ONE- AND TWO-PHOTON LOCALIZATION IN QUANTUM OPTICS

JOSEPH KRAISLER AND JOHN C. SCHOTLAND

Abstract. We consider the lattice analog of a recently proposed continuum model for the propagation of one- and two-photon states in a random medium. We find that there is localization of single photons in an energy band centered at the resonant energy of the atoms. Moreover, there is also localization of photons at arbitrarily large energies. For the case of two photons, there is localization in an energy band centered at twice the resonant frequency.

1. Introduction

We consider the following model for the propagation of a one-photon state in a medium of identical two-level atoms. As shown in [1], the probability amplitude $a(x,t)$ for exciting an atom at the point $x$ at the time $t$ and the probability amplitude $\psi(x,t)$ for creating a photon obey the equations

$$i\partial_t \psi = c(-\Delta)^{1/2} \psi + g\rho(x)a, \quad (1)$$

$$i\partial_t a = g\psi + \Omega a, \quad (2)$$

where $\rho$ is the number density of the atoms, $\Omega$ is their resonance frequency, and $g$ is the atom-field coupling constant. The amplitudes obey the normalization condition

$$\int dx \left( |\psi(x,t)|^2 + \rho(x)|a(x,t)|^2 \right) = 1, \quad (3)$$

which has the interpretation that $|\psi|^2$ is the one-photon probability density and that $\rho|a|^2$ is the atomic probability density. The density $\rho$ is taken to be a random field of the form

$$\rho(x) = \rho_0(1 + V(x)), \quad (4)$$

where $\rho_0$ is constant, and the potential $V$ has zero mean, corresponding to density fluctuations about a constant background.

In this paper we consider the discrete analog of (1) and (2) formulated on the $d$-dimensional lattice $\mathbb{Z}^d$. In addition, we assume that the random variables $\{V(x)\}_{x \in \mathbb{Z}^d}$ are i.i.d. and uniformly distributed on $[-1,1]$. Thus $\rho(x)$ takes values in the interval $[0,2\rho_0]$. This problem, which is simpler to analyze than the corresponding problem in the continuous setting, is a first step towards understanding Anderson localization in quantum optics.

Date: June 22, 2021.
It will prove useful to introduce a Hamiltonian description of the system (1) and (2). The Hamiltonian $H$ is defined in section 2. We find that there is localization of single photons in an energy band centered at the resonant energy of the atoms. Moreover, there is also localization of photons at arbitrarily large energies. These results form the content of the following theorem.

**Theorem 1.** Consider the Hamiltonian $H = H_0 + V$, where $H_0$ and $V$ are given by (10), and (11) with $g^2 \rho_0 > 0$. Then the following statements hold.

1. There exists $K > 0$ such that for almost every realization of the random variables $\{V(x)\}_{x \in \mathbb{Z}^d}$, every $E \neq \Omega$ in the range $|E - \Omega| < Kg^2 \rho_0$ the operator $H$ has only pure point spectrum.

2. There exists $E_0 = E_0(g, \rho_0, \Omega)$ such that for almost every realization of the random variables $\{V(x)\}_{x \in \mathbb{Z}^d}$, for every $E$ in the range $|E| > E_0$ the operator $H$ has only pure point spectrum.

Next we turn our attention to localization of two-photon states. For simplicity, we assume that at least one photon is present in the system at all times. Following [2], we consider the probability amplitudes $\psi_2(x_1, x_2, t)$ and $\psi_1(x_1, x_2, t)$ for creating two photons at the points $x_1$ and $x_2$, and creating a photon at $x_1$ and exciting an atom at $x_2$, respectively. Then $\psi_2$ and $\psi_1$ obey

\[
i \frac{\partial}{\partial t} \psi_2 = c(-\Delta_{x_1})^{1/2} \psi_2 + c(-\Delta_{x_2})^{1/2} \psi_2 + \frac{g}{2}(\rho(x_1) + \rho(x_2)) \psi_1 ,
\]

\[
i \frac{\partial}{\partial t} \psi_1 = 2g \psi_2 + \frac{1}{2} \left[ c(-\Delta_{x_1})^{1/2} + c(-\Delta_{x_2})^{1/2} + 2\Omega \right] \psi_1 .
\]

We note that $\psi_2$ is symmetric with $\psi_2(x_2, x_1, t) = \psi_2(x_1, x_2, t)$, consistent with the bosonic character of the optical field. In addition, the amplitudes obey the normalization condition

\[
\int dx_1 dx_2 (2|\psi_2(x_1, x_2, t)|^2 + \rho(x_1)|\psi_1(x_1, x_2, t)|^2) = 1 .
\]

The analysis of localization in the above model relies on a Hamiltonian formulation of the system (3) and (4), as described in section 3. As described in the following theorem, there is localization of photons in an energy band centered at twice the resonant frequency of each atom.

**Theorem 2.** Let $H$ be the Hamiltonian corresponding to the system (3) and (4). Then there exists a $K > 0$ such that if $g^2 \rho_0 > K$, for almost every realization of the random variables $\{V(x)\}_{x \in \mathbb{Z}^d}$, the operator has only pure point spectra in an interval of the form $[2\Omega - R, 2\Omega + R]$. Moreover, $R$ is an increasing function of $g^2 \rho_0$.

