Abstract
Fourier expansion of the integrand in the path integral formula for the partition function of quantum systems leads to a potentially useful tool both for rigorous and for numerical work. It can also inspire new kinds of analytic approximations.

1 The result
The Feyman-Kac formula [F1, K1,2] provides a stochastic representation of the partition function of quantum systems [F2, G1-4]. Working on it one can arrive at a deterministic expression as follows.

Theorem. Consider N identical bosons or fermions on a d ≥ 1-torus of side L which interact via a pair potential u : Rd → R of the following properties:
1. u(−x) = u(x).
2. The Fourier-transform ̂u of u exists and ̂u ∈ L1 ∩ C(Rd).
3. u(x) = O(|x|−d−η) with some η > 0 as x → ∞.

Then the canonical partition function of the system at inverse temperature β can be set in the form

\[ Q_{N,L} = \exp \left\{ -\frac{β ̂u(0)}{2L^d} N(N-1) \right\} \sum_{p=1}^{N} \varepsilon(p) \prod_{n_1,...,n_p \geq 1; \sum n_i = N} \prod_{l=1}^{p} \frac{1}{n_l} \sum_{\alpha_1^1,\alpha_2^2,...,\alpha_{N-1}^N=0}^{\infty} \prod_{1 \leq j < k \leq N} \left[ \frac{(-β)\alpha_j^k}{\alpha_j^k!} \prod_{r=1}^{l} \frac{1}{L^d} \sum_{z_{j,r} \in Z^d \setminus \{0\}} ̂u \left( \frac{z_{j,r}}{L} \right) \right] \prod_{l=1}^{p} \delta_{Z^d,0} \sum_{z \in Z^d} \exp \left\{ -\frac{\pi \lambda_{l}^2}{L^2} \sum_{q \in C_l} \int_0^1 \left[ z + Z_q(t) \right]^2 \, dt \right\}. \]

(1.1)

Here \( \varepsilon(p) = 1 \) for bosons and \( (-1)^{N-p} \) for fermions, and \( \lambda_{l} = \sqrt{2\pi\hbar^2/\beta m_0} \) is the thermal wave length for particles of mass \( m_0 \). There is a summation with respect to \( \alpha_j^k \) for every pair \( 1 \leq j < k \leq N \), and what comes after the square bracket is under all these summations/integrals. Furthermore,

\[ N_l = \sum_{l'=1}^{l} n_{l'}, \quad C_l = \{ N_{l-1} + 1, N_{l-1} + 2, \ldots, N_l \} \]

(1.2)

*Work supported by OTKA Grant No. K128989.
and for \( q \in C_l \)

\[
Z_q(t) = - \sum_{j=1}^{q-1} \sum_{k=q+1}^{N_q} \sum_{r=1}^{\alpha_j^k} 1(t_{j,r}^k \geq t) z_{j,r}^k + \sum_{j=q}^{N_q} \sum_{k=N_q+1}^{N} \sum_{r=1}^{\alpha_j^k} 1(t_{j,r}^k \geq t) z_{j,r}^k \\
- \sum_{j=1}^{q} \sum_{k=q+1}^{N_q} \sum_{r=1}^{\alpha_j^k} 1(t_{j,r}^k < t) z_{j,r}^k + \sum_{j=q+1}^{N_q} \sum_{k=N_q+1}^{N} \sum_{r=1}^{\alpha_j^k} 1(t_{j,r}^k < t) z_{j,r}^k. 
\]

(1.3)

In particular,

\[
Z_l^1 := Z_{N_l-1+1}(0) = - \sum_{j=1}^{N_l-1} \sum_{k \in C_l} \sum_{r=1}^{\alpha_j^k} z_{j,r}^k + \sum_{j \in C_l} \sum_{k=N_l+1}^{N} \sum_{r=1}^{\alpha_j^k} z_{j,r}^k. 
\]

(1.4)

**Remark 1.** It will be seen that \( l \) labels a permutation cycle of length \( n_l = N_l - N_{l-1} \) \((N_0 = 0, N_p = N)\) which stands for a closed effective single-particle trajectory composed of \( n_l \) physical particles. The product \( \prod_{j \in k \cdots} \) alone is independent of the order of the \( N \) particles. In contrast to this, the definition of \( Z_q(t) \) assumes that the \( l \)th permutation cycle is \((N_{l-1} + 1 \ldots N_l)\). Still, the whole expression does not change if the cycles are taken in a different order, as comparison of Eqs. (1.20) and (1.22) in the Lemma below shows it. However, the invariance is deeper in the formulas. Noting that \( \hat{u} \) is (also) an even function, this can be seen as follows.

**Proposition 1.** For any given set of variables

\[
\{ \alpha_j^k \geq 1, \ t_{j,r}^k \in [0, 1], \ \tilde{z}_{j,r}^k \in \mathbb{Z}^d \setminus \{0\} \mid 1 \leq j < k \leq N, \ r = 1, \ldots, \alpha_j^k \}
\]

let

\[
\mathcal{V} = \left\{ \{ \tilde{z}_{j,r}^k \} \in (\mathbb{Z}^d \setminus \{0\})^{\sum_{j<k} \alpha_j^k} \mid \sum_{j=r}^{\alpha_j^k} \tilde{z}_{j,r}^k = \pm \tilde{z}_{j,r}^k \right\}.
\]

Then

\[
\sum_{\{ \tilde{z}_{j,r}^k \} \in \mathcal{V}} \prod_{l=1}^{p} \delta_{z_{l,0}} \sum_{z \in \mathbb{Z}^d \setminus \{0\}} \exp \left\{ -\frac{\pi \alpha_j^k}{L^2} \sum_{q \in C_l} \int_0^1 [z + Z_q(t)]^2 \, dt \right\}
\]

is independent of the order of the cycles.

**Proof.** It is easier to verify the statement if the particles are numbered by cycles. Particle \( q \in C_l \) will carry the double label \( li \) where \( i = q - N_{l-1} - 1; \) thus \( i \in [0, n_l - 1] \). Furthermore, \( j, k \in C_l \) will be replaced by \( lj, lk \), with the new \( j, k \) varying from 0 to \( n_l - 1 \). The new notations change \( Z_q(t) \) into

\[
Z_{li}(t) = - \sum_{l < l'} \sum_{j=0}^{n_{l'-1}} \left[ \sum_{k=i+1}^{n_{l'-1}} \sum_{r: t_{j,r}^k \geq t} z_{j,r}^k + \sum_{k=i+1}^{n_{l'-1}} \sum_{r: t_{j,r}^k < t} z_{j,r}^k \right] \\
+ \sum_{l' > l} \sum_{k=0}^{n_{l-1}} \left[ \sum_{j=i}^{n_l-1} \sum_{r: t_{j,r}^k \geq t} z_{j,r}^k + \sum_{j=i+1}^{n_{l-1}} \sum_{r: t_{j,r}^k < t} z_{j,r}^k \right] \\
- \sum_{j=0}^{n_{l-1}} \sum_{k=i}^{n_l-1} \sum_{r: t_{j,r}^k \geq t} z_{j,r}^k + \sum_{j=0}^{n_{l-1}} \sum_{k=i+1}^{n_{l-1}} \sum_{r: t_{j,r}^k < t} z_{j,r}^k \right] 
\]

(1.5)

and

\[
\sum_{q \in C_l} \int_0^1 [z + Z_q(t)]^2 \, dt = \sum_{i=0}^{n_{l-1}} \int_0^1 [z + Z_{li}(t)]^2 \, dt.
\]

(1.6)
In cycle \( l \) particles above the \( \delta \) are coupled to all the particles in cycles \( l' < l \) with a global minus sign and to all the particles in cycles \( l' > l \) with a global plus sign. When the order of the cycles is changed, it is not necessary to change the numbering: all that can happen is that some global signs go wrong. This occurs always in pairs because \( z_{ij}^{k} \) appears in \( Z_{l}(\cdot) \) and \( Z_{j}(\cdot) \), and only in them, with opposite signs. Replacing the involved variables by their negative restores the correctness of \( \{Z_{li}(t)\} \) with a new set of variables within \( V \) and the cycles taken in the original order determined by the sequence \( (N_{l}) \).

**Remark 2.** In Eq. (1.1) the sum over \( p \)-partitions of \( N \),

\[
\frac{1}{p!} \sum_{n_{1}, \ldots, n_{p} \geq 1, \sum n_{i} = N} \frac{1}{n_{1} \cdots n_{p}} \prod_{l=1}^{p} \frac{1}{n_{l}} = \prod_{n_{1} \geq \cdots \geq n_{p} \geq 1, \sum n_{i} = N} \frac{1}{n} \left( \frac{1}{n} \right)^{\frac{1}{\mu} \left( \left\{ n_{i} \right\}^{p} \right)} \frac{1}{\mu \left( \left\{ n_{i} \right\}^{p} \right)}! \tag{1.7}
\]

can be replaced by the sum over \( p \)-compositions of \( N \)

\[
\sum_{(n_{1}, \ldots, n_{p}) \in \mathbb{N}^{p}: \sum n_{i} = N} \frac{1}{N(N - n_{1}) \cdots (N - n_{1} - \cdots - n_{p-1})} = \sum_{1 \leq n_{1} < \cdots < n_{p-1} < N} \frac{1}{N(N - n_{1})(N - n_{2}) \cdots (N - n_{p-1})} \tag{1.8}
\]

In (1.7) the product on the right side is over the different numbers among \( n_{1}, \ldots, n_{p} \) and \( \mu \left( \left\{ n_{i} \right\}^{p} \right) \) is the multiplicity of \( n \) in \( \left\{ n_{i} \right\}^{p} \). Both (1.7) and (1.8) are equal to the fraction of permutations built up from \( p \) cycles (for (1.8) see later). Thus, summing either of them with respect to \( p \) from 1 to \( N \) gives 1. In some applications the form (1.8) or a combination of (1.7) and (1.8) may be useful.

**Remark 3.** In the proof we will obtain

\[
\int_{0}^{1} \, dt_{j,\alpha_{j}}^{k} \int_{0}^{t_{j,\alpha_{j}}^{k}} \, d^{k - 1}_{j,\alpha_{j}} \int_{0}^{t_{j,\alpha_{j}}^{k}} \, d^{k - 2}_{j,\alpha_{j}} \cdots \int_{0}^{t_{j,\alpha_{j}}^{k}} \, d_{j,\alpha_{j}}^{k}
\]

and replace it by the symmetric

\[
\frac{1}{\alpha_{j}^{k!}} \int_{0}^{1} \, dt_{j,\alpha_{j}}^{k} \int_{0}^{t_{j,\alpha_{j}}^{k}} \, d_{j,\alpha_{j}}^{k} \cdots \int_{0}^{t_{j,\alpha_{j}}^{k}} \, d_{j,\alpha_{j}}^{k}
\]

This can be done because in the formula (1.3) the times \( t_{j,r}^{k} \) are compared to \( t \), not to each other, therefore any permutation of \( t_{j,1}^{k}, \ldots, t_{j,r}^{k} \) rearranges only the sums with respect to \( r \).

