A micropolar isotropic plasticity formulation for non associated flow rule and softening featuring multiple classical yield criteria.
Part II - FE integration and applications

Andrea Panteghini, Rocco Lagioia
June 25, 2021

1 Abstract

A Finite Element procedure based on a full implicit backward Euler predictor/corrector scheme for the Cosserat continuum is here presented. Since this is based on invariants of the stress and couple stress tensors and on the spectral decomposition of the former, considerable benefits are achieved. The integration requires the solution of a single equation in a single unknown, which is a considerable improvement as compared to the system of seven or four equations required by other approaches available in the literature for the Cauchy medium. The scheme also allows for a very efficient treatment of the singularity which affects the apex of most of the existing yield and plastic potential surfaces. Moreover, no complications arise when some of the principal stresses coincide. The algorithm has been implemented in a proprietary Finite Element program, and used for the constitutive model proposed in part I of this paper. Numerical analyses have been conducted to simulate a biaxial compression test and a shallow strip footing resting on a Tresca, Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan soil. The benefits of the Cosserat continuum over the Cauchy/Maxwell medium are discussed considering mesh refinement, non-associated flow and softening behaviour.

2 Introduction

The rotational degrees of freedom of the Cosserat continuum introduce a characteristic length which prevents the governing equations of static problems from losing ellipticity when localisations occur in materials characterized by softening and/or non associated flow. The Cosserat continuum is then an effective tool for regularizing ill-posed boundary value problems.
Mesh sensitivity, lack of convergence to the exact solution, dependence of the thickness of the shear band on the mesh refinement can all be effectively dealt with. It can also be effective in preventing early crushing of numerical analyses involving non-associated plastic flow.

Constitutive models for the Cosserat continuum can also be integrated using a full implicit backward Euler scheme, although this is particularly time consuming. However, since it is the only unconditionally stable method, even with very non linear yield and plastic potential surfaces such as those adopted here, its use is particularly recommended and it is indeed chosen in this study. Moreover in combination with a consistent tangent operator, quadratic convergence in the structural Newton loop is achieved.

The classical approach to the implicit integration uses the components of the strain tensor as the main variables, resulting in a system of seven equations in seven unknowns to be iteratively solved. An alternative approach is that proposed by Tamagnini et al. [10] and Borja et al. [2], which is based on the observation that the tensorial derivative of an isotropic scalar valued function of that tensor is coaxial with the tensor itself. The spectral decomposition of the stress and strain tensors is then exploited to use the principal strains as the main variables, thus reducing the system of equations and unknown to four. Complications however occur when two of the principal stresses coincide (e.g. Miehe [8]).

More recently a different approach has been presented by Panteghini and Lagioia [10] [11] which is based on the use of invariants as the main variables during the iterations. This considerably improves the efficiency of the backward Euler scheme since a single equation in a single unknown needs to be solved to integrate the constitutive relationship. Moreover no difficulties arise when two or even three of the principal stresses coincide. This approach presents also another considerable advantage. The De Souza Neto et al. [3] method can be used to deal with singularities in the yield and plastic potential surfaces, which results in an extremely stable integration algorithm. In fact, as reported by Panteghini and Lagioia [10] [11] numerical analyses of a shallow footing problem, with no lateral surcharge and no effective cohesion in the failure criterion can be carried out without any difficulty, provided that an associated flow is adopted. The analysis of that boundary value problem is usually considered not feasible. However, when non associated plasticity is considered even this approach is not sufficient to avoid very early crushing of the analyses.

In this article the Panteghini and Lagioia [11] scheme is extended to the Cosserat continuum. As shown in what follows the formulation is laborious, as it requires the evaluation of an elevated number of derivatives and of fourth order tensors. However the rewards in terms of stability of the Finite Element program and speed of the analyses is extremely high. The algorithm has been implemented in a proprietary FE program and numerical analyses have been conducted to simulate a biaxial compression test on a specimen.
with a defect inclusion.

The effectiveness of the constitutive model presented in part I of this paper and of the integration scheme has been tested in extreme conditions. The very demanding footing problem previously described has been analysed using a high rate of softening, described by an exponential law, and a high non-associativeness. Analyses were conducted using failure criteria which are significant in both research and engineering practice, such as the Mohr-Coulomb and the Muutoska-Nakai, showing the potentiality also in real world applications.

3 The backward Euler incremental initial value problem in terms of invariants

3.1 The general case

The incremental elasto-plastic initial value problem aims at the evaluation of all stresses, couple-stresses, strains and curvatures at the end of a pseudo time interval \([t_n, t_{n+1}]\) during which a given increment of strains \(\Delta \gamma\) and curvatures \(\Delta \chi\) is applied and all quantities are known at time \(t_n\). To keep the notation as simple as possible, all quantities at time \(t_{n+1}\) are indicated without the \(n+1\) subscript whilst for those at the beginning of the pseudo time interval the \(n\) subscript is retained.

