots,N-2) \times \{1,\ldots,N-2\}\},
\]

\[
M_{r_3,s_3}^{(N-3)} = M_{r_2,s_2}^{(N-2)} \left( \bigcup_{\sigma_{r_3}=3}^{N-1} (\sigma_3 - H_{r_3,s_3}); \bigcup_{\tau_{r_3}=3}^{N-1} (\tau_3 - H_{r_3,s_3}) \right), \{r_3,s_3\} \in \{(1,2,3) \times \{1,2,3\}\},
\]

\[
M_{r_4,s_4}^{(N-4)} = M_{r_3,s_3}^{(N-3)} \left( \bigcup_{\sigma_{r_4}=4}^{N-1} (\sigma_4 - H_{r_4,s_4}); \bigcup_{\tau_{r_4}=4}^{N-1} (\tau_4 - H_{r_4,s_4}) \right), \{r_4,s_4\} \in \{(1,2,3,4) \times \{1,2,3,4\}\}, N \geq 4
\]

\[
A \left( 2 - H_{r_1,s_1} , 3 - H_{r_1,s_1}; 2 - H_{r_2,s_2} , 3 - H_{r_2,s_2} \right), \{r_1,s_1\} \in \{(1,2) \times \{1,2\}\}, \text{if } N = 3
\]

The LHS matrix is termed the parent minor-matrix, and is the primary minor-matrix when the RHS matrix is the original matrix \(A\) itself. The dimensions of the matrix \(A\) is stated as \(N \times N = N^2\), and in the above progression, the superscript of a minor-matrix \(M\) indicates the square-root of its dimension. The index subscript indicates the number of telescoping steps used to attain the corresponding minor-matrix \(M\). For instance, if \(A\) were a \(3 \times 3\) matrix, the couple \((r_{N-2},s_{N-2}) = (r_1,s_1)\) in which the indices are both subscripted with a 1 implies that its corresponding \(2 \times 2\) minor-matrix \(M_{r_1,s_1}^{(N-2)} = M_{r_1,s_1}^{(2)}\) is obtained after 1 telescoping step-from \(A\). In general, and with one exception, the index subscript is obtained by negating the superscript and adding the square-root of the dimensions of \(A\). Once all the minor matrices are found by the telescoping process, they are processed in the formula for the inverse of matrix \(A\) (6.1)

\[
A^{-1} \sim \alpha_{r_0,s_0} = \frac{(-1)^{\rho + \lambda} \prod_{\rho'=2}^{\rho} \sum_{s_{\rho'-1}=1}^{N-1} \delta_{s_{\rho'-1},1} \cdot (-1)^{s_{\rho} + s_{\rho'-1}} m_{s_{\rho},s_{\rho'}}^{(\rho)} \cdot (H_{r_{\rho},s_{\rho}} + \delta_{\rho-2} m_{s_{\rho},s_{\rho}}^{(2)})}{\prod_{\rho'=2}^{N} \sum_{s_{\rho'-1}=1}^{N-1} \delta_{s_{\rho'-1},1} \cdot (-1)^{s_{\rho} + s_{\rho'-1}} (\delta_{\rho-2} a_{s_{\rho},s_{\rho}} + H_{s_{\rho},s_{\rho}}^{(\rho)} m_{s_{\rho},s_{\rho}}^{(\rho)}) (H_{r_{\rho},s_{\rho}} + \delta_{\rho-2} m_{s_{\rho},s_{\rho}}^{(2)})}, \{s_0,r_0\} \in \{(1,\ldots,N) \times \{1,\ldots,N\}\}, N \geq 3.
\] (8.2)
where the functional dependence of the various matrix elements is as follows:

\[ m_{n-r,s-N}^{(\rho)} \sim m_{n-r,s-N}^{(\rho)} \left( r_{N-r-1}, s_{N-r-1} \right), \quad (8.3) \]

\[ m_{n-r,s-N}^{(2)} \sim m_{n-r,s-N}^{(2)} \left( r_{N-r-2}, s_{N-r-2} \right). \quad (8.4) \]

The procedure, which is termed the surrogate matrix approach, relies heavily on discrete generalized functions explained in the previous section, specifically the Kronecker delta-function and/or the Heaviside step-function,

\[ \delta_{z-n} = \delta_{z-n} = \delta[z - n] = \begin{cases} 1, & z = n \\ 0, & z \neq n \end{cases} \quad (8.5) \]

\[ H_{z-n} = H[z - n] = \begin{cases} 0, & z < n \\ 1, & z \geq n \end{cases} \quad (8.6) \]