This paper is organized as follows. In section 2 we recall a well known criterion due to Simon and Wolff [4] for spectral localization of discrete Hamiltonians and prove Theorem 1. The proof of Theorem 2 is presented in section 3. Finally, the appendix discusses the proof of Lemma 2.
2. One-Photon Problem

The Hilbert space of interest for the analysis of the system (1) and (2) is defined by
\[
\mathcal{H} = \ell^2(\mathbb{Z}^d) \oplus \ell^2(\mathbb{Z}^d) = \{ (\phi, \psi) : \phi, \psi \in \ell^2(\mathbb{Z}^d) \},
\]
with the corresponding inner product
\[
\langle (\phi_1, \psi_1), (\phi_2, \psi_2) \rangle = \sum_{x \in \mathbb{Z}^d} (\phi_1(x)\overline{\phi_2(x)} + \psi_1(x)\overline{\psi_2(x)}).
\]

We consider the Hamiltonian \( H = H_0 + \mathcal{V} \), where \( H : \mathcal{H} \rightarrow \mathcal{H} \)
\[
H_0(\phi, \psi) = \langle (-\Delta)^{1/2} \phi, \Omega \psi \rangle, \quad \mathcal{V}(\phi, \psi) = \langle \sqrt{g^2 \rho_0(1+V)} \phi, \sqrt{g^2 \rho_0(1+V)} \psi \rangle, \quad (\phi, \psi) \in \mathcal{H}.
\]

Here \( H_0 \) is the free Hamiltonian and \( V \) is a random potential. For each \( x \in \mathbb{Z}^d \), \( V(x) \) is a random variable uniformly distributed in the interval \([-1, 1]\) and the collection of random variables \( \{V(x)\}_{x \in \mathbb{Z}^d} \) are i.i.d.. The fractional Laplacian \((-\Delta)^{1/2}\) can be defined several ways. We first introduce the Fourier transform \( \mathcal{F} : \ell^2(\mathbb{Z}^d) \rightarrow L^2([0, 2\pi]^d) \) and its inverse \( \mathcal{F}^{-1} : L^2([0, 2\pi]^d) \rightarrow \ell^2(\mathbb{Z}^d) \) by
\[
(\mathcal{F} \phi)(k) = \sum_{x \in \mathbb{Z}^d} \phi(x)e^{-ik \cdot x},
\]
\[
(\mathcal{F}^{-1} f)(x) = \frac{1}{(2\pi)^d} \int_{[0,2\pi]^d} e^{ik \cdot x} f(k) dk.
\]

We then define \((-\Delta)^{1/2} : \ell^2(\mathbb{Z}^d) \rightarrow \ell^2(\mathbb{Z}^d) \) by
\[
\left((-\Delta)^{1/2} \phi\right)(x) = \mathcal{F}^{-1} \left(h^{1/2} \mathcal{F} \phi\right)(x),
\]
where the function \( h(k) \) is given by
\[
h(k) = 4 \sum_{i=1}^d \sin^2(k_i).
\]

The idea of the proof of Theorem 1 is to reduce the study of the Hamiltonian \( H \) on \( \mathcal{H} \) to a one-parameter family of Hamiltonians \( H_\mu \) on \( \ell^2(\mathbb{Z}^d) \) and apply results due to Aizenman and Molchanov [3]. To that end, we define the one parameter family of Hamiltonians \( H_\mu : \ell(\mathbb{Z}^d) \rightarrow \ell(\mathbb{Z}^d) \) for \( \Omega \neq \mu \in \mathbb{R} \) as
\[
H_\mu \phi = (-\Delta)^{1/2} \phi + \frac{g^2 \rho_0}{\mu - \Omega}(1+V)\phi, \quad \phi \in \ell^2(\mathbb{Z}^d),
\]
We can now state the relationship between the spectra of the operators \( H \) and \( H_\mu \).

**Lemma 1.** Let \( H \) and \( H_\mu \) be as above and \( \Omega \neq E \in \mathbb{R} \). For a.e. realization of \( V \)
\begin{enumerate}
  \item \( E \in \sigma_p(H) \) if and only if \( E \in \sigma_p(H_E) \)
  \item \( E \in \sigma_c(H) \) if and only if \( E \in \sigma_c(H_E) \)
\end{enumerate}
Proof. For (1) We will prove that $H - E$ is injective if and only if $H_E - E$ is injective and for (2) we will prove that $H - E$ is surjective if and only if $H_E - E$ is surjective. As the operators involved are bounded and self adjoint this is enough.

Suppose that $H - E$ is not injective. Then $H \Psi = E \Psi$ for some $\Psi = (\phi, \alpha) \in \mathcal{H}$. Then we obtain the pair of equations

$$(-\Delta)^{1/2}\phi + \sqrt{g^2 \rho_0(1 + V)} \alpha = E \phi, \quad (17)$$

$$\Omega \alpha + \sqrt{g^2 \rho_0(1 + V)} \phi = E \alpha. \quad (18)$$

Eliminating $\alpha$ gives

$$(-\Delta)^{1/2}\phi + \frac{g^2 \rho_0}{E - \Omega} (1 + V) \phi = E \phi, \quad (19)$$

which shows that $H_E \phi = E \phi$ and hence $H_E - E$ is not injective. For the converse, if $H_E - E$ fails to be injective, then we have $H_E \phi = E \phi$ for some $\phi \in \ell^2(\mathbb{Z}^d)$. We then define $\alpha$ by

$$\alpha = \frac{g}{E - \Omega} \phi, \quad (20)$$

and observe that $H(\phi, \alpha) = E(\phi, \alpha)$.