The integration algorithm presented in this section is an extension to the Cosserat continuum of that proposed by Panteghini and Lagioia [11] for the classical Cauchy medium. It is a backward Euler predictor/corrector algorithm formulated in terms of invariants of stress, couple-stress, strain and curvature tensors. At variance with other algorithms it requires the solution of a single equation in a single unknown, resulting in an extremely fast numerical integration.

The usual assumption is made that the strains and curvatures can be decomposed into their recoverable, elastic, and permanent, plastic, components

\[
\dot{\gamma} = \dot{\gamma}^e + \dot{\gamma}^p \\
\dot{\chi} = \dot{\chi}^e + \dot{\chi}^p
\]

The tentative assumption that strain increments over the pseudo time interval are elastic leads to the classical definition of strain predictors

\[
\gamma^* = \gamma^n + \Delta \gamma \\
\chi^* = \chi^n + \Delta \chi
\]

which is here rewritten exploiting the decomposition of a general second
order tensor into its symmetric and skew-symmetric components

\[ \varepsilon^* = \varepsilon_n^\ast + \Delta \varepsilon \]

\[ \omega^* = \omega_n^\ast + \Delta \omega \]

\[ \text{sym} \chi^* = \text{sym} \chi_n^\ast + \text{sym} \Delta \chi \]

\[ \text{skw} \chi^* = \text{skw} \chi_n^\ast + \text{skw} \Delta \chi \]  \( (3) \)

and also separating the spherical and the deviatoric parts (note that the skew-symmetric tensor is by definition deviatoric)

\[ \varepsilon_v^* = \text{tr} \varepsilon_n^\ast + \Delta \varepsilon_v \]

\[ \varepsilon^* = \varepsilon_n^\ast + \Delta \varepsilon \]

\[ \omega^* = \omega_n^\ast + \Delta \omega \]

\[ \text{tr} \chi^* = \text{tr} \chi_n^\ast + \text{tr} \Delta \chi \]

\[ \text{sym} g^* = \text{sym} g_n^\ast + \text{sym} \Delta g \]

\[ \text{skw} g^* = \text{skw} g_n^\ast + \text{skw} \Delta g \]  \( (4) \)

where the standard definition of deviatoric tensors has been used

\[ e = \varepsilon - \frac{1}{3} \text{tr} \varepsilon I \]

\[ g = \chi - \frac{1}{3} \text{tr} \chi I \]

Since the elastic constitutive equations retrieved in Part I of this paper are

\[ \sigma = K \text{tr} \varepsilon^\ast I + 2G e^\ast + 2G_c \omega^\ast \]

\[ \mu = K_c \text{tr} \chi^\ast I + 2B g_{\text{sym}}^\ast + 2B_c g_{\text{skw}}^\ast \]  \( (5) \)

the stress predictors can be evaluated

\[ p^* = K \varepsilon_v^* \]

\[ s_{\text{sym}}^* = 2G e^* \]

\[ s_{\text{skw}}^* = 2G_c \omega^* \]

\[ \text{tr} \mu^* = K_c \text{tr} \chi^* \]

\[ m_{\text{sym}}^* = 2B g_{\text{sym}}^* \]

\[ m_{\text{skw}}^* = 2B_c g_{\text{skw}}^* \]  \( (6) \)

The definition of the equivalent von Mises stress formulated in the Part I of this paper

\[ q = \left\{ \frac{3}{2} \left[ s_{\text{sym}} : s_{\text{sym}} + \frac{G}{G_c} s_{\text{skw}} : s_{\text{skw}} + \frac{G}{B} m_{\text{sym}} : m_{\text{sym}} + \frac{G}{B_c} m_{\text{skw}} : m_{\text{skw}} \right] + \frac{2G \text{tr}^2 \mu}{K_c} \right\}^{\frac{1}{2}} \]

\( (7) \)
can then be used to determine the invariants of the stresses and couple stress predictor $\theta^*_s$ (Lode’s angle), $q^*_s$ and $q^*$

$$q_s^* = \sqrt{\frac{3}{2} \hat{s}_{sym}^*: \hat{s}_{sym}^*}, \quad \theta^*_s = \frac{1}{3} \arcsin \left[ -\frac{27}{2} \frac{\det \hat{s}_{sym}^*}{q_s^*} \right]$$

$$q^* = \left\{ \frac{3}{2} \left[ \hat{s}_{sym}^*: \hat{s}_{sym}^* + \frac{G}{G_c} \hat{s}_{skw}^*: \hat{s}_{skw}^* + \frac{G}{B} \hat{m}_{sym}^*: \hat{m}_{sym}^* + \frac{G}{B_c} \hat{m}_{skw}^*: \hat{m}_{skw}^* \right. \right.$$  

$$\left. + \frac{2G \text{tr}^2 \mu^*}{K_c} \right\}^{\frac{1}{2}}$$

where the subscript $s$ in the first two invariants refers to the symmetric part of the deviatoric stress tensor alone.