**Remark 4.** The exponents in Eq. (1.1) can be expanded with the result

\[
\sum_{z \in \mathbb{Z}^{d}} \exp \left\{ -\frac{\pi \lambda_{2}^{2}}{L^{2}} \sum_{q \in C_{1}} \int_{0}^{1} \left[ z + Z_{q}(t) \right]^{2} \, dt \right\} = \exp \left\{ -\frac{\pi n_{1} \lambda_{2}^{2}}{L^{2}} \left[ \overline{Z} \right]^{2} - \overline{Z} \right\} \sum_{z \in \mathbb{Z}^{d}} \exp \left\{ -\frac{\pi n_{1} \lambda_{2}^{2}}{L^{2}} (z + \overline{Z})^{2} \right\} \tag{1.9}
\]

where

\[
\overline{Z} = \frac{1}{n_{1}} \sum_{q \in C_{1}} \int_{0}^{1} Z_{q}(t) \, dt, \quad (\overline{Z})^{2} = \frac{1}{n_{1}} \sum_{q \in C_{1}} \int_{0}^{1} Z_{q}^{2}(t) \, dt. \tag{1.10}
\]
Performing the time integral and interchanging the order of summations,

$$n_l Z_l = \sum_{q \in C_l} \int_0^1 Z_q(t) \, dt = - \sum_{j=1}^{N_l-1} \sum_{k \in C_l} \alpha_j^k \sum_{r=1}^{N_l} (k - N_l-1 - 1 + t_{j,r}^k) z_{j,r}^k$$

$$- \sum_{\{j<k\} \subset C_l} (k-j) \sum_{r=1}^{N_l} \alpha_j^k z_{j,r}^k + \sum_{j \in C_l} \sum_{k=N_l+1}^{N} \sum_{r=1}^{N_l} (j - N_l-1 + t_{j,r}^k) z_{j,r}^k$$

$$\equiv - \sum_{k \in C_l} \sum_{j=1}^{k-1} \sum_{r=1}^{N_l} (k - N_l-1 + t_{j,r}^k) z_{j,r}^k + \sum_{j \in C_l} \sum_{k=j}^{N_l} \sum_{r=1}^{N_l} (j - N_l-1 + t_{j,r}^k) z_{j,r}^k.$$

(1.11)

The second form is derived differently, cf. Eq. (3.36) below, but the identity is evident if we write

$$k - j = (k - N_l-1 - 1 + t_{j,r}^k) - (j - N_l-1 - 1 + t_{j,r}^k).$$

$$\overline{(Z_l)^2}$$ can be obtained by integration with respect to $t$, but there is still another way described later.

**Remark 5.** $\overline{(Z_l)^2} - \overline{Z_l^2} = 0$ if and only if $\overline{(Z_l)^2} = \overline{Z_l^2} = 0$ and this holds if and only if

$$\alpha_j^k = 0 \quad \text{whenever} \quad \{j, k\} \cap C_l \neq \emptyset.$$  

(1.12)

Equation (1.12) implies $Z_q(t) \equiv 0$ and hence $\overline{(Z_l)^2} = \overline{Z_l^2} = 0$. For a proof in the other direction one must inspect Eqs. (1.3), (1.4) and (1.10). $(Z_l^l)^2 - \overline{Z_l^2} = 0$ if and only if $Z_q(t)$ is the same constant for all $q \in C_l$ for almost all $t \in [0, 1]$. The times $t_{j,r}^k$ occurring in (1.3) are almost surely positive, so there is an interval above 0 in which $Z_{N_l+1}(t) = Z_{N_l+1}(0) = Z_l^l$; therefore $Z_q(t) = Z_l^l$ (cf. $\delta_{Z_q^l,0}$) for all $q \in C_l$ for almost all $t \in [0, 1]$. This however needs the condition (1.12).

A physical interpretation is the following. $h(2\pi/L) Z_q(t)$ may be considered as the shift due to interactions of the momentum of the $q$th particle at “time” $t$ compared to its value in the ideal gas. The shift does not fluctuate if the interaction does not fluctuate, like when the particle is exposed only to a constant external field. This is precisely what (1.12) means, cf. the next remark.

**Remark 6.** In Eq. (1.1) the sum $\sum_{q \in \mathbb{Z}^d}$ is invariant with respect to the value of $Z_{N_l+1}(0)$. Imposing $Z_l^l = 0$ breaks this invariance. As it will turn out, these conditions arise from the closedness of the effective single-particle trajectories. They set a constraint both on the nonzero values of $\alpha_j^k$ and on the number of independent summation variables. One of $\delta Z_l^l,0$ could be dropped because $\sum_{p=1}^p Z_l^l \equiv 0$. The constraint is absent in the mean-field contribution to the partition function which corresponds to $\alpha_j^k \equiv 0$,

$$Q_{N,L}^{m,f} = \exp \left\{ -\frac{\beta \mu(0)(N-1)}{2} \right\} \sum_{p=1}^{N_l} \epsilon(p) \prod_{n=1}^{p} \frac{1}{n!} \prod_{n_1, \ldots, n_p \geq 1, \sum_{n_i=n}^N} 1 \prod_{l=1}^{p} \frac{1}{n_l} \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi n_l \lambda^2}{L^2} z^2 \right\}$$

(1.13)

where $\rho = N/L^d$. One can go beyond the mean-field approximation and still avoid the constraint. $Z_l^l$ depends only on $z_{j,r}^k$ where one and only one of $j$ and $k$ is in $C_l$, i.e., in the $l$th cycle. A meaningful completion of the mean-field result is to add terms in which the cycles are decoupled by keeping $\alpha_j^k = 0$ if $j$ and $k$ are in different
cycles (so their interaction is only via the commonly created mean field) and to choose $\alpha_j^k$ at will if they are in the same cycle. Then, for $q$ in any of the $p$ sets $C_l$

$$Z_q(t) = - \sum_{j=N_{l-1}+1}^{N_l} \sum_{k=q}^{q+1} \sum_{r=1}^{N_l} \alpha_j^k \mathbb{1}(t_{j,r}^k \geq t) z_{j,r}^k - \sum_{j=N_{l-1}+1}^{N_l} \sum_{k=q}^{q+1} \sum_{r=1}^{N_l} \mathbb{1}(t_{j,r}^k < t) z_{j,r}^k$$

(1.14)

and in Eq. (1.1) the product over $l = 1, \ldots, p$ in itself is invariant with respect to the order of the cycles.

To go even further, $A_l := \sum_{j=1}^{N_{l-1}} \sum_{k \in C_l} \alpha_j^k + \sum_{j \in C_l} \sum_{k=1}^{N_l} \alpha_j^k \geq 2$ (1.15)
is necessary to satisfy $Z'_l = 0$ with nonzero vectors. Such an equation cannot stand alone: if $\alpha_j^k > 0$, one of $j$ and $k$ is in another cycle $l'$, implying a coupled equation $Z'_{l'} = 0$. Suppose that $l_1 < \cdots < l_s \ (s \geq 2)$ label a maximal set of coupled permutation cycles, giving rise to $s$ homogeneous linear equations. Clearly, $s \leq \frac{1}{2} \sum_{k=1}^{N_l} A_{l_k}$, the number of involved pairs $(j, k)$ at $\alpha_j^k$ different times, i.e., the total number of variables in the $s$ equations. Explicitly, these variables are

$$\bigcup_{1 \leq j' < j \leq s} \{ z_{j,r}^k | j \in C_{l_j}, \ k \in C_{l_j}, \ r = 1, \ldots, \alpha_j^k \}.$$

In general, if $j$ is in cycle $l$ and $k$ is in cycle $l' > l'$, $z_{j,r}^k$ appears in two equations with different signs: as $+z_{j,r}^k$ in $Z'_l = 0$ and as $-z_{j,r}^k$ in $Z'_{l'} = 0$. For a given set $\{ \alpha_j^k \}$ the system of equations may not be soluble with all $z_{j,r}^k$ nonzero. Such an $\{ \alpha_j^k \}$ is illicit and is discarded by $\prod_{l=1}^{p} \delta_{Z'_l \neq 0}$. On the other hand, if $\{ \alpha_j^k \}$ is a valid set and if the number of linearly independent equations is $K(\alpha_j^k)$ then $\prod_{l=1}^{p} \delta_{Z'_l \neq 0}$ makes $K(\alpha_j^k)$ sums over $\mathbb{Z}^d \setminus \{0\}$ collapse into a single vector leaving a factor $(L^{-d})^K(\alpha_j^k)$ uncompensated by sums. This appears as a loss of weight in $Q_{N,L}$ compared to the mean-field and other contributions with uncoupled cycles.

The simplest example of a valid $\{ \alpha_j^k \}$ is $s = 2$, $\alpha_1^2 = 2$. With the variables $z_{1,1}^2$ and $z_{1,2}^2$, the two equations are $Z'_1 \equiv z_{1,1}^2 + z_{1,2}^2 = 0$ and $Z'_2 \equiv -z_{1,1}^2 - z_{1,2}^2 = 0$. Thus, $K(\alpha_j^k) = 1$.

The next simplest example is $s = 3$, $1$ in cycle $l_1$, $2$ in cycle $l_2$, $3$ in cycle $l_3$, and $\alpha_2^2 = \alpha_3^3 = \alpha_1^1 = 1$. Then

$$A_{l_1} = \alpha_2^1 + \alpha_3^3 = 2, \quad A_{l_2} = \alpha_1^2 + \alpha_3^3 = 2, \quad A_{l_3} = \alpha_1^1 + \alpha_2^2 = 2,$$

and, if $l_1 < l_2 < l_3$, the three equations are

$$Z_{l_1}^1 \equiv z_{1,1}^2 + z_{1,1}^3 = 0, \quad Z_{l_2}^2 \equiv -z_{1,1}^2 - z_{1,1}^3 = 0, \quad Z_{l_3}^3 \equiv -z_{1,1}^3 - z_{2,1}^3 = 0.$$

Choosing any nonzero vector $v$,

$$z_{1,1}^2 = v, \quad z_{1,1}^3 = -v, \quad z_{2,1}^3 = v$$

is a solution. Two of the equations represent linearly independent constraints. So the above is the general solution, only one of $z_{1,1}^2, z_{1,1}^3, z_{2,1}^3$ is a free summation variable in Eq. (1.1), $K(\alpha_j^k) = 2$.

A systematic study of the constraint can be done with the help of graph theory. Consider a graph $G(\alpha_j^k)$ of $p$ vertices numbered from 1 to $p$ with

$$b_{r,l} = \sum_{j \in C_{l'}} \sum_{k \in C_{l'}} \alpha_j^k$$

edges between the vertices $l'$ and $l > l'$. The edge set is valid if to every edge one can assign a nonzero vector so that at any vertex $l$ the sum of the vectors on the incident edges $(l, l_1), (l, l_2), \ldots$, taken with minus sign if $l_i < l$ and with plus sign if $l_i > l$, is zero. A solution to this graph problem is presented in the Appendix. Here is the result:
A set \( \{\alpha_j^k\} \) is compatible with the constraint \( \prod_{i=1}^p \delta_{x_{i,0}^k} \) if and only if every maximal connected subgraph of \( G(\alpha_j^k) \) is either a single vertex or a merger through vertices or along edges of circular graphs of arbitrary length.