Suppose $H - E$ is surjective and let $\phi' \in \ell^2(\mathbb{Z}^d)$. Then there exists $(\phi, \alpha)$ such that

$$(H - E)(\phi, \alpha) = (\phi', 0). \quad (21)$$

This is equivalent to the pair of equations

$$((-\Delta)^{1/2} - E)\phi + g \rho_0 \alpha + g \rho_0 V \alpha = \phi', \quad (22)$$

$$(\Omega - E)\alpha + g \phi = 0. \quad (23)$$

Eliminating the second equation we obtain

$$((-\Delta)^{1/2} - E)\phi + \frac{g^2 \rho_0}{E - \Omega} (1 + V) \phi = \phi', \quad (24)$$

which shows that $H_E - E$ is surjective. Conversely, suppose $H_E - E$ is surjective and let $(\phi', \alpha') \in \mathcal{H}$. Let $\phi \in \ell^2(\mathbb{Z}^d)$ be the solution to

$$(-\Delta)^{1/2}\phi + \frac{g^2 \rho_0}{E - \Omega} (1 + V) \phi = \left[\phi' + \frac{\alpha'}{E - \Omega}\right]. \quad (25)$$

It is straightforward to check that

$$(H - E)(\phi, \frac{1}{\Omega - E}(\alpha' - g \phi)) = E(\phi', \alpha'), \quad (26)$$

which shows $H - E$ is surjective. \square

Now we state a lemma that describes the spectrum of $H_\mu$ almost surely for certain values of $\mu$ and certain ranges of energy. It follows immediately from Theorems 3.1 and 3.2 in [3], but we include the proof in the Appendix.

Lemma 2. Let $H_\mu$ be given by (16). Then
1. There exists a $K > 0$ independent of $\mu$ such that for all $\mu \neq \Omega$ such that $|\mu - \Omega| < Kg^2\rho_0$ the operator $H_\mu$ has, for almost every realization of the potential $\{V(x)\}_{x \in \mathbb{Z}^d}$, only pure point spectrum.

2. There exists $E_0 = E(\Omega, \rho_0, g)$ independent of $\mu$ such that $H_\mu$ has, for almost every realization of the potential $\{V(x)\}_{x \in \mathbb{Z}^d}$, only pure point spectrum in the range $|E| > E_0$.

We can now prove Theorem 1.

**Proof of Theorem 1.** Let $E \in S := \{\mu \in \mathbb{R} | \mu \neq \Omega \text{ and } |\mu - \Omega| < Kg^2\rho_0\}$, with $K$ as in Lemma 2. Then $H_E$ has, almost surely, empty continuous spectrum. Suppose that $E \in \sigma(H)$. Then by Lemma 1, $E$ must be in $\sigma_p(H)$ as otherwise $E \in \sigma_c(H_E) = \emptyset$. This proves $\sigma_c(H) \cap S = \emptyset$. The proof of (2) is similar, except that we consider $E$ satisfying $|E| > E_0$. □

**Remark 1.** For the case of resonance, it is straightforward to see that $\Omega$ is not an eigenvalue of $H$ for almost every realization of $V$, so long as $g^2\rho_0 \neq 0$. The equation $H\Psi = \Omega\Psi$ with $\Psi = (\phi, \alpha)$ immediately implies that $\phi = 0$ and in turn $\alpha = 0$.

Each part of Theorem 1 guarantees that the spectrum of $H$ is localized in a specific subset of the real line, first in a bounded interval around $\Omega$ and second in the complement of a symmetric neighborhood around 0. The following corollary shows that $\Omega$, $g$, and $\rho_0$ can be chosen so that these two subsets overlap and their union is the entire real line.

**Corollary 1.** Let $H$ be the Hamiltonian in Theorem 1. There is a constant $C$ such that if $g^2\rho_0 > C$ for almost every realization of the random variables $\{V(x)\}$, $H$ has only pure point spectrum in $\mathbb{R} \setminus \{\Omega\}$.

**Proof.** The idea is to combine the two regimes given in the previous theorem. The first statement says that the Hamiltonian is localized in a finite interval around $\Omega$ and second in the complement of a symmetric neighborhood around 0. We need only show that $g^2\rho_0$ can be chosen so that these two intervals overlap. To proceed let

$$C = \frac{2C_s^{1/s}}{\kappa_s} \left[ (4 + \kappa_s) \frac{C_s^{1/s}}{\kappa_s} + \Omega \right] ,$$

where the constant $C_s$ is satisfies

$$\sum_{x \in \mathbb{Z}^d} |\delta_x, (-\Delta)^{1/2} \delta_y|^s \leq C_s ,$$

and $\kappa_s$ is the minimum of the function $\theta_s$ defined in the Appendix. Inspection of (101) in the proof of Lemma 2 in the Appendix, shows that the constant $K$ may be taken to be

$$K = \frac{\kappa_s}{C_s^{1/s}} .$$

Thus, by the second statement of Lemma 2, $H$ has only pure point spectrum for $E$ in the region