All quantities for the evaluation of the yield function

$$f(p, q, \theta_s) = q \Gamma (\theta_s) + M_c p - \sigma_0 (\lambda)$$

in the predictor conditions have been determined. The resulting value, $f^* = f(p^*, q^*, \theta^*_s, \sigma_0 (\lambda_n))$ enables to assess whether the tentative assumption of a completely elastic strain/curvature increment was correct (i.e. $f^* \leq 0$), hence resulting in all stress, couple stress, strain and curvature predictor quantities being the actual values at the end of time $t_{n+1}$.

If on the other hand $f^* > 0$ the strain/curvature increment applied during the pseudo time interval $[t_n, t_{n+1}]$ was elasto-plastic and a return to the appropriate yield surface must be performed to evaluate the correct elastic and plastic parts of that increment

$$\Delta \varepsilon_v = \Delta \varepsilon^e_v + \Delta \varepsilon^p_v$$

$$\Delta \varepsilon = \Delta \varepsilon^e + \Delta \varepsilon^p$$

$$\Delta \omega = \Delta \omega^e + \Delta \omega^p$$

$$\text{tr} \Delta \chi = \text{tr} \Delta \chi^e + \text{tr} \Delta \chi^p$$

$$\text{sym} \Delta g = \text{sym} \Delta g^e + \text{sym} \Delta g^p$$

$$\text{skw} \Delta g = \text{skw} \Delta g^e + \text{skw} \Delta g^p$$

The return algorithm requires the formulation of all stress and couple stress at the end of the pseudo time interval as a function of the respective predictor quantities, which is readily done with the exception of the symmetric component of the deviatoric stress tensor

$$p = p_n + K(\Delta \varepsilon_v - \Delta \varepsilon^p_v) = p^*_n - K \Delta \varepsilon^p_v$$

$$g_{skw} = g_{skw,n} + 2G_c(\Delta \omega - \Delta \omega^p) = g_{skw,n}^* - 2G_c \Delta \omega^p$$

$$\text{tr} \mu = \text{tr} \mu_n + K_c(\text{tr} \Delta \chi - \text{tr} \Delta \chi^p) = \text{tr} \mu^*_n - K_c \text{tr} \Delta \chi^p$$

$$m_{sym} = m_{sym,n} + 2B(\Delta g_{sym} - \Delta g^p_{sym}) = m_{sym,n}^* - 2B \Delta g^p_{sym}$$

$$m_{skw} = m_{skw,n} + 2B_c(\Delta g_{skw} - \Delta g^p_{skw}) = m_{skw,n}^* - 2B_c \Delta g^p_{skw}$$
The plastic components in the previous equation can be evaluated in the standard manner by deriving the plastic potential

\[ g(p, q, \theta) = q \hat{\Gamma}(\theta_s) + M_c p \]

with respect to the associated stress quantities, resulting in

\[ \Delta \varepsilon^p_v = -\hat{M} \Delta \lambda \]
\[ \Delta \omega^p = \frac{\partial g}{\partial \sigma_{sym}} \Delta \lambda = \frac{3 G \hat{\Gamma}(\theta_s) \Delta \lambda}{2 G_c} q \hat{s}_{skw} \]
\[ \text{tr} \Delta \chi^p = \frac{\partial g}{\partial k_{tr} \mu} \Delta \lambda = \frac{3 2 G \hat{\Gamma}(\theta_s) \Delta \lambda \text{tr} \mu}{2 K_c} q \hat{m}_{skw} \]
\[ \Delta g^p_{sym} = \frac{\partial g}{\partial m_{sym}} \Delta \lambda = \frac{3 G \hat{\Gamma}(\theta_s) \Delta \lambda}{2 B_c} q \hat{m}_{sym} \]
\[ \Delta g^p_{skw} = \frac{\partial g}{\partial m_{skw}} \Delta \lambda = \frac{3 G \hat{\Gamma}(\theta_s) \Delta \lambda}{2 B_c} q \hat{m}_{skw} \]

where \( \Delta \lambda \) is the plastic multiplier. The stresses and couple stress at time \( t_{n+1} \) are hence expressed in terms of their respective predictor quantities

\[ p = p^*_n - K \hat{M} \Delta \lambda \]
\[ \hat{s}_{skw} = \frac{q}{q + 3 G \hat{\Gamma}(\theta_s) \Delta \lambda} \hat{s}^*_{skw} \]
\[ \hat{\mu} = \frac{q}{q + 3 G \hat{\Gamma}(\theta_s) \Delta \lambda} \hat{\mu}^* \]

This set of equations is not complete, since a similar expression would be required for the symmetric component of the deviatoric stress tensor \( s_{sym} \).

However since

\[ \Delta \varepsilon^p = \frac{\partial g}{\partial s_{sym}} \Delta \lambda = \left( \frac{\partial g}{\partial p} \frac{\partial p}{\partial s_{sym}} + \frac{\partial g}{\partial q} \frac{\partial q}{\partial s_{sym}} + \frac{\partial g}{\partial \theta} \frac{\partial \theta}{\partial s_{sym}} \right) \Delta \lambda \]

an explicit dependence on \( s_{sym} \) on its predictor quantity cannot be obtained.