Using this procedure, the following formulas were respectively developed for the inverses of the 3 x 3 (C), 4 x 4 (B) and 5 x 5 (A) matrices

\[ C^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2} (-1)^{j+k+l} (d_{i,j}d_{j,2}) (k,l)}{\sum_{j=1}^{2} \sum_{l=1}^{2} (-1)^{j+l} c_{i,j} (d_{i,j}d_{j,2}) (1,l)}, \quad (8.7) \]

\[ \{l,k\} \in \{(1,2,3) \times (1,2,3)\} \]

\[ B^{-1} \sim \beta_{nm} = \frac{\sum_{j=1}^{3} \sum_{l=1}^{2} (-1)^{j+l+m+n} c_{i,j} (m,n) \cdot (d_{i,j}d_{j,2}) (1,l)}{\sum_{n=1}^{3} \sum_{l=1}^{2} \sum_{j=1}^{2} (-1)^{j+l+m+n} b_{i,n} \cdot c_{i,j} (1,n) \cdot (d_{i,j}d_{j,2}) (1,l)}, \quad (8.8) \]

\[ \{n,m\} \in \{(1,2,3,4) \times (1,2,3,4)\} \]

\[ A^{-1} \sim \alpha_{pq} = \frac{\sum_{n=1}^{4} \sum_{j=1}^{3} \sum_{l=1}^{2} (-1)^{j+l+n+p+q} b_{i,n} (p,q) \cdot c_{i,l} (1,n) \cdot (d_{i,j}d_{j,2}) (1,l)}{\sum_{q=1}^{4} \sum_{n=1}^{3} \sum_{l=1}^{2} \sum_{j=1}^{2} (-1)^{j+l+n+q} a_{i,q} \cdot b_{i,n} (1,q) \cdot c_{i,l} (1,n) \cdot (d_{i,j}d_{j,2}) (1,l)}, \quad (8.9) \]

\[ \{n,m\} \in \{(1,2,3,4,5) \times (1,2,3,4,5)\} \]

In each case, the expression is not explicitly in terms of the elements of the original matrix. However, in §6, it was found possible to do so, so that for a N x N matrix A,
\[
A^{-1} \sim \alpha_{h_{N-1}} = \frac{(-1)^{\nu_{k}+\nu_{s}} \prod_{\rho=2}^{H_{k}} \sum_{\delta=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} \delta_{h_{N-1}} \cdot (-1)^{\nu_{k}+\nu_{s}} a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \left( H_{\rho-3} + \delta_{\rho-2} a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \right)}{\prod_{\rho=2}^{H_{k}} \sum_{\delta=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} \delta_{h_{N-1}} \cdot (-1)^{\nu_{k}+\nu_{s}} a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \left( H_{\rho-3} + \delta_{\rho-2} a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \right)}},
\]

\{ s_{0}, s_{N} \} \in \{ [1, \cdots, N] \times [1, \cdots, N] \}, \quad N \geq 3.
(8.10)

for which the functional dependence of each of the elements is as follows:

\[
a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \sim a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \left( r_{N-1}^{r_{N-1}}, s_{N-1}^{s_{N-1}} \right)
\]

(8.11)

\[
a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \sim a_{r_{N-1}, \nu_{k}} a_{s_{N-1}, \nu_{s}} \left( r_{N-1}^{r_{N-1}}, s_{N-1}^{s_{N-1}} \right)
\]

(8.12)

and with the following indicial functions, all being valid over \( K \in \{ 1, 2, 3, \cdots, N - 3, N - 2 \} \).

\[
r_{k}^{(K)} = \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} r_{k} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} + H \left( r_{k} - r_{0} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} \right) \prod_{k=1}^{K-H_{k}} H \left( -1 \right) \left( \delta_{k-1} + r_{k} - r_{0} - 1 + 2 u_{k} - \sum_{l=k}^{K-H_{k}} u_{l} \right),
\]

(8.13)

\[
s_{k}^{(K)} = \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} s_{k} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} + H \left( s_{k} - s_{0} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} \right) \prod_{k=1}^{K-H_{k}} H \left( -1 \right) \left( \delta_{k-1} + s_{k} - s_{0} - 1 + 2 u_{k} - \sum_{l=k}^{K-H_{k}} u_{l} \right),
\]

(8.14)

\[
(3 - r_{k})^{(K)} = \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} \left( 3 - r_{k} - r_{0} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} \right) \prod_{k=1}^{K-H_{k}} H \left( -1 \right) \left( \delta_{k-1} - r_{k} - r_{0} + 2 u_{k} - \sum_{l=k}^{K-H_{k}} u_{l} \right),
\]