$$|E - \Omega| < \kappa_s g^2 \rho_0 / C_s^{1/s} .$$
Now suppose \( g^2 \rho_0 > C \) and consider \( E \) satisfying
\[
|E - \Omega| > \kappa_s g^2 \rho_0 / 2C_s^{1/s} .
\] (30)
Inspecting the proof of Lemma 2 in order to show that the \( H \) has pure point spectrum in this set we must show that the inequality
\[
C_s \left[ \left| \frac{g^2 \rho_0}{E - \Omega} \right| \theta_s \left( \frac{E(E - \Omega)}{g^2 \rho_0} - 1 \right) \right]^{-s} < 1 ,
\] (31)
is satisfied, where \( \theta_s \) is defined in Lemma 7. Using the definition of \( C \) and \( \theta_s \), the left-hand side of (31) becomes
\[
C_s \left[ \left| \frac{g^2 \rho_0}{E - \Omega} \right| \theta_s \left( \frac{E(E - \Omega)}{g^2 \rho_0} - 1 \right) \right]^{-s} \leq C_s \left[ \left| E - \left| \frac{g^2 \rho_0}{E - \Omega} \right| \frac{g^2 \rho_0}{E - \Omega} \right| \right]^{-s} \leq C_s \left[ \left| E \right| - 2 \left| \frac{g^2 \rho_0}{E - \Omega} \right| \right]^{-s} \leq C_s \left[ \frac{4 + \kappa_s}{\kappa_s} \right]^{-s} = 1 .
\] (32)

3. Two-Photon Problem

In this section we prove Theorem 2. The Hilbert space of interest for the analysis of the system (5) and (6) is defined as
\[
\mathcal{H} = \ell^2(\mathbb{Z}^d) \oplus \ell^2(\mathbb{Z}^d) ,
\] (38)
with the standard inner product. The Hamiltonian \( H \) is of the form \( H = H_0 + \mathcal{V} \), where
\[
H_0(\phi, \psi) = \left( T \phi, \frac{1}{2} T \psi + \Omega \psi \right) ,
\] (39)
\[
\mathcal{V}(\phi, \psi) = \left( \frac{g \rho_0}{2} (2 + V_1 + V_2) \psi, 2g \phi \right) ,
\] (40)
\[
T \phi = (-\Delta_{x_1})^{1/2} \phi + (-\Delta_{x_2})^{1/2} \phi \quad \text{and} \quad (\phi, \psi) \in \mathcal{H}
\] (41)
and \( V_i : \ell^2(\mathbb{Z}^d) \rightarrow \ell^2(\mathbb{Z}^d) \) are multiplication operators given by the formula
\[
(V_i u)(x_1, x_2) = V(x_i)u(x_1, x_2) .
\] (42)
Here \( \{V(x)\}_{x \in \mathbb{Z}^d} \) are a family of i.i.d. uniform random variables on the interval \([-1, 1]\) and \(x = (x_1, x_2) \in \mathbb{Z}^2\).

Theorem 2 states that for the above Hamiltonian there is spectral localization in an interval centered around the energy level \(2\Omega\) (twice the resonant frequency of the atoms), given a certain minimal level of the coupling \(g^2 \rho_0\) between the matter and the field.

**Proof of Theorem 2.** As in the proof of Theorem 1, we reduce the problem to the study of a one-parameter family of Hamiltonians on \(\ell^2(\mathbb{Z}^d)\). To this end, we define \(H_\mu : \ell^2(\mathbb{Z}^d) \to \ell^2(\mathbb{Z}^d)\) for \(\Omega \lesssim \mu \in \mathbb{R}\) by

\[
H_\mu \psi = \left[ -\frac{T^2}{2(\mu - \Omega)} + \frac{\mu - 2\Omega}{2(\mu - \Omega)} T \right] \psi + \frac{g^2 \rho_0}{\mu - \Omega} (2 + V_1 + V_2) \psi , \quad \psi \in \ell^2(\mathbb{Z}^d). \tag{43}
\]

We must now relate the spectra of the operators \(H\) and \(H_\mu\). The following lemma is the analog of Lemma 1.

**Lemma 3.** Let \(H = H_0 + V\) be defined by (39) and (40), and \(H_\mu\) by (43) with \(\Omega \neq \mu \in \mathbb{R}\). Then for almost every realization of \(V\)

1. \(E \in \sigma_p(H)\) if and only if \(E \in \sigma_p(H_\mu)\),
2. \(E \in \sigma_c(H)\) if and only if \(E \in \sigma_c(H_\mu)\).

**Proof.** Suppose that \(E \in \sigma_p(H)\). Then there exists \(\Psi = (\phi, \psi) \in \mathcal{H}\) such that

\[H\Psi = E\Psi.\tag{44}\]

We thus obtain the system of equations

\[
T\phi + \frac{g^2 \rho_0}{2} (2 + V_1 + V_2) \psi = E \phi , \tag{45}
\]

\[
\frac{1}{2} T\psi + \Omega \psi + 2g\phi = E \psi. \tag{46}
\]

Eliminating \(\phi\) from the above, we have

\[
\left[ -\frac{T^2}{2(E - \Omega)} + \frac{E - 2\Omega}{2(E - \Omega)} T \right] \psi + \frac{g^2 \rho_0}{E - \Omega} (2 + V_1 + V_2) \psi = E \psi , \tag{47}
\]

which shows \(H_\mu \psi = E \psi\) and hence \(E \in \sigma_p(H_\mu)\). For the converse, if \(E \in \sigma_p(H_\mu)\) and \(H_\mu \psi = E \psi\) with \(\psi \in \ell^2(\mathbb{Z}^d)\), we define \(\phi \in \ell^2(\mathbb{Z}^d)\) by

\[
\phi = \frac{1}{2g} \left[ E - \Omega + \frac{1}{2} T \right] \psi. \tag{48}
\]

It is straightforward to verify that \(H(\psi, \phi) = E(\psi, \phi)\), which implies that \(E \in \sigma_p(H)\). This completes the proof of the first statement of the lemma.