From Proposition 5 (Appendix) one can deduce bounds on the loss due to the coupling of cycles. Let \( g(\alpha_j^k) \) be the simple graph obtained from \( G(\alpha_j^k) \) by keeping only a single edge between \( l \) and \( l' \) if \( b_{ll'} \geq 1 \). Let

\[
S = \sum_{1 \leq l < l' \leq p} \text{sgn} b_{ll'},
\]

the total number of edges of \( g(\alpha_j^k) \). Then

\[
S/2 \leq K(\alpha_j^k) \leq S.
\]

An entropic compensation of the loss \( (L^{-d})^K(\alpha_j^k) \) is sometimes possible. As an example, consider the partition \( p = N/2, n_1 = \cdots = n_{N/2} = 2 \), cycle \( l \) containing \( 2l - 1, 2l \). Suppose that the cycles are coupled in a single circle; this can be done in \( (N/2 - 1)! \) different orders. Fix an order \( (l_1, l_2, \ldots, l_{N/2}) \) along the circle. In the simplest case, when \( b_{l_1,l_{i+1}} = 1 \), cycle \( l_i \) can be coupled to cycle \( l_{i+1} \) in four different ways. Now \( S = N/2 \), the number of linearly independent constraints is \( N/2 - 1 \), so the overall factor due to coupling (but disregarding the change of \( Z_q(t) \)) is

\[
(N/2 - 1)! 4^{N/2} (L^{-d})^{N/2 - 1} \sim (2 \rho/\varepsilon)^{N/2}.
\]

If, on the other hand, the \( N/2 \) 2-cycles are coupled in a complete graph, the factor due to coupling stays below

\[
4^{N/2} (L^{-d})^{N/2 - 1} = (16 \rho/N)^{N/2}.
\]

The coupling of the cycles also increases the fluctuation of the shift \( Z_q(t) \) of the momenta, hence \( \overline{Z(t)^2 - Z(t)^2} \). This is another source of loss that decreases the weight of \( \{\alpha_j^k\} \) in the partition function.

**Remark 7.** Asymptotically, when \( N \) and \( L \) are large, \( Q_{N,L} \) becomes

\[
Q_{N,L} \approx \exp \left\{ -\beta \rho \hat{u}(0) N \right\} \sum_{p=1}^P \epsilon(p) \prod_{n_1, \ldots, n_{N/2} = 1}^p \prod_{l=1}^p \frac{1}{n_l!} \left( \sum_{n_l = N}^N \sum_{\alpha_{n_l}^k = 0}^{\infty} (L^{-d})^{K(\alpha_{n_l}^k)} \right)
\]

\[
\times \prod_{\alpha_j^k \neq 0} \prod_{1 \leq j < k \leq N} \frac{(-\beta)^{\alpha_j^k}}{\alpha_j^k!} \prod_{r=1}^p \int dz_{j,r}^k \hat{u}(z_{j,r}^k) \int_0^1 dt_{j,r}^r \times \left\{ \prod_{l=1}^p \delta(X_1^l, \ldots, X_p^l) \sum_{l=1}^p \delta(X_1^l, \ldots, X_p^l) \right\}
\]

\[
(1.16)
\]

Above \( X_1^l \) and \( X_q(t) \) are obtained from \( Z_1^l/L \) and \( Z_q(t)/L \), respectively, by replacing \( z_{j,r}^k \) with the continuous variable \( x_{j,r}^k \) for all \( j, k, r \). The factor \( (L^{-d})^{K(\alpha_j^k)} \) appears explicitly because

\[
\left( \prod_{1 \leq j < k \leq N} \prod_{r=1}^p \frac{1}{L^d} \sum_{z_{j,r}^k \in \mathbb{Z}^d \setminus \{0\}} \hat{u}(z_{j,r}^k/L) \right) \prod_{l=1}^p \delta(z_l^0, 0)
\]

\[
\approx (L^{-d})^{K(\alpha_j^k)} \left( \prod_{1 \leq j < k \leq N} \prod_{r=1}^p \int dx_{j,r}^k \hat{u}(x_{j,r}^k) \right) \delta(X_1^l, \ldots, X_p^l)
\]

\[
(1.17)
\]
where $\delta(X_1^1, \ldots, X^p_1)$ restricts the multiple integral to a $d\left(\sum_{j<k} \alpha_j^k - K_{\{\alpha_j^k\}}\right)$-dimensional manifold on which $X_1^1 = \cdots = X_1^p = 0$. As in Eqs. (1.9) and (1.10),

$$\sum_{x \in \mathbb{Z}^d} \exp \left\{ -\pi \lambda^2 \int_0^1 \left[ z + LX_0(t) \right]^2 dt \right\}$$

$$= \exp \left\{ -\pi \lambda \left[ (X^1)^2 - (X^1)^2 \right] \right\} \sum_{x \in \mathbb{Z}^d} \exp \left\{ -\pi \lambda \left[ (z + LX^1)^2 \right] \right\}$$

(1.18)

where

$$\overline{X}^1 = \frac{1}{n_1} \sum_{q \in C_1} \int_0^1 X_0(t) dt, \quad \overline{(X^1)^2} = \frac{1}{n_1} \sum_{q \in C_1} \int_0^1 X_0(t)^2 dt.$$  

(1.19)

The heart of the proof of the Theorem is the following lemma.

**Lemma.** Let $W^\beta_x(d\omega)$ denote the Wiener measure on the d-torus $\Lambda$ of side $L$ defined on the trajectories that start in $x$ at time 0 and end in $y$ at time $\beta$. Choose $p - 1$ integers $1 \leq N_1 < \cdots < N_{p-1} < N$ and define $n_l = N_l - N_{l-1}$, $l = 1, \ldots, p$ ($N_0 = 0, N_p = N$). Let moreover

$$G[[n]]_1 := \int_\Lambda dx_1 \int W^{n_1\beta}_{x_1}(d\omega_1) \prod_{0 \leq j < k \leq n_1-1} \exp \left\{ -\int_0^\beta u_L(\omega_1(k\beta + t) - \omega_1(j\beta + t)) dt \right\}$$

$$\cdots \int_\Lambda dx_p \int W^{n_p\beta}_{x_p}(d\omega_p) \prod_{0 \leq j < k \leq n_p-1} \exp \left\{ -\int_0^\beta u_L(\omega_p(k\beta + t) - \omega_p(j\beta + t)) dt \right\}$$

$$\prod_{1 \leq \nu < \nu' \leq p} \prod_{j=0}^{n_{\nu'-1}} \prod_{k=0}^{n_{\nu}-1} \exp \left\{ -\int_0^\beta u_L(\omega_1(k\beta + t) - \omega_{\nu'}(j\beta + t)) dt \right\}$$

(1.20)

where

$$u_L(x) = \sum_{z \in \mathbb{Z}^d} u(x + Lz).$$

(1.21)

Then

$$G[[n]]_1 = \exp \left\{ \beta \hat{u}(0) N(N - 1) \right\}$$

$$\times \sum_{\alpha_1^1, \alpha_2^1, \ldots, \alpha_N^1 = 0}^{\infty} \prod_{1 \leq j < k \leq N} \hat{u} \left( \frac{z_j^k}{L} \right) \hat{u} \left( \frac{z_k^j}{L} \right) \cdots \hat{u} \left( \frac{z_k^j \alpha_j^k}{L} \right) \hat{u} \left( \frac{z_j^k \alpha_j^k}{L} \right)$$

$$\int_0^1 dt_j^{0} \int_0^{t_j^{0}} dt_j^{0} \int_0^{t_j^{0}} \cdots \int_0^{t_j^{0}} dt_j^{0} \prod_{l=1}^{p} \int_{C_l} \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\pi \lambda^2 \sum_{q \in C_l} \int_0^1 \left[ z + Z_q(t) \right]^2 dt \right\}.$$  

(1.22)
2 Proof of the Theorem

We must prove that

\[
Q_{N,L} = \sum_{p=1}^{N} \frac{\epsilon(p)}{p!} \prod_{n_1, \ldots, n_p \geq 1, \sum n_i = N} G\{\{n_i\}|^p_i = 1 \pi^p_i = 1 \} \prod_{i=1}^{p} n_i
\]

\[
= \frac{1}{N} \sum_{p=1}^{N} \epsilon(p) \sum_{(n_1, \ldots, n_p) \in \mathbb{N}^p, \sum n_i = N} \frac{G\{\{n_i\}|^p_i = 1 \pi^p_i = 1 \} \prod_{i=1}^{p} (N - n_1) \cdots (N - n_1 \cdots - n_{p-1})}{N!}
\]

(2.1)

i.e., that the partition function is an average of \(\epsilon(p)G\{\{n_i\}|^p_i = 1 \pi^p_i = 1 \} \prod_{i=1}^{p} n_i\) over the partitions/compositions of \(N\). For a system whose Hamiltonian is

\[
H_{N,L} = -\frac{\hbar^2}{2m_0} \sum_{i=1}^{N} \Delta_i + \sum_{1 \leq i < j \leq N} u_L(x_j - x_i)
\]

(2.2)

the canonical partition function on the torus \(\Lambda\) in path integral representation reads

\[
Q_{N,L} = \text{Tr} P_{\pm} e^{-\beta H_{N,L}} = \frac{1}{N!} \sum_{\pi \in S_N} \epsilon_{\pm}(\pi) \int_{\Lambda} dx_1 \cdots dx_N \int W^0_{x \in \pi(1)} (d\omega_1) \cdots \int W^0_{x \in \pi(N)} (d\omega_N)
\]

\[
\prod_{1 \leq j < k \leq N} \exp \left\{ - \int_0^\beta u_L(\omega_k(t) - \omega_j(t)) dt \right\}.
\]

(2.3)

Here \(\pm\) refers to bosons or fermions, respectively, and

\[
P_{\pm} = \frac{1}{N} \sum_{\pi \in S_N} \epsilon_{\pm}(\pi) P_{\pi}
\]

(2.4)

is the orthogonal projection to the symmetric or antisymmetric subspace of the \(N\)-particle Hilbert space: \(S_N\) is the symmetric group of \(N\) elements, \(P_{\pi}\) is the unitary representation of \(\pi\), \(\epsilon_{+}(\pi) \equiv 1\) and \(\epsilon_{-}(\pi)\) is the sign of the permutation \(\pi\). Furthermore, \(W^0_{x \in y} (d\omega)\) is the conditional Wiener measure adapted to periodic boundary conditions on a cube \(\Lambda\) of side \(L\):