An alternative route can be followed, which was outlined by Panteghini and Lagioia [11] who showed that a relationships can be formulated between the invariants of \( s_{sym} \) and of \( s^*_{sym} \). This is based on geometrical considerations in the deviatoric plane and is valid only if the elastic strain energy potential is not dependent on the third invariant, which results in the deviatoric stress and strain tensors having the same Lode’s angle.

Fig[1] shows a portion of the deviatoric plane in the Haigh-Westergaard principal symmetric strain space. In that figure \( \varepsilon_{qs} \) indicates the second invariant of the symmetric deviatoric strain tensor which is energetically conjugated to the equivalent von Mises stress \( q_s \), and * and c superscripts
Figure 1: Geometric representation in the deviatoric plane of the HighWestergaard principal symmetric strain space. Elastic predictor, plastic and final elastic strain (modified from Panteghini and Lagioia [11]).

are as usual used to distinguish the predictor and the elastic deviatoric strains associated to the pseudo time interval \([t_n, t_{n+1}]\)

\[
\varepsilon_{qs}^e = \sqrt{\frac{2}{3}} \varepsilon^e : \varepsilon^e, \quad \varepsilon_{qs}^* = \sqrt{\frac{2}{3}} \varepsilon^* : \varepsilon^*, \quad q_s = \sqrt{\frac{3}{2} \mathbb{S}_{sym} : \mathbb{S}_{sym}}
\]

The figure shows that the actual elastic strain at the end of an elastoplastic strain increment is obviously different from the predictor quantity, and that they are associated to different Lode’s angle. The right handside diagram shows that the difference between those strains represents the plastic strain increment during that time interval and the radial and circumferential components are highlighted.

The figure shows that the radial plastic component is

\[
\Delta \varepsilon_{qs}^p = \varepsilon_{qs}^* \cos (\theta^*_s - \theta_s) - \varepsilon_{qs}^e
\]  

and by applying the elastic constitutive law

\[
q_s = 3G\varepsilon_{qs}^e
\]  

to Eq. (15) and solving for \(q_s\) one obtains

\[
q_s = q_s^* \cos (\theta^*_s - \theta_s) - 3G\Delta \varepsilon_{qs}^p
\]

Finally substituting the plastic strain increment definition

\[
\Delta \varepsilon_{qs}^p = \frac{\partial g}{\partial q} \Delta \lambda = \frac{q_s \hat{\Gamma} (\theta_s) \Delta \lambda}{q}
\]
into Eq. (17), and collecting $q_s$ yields

$$q_s = \left(\frac{q}{q + 3G\Gamma(\theta_s)\Delta\lambda}\right) q_s^* \cos(\theta_s^* - \theta_s)$$

(19)

which integrates Eqs. (13) in the definition of stress quantities at the end of the pseudo time interval as a function of the respective predictor. If this equation is further introduced into Eq. (7) one obtains

$$q = \left\{ q_s^2 \cos^2(\theta_s^* - \theta_s) + \frac{3}{2} \left[ \left(\frac{G}{G_c}\right) s_{skw}^* : s_{skw}^* + \left(\frac{G}{B}\right) m_{sym}^* : m_{sym}^* + \left(\frac{G}{B_c}\right) m_{skw}^* : m_{skw}^* + \frac{2G tr^2 \mu^*}{K_c} \right] \right\}^{1/2} - 3G\Gamma(\theta_s)\Delta\lambda$$

(20)

which can be furthermore simplified by observing that

$$\frac{3}{2} \left[ \left(\frac{G}{G_c}\right) s_{skw}^* : s_{skw}^* + \left(\frac{G}{B}\right) m_{sym}^* : m_{sym}^* + \left(\frac{G}{B_c}\right) m_{skw}^* : m_{skw}^* + \frac{2G tr^2 \mu^*}{K_c} \right] = q^* - q_s^2$$

so that Eq. (20) becomes

$$q = r - 3G\Gamma(\theta_s)\Delta\lambda$$

(21)

where

$$r = \sqrt{q^*_s - q_s^2 \sin^2(\theta_s^* - \theta_s)}$$

(22)

In conclusion, the developments so far presented, result in

$$p = p_{n}^* \hat{M} \Delta\lambda$$

$$q_s = \left(\frac{q}{r}\right) q_s^* \cos(\theta_s^* - \theta_s)$$

$$s_{skw} = \left(\frac{q}{r}\right) s_{skw}^*$$

$$\mu = \left(\frac{q}{r}\right) \mu^*$$

(23)

where the definition of $r$ has been substituted in Eqs. (13). The meaning of the last set of equations is that the stress invariants $p$ and $q$ at the end of the pseudo time interval $[t_n, t_{n+1}]$ are a function of the known predictor invariants $p^*$, $q^*$, $q_s^*$ and $\theta_s^*$ and of two unknowns, namely the Lode’s angle $\theta_s$ and the plastic multiplier $\Delta\lambda$ at the end of time interval $t_{n+1}$. However, as shown by Panteghini and Lagioia [10] [11], these two unknown are not independent as $\Delta\lambda$ is a function of $\theta_s$

$$\Delta\lambda = \frac{q_s^* 2^{1/2} \sin(2\theta_s^* - 2\theta_s)}{3G r \Gamma'(\theta_s)}$$