To prove the second statement, we show that \(H - E\) is surjective if and only if \(H_\mu - E\) is surjective. Let \(\psi' \in \ell^2(\mathbb{Z}^d)\) and suppose \(H - E\) is surjective. Then there exists \((\psi, \phi) \in \mathcal{H}\)
such that \((H - E)(\phi, \psi) = (\psi', 0)\). That is,
\[
T\phi + \frac{g\rho_0}{2}(2 + V_1 + V_2)\psi - E\phi = \psi', \\
\frac{1}{2}T\psi + \Omega\psi + 2g\phi - E\psi = 0.
\] (49)

By eliminating \(\phi\) from the above we obtain
\[
\left[-\frac{T^2}{2(E - \Omega)} + \frac{E - 2\Omega}{2(E - \Omega)} T\right] \psi + \frac{g^2\rho_0}{E - \Omega}(2 + V_1 + V_2)\psi - E\psi = \psi',
\] (51)
which shows that \(H_E - E\) is surjective. Conversely, suppose that \(H_E - E\) is surjective and let \((\phi', \psi') \in \mathcal{H}\). Then there exists a \(\psi \in \ell^2(\mathbb{Z}^d)\) such that
\[
(H_E - E)\psi = \frac{1}{E - \Omega}[2g\phi' - (T - E)\psi'].
\] (52)

A direct calculation shows that
\[
(H - E) \left(\frac{1}{2g} \left(\psi' + (E - \Omega - \frac{1}{2} T)\psi\right), \psi\right) = (\phi', \psi'),
\] (53)
which implies that \(H - E\) is surjective. \(\Box\)

The following lemma, which describes the spectrum of \(H_\mu\), is the two-photon analog of the first statement in Lemma 2.

**Lemma 4.** Let \(H_\mu\) be defined by (43). Then there exist constants \(K, R > 0\) such that if \(g^2\rho_0 > K\) and \(|\mu - 2\Omega| < R\), \(\mu \neq \Omega\), then for almost every realization of the random variables \(\{V(x)\}_{x \in \mathbb{Z}^d}\), the operator \(H_\mu\) has only pure point spectrum.

**Proof.** Following the Appendix, let \(G(x) = G^\Lambda(x, x_0, E)\) be the Green’s function given by
\[
G^\Lambda(x, x_0, E) = \langle \delta_x, (H_\mu - E)^{-1} \delta_{x_0} \rangle,
\]
restricted to a finite set \(\Lambda \in \mathbb{Z}^d\). Then for \(x \neq x_0\), \(G(x)\) satisfies the equation
\[
4g^2\rho_0 G(x) + 2g^2\rho_0 (V(x_1) + V(x_2))G^\Lambda_2,1(x) - 2E(\mu - \Omega)G(x) = \sum_{x'} K_\mu(x, x')G(x'),
\] (54)
where
\[
K_\mu(x, x') = \langle \delta_x, \left[\Delta_{x_1}\right]^{1/2} + \left[\Delta_{x_2}\right]^{1/2} \rangle \left[\mu - 2\Omega - \left(\Delta_{x_1}\right)^{1/2} - \left(\Delta_{x_2}\right)^{1/2}\right] \delta_{x'}\rangle.\] (55)

Using the bound for the discrete fractional Laplacian given in (36), we see that for \(0 < s < 1\) sufficiently close to 1,
\[
\sum_{x'} |K_\mu(x, x')|^s \leq |\mu - 2\Omega|^s \sum_{x'} |\langle \delta_x, \left[\Delta_{x_1}\right]^{1/2} + \left(\Delta_{x_2}\right)^{1/2}\rangle \delta_{x'}\rangle|^s + \sum_{x'} |\langle \delta_x, \left[\Delta_{x_1} + \Delta_{x_2}\right] \delta_{x'}\rangle|^s \leq |\mu - 2\Omega|^s C_1 + C_2. \] (56)

\[
\sum_{x'} |K_\mu(x, x')|^s \leq |\mu - 2\Omega|^s \sum_{x'} |\langle \delta_x, \left[\Delta_{x_1}\right]^{1/2} + \left(\Delta_{x_2}\right)^{1/2}\rangle \delta_{x'}\rangle|^s + \sum_{x'} |\langle \delta_x, \left[\Delta_{x_1} + \Delta_{x_2}\right] \delta_{x'}\rangle|^s \leq |\mu - 2\Omega|^s C_1 + C_2. \] (57)
Next, we raise (53) to the power \( s \) for \( 0 < s < 1 \) and take expectations, thus arriving at

\[
\langle |4g^2 \rho_0 + 2g^2 \rho_0 (V(x_1) + V(x_2)) - 2E(\mu - \Omega)|^s |G(x)|^s \rangle \approx \sum_{x'} |K_{\mu}(x, x')|^s \langle |G(x')|^s \rangle. \tag{59}
\]

In the above we can also see explicitly the dependence of \( G(x) \) on the random variables \( V(x_1) \) and \( V(x_2) \) by applying the Krein formula (see the Appendix) and Cramer’s rule:

\[
G(x) = \frac{\alpha}{V(x_1) + V(x_2) - \beta}. \tag{60}
\]