Let \(f\) be an \(LZ^d\)-periodic functional over the space of trajectories \(\omega : [0, \beta] \rightarrow \mathbb{R}^d\) where periodicity is understood in the sense that \(f\) depends only on \(\{\omega(t) \pmod{L} | i = 1, \ldots, d, t \in [0, \beta]\}\). Then by definition

\[
\int_{\Lambda} W^0_{x \in y} (d\omega)f(\omega) = \sum_{z \in \mathbb{Z}^d} \int_{\mathbb{R}^d} P^0_{x,y+z} (d\omega)f(\omega),
\]

(2.5)

where \(P^0_{x,y}\) is the Brownian bridge measure in \(\mathbb{R}^d\). The measure of the set \(\{\omega|\omega(0) = x, \omega(\beta) = y\}\) is

\[
\int P^0_{x,y} (d\omega) = \lambda^{-d} e^{-\pi(x-y)^2/\lambda^2} =: \psi_0(x-y)
\]

(2.6)

with the contraction property

\[
\int dr \int P^0_{x,r} (d\omega_1) P^0_{y,r} (d\omega_2) = \int P^0_{x+y} (d\omega).
\]

(2.7)

Using invariance by space translations of \(P^0_{x,y}\) it is easy to verify that this property extends to \(W^0_{x,y}\),

\[
\int \Lambda \int dr \int W^0_{x,r} (d\omega_1) W^0_{y,r} (d\omega_2) = \int W^0_{x+y} (d\omega).
\]

(2.8)
In general, if the trajectories $\omega_1, \omega_2$ with $\omega_1(0) = x$, $\omega_1(\beta_1) = \omega_2(0) = r$, $\omega_2(\beta_2) = y$ are continuous and $f(\omega_1, \omega_2)$ is a continuous functional then

$$
\int dr \int P^{\beta_1}_{xy}(d\omega_1)P^{\beta_2}_{y\omega_2}(d\omega_2)f(\omega_1, \omega_2) = \int P^{\beta_1+\beta_2}_{\omega_1\omega_2}(d\omega)f(\omega)
$$

(2.9)

where $f(\omega_1, \omega_2) = \tilde{f}(\omega_1 \circ \omega_2)$ and $\omega_1 \circ \omega_2$ is the concatenation of $\omega_1$ and $\omega_2$. This follows from invariance also by time translations,

$$
\int P^{\beta}_{xy}(d\omega) \equiv \int P^{\beta_{1+t}}_{xy}(d\omega)
$$

(2.10)

via the construction of the Wiener measure as the limit of finite distributions: if $0 < t_1 < \cdots < t_n < \beta_1 < \tau_1 < \cdots < \tau_m < \beta_1 + \beta_2$, $x_i = \omega_1(t_i)$ and $y_j = \omega_2(\tau_j)$, then both sides of Eq. (2.9) are equal to

$$
\lim_{n,m \to \infty} \int \psi_{t_1}(x_1 - x)\psi_{t_2-t_1}(x_2 - x_1)\cdots\psi_{t_n-t_{n-1}}(r - x_1)\psi_{\tau_1-\beta_1}(y_1 - r)\psi_{\tau_2-\tau_1}(y_2 - y_1)
$$

$$
\cdots\psi_{\beta_n+\beta_2-\tau_m}(y - y_m)\tilde{f}(x_1, \ldots, x_n, r, y_1, \ldots, y_m, y) \, dx_1 \cdots dx_n \, dr \, dy_1 \cdots dy_m
$$

provided that all the time intervals go to zero and $\tilde{f}$ is a suitable approximation of and converging to $\tilde{f}$ in the above limit. If $f$ is also periodic in both $\omega_1$ and $\omega_2$ then

$$
\int_A dr \int W^{\beta_1}_{xy}(d\omega_1)W^{\beta_2}_{y\omega_2}(d\omega_2)f(\omega_1, \omega_2) = \int W^{\beta_1+\beta_2}_{\omega_1\omega_2}(d\omega)\tilde{f}(\omega).
$$

(2.11)

Here we focused on the particularities of the toroidal geometry; for more details about the general theory see [G1], [LHB].

The permutations form cycles; if one integrates with respect to all but one $x_i$ within each cycle, then by a repeated application of the contraction (2.11) the $N$-times integral in Eq. (2.3) transforms into the $p$-times integral in Eq. (1.20). This one depends on $\pi$ only via $n_1, \ldots, n_p$, the lengths of the cycles that constitute the permutation. In fact, the total potential energy is independent of $\pi$ and the sign depends only on the number of cycles: a cycle of length $n$ gives a factor $(-1)^{n-1}$, so the sign of a permutation $\pi$ of $p$ cycles is $
$$
\epsilon(\pi) = (-1)^{\sum_{n=1}^{p}(n-1)} = (-1)^{N-\beta}. \n$$

Therefore in (2.3) each conjugation class can be represented by any of its elements if one inserts a factor that gives the number of elements of the class. This yields the standard form of the partition function shown in the first line of Eq. (2.1): $Q_{N,L}$ is the average of $\epsilon(\pi)G[\{n_i\}]$ over the conjugation classes of $S_N$. The form given in the second line of (2.1) is slightly more tricky, because each conjugation class that contains cycles of different lengths is decomposed into as many parts as the possible orderings of the cycle lengths, and the associated factors depend on the order of the cycles. The result is an average based on a different resolution of the unity,

$$
1 = \frac{1}{N} \left( 1 + \sum_{n_1=1}^{N-1} \frac{1}{N - n_1} \left( 1 + \sum_{n_2=1}^{N-n_1-1} \frac{1}{N - n_1 - n_2} (1 + \cdots) \right) \cdots \right)
$$

$$
= \frac{1}{N} + \sum_{n_1=1}^{N-1} \frac{1}{N(N - n_1)} + \sum_{n_1=1}^{N-1} \sum_{n_2=1}^{N-n_1-1} \frac{1}{N(N - n_1)(N - n_1 - n_2)} + \cdots
$$

(2.12)

This expression is obtained by "skew" simplification from

$$
1 = \frac{1}{N!} \sum_{n_1=1}^{N} \frac{(N-1)!}{(N - n_1)!} \sum_{n_2=1}^{N-n_1} \frac{(N-n_1-1)!}{(N-n_1-n_2)!} \cdots
$$

(2.13)

To arrive at Eq. (2.13) we write $\pi = \cdots \pi_3 \pi_2 \pi_1$, where $\pi_1$ is the cycle that contains 1, $\pi_2$ is the cycle that contains the smallest number not in $\pi_1$, $\pi_3$ is the cycle that contains the smallest number not in $\pi_1$ and $\pi_2$,
and so on. The number of permutations with 1 in a cycle of length \(n_1\) is
\[
\binom{N-1}{n_1-1}(n_1-1)! = \frac{(N-1)!}{(N-n_1)!}
\]
and the other factors are obtained similarly. The proof of the theorem is done provided the Lemma is verified.

3 Proof of the Lemma

The main steps of the proof are as follows.

1. Discrete-time approximation: the time integrals of the pair potentials are replaced by their Riemann approximating sum. Then the Wiener measure depends only on a finite sequence of values that the trajectory assumes in the selected instants, and appears as a product of a finite number of (periodized) Gaussians.

2. Each Gaussian and each Boltzmann factor is Fourier-expanded, making possible the integration with respect to the spatial variables. This introduces relations among the Fourier variables and permits to eliminate those associated with the Gaussians, i.e., with the kinetic energy.

3. One takes the limit that restores the continuous time.

The functional integration could be short-circuited by starting with the Trotter formula for \(\exp\{-\beta H_{N,L}\}\) and stopping at the finite-product stage. However, the bulk of the work, points (2) and (3), would not change.

3.1 Discrete-time approximation

The interval \([0, \beta]\) is divided into \(m\) subintervals of length \(\beta/m\). Let
\[
x_{km+i}^l = \omega_l((km + i)\beta/m), \quad l = 1, \ldots, p, \quad k = 0, \ldots, n_i - 1, \quad i = 1, \ldots, m, \quad x_{n_i}^l \equiv x_0^l = x_l,
\]
and
\[
x_{km+i}^l = x_{n_i}^l \equiv x_0^l = x_l,
\]
cf. Eq. (1.20). Then, with the notation
\[
E_m(x) = \exp \left\{ -\frac{\beta}{m} u_L(x) \right\}
\]
the discrete-time approximation of \(G\{(n_l)_i^p\}\) is
\[
G_m\{(n_l)_i^p\} = \frac{1}{\lambda \prod_{l=1}^{m} x_{j-1}^l \prod_{j=1}^{\lambda} W_{\beta/m} x_{j-1}^l} \prod_{l=1}^{\lambda} \sum_{0 \leq j < n_l - 1} \sum_{k=0}^{n_l-1} \prod_{l=1}^{m} \prod_{j=0}^{n_l-1} E_m(x_{km+i}^l - x_{jm+i}^l).
\]

3.2 Fourier expansions

Let us start with the Wiener measure. From Eqs. (2.5) and (2.6)
\[
\int W_{xy}^\beta/dw = \sum_{z \in \mathbb{Z}^d} \int P_{xy+Lz}^\beta (dw) = \frac{1}{L^d} \sum_{z \in \mathbb{Z}^d} e^{-\pi(x-y+Lz)^2/\lambda^2_{\beta/m}} = \frac{1}{L^d} \sum_{z \in \mathbb{Z}^d} e^{-\pi x^2/\lambda^2_{\beta/m}} e^{i\frac{2\pi}{L} z \cdot (x-y)}.
\]
The rightmost form, obtained via the Poisson summation formula, is the Fourier representation we need. Then,

\[
\int \prod_{j=1}^{n/m} W_{j,j-1,j}^{j/m} (d\omega_j^l) = \frac{1}{L^{d(n/m)}} \sum_{v_{10},v_{21},\ldots,v_{n/m,1} \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi \lambda^2}{mL^2} \sum_{j=1}^{n/m} (v_{j,j-1}^l)^2 \right\} \times \exp \left\{ i\frac{2\pi}{L} \sum_{j=1}^{n/m} v_{j,j-1}^l \cdot (x_{j}^l - x_{j-1}^l) \right\}. \quad (3.5)
\]

Now

\[
\sum_{j=1}^{n/m} v_{j,j-1}^l \cdot (x_{j}^l - x_{j-1}^l) = \sum_{j=1}^{n/m} (v_{j,j-1}^l - v_{j,j+1,j}^l) \cdot x_{j}^l \quad \text{where} \quad v_{n/m+1,n/m}^l \equiv v_{10}^l.
\]

Introduce

\[
v_j^l = v_{j,j-1}^l - v_{j+1,j}^l, \quad j = 1, \ldots, n/m,
\]

then

\[
\sum_{j=1}^{n/m} v_j^l = 0. \quad (3.8)
\]

Furthermore, with the notation

\[
v_{j,j-1}^l = v_l + \sum_{j'=j}^{n/m-1} v_{j'}^l, \quad j = 1, \ldots, n/m. \quad (3.10)
\]