(24)
as can be easily shown on the basis of geometrical reasoning from Fig. 1

\[ \Delta \varepsilon_{\theta_s}^p = \varepsilon^*_{qs} \sin (\theta^*_s - \theta_s) \]  

(25)

and substituting \( \varepsilon^*_{qs} \) with \( q^*/(3G) \) using the linear elastic relationship and \( \Delta \varepsilon_{\theta_s}^p \) with its definition using the plastic potential

\[ \Delta \varepsilon_{\theta_s}^p = \frac{1}{q_s} \frac{\partial g}{\partial \theta_s} \Delta \lambda = \frac{r \hat{\Gamma}'(\theta_s) \Delta \lambda}{q_s \cos (\theta^*_s - \theta_s)} \]  

(26)

The whole framework on which the integration algorithm is based has been presented. The important results is that all stress quantities at the end of the pseudo time interval \( [t_n, t_{n+1}] \) are a function of the predictor quantities, which are known, and of the plastic multiplier \( \Delta \lambda \) alone. Hence the numerical integration of the constitutive law is obtained by iterating on a single equation in one unknown. This brings considerable advantages in terms of machine run-time as compared to classical approaches where a system of seven equations needs to be solved and also to approaches based on principal stresses where the number of equations in the system is reduced to four.

### 3.2 A particular case

The general mathematical formulation of the return algorithm presented in the previous subsection shows that the converged Lode’s angle \( \theta_s \) at time \( t_{n+1} \) of the symmetric part of the stress tensor differs from its predictor \( \theta^*_s \). Eq. (24) is then exploited to reduce the number of unknowns from two to one.

However a particular case also occurs, which allows a significant simplification of the integration algorithm. Fig. 2 shows the plastic potential section in the deviatoric plane of the Haigh-Westergaard symmetrical principal stress space. For symmetry reasons the derivative of the plastic potential with respect to the Lode’s angle \( \hat{\Gamma}'(\theta_s) \) vanishes when \( \theta_s = -\pi/6 \) and \( \theta_s = \pi/6 \). Since a particular instance of an implicit integration scheme is here presented, hence plastic strains are evaluated using the derivatives of the plastic potential at the end of pseudo-time interval, the converged circumferential plastic strain \( \Delta \varepsilon_{\theta_s}^p \) also vanishes, as shown by Eq. (26).

Specific shapes of the plastic potential in the deviatoric plane, e.g. those provided by classical yield/failure criteria, might result in additional Lode’s angle values where that derivative vanishes. As an example this does not occur in the case of the Matsuoka-Nakai criterion, whilst an additional \( \pi/6 \geq \theta_s \geq -\pi/6 \) exists in the case of the Mohr-Coulomb criterion. \(^1\)

---

\(^1\)The original Mohr-Coulomb criterion presents cusps in the deviatoric plane, however smooth versions of that criterion are part of the General Classical yield function retrieved by Lagioia and Panteghini \(^2\) also with the defining parameters derived for that function by Lester and Sloan \[^6\].
interesting instance is that provided by the von Mises and Drucker-Prager criteria. These are characterized by a circular deviatoric section, hence \( \dot{\Gamma}'(\theta_s) \) is identically nil.

When \( \Delta \varepsilon^{p}_s \) vanishes no plastic correction of the strain predictor \( \varepsilon^*_q \) is possible in the circumferential direction of the deviatoric plane, hence \( \theta^*_s \) must coincide with the converged \( \theta_s \) (Fig. 1). This also emerges from Eq. (25). A simplified radial return algorithm can then be used.

It should be noted that not only is \( \theta^*_s = \theta_s \) when \( \dot{\Gamma}'(\theta_s) = 0 \), but also the reverse is true, i.e. when \( \dot{\Gamma}'(\theta^*_s) = 0 \) then \( \theta_s = \theta^*_s \). In fact if \( \theta^*_s \) is such that \( \dot{\Gamma}'(\theta^*_s) = 0 \) then the converged solution cannot be other than \( \theta_s = \theta^*_s \), otherwise two stress predictor characterized with the same \( \theta^*_s \) and \( \dot{\Gamma}'(\theta^*_s) = 0 \) could be associated to different values of \( \theta_s \), one of which with \( \dot{\Gamma}'(\theta_s) \neq 0 \).

This would not be not compatible with the fact that the set of algebraic solving equations is of implicit type and uses stress predictors as principal variables.

The main implication of this argument is that given \( \theta^*_s \) it is a priori known whether a generic or a radial return algorithm can be used, depending only on whether or not \( \dot{\Gamma}'(\theta^*_s) = 0 \). Moreover, when the radial return algorithm applies, since the converged \( \theta_s \) is known already at the beginning of the pseudo-time interval, it is not anymore an unknown in Eqs (23), which only depends on \( \Delta \lambda \) (i.e. there is no need of Eq. (24)).