Here \( \alpha \) and \( \beta \) depend on the potential only at points other than \( x_1 \) and \( x_2 \). We can decouple the expectation on the left as follows. There are two cases: \( x_1 = x_2 \) or \( x_1 \neq x_2 \). In the first case we have

\[
\begin{align*}
\langle |4g^2 \rho_0 + 2g^2 \rho_0 (V(x_1) + V(x_2)) - 2E(\mu - \Omega)|^s |G(x)|^s \rangle & \\
= \langle |4g^2 \rho_0 + 4g^2 \rho_0 V(x_1) - 2E(\mu - \Omega)|^s |G(x)|^s \rangle & \\
= |4g^2 \rho_0|^s \theta_s \left( \frac{E(\mu - \Omega)}{2g^2 \rho_0} - 1 \right)^s \left( \int \int dV(x_i) \right) \frac{\alpha}{2V(x_1) - \beta} & \\
\geq |4g^2 \rho_0|^s \kappa_s^s \langle |G(x)|^s \rangle, & \\
\end{align*}
\]

where we have used Lemma 7 and \( \kappa_s \) is the minimum value of \( \theta_s \) (also defined in Lemma 4). In the second case we have

\[
\begin{align*}
\langle |4g^2 \rho_0 + 2g^2 \rho_0 (V(x_1) + V(x_2)) - 2E(\mu - \Omega)|^s |G(x)|^s \rangle & \\
= \int \prod_{i \neq 1, 2} dV(x_i) \int_{-1}^{1} dV(x_1) \int_{-1}^{1} dV(x_2) |\eta - 2g^2 \rho_0 V(x_1) + 2g^2 \rho_0 V(x_2)|^s \frac{\alpha}{V(x_1) + V(x_2) - \beta} & \\
\geq \int \prod_{i \neq 1, 2} dV(x_i) \int_{-1}^{1} dV(x_1) \int_{-1}^{1} dV(x_2) |\eta - 2g^2 \rho_0 V(x_1) + 2g^2 \rho_0 V(x_2)|^s \frac{\alpha}{V(x_1) + V(x_2) - \beta} & \\
\geq |2g^2 \rho_0|^s \kappa_s^s \langle |G(x)|^s \rangle. & \\
\end{align*}
\]

In either case, we have that

\[
\langle |G(x)|^s \rangle \leq (2g^2 \rho_0 \kappa_s)^{-s} \sum_{x'} |K_{\mu}(x, x')|^s \langle |G(x')|^s \rangle. \tag{71}
\]

Defining the auxiliary quantity \( \Xi(s) \) as

\[
\Xi(s) = \sum_{x \in \Lambda} \langle |G(x)|^s \rangle, \tag{72}
\]
and applying the apriori bound $|G(x')|^s < D_s$ (once again guaranteed by Lemma[4]), we have

$$\Xi(s) \leq D_s + \left| \frac{\mu - 2\Omega}{C_1 s} + C_2 \right| \Xi(s).$$  \hfill (73)

As long as the quantity in brackets can be made strictly less than 1, we have that $\Xi$ is uniformly bounded and the result follows from the same arguments used in the appendix to extend the results to the infinite volume case. This inequality can be satisfied given that

$$g^2 \rho_0 > \left( \frac{C_2}{2} \right)^{1/s},$$  \hfill (74)

and

$$|\mu - 2\Omega| < \left( \frac{(2g^2 \rho_0)^s - C_2}{C_1} \right)^{1/s},$$  \hfill (75)

□

The constants on the right hand side of the two inequalities are the values $K$ and $R$. Now to prove the theorem we combine the two lemmas. Suppose $g \rho_0^2 > K$ and let $S$ be the set

$$S = \{ E \in \mathbb{R} : |E - 2\Omega| < R, E \neq \Omega \},$$  \hfill (76)

where $K$ and $R$ are given in Lemma[4]. Since $\sigma_c(H_\mu) = \emptyset$ for $\mu \in S$ and $E \in \sigma_c(H)$ if and only if $E \in \sigma_c(H_E)$, we have $\sigma_c(H) \cap S = \emptyset$. □

4. Discussion

We conclude with several remarks. We do not know whether the minimal coupling requirement of Theorem 2 is an artifact of our methods rather than a consequence of the models considered. While a minimum strength of the randomness is common in localization results for the Schrodinger equation in dimension $d \geq 2$, it is not required in the one-photon case. In addition, the question of whether all states are localized, regardless of the strength of the coupling constant $g$, in dimension $d = 1$ is of interest and remains open. Finally, we are interested in determining whether the analogous results are true for the continuum models. The Green’s function estimates that we employ do not hold in the limit when the lattice spacing vanishes. While there has been work on localization in the continuous setting, the results we are aware of rely on the locality of the operators involved.

Appendix

Here we present the proof of Lemma[2]. We follow[3] and make use of a criterion due to Simon and Wolff[4].

**Proposition 1** (Simon-Wolff criterion). Let $H = T + V$ be a self adjoint operator on $l^2(\Gamma)$, where $\Gamma \subset \mathbb{Z}^d$ is a countable set. Suppose that $T$ is bounded, and $V$ is a multiplication operator such that for each $x \in \Gamma$, $V(x)$ is a random variable such that the probability distribution of $V(x)$ conditioned on all other sites is absolutely continuous with respect to
the Lebesgue measure. Then $H$ almost surely has only pure point spectrum in $[a, b]$ if for all $x \in \Gamma$ and almost every $E \in [a, b]$

$$\lim_{\epsilon \to 0} \sum_{y \in \Gamma} |G(x, y, E + i\epsilon)|^2 < \infty, \quad y \in \Gamma,$$

(77)

for almost every realization of $V$, where $G(x, y, E + i\epsilon)$ is defined by

$$G(x, y, E + i\epsilon) = \langle \delta_x, (H - E + i\epsilon)^{-1}\delta_y \rangle.$$

(78)

Next we state several lemmas from [3].