Therefore

\[
\sum_{j=1}^{n/m} (v_{j,j-1}^l)^2 = \sum_{j=1}^{n/m} (v_l + \sum_{j'=j}^{n/m-1} v_{j'}^l)^2, \quad (3.11)
\]

\[
\sum_{j=1}^{n/m} v_{j,j-1}^l \cdot (x_{j}^l - x_{j-1}^l) = \sum_{j=1}^{n/m} v_j^l \cdot x_{j}^l. \quad (3.12)
\]

Substituting these two expressions into Eq. (3.5),

\[
\int \prod_{j=1}^{n/m} W_{j,j-1,j}^{j/m} (d\omega_j^l) = \frac{1}{L^{d(n/m)}} \sum_{v_{10},v_{21},\ldots,v_{n/m,1} \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi \lambda^2}{mL^2} \sum_{j=1}^{n/m} (v_l + \sum_{j'=j}^{n/m-1} v_{j'}^l)^2 \right\} \times \prod_{i=1}^{m} \prod_{k=0}^{n/m-1} \exp \left\{ i\frac{2\pi}{L} v_{km+i}^l \cdot x_{km+i}^l \right\}. \quad (3.13)
\]

We extended the summation with respect to \( j' \) up to \( n/m \) for aesthetic reasons; the added integer vector \( v_{n/m}^l \) is not a summation variable and it does not change the sum with respect to \( v_l \) in \( \mathbb{Z}^d \). Because of \( v_{n/m}^l = -\sum_{j=1}^{n/m-1} v_j^l \),

\[
\sum_{j'=j}^{n/m-1} v_j^l = -\sum_{j'=j}^{n/m-1} v_j^l. \quad (3.14)
\]

The Fourier expansion of the Boltzmann factors is

\[
E_m(x_{km+i}^l - x_{jm+i}^l) = \sum_{z_{jk}^l(i)} z_{jk}^l(i) \exp \left\{ i\frac{2\pi}{L} v_j^l(i) \cdot (x_{km+i}^l - x_{jm+i}^l) \right\}. \quad (3.15)
\]

11
Here
\[ \hat{E}_m(z) = \frac{1}{L^d} \int_{\Lambda} \exp \left\{ -\frac{2\pi}{L} z \cdot x \right\} \exp \left\{ -\frac{\beta}{m} u_L(x) \right\} \, dx = \delta_{z,0} - \frac{\beta}{mL^d} \hat{u}(z/L) + \frac{1}{L^d} O(1/m^2) \] (3.16)
with
\[ \hat{u}(z/L) = \int \exp \left\{ -\frac{2\pi}{L} z \cdot x \right\} u(x) \, dx. \] (3.17)

Some short notations will be useful:
\[ Z_i = (\mathbb{Z}^d)^{m_n(n_l-1)/2}, \quad Z_\zeta = (\mathbb{Z}^d)^{m \sum_{l' < l} n_{l' n_l}}, \quad Z = (\mathbb{Z}^d)^{m N(N-1)/2}. \] (3.18)
The elements of these sets are considered as sets of vectors from \( \mathbb{Z}^d \), and the notation
\[ \hat{E}_m^Z = \prod_{z \in Z} \hat{E}_m(z) \] (3.19)
will be used for \( Z \in Z_i, Z_\zeta, Z \). Now
\[ \prod_{i=1}^{m} \prod_{0 \leq j < k \leq n_{l-1}} E_m(x^l_{km+i} - x^l_{jm+i}) = \sum_{Z \in Z_i} \hat{E}_m^Z \prod_{i=1}^{m} \exp \left\{ \frac{2\pi}{L} \sum_{k=1}^{n_l-1} \sum_{j=0}^{k-1} z^l_{jk}(i) \cdot (x^l_{km+i} - x^l_{jm+i}) \right\} \] (3.20)
which, after substituting
\[ \sum_{k=1}^{n_l-1} \sum_{j=0}^{k-1} z^l_{jk}(i) \cdot (x^l_{km+i} - x^l_{jm+i}) = \sum_{k=0}^{n_{l-1}} x^l_{km+i} \cdot \left( \sum_{j=0}^{k-1} z^l_{jk}(i) - \sum_{j=k+1}^{n_{l-1}} z^l_{jk}(i) \right) \] (3.21)
results in
\[ \prod_{i=1}^{m} \prod_{0 \leq j < k \leq n_{l-1}} E_m(x^l_{km+i} - x^l_{jm+i}) = \sum_{Z \in Z_i} \hat{E}_m^Z \prod_{i=1}^{m} \prod_{k=0}^{n_l-1-1} \exp \left\{ \frac{2\pi}{L} x^l_{km+i} \cdot \left( \sum_{j=0}^{k-1} z^l_{jk}(i) - \sum_{j=k+1}^{n_{l-1}} z^l_{jk}(i) \right) \right\}. \] (3.22)
Furthermore,
\[ \sum_{1 \leq l' < l \leq p} \sum_{k=0}^{n_{l-1}} \sum_{j=0}^{n_{l'}-1} z^l_{l'j}(i) \cdot (x^l_{km+i} - x^{l'}_{jm+i}) = \sum_{l=1}^{p} \sum_{k=0}^{n_{l-1}} x^l_{km+i} \cdot \left( \sum_{j=0}^{n_{l'}-1} z^l_{l'j}(i) - \sum_{j=0}^{n_{l'}-1} \sum_{l'=l+1}^{p} \sum_{j=0}^{n_{l'}-1} z^l_{l'j}(i) \right), \] (3.23)
so
\[ \prod_{i=1}^{m} \prod_{1 \leq l' < l \leq p} \prod_{j=0}^{n_{l'-1}} \prod_{k=0}^{n_{l-1}} E_m(x^l_{km+i} - x^{l'}_{jm+i}) = \sum_{Z \in Z_\zeta} \hat{E}_m^Z \prod_{i=1}^{m} \prod_{l=1}^{p} \prod_{k=0}^{n_{l-1}} \prod_{j=0}^{n_{l-1}} \prod_{l'=l+1}^{p} \exp \left\{ \frac{2\pi}{L} x^l_{km+i} \cdot \left( \sum_{j=0}^{n_{l-1}} \sum_{j=0}^{n_{l'}-1} z^l_{l'j}(i) - \sum_{j=0}^{n_{l-1}} \sum_{j=0}^{n_{l'}-1} \sum_{l'=l+1}^{p} z^l_{l'j}(i) \right) \right\}. \] (3.24)

From Eqs. (3.13), (3.22) and (3.24) one can collect the multiplier of \( x^l_{km+i} \). If we write \( G_m[(n_l)]_p^p \) as
\[ G_m[(n_l)]_p^p = \int_{\Lambda} \prod_{l=1}^{p} \prod_{j=1}^{n_{l}} da^l_j \ G \left[ \{ (x^l_j)_{j=1}^{n_{l}}, n_l \}_{l=1}^{p} \right] \] (3.25)
The multiple sum (3.26) is absolutely convergent and can be integrated term by term. Integration with respect to \(x^l_j\) in \(\Lambda\) makes \(v^l_j\) coincide with \(z^l_j\) for all \(j\) (including \(n_im\) via \(v^l_{n_im} = -\sum_{j=1}^{n_im} v^l_j\)) and turns Eq. (3.8) into

\[
\sum_{j=1}^{n_im} z^l_j = 0.
\]

Thus,

\[
G_m \left[ \{n_l\}_{l=1}^p \right] = \sum_{Z \in \mathbb{Z}} \left( \prod_{l=1}^p \delta_{z_{l,j_0}^l,0} \right) \hat{E}_m^Z \sum_{v \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi \lambda_3^2}{mL^2} \sum_{j=1}^{n_im} (v_j + \sum_{j' = j}^{n_im} z^l_{j'} - z^l_j)^2 \right\}.
\]

Finally, defining

\[
Z^l_j = \sum_{j' = j}^{n_im} z^l_{j'}, \quad Z^l = \sum_{j=1}^{n_im} Z^l_j, \quad (Z^l)^2 = \sum_{j=1}^{n_im} (Z^l_j)^2,
\]

where we use the same notations for the averages as for their \(m \to \infty\) limit in (1.9), Eq. (3.29) becomes

\[
G_m \left[ \{n_l\}_{l=1}^p \right] = \sum_{Z \in \mathbb{Z}} \left( \prod_{l=1}^p \delta_{Z^l,j_0} \right) \hat{E}_m^Z \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi \lambda_3^2}{mL^2} \sum_{j=1}^{n_im} (z + Z^l_j)^2 \right\}
\]

\[
= \sum_{Z \in \mathbb{Z}} \left( \prod_{l=1}^p \delta_{Z^l,j_0} \right) \hat{E}_m^Z \exp \left\{ -\frac{\pi \lambda_3^2}{L^2} \left[ (Z^l)^2 - Z^l \right] \right\}
\]

A consequence of \(Z^l_1 = 0\) is that \((Z^l)^2 - Z^l = 0\) if and only if \(Z^l_j = 0\) for \(j = 1, \ldots, n_im\) which holds if and only if \(z^l_j = 0\) for \(j = 1, \ldots, n_im\). (Note: \(Z^l_j = -\sum_{j=1}^{n_im} z^l_j\) as well, cf. Eq. (3.8).) This is the finite-\(m\) equivalent of Remark 5.

At this point it is useful to change the notation and number the particles continuously from 1 to \(N\). Particle \(lk\), the \(k\)th particle (starting from 0) of the \(l\)th cycle will carry the number \(N_{l-1} + k + 1\) when counted continuously, so the identities new≡old are

\[
z_{N_{l-1}+k+1} = z_{l,j}^k(i) \text{ or } z_{N_{l-1}+k+1}^q = z_{l,j}^{q-N_{l-1}+1}(i), \quad z_{N_{l-1}+k+1} = z_{l,k+m+1} \text{ or } z_q(i) = z_{q-N_{l-1}+m+i}^l
\]

for \(q \in C_l\) and \(j' \in C_{l'}\). The new notation is better suited to \(\hat{E}_m^Z\) which is independent of the cycle structure. Also, the expression (3.27) is replaced by the cycle-independent

\[
z_q(i) = -\sum_{j=1}^{q-1} z^q_{j}(i) + \sum_{k=q+1}^{N} z^k_{q}(i), \quad q = 1, \ldots, N, \quad i = 1, \ldots, m,
\]
and the expanded form of $Z^l_i$, $\overline{Z^l}$ and $(\overline{Z^l})^2$ in terms of the individual $z$ vectors becomes more transparent. For $q \in C_l$ one finds

$$Z^l_{(q-N_{l-1}-1)m+i} = \sum_{i'=1}^{N_l} \sum_{j=1}^{N_l} z^l_k(i) + \sum_{i'=1}^{N_l} \sum_{j=N_l+1}^{N_l+1} z^l_i(i')$$

$$= \sum_{i'=1}^{N_l-1} \left[ -\sum_{j=1}^{N_l} z^l_j(i') + \sum_{j=N_l+1}^{N_l+1} z^l_j(i') \right] + \sum_{i'=1}^{N_l} \left[ -\sum_{j=1}^{N_l} z^l_j(i') + \sum_{j=N_l+1}^{N_l+1} z^l_j(i') \right].$$

In particular,

$$Z^l_i = \sum_{i=1}^{N_l-1} \left[ -\sum_{j=1}^{N_l} z^l_j(i) + \sum_{j=N_l+1}^{N_l+1} z^l_j(i) \right].$$

Moreover,

$$\overline{Z^l} = \frac{1}{n_l} \sum_{q \in C_l} \sum_{i=1}^{m} \left( q - N_{l-1} - 1 + \frac{i}{m} \right) z_q(i)$$

$$= \frac{1}{n_l} \sum_{q \in C_l} \left[ -\sum_{j=1}^{N_l} \left( q - N_{l-1} - 1 + \frac{i}{m} \right) z^q_j(i) + \sum_{j=N_l+1}^{N_l+1} \sum_{i=1}^{m} \left( q - N_{l-1} - 1 + \frac{i}{m} \right) z^q_j(i) \right]$$

and

$$(\overline{Z^l})^2 = \frac{1}{n_l} \sum_{k, k'=0}^{N_l-1} \sum_{i, i'=1}^{m} \min \left\{ k + \frac{i}{m}, k' + \frac{i'}{m} \right\} z^l_{km+i} \cdot z^l_{km+i}$$

$$= \frac{1}{n_l} \sum_{q, q' \in C_l} \sum_{i, i'=1}^{m} \left( \min \left\{ q + \frac{i}{m}, q' + \frac{i'}{m} \right\} - N_{l-1} - 1 \right) z_q(i) \cdot z_q(i').$$

The last formula becomes complete after (3.33) is substituted in it.