3.3 Return algorithms

The arguments presented in the previous subsection indicate that a general and a radial return algorithms are required. However many constitutive
models, e.g. those used in perfect plasticity, adopt classical yield/failure criteria to define the yield and the plastic potential surfaces (non-associated plasticity typically being achieved by choosing different sets of defining parameters). Such criteria are characterized by linear meridional sections which generate a cusp at the apex of the surface toward the origin of the stress space. In the case of the plastic potential this results in an undefined plastic flow normal, which is particularly problematic when backward Euler implicit integration schemes are adopted. However this issue can be very effectively handled using the approach proposed by de Souza Neto et al. [3], which then requires the formulation of a third return algorithm.

The cusp at the apex is associated to the lack of continuity of the first derivative of its defining function and has been a major topic of discussion and research, particularly in the Soil Mechanics community. It has very often been considered an unwelcome feature of numerous functions and many attempts have been made to smoothen their apex (e.g. Abbo and Sloan [1], Panteghini and Lagioia [12]).

However Panteghini and Lagioia [10] performed Finite Element analyses of a shallow foundation problem using a classical criteria to define the yield and plastic potential surfaces characterized by the apex singularity and compared the results of either modifying the original formulation to provide smoothness or adopting the de Souza Neto et al. [3] approach. The analyses showed that the latter approach is considerably more efficient, resulting in reduced machine run-time.

Since the constitutive model adopted in this study also uses classical yield/failure criteria together with the de Souza Neto et al. approach, three different return algorithms are required. The first two apply the mathemat-
ical developments described in the previous subsections and are mutually exclusive, the one to be used being know a priori on the basis of the predictor Lode’s angle. The first algorithm is valid when $\Gamma'(\theta^*_s) = 0$ which corresponds for plastic potentials with non-circular deviatoric sections to predictor Lode’s angles $\theta^*_s = \pm \frac{\pi}{6}$, whilst for other (e.g. the Mohr-Coulomb failure criterion) also to an additional intermediate value which only depends on the angle of shearing resistance $\phi$. The second algorithm is valid for the general case of $\Gamma'(\theta^*_s) \neq 0$, i.e. $\theta^*_s \neq \pm \frac{\pi}{6}$ (and for the intermediate Lode’s angle for the Mohr-Coulomb criterion).

To deal with the cusp at the apex of the surface a control of the validity of the converged solution is needed, which in case of violation requires the use of the third algorithm. The validity check is based on the simple observation that the equivalent von Mises stress $q$ is by definition a positive quantity. As shown in Fig. 3 for a generic meridional section of the surface, given a generic predictor $q^*$ the return algorithm either results in a non-negative or in a negative value of $q$. In the former case the solution is clearly correct and can be accepted, whereas the case of a negative $q$ is theoretically incorrect. Since the solution is unique and the positive $q$ is excluded because it is characterized by a uniquely defined plastic normal, then the only remaining valid possibility is a return to an isotropic stress state which is associated to an undefined plastic flow normal. Hence a third return algorithm needs to be formulated to bring the stress state back to the apex of the yield surface.

**First return algorithm:** $\Gamma'(\theta^*_s) = 0$.

Considerable simplifications occurs, as Eqs. (26), (25) and (22) indicate that $\Delta \varepsilon_{\theta_s} = 0$, $\theta_s = \theta^*_s$ and $r \equiv q^*$. The stress invariants at the end of the increment can then be computed by solving a single non-linear scalar equation in the unknown $\Delta \lambda$ according to the step sequence:

- choose a starting trial value for $\Delta \lambda$;
- evaluate $\sigma_0(\Delta \lambda)$ using the hardening/softening law;
- compute $p$ using the first of Eqs. (23);
- compute $q$ from Eq. (21),
- iterate on $\Delta \lambda$ until $f = q \Gamma(\theta^*_s) + Mp - \sigma_0(\lambda) = 0$.

---

2It should be noted that if a linear isotropic hardening/softening law is adopted

$$\sigma_0(\lambda) = \bar{\sigma}_0 + h (\lambda_n + \Delta \lambda)$$

then a close form solution for $\Delta \lambda$ can be obtained

$$\Delta \lambda = \frac{q^* \Gamma(\theta^*_s) + Mp^* - \bar{\sigma}_0 - h \lambda_n}{\Gamma(\theta^*_s) \hat{\Gamma}(\theta^*_s) 3G + (\hat{M} \hat{M} K + h)}$$
check the validity of the converged solution: If \( q \geq 0 \) the solution is valid, otherwise the third algorithm needs to be run to return to the apex of the yield surface.