**Lemma 5.** Let $H = T + U_0 + \lambda V$ be an operator on $\ell^2(\Gamma)$ with $\Gamma$ countable, $U_0$ a deterministic multiplication operator, $V$ a random multiplication operator with $V(x)$ i.i.d. random variables uniform in $[-1, 1]$, and $T$ a bounded self adjoint operator. Then for any finite $\Lambda \subset \Gamma$

$$P(|G^\Lambda(x, y, E)| \geq t) \leq \frac{4\sqrt{2}}{\lambda t}, \quad x, y \in \Lambda.$$

(79)

**Lemma 6** (Krein formula). Let $H = T + \lambda V$ be as in the previous lemma. Let $\hat{H}$ be the operator obtained from $H = T + \lambda V$ by replacing $V(x)$ and $V(y)$ by 0, and let $R_{x,y}$ be the orthogonal projection onto the two dimensional space spanned by the vectors $\delta_x$ and $\delta_y$. Then

$$G^\Lambda(x, y, E) = \left[ \begin{array}{cc} \lambda V(x) & 0 \\ 0 & \lambda V(y) \end{array} \right] + A^{-1}, \quad x, y \in \Lambda,$$

(80)

where $A$ is the $2 \times 2$ matrix which gives the restriction of the resolvent of $\hat{H}$ to the range of $R_{x,y}$. That is,

$$A = R_{x,y}(\hat{H} - E)^{-1}R_{x,y}$$

(81)

**Lemma 7** (Decoupling lemma). For each $0 < s < 1$ there is an increasing, positive function $\theta_s$ such that

$$\lim_{\eta \to \infty} \frac{\theta_s(\eta)}{\eta} = 1,$$

(82)

where

$$\int_{-1}^1 |\eta - V|\left( \frac{1}{|\beta - V|^s} \frac{dV}{2} \right) \geq \theta_s(|\eta|)^s \int_{-1}^1 \frac{1}{|\beta - V|^s} \frac{dV}{2},$$

(83)

for all $\eta, \beta \in \mathbb{C}$. Moreover if $|\eta| \geq 2$, then $\theta_s(\eta) = |\eta| - 1$.

Let $G(x) = G^\Lambda(x, x_0, E)$ be the Green’s function given by

$$G^\Lambda(x, x_0, E) = \langle \delta_x, (H_\mu - E)^{-1}\delta_{x_0} \rangle,$$
restricted to a finite set $\Lambda \subset \mathbb{Z}^d$. Then for $x \neq x_0$, $G(x)$ satisfies the equation

$$
\left( E - \frac{g^2 \rho_0}{\mu - \Omega} (1 + V(x)) \right) G(x) = \sum_{x' \in \Lambda} T(x, x') G(x'),
$$

(84)

where $T(x, x')$ are the matrix elements of $(-\Delta)^{1/2}$:

$$
T(x, x') = \langle \delta_x, (-\Delta)^{1/2} \delta_{x'} \rangle.
$$

(85)

The coefficients $T(x, x')$ decay algebraically [5] as

$$
|T_{x,x_1}^p| \sim \frac{1}{|x-x'|^{d+1}}.
$$

(86)

We will show that the Simon-Wolff criterion is satisfied by studying the fractional moments $\langle |G^\Lambda(x, y, E)|^s \rangle$ for $0 < s < 1$. First, we derive an apriori bound on the fractional moments. Lemma 5 implies that the Green’s functions $G^\Lambda(x, y, E)$ satisfy the inequality

$$
P(|G^\Lambda(x, y, E)| \geq t) \leq \frac{|E - \Omega| 4 \sqrt{2}}{g^2 \rho_0} t,
$$

(87)

from which one can deduce that

$$
\langle |G^\Lambda(x, y, E)|^s \rangle = \int_0^\infty P(|G^\Lambda_1(x, y, E)|^s \geq t) dt
\leq \int_0^\infty \min\{1, \frac{|E - \Omega| 4 \sqrt{2}}{g^2 \rho_0} t^{1/s}\} dt
= D_s(\Omega, g, \rho_0, E) < \infty.
$$

(88)

Next, raising (84) to the power $s$ for $0 < s < 1$ and taking expectations, we arrive at

$$
\langle |G^\Lambda(x, y, E)|^s \rangle \leq \sum_{x'} |T(x, x')|^s \langle |G(x')|^s \rangle,
$$

(89)

where we have used the subadditivity of the function $f(x) = |x|^s$ for $0 < s < 1$.