### 3.3 The limit of continuous time

The result of the limit when $m$ tends to infinity can be seen on the simplest example, that of $N = 2$. Because in this case there is a single pair, the notation can be simplified by writing $z(i)$ instead of $z^l_i(i)$. Now $Z = (Z^l)^m$ whose elements are $Z = \{ z(1), \ldots, z(m) \}$. There are two partitions of 2: $p = 1, n_1 = 2$ and $p = 2, n_1 = n_2 = 1$.

#### One two-particle trajectory

When $p = 1$ then $l = 1, N_{l-1} = 0, N = N_1 = n_1 = 2$, so from (3.33) and (3.35)

$$z_1(i) = z(i), \quad z_2(i) = -z(i), \quad Z^l_1 \equiv 0.$$  \hfill (3.38)

Moreover,

$$\overline{Z^l} = \frac{1}{2} \sum_{i=1}^{m} \left[ -\left( 1 + \frac{i}{m} \right) z(i) + \frac{i}{m} z(i) \right] = -\frac{1}{2} \sum_{i=1}^{m} z(i),$$  \hfill (3.39)
\[
\overline{(Z^1)}^2 = \frac{1}{2} \sum_{j,j'=1}^{2} \sum_{i,i'=1}^{m} \left( \min \left\{ j + \frac{i}{m}, j' + \frac{i'}{m} \right\} - 1 \right) z_j(i) \cdot z_{j'}(i')
\]
\[
= \frac{1}{2} \left( \sum_{i=1}^{m} z(i) \right)^2 - \frac{1}{2} \sum_{i,i'=1}^{m} \frac{|i-i'|}{m} z(i) \cdot z(i')
\]
\[
= 2Z^1 \overline{Z}^2 - \frac{1}{2} \sum_{i,i'=1}^{m} |i-i'| z(i) \cdot z(i').
\] (3.40)

Thus,
\[
\overline{(Z^1)}^2 - \overline{Z^2}^2 = \sum_{i,j=1}^{m} \left( \frac{1}{4} - \frac{|i-j|}{2m} \right) z(i) \cdot z(j).
\] (3.41)

Although it will not be used, we mention that the spectral problem associated with the above quadratic form can be solved exactly.

**Proposition 2.** Let \(A\) be the \(m \times m\) matrix of elements \(A_{ij} = \frac{m^2}{4} - \frac{|i-j|}{2m}\). Then
\[
A^{-1} = \begin{bmatrix}
2 & -1 & 0 & \ldots & 0 & 0 & 1 \\
-1 & 2 & -1 & \ldots & 0 & 0 & 0 \\
& \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0 & 0 & 0 & \ldots & -1 & 2 & -1 \\
1 & 0 & 0 & \ldots & 0 & -1 & 2
\end{bmatrix},
\] i.e., minus the discrete Laplace operator with antiperiodic boundary condition \(v(j+m) = -v(j)\). The eigenvalues and eigenvectors of \(A^{-1}\) are
\[
\lambda_{2q-1} = \lambda_{2q} = 2 \left( 1 - \cos \left( \frac{(2q-1)\pi}{m} \right) \right)
\]
\[
v_{2q-1}(j) = \sin \left( \frac{(2q-1)\pi}{m} \right) j, \quad v_{2q}(j) = \cos \left( \frac{(2q-1)\pi}{m} \right) j \quad (q = 1, \ldots, \lfloor m/2 \rfloor)
\]
and
\[
\lambda_m = 4, \quad v_m(j) = (-1)^j \quad \text{if } m \text{ is odd.}
\]

The proof was obtained by making and verifying an ansatz based on numerical calculations of the eigenvalues and eigenvectors of \(A\) up to \(m = 50\).

**Two one-particle trajectories**

In this case
\[
Z^1 = -Z^2 = \sum_{i=1}^{m} z(i)
\]
\[
\overline{Z}_1 = -\overline{Z}_2 = \sum_{i=1}^{m} \frac{i}{m} z(i)
\]
\[
\overline{(Z^1)}^2 = \overline{(Z^2)}^2 = \sum_{i,j=1}^{m} \min \left\{ \frac{i}{m}, \frac{j}{m} \right\} z(i) \cdot z(j).
\]

If \(z(i) \neq 0\) precisely for \(\alpha\) values of \(i\), say, for \(i_1 < i_2 < \cdots < i_\alpha\) then everywhere one can replace \(\sum_{i=1}^{m} z(i)\) by \(\sum_{r=1}^{\alpha} i_r\) and \(i\) in the summand by \(i_r\). Because \(z(i_r)\) is a summation variable over \(Z^d \setminus \{0\}\), for its labelling the
value of \( i_r \) is unimportant and the notation \( z_r \) can be used for it. All this permits to rewrite

\[
G_m \left\{ \{n_1\}^p_1 \right\} = \sum_{Z \in (\mathbb{Z}^d)^m} \left( \prod_{l=1}^p \delta_{Z_l,0} \right) \hat{E}_m \sum_{\{i/m\}_{i=1}^m} \{Z\} \]

where

\[
f_{[\alpha]} \left( \{i/m\}_{i=1}^m, Z \right) = \exp \left\{ -\frac{2\pi \lambda^2}{L^2} \sum_{i,j=1}^m \left[ \min \left\{ \left\lfloor \frac{i}{m} \right\rfloor, \left\lfloor \frac{j}{m} \right\rfloor \right\} - \frac{ij}{m^2} \right] \right\}
\]

and

\[
f_{[1,1]} \left( \{i/m\}_{i=1}^m, Z \right) = \exp \left\{ -\frac{2\pi \lambda^2}{L^2} \sum_{i,j=1}^m \left[ \min \left\{ \left\lfloor \frac{i}{m} \right\rfloor, \left\lfloor \frac{j}{m} \right\rfloor \right\} - \frac{ij}{m^2}, z(i) \right] \right\}
\]

as

\[
G_m \left\{ \{n_1\}^p_1 \right\} = \sum_{z(1), \ldots, z(m) \in \mathbb{Z}^d} \left( \prod_{i=1}^p \delta_{Z_i,0} \right) \hat{E}_m(z(1)) \cdots \hat{E}_m(z(m)) \sum_{\{i/m\}_{i=1}^m} \{Z\} \]

\[
= \sum_{\alpha=0}^m \frac{\hat{E}_m(0)^{m-\alpha}}{m!} \sum_{z_1, \ldots, z_m \in \mathbb{Z}^d \setminus \{0\}} \left( \prod_{i=1}^p \delta_{Z_i,0} \right) \hat{E}_m(z_1) \cdots \hat{E}_m(z_m)
\]

\[
\times \sum_{1 \leq i_1 < \cdots < i_n \leq m} f_{[\alpha]} \left( \{i_r/m\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1} \right).
\]

Now

\[
\sum_{1 \leq i_1 < \cdots < i_n \leq m} f_{[\alpha]} \left( \{i_r/m\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1} \right) = \sum_{i_n=\alpha}^m \sum_{i_{n-1}=(\alpha-1)/m}^{i_n-1} \cdots \sum_{i_1=1}^{i_2-1/m} f_{[\alpha]} \left( \{i_r/m\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1} \right)
\]

\[
= m^{\alpha - 1} \sum_{i_n=\alpha}^m \sum_{i_{n-1}=(\alpha-1)/m}^{i_n-1} \cdots \sum_{i_1=1}^{i_2-1/m} f_{[\alpha]} \left( \{i_r/m\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1} \right)
\]

\[
= \frac{1}{m} \sum_{t_n=\alpha/m}^m \sum_{t_{n-1}=(\alpha-1)/m}^{t_n-1} \cdots \sum_{t_1=1/m}^{t_2-1/m} \frac{1}{m} \sum_{t_1=1/m}^{t_2-1/m} f_{[\alpha]} \left( \{t_r\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1} \right)
\]

where each \( t_r = i_r/m \) varies by steps \( 1/m \). From Eq. (3.16) we substitute \( \hat{E}_m(z) \), dropping the \( O(1/m^2) \) term which disappears in the \( m \to \infty \) limit. This gives

\[
G_m \left\{ \{n_1\}^p_1 \right\} = \sum_{\alpha=0}^m \left( 1 - \frac{\beta \hat{u}(0)}{mL^d} \right)^{m-\alpha} \sum_{z_1, \ldots, z_m \in \mathbb{Z}^d \setminus \{0\}} \left( \prod_{l=1}^p \delta_{Z_l,0} \right) \hat{u}(z_1/L) \cdots \hat{u}(z_m/L)
\]

\[
\times \frac{1}{m} \sum_{t_n=\alpha/m}^m \sum_{t_{n-1}=(\alpha-1)/m}^{t_n-1} \cdots \sum_{t_1=1/m}^{t_2-1/m} \sum_{\{t_r\}^\alpha_{r=1}, \{z_r\}^\alpha_{r=1}} \frac{M}{\alpha} + \sum_{\alpha=M+1}^m \cdots
\]

(3.47)
Taking the modulus of the second sum, \( |f_{\{n_l\}^p}| \) has the \( \alpha \)-independent upper bound

\[
|f_{[2]}| \leq \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\frac{2\pi \lambda_\beta^2}{L^2} z^2 \right\}, \quad f_{[1,1]} \leq \left[ \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\frac{\pi \lambda_\beta^2}{L^2} z^2 \right\} \right]^2, \tag{3.48}
\]

and the remaining part of the summand is bounded above by

\[
\frac{1}{\alpha!} \left( \frac{\beta \sum_{z \neq 0} |\hat{u}(z/L)|}{L^d} \right)^\alpha.
\]

Therefore \( \lim_{m \to \infty} \sum_{\alpha=M+1}^\infty \) is absolutely convergent and goes to zero as \( M \) goes to infinity, implying

\[
G\{\{n_l\}^p\} = e^{-\beta \hat{u}(0)/L^d} \sum_{\alpha=0}^\infty \frac{(-\beta)}{L^d} \sum_{z_1,\ldots,z_\alpha \in \mathbb{Z}^d \setminus \{0\}} \left( \prod_{l=1}^p \delta_{z_l,0} \right) \hat{u}(z_1/L) \cdots \hat{u}(z_\alpha/L) \times \int_0^1 dt_\alpha \int_0^{t_\alpha} dt_{\alpha-1} \cdots \int_0^{t_2} dt_1 \sum_{\{n_l\}^p} \{ \{t_l\}^\alpha \}, \{z_r\}^\alpha \}.
\tag{3.49}
\]

This ends the proof of the Lemma for \( N = 2 \). Note that for \( p = 2 \) the constraint \( \sum_{r=1}^\alpha z_r = 0 \) acts both on \( \alpha \) and on the set of variables \( z_1, \ldots, z_\alpha \); for \( \alpha = 1 \) the sum over \( \mathbb{Z}^d \setminus \{0\} \) is empty and for \( \alpha > 1 \) only \( \alpha - 1 \) variables can be chosen freely from \( \mathbb{Z}^d \setminus \{0\} \), meaning that these terms are of order \( L^{-d} \).