(8.15)

\[
(3 - s_{k})^{(K)} = \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} \left( 3 - s_{k} - s_{0} + \sum_{u_{k-1}=0}^{H_{k-1}} \sum_{u_{k}=0}^{H_{k}} \sum_{u_{h_{N-1}}=0}^{H_{k}} \sum_{u_{s}=0}^{H_{k}} u_{k} \right) \prod_{k=1}^{K-H_{k}} H \left( -1 \right) \left( \delta_{k-1} - s_{k} - s_{0} + 2 u_{k} - \sum_{l=k}^{K-H_{k}} u_{l} \right).
\]

(8.16)

The indicial functions are complicated, but only one of them need be derived, whereas the rest may be obtained from simple operations on the resultant expression. For example, after deriving the expression for \( r_{k}^{(K)} \) (8.13), the remaining indicial functions are

\[
s_{k}^{(K)} = r_{k}^{(K)} \cdot \prod_{k=0}^{K} \delta_{h_{N-1}}
\]

(8.17)

\[
(3 - r_{k})^{(K)} = r_{k}^{(K)} \otimes \delta_{3-r_{k}}
\]

(8.18)

\[
(3 - s_{k})^{(K)} = (3 - r_{k})^{(K)} \cdot \prod_{k=0}^{K} \delta_{h_{N-1}}
\]

(8.19)
Although the complexity of (8.10) is similar to that of (8.2), insisting on the explicit dependence of the expression on the original elements of the general $N \times N$ matrix $A$ has resulted in complicated expressions for the indicial functions. Using this approach, the following expressions for the inverses of the $2 \times 2$ ($C$), $3 \times 3$ ($C$), $4 \times 4$ ($B$) and $5 \times 5$ ($A$) matrices, explicitly in terms of the original elements of their respective matrices, were found

\[
D^{-1} \sim \delta_{ij} = \frac{(-1)^{i+j} d_{i+\delta_{z-1},j+\delta_{z-1}}}{3 \sum_{j=1}^{2} \delta_{i-j} d_{ij} (-1)^{i+j} d_{i+\delta_{z-1},j+\delta_{z-1}}}, \quad \{i, j\} \in \{(1,2) \times (1,2)\}.
\]

\[
C^{-1} \sim \gamma_{lk} = \frac{\sum_{j=1}^{2}(-1)^{1+j+k+l} c_{2-H_{l-2},j+1-H_{l-2},z} \cdot c_{3-H_{l-3},4-j-H_{l-4},j}}{3 \sum_{j=1}^{2} \sum_{j=1}^{2} (-1)^{2+j+k+l} c_{i+l} \cdot c_{2,H_{l-1},H_{j} \cdot c_{3,4-j-H_{l-4},j}}} , \quad \{l, k\} \in \{(1,2,3) \times (1,2,3)\},
\]

\[
B^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \sum_{j=1}^{2} \sum_{j=1}^{2} (-1)^{1+j+k+l} b_{2-H_{z-2},x_{(m,n)}} \cdot b_{1-H_{z-1},x_{(l,n)}} \cdot b_{4-H_{z-4},x_{(j,l,n)}}}{3 \sum_{j=1}^{2} \sum_{j=1}^{2} (-1)^{2+j+k+l} b_{m,n} \cdot b_{x_{k}(l,n)} \cdot b_{x_{j}(l,n)} \cdot b_{x_{j}(l,n)}}, \quad \{n, m\} \in \{(1,2,3,4) \times (1,2,3,4)\},
\]

\[
A^{-1} \sim \alpha_{pq} = \frac{(-1)^{p+q} \sum_{j=1}^{3} \sum_{j=1}^{3} \sum_{j=1}^{2} (-1)^{3+j+k+l} a_{2-H_{z-2},x_{(p,q)}} \cdot a_{5-H_{z-5},x_{(l,n,q)}} \cdot a_{3-H_{z-3},x_{(k,l,n,q)}} \cdot a_{5-H_{z-5},x_{(j,l,n,q)}}}{3 \sum_{j=1}^{2} \sum_{j=1}^{2} \sum_{j=1}^{2} (-1)^{3+j+k+l} a_{p,q} \cdot a_{2,k(x_{(m,n)})} \cdot a_{3,k(x_{(l,n,q)})} \cdot a_{5,k(p(l,n,q))} \cdot a_{5(k,l,n,q)}}, \quad \{q, p\} \in \{(1,2,3,4,5) \times (1,2,3,4,5)\},
\]

\[
{\kappa(m, p) = m + 1 - H_{p-m-1}, \ \lambda(k, m, p) = \sum_{a=1}^{2} (k + u - H_{p-k-a}) H_{(-1)^{a} (k-m-a+2)},}
\]

\[
{\mu(i, k, m, p) = \sum_{a=1}^{3} \sum_{a=1}^{3} (i + u + v - H_{p-i-u-v}) H_{(-1)^{a} (i-m-a+2)},}
\]

\[
{\nu(j, l, n, q) = \sum_{a=1}^{3} \sum_{a=1}^{3} (-j + u + v + 3 - H_{q+i-u-v}) H_{(-1)^{a} (j-n-4+1)},}
\]

along with their attendant indicial functions, where noted within the brace.