If the converged solution is valid, all stress tensors at time \( t_{n+1} \) can be easily evaluated, in terms of the stress invariants \( p, q \) and \( \theta_s \) and of the predictor quantities using Eqs. (23) and remembering that since \( \theta_s = \theta_s^* \) then \( r \equiv \frac{q}{q^*} \) and the stress and couple stress tensors can be updated using the following equations:

\[
\begin{align*}
    p &= p_s^* + K \hat{M} \Delta \lambda \\
    s_{sym} &= \frac{q}{q^*} s_{sym}^* \\
    s_{skw} &= \frac{q}{q^*} s_{skw}^* \\
    \mu &= \left( \frac{q}{q^*} \right) \mu^*
\end{align*}
\]  

(30)

The symmetric part of the stress tensor is then

\[
\sigma_{sym} = pI + s_{sym} = pI + \frac{q}{q^*} s_{sym}^* 
\]

(31)

whilst the Cosserat stress is

\[
\sigma = pI + s_{sym} + s_{skw}
\]

(32)

**Second return algorithm:** \( \hat{\Gamma}'(\theta_s^*) \neq 0 \).

This is the general return algorithm for plastic potentials with a non-circular deviatoric section. In this case the Lode’s angle \( \theta_s \) at the end of the pseudo time interval is different from its predictor \( \theta_s^* \). As in the previous situation,

\[3\] The symmetric component of the deviatoric stress tensor at time \( t_s \), is also proportional to \( q/q^* \). Since in the first return algorithm \( \hat{\Gamma}'(\theta_s) = 0 \), only the second term on the right hand side of Eq. (14) in other than zero

\[
\Delta \varepsilon^p = \frac{\partial g}{\partial q} \frac{\partial q}{\partial \varepsilon_{sym}} \Delta \lambda = \frac{3}{2} \frac{\hat{\Gamma}(\theta_s^*) \Delta \lambda}{q} s_{sym}
\]

Morover since

\[
\Delta \varepsilon = \Delta \varepsilon^e + \Delta \varepsilon^p
\]

and

\[
s_{sym} = s_{sym,n} + 2G (\Delta \varepsilon - \Delta \varepsilon^p)
\]

one obtains

\[
s_{sym} = \frac{q}{q + 3G(\theta_s^*) \Delta \lambda} s_{sym}^* = \frac{q}{q^*} s_{sym}^*
\]

(29)

where

\[
s_{sym}^* = s_{sym,n} + 2G \Delta \varepsilon
\]
stresses and couple stresses at time \( t_{n+1} \) are obtained by solving a single non-linear scalar equation, but iteration are now performed on \( \theta_s \) (for example by employing a dumped Newton’s method, restricting the solution in the range \(-\pi/6 \leq \theta_s \leq \pi/6\)) rather than on the plastic multiplier \( \Delta \lambda \) according to the step sequence:

1. choose a starting trial value for \( \theta_s \);
2. evaluate \( \Delta \lambda \) using Eq. (24) as a function of \( \theta_s \) (and of the predictors of the stress invariants);
3. evaluate \( \sigma_0(\Delta \lambda) \) using the hardening/softening law;
4. evaluate \( p \) using the first of Eqs. (23);
5. evaluate \( r \) and \( q \) using Eqs. (22) and (21);
6. iterate on \( \theta_s \) until \( f = q\Gamma(\theta_s^*) + Mp - \sigma_0(\lambda) = 0 \);
7. check the validity of the converged solution: If \( q \geq 0 \) the solution is valid, otherwise the third algorithm needs to be run to return to the apex of the yield surface.

If the converged solution is valid, the stresses at time \( t_{n+1} \) need to be evaluated following the following procedure.

1. evaluate \( q_s \) from the second of Eqs. (23);
2. evaluate the ordered principal stresses of the symmetric part of the stress tensor \( \sigma_{sym} \) at time \( t_{n+1} \)
   \[
   \begin{align*}
   \sigma_I &= p + \frac{2}{3}q_s \sin \left( \theta_s + \frac{2}{3} \pi \right) \\
   \sigma_{II} &= p + \frac{2}{3}q_s \sin (\theta_s) \\
   \sigma_{III} &= p + \frac{2}{3}q_s \sin (\theta_s - \frac{2}{3} \pi)
   \end{align*}
   \]
   \( (33) \)
   where \( \sigma_I \geq \sigma_{II} \geq \sigma_{III} \)
3. evaluate \( \sigma_{sym} \) by applying the spectral theorem
   \[
   \sigma_{sym} = \sum_{i=I,II,III} \sigma_i b_i^s
   \]
   \( (34) \)

\footnote{Note that since \( \theta_s \neq \pm \frac{\pi}{3} \) these are strict inequalities.}
where $b_i^* = n_i^* \otimes n_i^*$ and $n_i^*$ for the hypothesis of isotropy are the principal directions of $\varepsilon^*$, which are known quantities for each pseudo-time step.