Computing the inverse of the matrix in Lemma 6, we find that the functional dependence of $G(x)$ on $V(x)$ is given by

$$
G(x) = \frac{\alpha}{V(x) - \beta},
$$

(90)

where $\alpha$ and $\beta$ are independent of $V(x)$. Using this result, the left-hand side of (91) may be written as

$$
\langle \left| \frac{g^2 \rho_0}{\mu - \Omega} + \frac{g^2 \rho_0}{\mu - \Omega} V(x) - E \right|^s |G(x)|^s \rangle
= \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \prod_{y \neq x} dV(y) \int_{-1}^1 |\eta - V(x)|^s \frac{\alpha}{\beta - V(x)|^s} dV(x),
$$

(91)
where
\[ \eta = 1 - \frac{E(\mu - \Omega)}{g^2 \rho_0} . \] (95)

Next we apply Lemma 7 to obtain the inequality
\[ \langle \left| \frac{g^2 \rho_0}{\mu - \Omega} V(x) - E \right|^s |G(x)|^s \rangle \geq \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \right]^s \langle |G(x)|^s \rangle . \] (96)

Along with (91) this implies that
\[ \langle |G(x)|^s \rangle \leq \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \sum_{x'} |T(x, x')|^s \langle |G(x')|^s \rangle , \quad x \neq x_0 . \] (97)

Now we will define the auxiliary quantity \( \Xi(s) = \sum_{x \in \Lambda} \langle |G^1(x)|^s \rangle \). Then using the previous inequality and the apriori bound given by (88), we see that
\[ \Xi(s) \leq D_s + C_s \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \right]^s \Xi(s) . \] (98)

Here we have used \[ \sum_{x \in \mathbb{Z}^d} |T(x, x')|^s \leq C_s \] for some \( C_s \), which is true for \( s \) sufficiently close to 1. As long as
\[ C_s \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \right]^s < 1 , \] (99)

we arrive at the bound
\[ \Xi(s) \leq \frac{D_s}{1 - C_s \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \right]^s} . \] (100)

There are two ways to ensure that (100) holds.

1. Let \( \kappa_s \) be the minimum value of \( \theta_s \). Then if
\[ |\mu - \Omega| < \frac{\kappa_s}{C_s^{1/s}} g^2 \rho_0 , \] (101)

the above inequality is satisfied.

2. Alternatively, for \( |E| \) sufficiently large we can take
\[ C_s \left[ \left| \frac{g^2 \rho_0}{\mu - \Omega} \right| \theta_s \left( \left| \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right| \right) \right]^s \approx C_s |E|^{-s} < 1 , \] (102)

which follows from the asymptotic behavior of \( \theta_s \) given in Lemma 7.

Note that the bound given in (100) is independent of the finite volume \( \Lambda \). We extend the bound to the infinite volume Green's function,
\[ G(x, y, E + i\epsilon) = \lim_{\epsilon \to 0^+} \sup_{\epsilon} G(x, y, E + i\epsilon) , \] (103)
as follows. Let \( \Lambda_n \subset \mathbb{Z}^d \) be an increasing sequence of nested finite subsets. Since \( G_{1,j}^{\Lambda_n} \) vanishes outside of \( \Lambda_n \), we have

\[
\lim_{n \to \infty} \left\langle \sum_{x \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^s \right\rangle \leq \lim_{n \to \infty} \left\langle \sum_{x \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^s \right\rangle \leq \frac{D_s}{1 - C_s} \left[ \frac{g^2 \rho_0}{\mu - \Omega} \theta_s \left( \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right) \right]^{-s},
\]

by Fatou’s Lemma. Hence for almost every realization of \( \{V(x)\}_{x \in \mathbb{Z}^d} \), the limit inferior of the sum in brackets is finite. We can then pick a subsequence for which the \( \lim\inf \) is attained and along this subsequence, the functions \( G^{\Lambda_n}(x_0, \cdot) \) are bounded in \( \ell^2(\mathbb{Z}^d) \) as

\[
\left\langle \left[ \sum_{x \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^2 \right]^{s/2} \right\rangle \leq \left\langle \sum_{x \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^s \right\rangle.
\]

By the weak compactness of the unit ball in \( \ell^2(\mathbb{Z}^d) \), there is a second subsequence which converges weakly and hence pointwise in \( \ell^2(\mathbb{Z}^d) \). That is, \( G^{\Lambda_n}(x_0, \cdot) \to G(x_0, \cdot, E) \) in \( \ell^2(\mathbb{Z}^d) \). Then the function \( G(x_0, \cdot, E) \) satisfies

\[
\sum_{x \in \mathbb{Z}^d} (H_\mu - E)(y, z)G(x_0, x, E) = \delta_{z, x_0},
\]

\[
\sum_{x \in \mathbb{Z}^d} |G(x_0, x, E)|^s \leq \liminf_{n \to \infty} \sum_{y \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^s.
\]

The first statement shows that \( G \) is given by

\[
G(x_0, x, E) = \lim_{\epsilon \to 0} G(x_0, x, E + i\epsilon),
\]

and the second gives us the bound

\[
\left\langle \left[ \sum_{x \in \mathbb{Z}^d} |G(x_0, x, E + i\epsilon)|^2 \right]^{s/2} \right\rangle \leq \left\langle \sum_{x \in \mathbb{Z}^d} |G(x_0, x, E + i\epsilon)|^s \right\rangle \leq \liminf_{n \to \infty} \left\langle \sum_{x \in \mathbb{Z}^d} |G^{\Lambda_n}(x_0, x, E)|^s \right\rangle \leq \frac{D_s}{1 - C_s} \left[ \frac{g^2 \rho_0}{\mu - \Omega} \theta_s \left( \frac{E(\mu - \Omega)}{g^2 \rho_0} - 1 \right) \right]^{-s}.
\]

It follows that the sum in brackets is finite for almost every realization of \( V(x) \) and for \( E \) in the ranges for which the bound in \( (100) \) is valid. Since the two cases discussed above cover the two regimes in the statement of the lemma, this concludes the proof.
Acknowledgements

We are grateful to Zaher Hani for valuable discussions. This work was supported in part by the NSF grant DMS-1912821 and the AFOSR grant FA9550-19-1-0320.