For a general \( N \), consider first the limit of the exponents in Eq. (3.31). In the first line

\[
\frac{1}{m} \sum_{j=1}^{n_l} (z + Z_j)^2 = \frac{1}{m} \sum_{k=0}^{n_l-1} \sum_{i=1}^{m} (z + Z_{km+i})^2 = \sum_{q \in C_l} \frac{1}{m} \sum_{i=1}^{m} (z + Z_{(q-N_{l-1}-1)m+i})^2.
\tag{3.50}
\]

Substituting for \( Z_{(q-N_{l-1}-1)m+i} \) the expression (3.34) and keeping only the nonzero \( z \) vectors,

\[
\sum_{i=1}^{m} z_j(i') = \sum_{i=1}^{m} 1 \left\{ \frac{i_j'}{m} \geq \frac{i}{m} \right\} z_j(i'), \quad \sum_{i=1}^{m} z_j(i') = \sum_{i=1}^{m} 1 \left\{ \frac{i_j'}{m} < \frac{i}{m} \right\} z_j(i').
\tag{3.51}
\]

When \( m \) tends to infinity

\[
i/m \to t, \quad i_{j,r}/m \to i_{j,r}, \quad z_j(i_{j,r}) \to z_j(i_{j,r}), \quad Z_{(q-N_{l-1}-1)m+i} \to Z_q(t).
\]

These together yield \( \int_0^1 [z + Z_q(t)]^2 dt \) as shown in Eqs. (1.1) and (1.3). For the \( m \to \infty \) limit of (3.36) first we rewrite it as

\[
\overline{Z}^2 = \frac{1}{n_l} \sum_{q \in C_l} \left[ -q \sum_{j=1}^{\alpha_q^j} \sum_{r=1}^{\alpha_q^j} \left( q - N_{l-1} - 1 + \frac{i^q_{j,r}}{m} \right) z_j^q(i^q_{j,r}) + \sum_{k=q+1}^{N} \sum_{r=1}^{\alpha_q^k} \left( q - N_{l-1} - 1 + \frac{i^k_{q,r}}{m} \right) z_k^q(i^k_{q,r}) \right].
\tag{3.52}
\]

Interchanging the order of summations with respect to \( q \) and \( j \), and to \( q \) and \( k \) and letting \( m \) go to infinity one obtains the second form of \( \overline{Z}^2 \), see Eq. (1.11). In particular,

\[
\int_0^1 Z_q(t) dt = -q \sum_{j=1}^{\alpha_q^j} \sum_{r=1}^{\alpha_q^j} \left( q - N_{l-1} - 1 + t_{j,r}^q \right) z_{j,r}^q + \sum_{k=q+1}^{N} \sum_{r=1}^{\alpha_q^k} \left( q - N_{l-1} - 1 + t_{q,r}^k \right) z_{q,r}^k.
\tag{3.53}
\]
The $m \to \infty$ limit of (3.37) by using (3.33) is

$$
n_{l}(Z_l)^2 = \sum_{k,k' \in C_l} \sum_{j=1}^{k-1} \alpha_k^l \alpha_{k'}^l \sum_{j'=1}^{k'-1} \sum_{r=1}^{l-1} A_{kk'} z_{j,r}^k z_{j',r}^{k'} - 2 \sum_{k,k' \in C_l} \sum_{j=1}^{k-1} \sum_{k'=j'}^{k} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{kj} z_{j,r}^k z_{j',r'}^{k'} + \sum_{j,j' \in C_l} \sum_{k=j+1}^{k'} \sum_{k'=j'+1}^{k'} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{jj'} z_{j,r}^k z_{j',r'}^{k'}
$$

(3.54)

where

$$
A_{kk'} = \min \left\{ k + t_{j,r}^k, k' + t_{j',r'}^{k'} \right\} - N_{l-1} - 1,
$$

$$
A_{kj} = \min \left\{ k + t_{j,r}^k, j' + t_{j',r'}^{k'} \right\} - N_{l-1} - 1,
$$

$$
A_{jj'} = \min \left\{ j + t_{j,r}^k, j' + t_{j',r'}^{k'} \right\} - N_{l-1} - 1.
$$

(3.55)

To $A$ we added as subscripts only the two integers that run from $N_{l-1} + 1$ to $N_l$; this is sufficient to distinguish the three cases. In the middle term the symmetry between $(j, k, r)$ and $(j', k', r')$ has been broken by contracting two equal sums. Equation (3.54) corresponds to the second form of $Z_l^2$ in Eq. (1.11). This latter can be used to compute the difference $(Z_l)^2 - Z_l'^2$. Starting with (3.54), the replacements

$$
A_{kk'} \to A_{kk'} - \frac{1}{n_l} (k + t_{j,r}^k - N_{l-1} - 1)(k' + t_{j',r'}^{k'} - N_{l-1} - 1)
$$

$$
A_{kj} \to A_{kj} - \frac{1}{n_l} (k + t_{j,r}^k - N_{l-1} - 1)(j' + t_{j',r'}^{k'} - N_{l-1} - 1)
$$

$$
A_{jj'} \to A_{jj'} - \frac{1}{n_l} (j + t_{j,r}^k - N_{l-1} - 1)(j' + t_{j',r'}^{k'} - N_{l-1} - 1)
$$

(3.56)

give $n_l[(Z_l)^2 - Z_l'^2]$. Clearly, all the three differences are nonnegative. In some cases another form of $(Z_l)^2$, the analogue of the first form of $Z_l^2$, may be useful. It can be obtained from (3.54) by cutting four sums into two: $\sum_{j=1}^{k-1} = \sum_{j=1}^{N_{l-1}} + \sum_{j=N_{l-1} + 1}^{k-1}$, $\sum_{k=j+1}^{k} = \sum_{k=j+1}^{N_{l-1}} + \sum_{k=N_{l-1} + 1}^{N}$, and similar for the sums with respect to $j'$, $k'$. This yields

$$
n_l(Z_l)^2 = \left[ \sum_{\{j<k\} \subset C_l} \sum_{\{j'<k\} \subset C_l} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} (A_{kk'} - A_{jj'}) \right]
$$

$$
+ \sum_{j,j'=1}^{N_{l-1}} \sum_{k,k' \in C_l} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{kk'} + \sum_{j,j'=1}^{N_{l-1}} \sum_{k,k'=N_{l-1} + 1}^{N} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{jj'}
$$

$$
+ 2 \sum_{j=1}^{N_{l-1}} \sum_{k' \in C_l} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{kk'} - 2 \sum_{j=1}^{N_{l-1}} \sum_{k,k'=N_{l-1} + 1}^{N} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{kk'}
$$

$$
- 2 \sum_{\{j<k\} \subset C_l} \sum_{j'=1}^{N_{l-1}} \sum_{k'=N_{l-1} + 1}^{N} \sum_{r=1}^{l-1} \sum_{r'=1}^{l-1} A_{jj'} z_{j,r}^k z_{j',r'}^{k'}
$$

(3.57)
All the sums extend to the scalar product. The explicit $l$-dependence drops from the differences

\[ A_{kj'k'} - A_{kk'} = \begin{cases} 
  k' - j' & \text{if } k' < k \\
  k' - j' + \min\{t^k_{j',r}, t^{k'}_{j',r'}\} - t^{j'}_{j,r'} & \text{if } k' = k \\
  j - j' + t^k_{j,r} - t^{k'}_{j',r'} & \text{if } j' < j < k' \\
  t^k_{j,r} - \min\{t^k_{j,r}, t^{k'}_{j',r'}\} & \text{if } j' = k \\
  0 & \text{if } k < j' 
\end{cases} \]

\[ A_{jj'k'} = A_{jk'k'} - A_{jj'} = \begin{cases} 
  k - j & \text{if } k < j' \\
  k - j + \min\{t^k_{j,r}, t^{k'}_{j',r'}\} - t^k_{j,r} & \text{if } k = j' \\
  j' - j + t^k_{j,r} - t^{k'}_{j',r'} & \text{if } j < j' < k \\
  t^k_{j,r} - \min\{t^k_{j,r}, t^{k'}_{j',r'}\} & \text{if } j = j' \\
  0 & \text{if } j' < j. 
\end{cases} \]

The reader can write down the explicit form of $A_{kj'k'} - A_{jj'k'}$, which falls into $5 + 5$ subcases $(j, k, r$ and $j', k', r'$ interchanged).

The last point to check is that the $m \to \infty$ limit could indeed be taken under the summation signs. The cycle-dependent part of the summand of $G_m \{\{n_i\}_i\}$,

\[ f_{\{n_i\}_i} \left( \{s^k_{j,r}\}_{r=1}^p, \{z^k_{j,r}\}_{r=1}^p \right) = \prod_{l=1}^p \delta_{Z_l, 0} \exp \left\{ -\pi n_l \lambda^2 \left( \frac{Z^2}{L^2} - \frac{Z_l^2}{L^2} \right) \right\} \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\pi n_l \lambda^2 \left( z + Z_l \right)^2 \right\} \]

is bounded as

\[ |f_{\{n_i\}_i}| \leq \prod_{l=1}^p \sum_{z \in \mathbb{Z}^d} \exp \left\{ -\pi n_l \lambda^2 z^2 \right\}. \]  

In $G_m \{\{n_i\}_i\}$ for each pair $j < k$ we cut the sum $\sum_{\alpha_i \neq 0}^m$ into two parts, as we did for $N = 2$. Then, using (3.60) the argument given for $N = 2$ can be repeated. This concludes the proof of the Lemma.