Another goal of this report is the expression of an inverse matrix in terms of standard functions. The discrete generalized functions (8.5) and (8.6) are not standard functions, although they can be expressed in terms of standard functions over the range of indices required. For instance, in terms of the gamma function $\Gamma(z)$,

\[
H_{z-n} = \left(1 + (-1)^{\Gamma(z-n+3)}\right)/2, \quad n \in \{2,3\}, \quad z \in \mathbb{Z}^+.
\]
Applying this relation to (8.21) for instance, yields a formula for an element in the inverse of $3 \times 3$ matrix $C$ in terms of the elements of that matrix, and in terms of standard functions,

$$C^{-1} \sim \gamma_{lk} = \sum_{i=0}^{1} (-1)^{i+k+l} c_{3-(-1)^{i+l+1}} \cdot c_{3-2(-1)^{i+l+1}} \cdot c_{3-5(-1)^{i+l+1}} \cdot c_{3-5(-1)^{i+l+1}}, \quad \{l,k\} \in \{(1,2,3) \times (1,2,3)\}. \quad (8.25)$$

It is however concluded that beyond a $3 \times 3$ matrix $C$, the indicial functions become large and unwieldy. For a $4 \times 4$ matrix $B$, it was found that

$$B^{-1} \sim \beta_{nm} = \frac{(-1)^{m+n} \sum_{l=1}^{3} \sum_{j=1}^{2} (-1)^{j+l} b_{1-(-1)^{j+l}} \cdot b_{2-(-1)^{j+l}} \cdot b_{3-(-1)^{j+l}} \cdot b_{4-(-1)^{j+l}}}{\sum_{l=1}^{1} \sum_{j=1}^{3} (-1)^{j+l+n} b_{1-(-1)^{j+l}} \cdot b_{2-(-1)^{j+l}} \cdot b_{3-(-1)^{j+l}} \cdot b_{4-(-1)^{j+l}}}, \quad \{n,m\} \in \{(1,2,3,4) \times (1,2,3,4)\}, \quad (8.26)$$

along with

$$M - H_{m-M} = M - \frac{1}{2} \left(1 - (-1)^{\Gamma[(m-M-5\Gamma(M-1)+8)(3-2\Gamma(M-1))] + 1}\right), \quad m \in \{1,2,3,4\}, M \in \{2,3,4\}, \quad (8.27)$$

$$\kappa(l,n) = l + 1 - H_{n-l-1} = l + 1 - \frac{1}{2} \left(1 - (-1)^{\Gamma[n-l-5\Gamma(l)+7](3-2\Gamma(l))}] + 1}\right), \quad l \in \{1,2,3\}, n \in \{1,2,3,4\}, \quad (8.28)$$

$$\lambda(j,l,n) = \sum_{a=1}^{2} (j + u - H_{n-a-j-u}) H_{(l,1)^{(j-1-\alpha+2)}} = \frac{1}{4} \sum_{a=0}^{1} \left(1 + 2(j + u) + (-1)^{\Gamma[6(n-\mu+1)]}(1 + (-1)^{a\Gamma(n-\mu+1)})\right). \quad (8.29)$$

$$\mu(j,l,n) = \sum_{a=4}^{5} (u - j - H_{n-a-j}) H_{(l,1)^{(j+1-\alpha+2)}} = \frac{1}{4} \sum_{a=0}^{1} \left(7 + 2(u - j) - (-1)^{\Gamma[6(n-\mu+1)]}(1 + (-1)^{a\Gamma(n-\mu+1)})\right). \quad (8.30)$$

This report is concluded by emphasizing that its goal has been the exploration of an analytical formula for the inverse of an invertible square matrix. Such a formula is not intended to be an alternative for a computationally efficient algorithm such as LU-decomposition which is often used as one of many possible algorithms for finding the inverse of a matrix [1]. The report merely demonstrates the complications involved in the attainment of an analytical formula. Alternative, even simpler, formulas may also be possible, although it is doubtful that they could compete with the established algorithms.