**Acknowledgements.** I am indebted to Gábor Oszlányi for his numerical analysis of the spectrum of the matrix $A$ appearing in Proposition 2. A correspondence with László Lovász about the graph problem is gratefully acknowledged.

**Appendix. Merger graphs**

We start with a class of graphs slightly different from the one presented under Remark 6 but interesting of its own right. A graph of $s$ vertices and $S$ edges in this class corresponds to a system of $s$ homogeneous linear equations for $S$ variables, each appearing with coefficient 1, that has a solution in which all the variables take a nonzero value.

**Definition 1.** 1. A (merger) generator is a circle of even length, two odd circles with a common vertex, or two odd circles joining through a vertex the opposite endpoints of a linear graph. 2. The generators are mergers; merging two mergers through one or more vertices and/or along one or more edges provides a merger. A graph composed of two disconnected mergers is a merger. 3. Given a merger, a set of generators whose merging
provides the graph is called a covering. A covering is minimal if each of its elements contributes to the merger with at least one edge not covered by the other generators. A max-min covering is a minimal covering that contains the largest number of generators.

As an example, the Petersen graph is a merger obtained by merging five "washtub" hexagons. The external edges are covered by three, the middle ones by two, the internal edges by one of the hexagons. Bipartite graphs, suitable subgraphs of the triangular lattice, complete graphs of more than three vertices are also mergers. The definition extends to multigraphs whose construction then involves also two-circles. In general the max-min covering is not unique, but the number of its constituting generators is uniquely determined because of the maximal property.

**Proposition 3.** A graph is a merger if and only if to every edge one can assign a nonzero number in such a way that at every vertex the sum of the numbers assigned to the incident edges is zero. The numbers as variables form a manifold whose dimension is equal to the number of generators in the max-min coverings.

**Proof.** To mark the edges of a generator one can use a single and only a single variable denoted by $x_i$ for the $i$th generator of a merger. To the edges of a circle of length $2n$ one assigns $x_i$ and $-x_i$ in alternation. The same can be done with two odd circles sharing a vertex. In the case of two odd circles linked by a linear graph one assigns $x_i$ to those two edges of one of the circles that join the vertex of degree 3, and $-x_i$ and $x_i$ in alternation to the remaining edges of the same circle. One then continues by alternating $-2x_i$ and $2x_i$ on the edges of the linear graph until reaching the second circle whose edges can again be marked by $x_i$ and $-x_i$ in a proper alternation. When merging, the generators carry their numbers. The number on a multiply covered edge is the sum of the numbers of the covering edges while one keeps the original number for the singly covered edges. Changing some $x_i$ in case of an accidental cancellation the sums on the edges are nonzero and the constraint remains satisfied. The number of free variables can be maximized by choosing a minimal covering that maximizes the number of generators.

In the opposite direction the proof goes by noting first that a graph does not contain any merger generator as a subgraph if and only if each of its maximal connected components is without circles or contains a single circle of odd length. The edges of such graphs cannot be marked in the required manner because either they have a vertex of degree 1 or they are unions of disjoint odd circles. Let $G$ be any graph with properly marked edges. Thus, it has subgraphs which are merger generators. We can proceed by successive demerging. Let us choose a generator $g$ in $G$ and select one of its edges denoted by $e$. Let $x$ be the number assigned to $e$. Prepare an image $g'$ of $g$ outside $G$ and assign $-x$ to the image $e'$ of $e$. This uniquely determines the numbering of the other edges of $g'$ in such a way that the constraint is satisfied. Add the number on every edge of $g'$ to the number on its pre-image in $g$. As a result, the new number on $e$ is zero. Dropping all the edges from $G$ whose new number is zero we obtain a new graph having at least one edge less than $G$ while the total numbering still satisfies the constraint. In a finite number of steps we can empty $G$ which is, therefore, a merger. \[\square\]

Now we define the class of graphs that we need for this paper. The vertices of a graph in this class correspond to permutation cycles, its edges represent the nonzero $a_j^k$ that allow the solution of all the equations $Z_1^1 = 0$, cf. (1.4), with all the variables taking a nonzero value. Below we use the terms "merger" and "merger generator" in a different sense as before.

**Definition 2.** 1. A (merger) generator is a circle of any (even or odd) length $n \geq 2$ with $n$ different positive integers assigned to the vertices in an arbitrary order. 2. The generators are mergers. Merging two generators through all their vertices carry the same number and optionally along some of the edges whose endpoints are common in the two mergers provides a merger. A graph composed of two disconnected mergers with disjoint vertex-numbering is a merger. 3. Given a merger, a set of generators whose merging provides the graph is called a covering. A covering is minimal if each of its element contributes to the merger with at least one edge not covered by the other generators. A max-min covering is a minimal covering that contains the largest number of generators.

**Proposition 4.** A graph whose vertices \{1, 2, \ldots\} carry different positive integers $l_1, l_2, \ldots$ is a merger if and only if to every edge one can assign a nonzero vector in such a way that at any vertex $i$ the sum of the vectors
on the incident edges \((i, j)\) taken with minus sign if \(l_j < l_i\) and with plus sign if \(l_j > l_i\), is zero. The vectors as variables form a manifold whose dimension is equal to the number of generators in the max-min coverings.

**Proof.** First let us see how to assign a vector to the edges of a generator. Let \(l_i\) be the number carried by the \(i\)th vertex of a \(n\)-circle, where \(i = 1, \ldots, n\) label the clockwise consecutive vertices. Let \(x_{12}, x_{23}, \ldots, x_{n-1,n}, x_{n1}\) denote the \(n\) edge variables that must assume a suitable value. The equation to be solved at vertex \(i\) is one of

\[
\begin{align*}
& (1) \quad x_{i-1,i} + x_{i,i+1} = 0 \quad \text{if} \quad l_{i-1}, l_{i+1} > l_i, \\
& (2) \quad -x_{i-1,i} + x_{i,i+1} = 0 \quad \text{if} \quad l_{i-1} < l_i < l_{i+1}, \\
& (3) \quad x_{i-1,i} - x_{i,i+1} = 0 \quad \text{if} \quad l_{i-1} > l_i > l_{i+1}, \\
& (4) \quad -x_{i-1,i} - x_{i,i+1} = 0 \quad \text{if} \quad l_{i-1}, l_{i+1} < l_i.
\end{align*}
\]

It is seen that whatever be the choice of, say, \(x_{12}\), the other variables must take the same value with plus or minus sign. So the solution, if any, is a one-dimensional manifold. To be definite, let \(l_1\) be the smallest number. Take an arbitrary nonzero vector \(v\) and set \(x_{12} = v\). The equation at vertex 1 is (1), it is solved with \(x_{n1} = -v\).

We must prove that going around the circle there is no "frustration", all the equations can be solved. Call \(i\) a source if \(l_i < l_{i-1}, l_{i+1}\) and a sink if \(l_i > l_{i-1}, l_{i+1}\). It is helpful to imagine an arrow on every edge, pointing towards the larger-numbered vertex. The problem is soluble because the number of sinks equals the number of sources and there is at least one source. Passing a source \(-v\) changes to \(v\) while solving equation (1), stays \(v\) until the next sink and solves equations of the type (2), passing the sink it changes to \(-v\) while solving equation (4), stays \(-v\) and solves equations of the type (3), and so on. The rest of the proof that the edges of a merger can be properly marked is the same as in Proposition 3.

The proof in the opposite direction goes again by successive demerging provided we can show that no other vertex-numbered graph than those defined as mergers can be edge-marked in the required manner. Suppose there is such a finite graph. It must contain at least one circle, since linear graphs, tree graphs obviously cannot satisfy the condition at vertices of degree 1. Demerging successively all the circles, what remains is nonempty and cannot be marked -- a contradiction. □

As a matter of fact, the numbering can be dropped from the definition because the vertices of any merger of circular graphs can be marked \textit{a posteriori} and in an arbitrary order with different \(l_1, l_2, \ldots\), still a proper assignment of nonzero vectors to the edges is possible.

**Examples.**

1. A multigraph of two vertices and \(n > 1\) edges is a merger of \(n - 1\) 2-circles. Let \(x_1, \ldots, x_n\) be the edge variables. The general solution with nonzero vectors of \(x_1 + \cdots + x_n = 0\), is \(x_1 = v_1, x_2 = -v_1 + v_2, \ldots, x_{n-1} = -v_{n-2} + v_{n-1}, x_n = -v_{n-1},\) a \((n - 1)\)-dimensional manifold.

2. Consider the complete 4-graph of vertices 1, 2, 3, 4. A max-min covering is for example the three circles (123), (234) and (134). If prior to merging

\[
\begin{align*}
& x_{12} = x, \quad x_{13} = -x, \quad x_{23} = x, \quad \text{for (123)} \\
& x_{23} = y, \quad x_{24} = -y, \quad x_{34} = y \quad \text{for (234)} \\
& x_{13} = z, \quad x_{14} = -z, \quad x_{34} = z \quad \text{for (134)}
\end{align*}
\]

then after merging the edges of the tetrahedron will carry

\[
\begin{align*}
& x_{12} = x, \quad x_{13} = -x + z, \quad x_{23} = x + y, \quad x_{14} = -z, \quad x_{24} = -y, \quad x_{34} = y + z
\end{align*}
\]

which solve the four equations

\[
\begin{align*}
& x_{12} + x_{13} + x_{14} = 0, \quad -x_{12} + x_{23} + x_{24} = 0, \quad -x_{13} - x_{23} + x_{34} = 0, \quad -x_{14} - x_{24} - x_{34} = 0.
\end{align*}
\]

A covering which is minimal but not max-min is the two 4-circles (1234), (1243). Using them we would get only two independent variables. A covering which is not minimal is obtained by merging e.g. (1234) to the above three triangles with a fourth variable \(v\). This only changes \(x\) to \(x' = x + v\) and \(z\) to \(z' = z + v\) without increasing the number of free variables.
**Proposition 5.** Let $\mathcal{G}$ be a simple merger graph of the second kind that has $S$ edges. Let $M$ be the number of generators in max-min coverings. Then $M \leq S/2$. If $\mathcal{G}$ can be generated by triangles then $M \geq S/3$.

**Proof.** $\mathcal{G}$ is generated by circles of length $\geq 3$. The largest number of generators in minimal coverings is obtained if each generator can be chosen to be a triangle which covers exclusively a single edge, while other two edges are shared with two other triangles. Let us call the shared edges half-covered by one of the triangles. Then each triangle covers $1 + \frac{1}{2} + \frac{1}{2} = 2$ edges, therefore $S/M = 2$. Examples when $S/M = 2$ is attained are the complete 4- and 5-graphs with $M = 3$ and 5, respectively.

Any graph that can be covered by edge-disjoint triangles satisfies $3M = S$ and no triangle-generated graph can be covered by less than $S/3$ triangles. A nontrivial example with $S/M = 3$ is the complete 7-graph. For a complete 6-graph $S/M = 2\frac{2}{5}$, for a complete 8-graph $S/M = 2\frac{5}{11}$. □