- evaluate the remaining stress tensors using Eqs. (23);
- evaluate the Cosserat stress tensor using Eq. (32):

**Third return algorithm:** $q < 0$
If either of the previous return algorithms converge to $q < 0$ the solution is not theoretically acceptable and a return to the apex is performed. The yield condition then reduces to

$$Mp - \sigma_0(\lambda) = 0 \quad (35)$$

and after accounting for the first of Eqs. (23) a single non-linear scalar equation in $\Delta \lambda$ is obtained \[^5\]

$$Mp^* - KM \hat{M} \Delta \lambda - \sigma_0(\lambda) = 0 \quad (37)$$

whose iterative solution provides the value of $\Delta \lambda$ at time $t_{n+1}$, whilst all stress tensor are obtained from Eqs. (23)

$$\sigma = \left( p^* - K \hat{M} \Delta \lambda \right) I$$

$$s_{sym} = s_{skw} = \mu = 0$$

**4 Consistent Jacobian matrices**

The consistent tangent operator is required to achieve quadratic convergence in the structural Newton loop (e.g. Nagtegaal [9], Simo and Taylor, [15]). In algorithms for classical Cauchy continuum it is a single fourth order tensor \[^6\]

\[^4\]It should be noted that the evaluation of the eigenvectors of the strain predictor $\varepsilon^*$ is actually not necessary, as, following Miehe (1998), [8] $b_i^*$ can be directly evaluated

$$b_i^* \equiv \frac{\partial \varepsilon_i^*}{\partial \varepsilon} = \frac{\partial \varepsilon_i^\ast}{\partial \varepsilon}$$

where $\varepsilon_i^*$ is the $i$–th ordered principal component of $\varepsilon^*$.

\[^6\]Let note that $\Delta \lambda$ can be computed analytically from Eq. (37) if the linear strain hardening-softening law of Eq. (28) is employed. In this case it results:

$$\Delta \lambda = \frac{Mp^* - \sigma_0 - h \lambda_n}{KM + h} \quad (36)$$
obtained by deriving with respect to the strains the constitutive function \( \hat{\sigma}(\varepsilon) \) which provides the stresses as a function of the strains at time \( t_{n+1} \)

\[
\frac{\partial \hat{\sigma}(\varepsilon)}{\partial \varepsilon}
\]  

(39)

For the Cosserat continuum the number of the consistent operators increases together with the number of stress tensors.

Since the approach presented in this paper to integrate the constitutive law exploits the spectral decomposition of the symmetric part of the deviatoric stress tensor, the computation of the consistent operator involves the derivation of the eigenvalues and eigenvectors (or alternatively of the bases) of that tensor. This is not a straight forward task for the special occurrences of two (i.e. \( \theta_s = \pm \pi/6 \)) or three (i.e. \( q_s = 0 \)) coinciding principal stresses, when some of the derivatives become singular (e.g. Miehe [8], de Souza Neto et al. [3]).

However, such difficulties can be easily overcome by formulating different consistent tangent operators for each of the return algorithms described in the previous section. When the second return algorithm applies (hence the solution is valid and \( q_s > 0 \)) all eigenvalues are distinct since \( \theta_s \neq \pm \pi/6 \). The derivatives of the spectral decomposition can be evaluated without problems following the approach presented by Miehe [8].

On the other hand when the first or the third return algorithms applies two or three of principal components, respectively, of \( \sigma_{sym} \) coincide and singularities would arise in the derivation of the basis \( \hat{b}_i^* = \hat{n}_i^* \otimes \hat{n}_i^* \). However, as discussed in the previous section, no spectral decomposition is required in both cases, since when the first return algorithm applies, stresses are proportional to their predictors, whilst when the third algorithm applies the symmetric tensor is spherical.

All necessary derivatives are provided in the appendix.

5 Biaxial compression tests

A first set of analyses was performed to simulate a biaxial compression test on a specimen of an elastic-perfect plastic, non-associated, Mohr-Coulomb material, characterized by a defect inclusion in its middle. Due to the symmetry of the problem, only half of the specimen was analysed, and its geometry is shown in Fig. 4 together with the boundary conditions. A vertical plane strain compression was applied, the initial stress being spherical. No boundary conditions were imposed to the Cosserat rotational degrees of freedom, the micro-volumes being hence allowed to rotate freely.

The analyses were conducted with three progressively finer meshes and both on the Cauchy and the Cosserat continuum, the same set of common parameters being used which is shown in Table 1. However in order to prevent a very early crush of the analyses involving the Cauchy continuum, a
Figure 4: Geometry of the domain used for analysing a biaxial compression test. A defect inclusion is located in the middle of the specimen.

moderate non-associativity was used, characterized by an angle $\phi_g$ of the plastic potential 33% lower than that used to define the yield surface $\phi$. The parameters of the defect inclusion only differ for the two angles $\phi$ and $\phi_g$ and are shown in Fig. 4. A rounded Mohr-Coulomb model was used, circumscribed to the original one which is otherwise characterized by discontinuities in the deviatoric plane. However, the rounding parameter $\beta$ of both the yield and the plastic potential surfaces was very close to unity, so that the surfaces practically coincide with those of the original criterion.

The stress-strain curves in the axial direction, for the six analyses are shown in Fig. 5. No structural softening was observed in the behaviour of the Cauchy material. The stress-strain behaviour of both the Cauchy and the Cosserat continuum is very similar, with the six curves very close to one another. However whilst for the Cauchy material a slight decrees of the failure load is observed as the mesh is refined, the three curves of the Cosserat model are perfectly coincident.

Figure 6 shows contours of the plastic multiplier $\lambda$ for the six analyses. The capability of the Cosserat continuum to eliminate mesh sensitivity is clearly apparent.

6 Analysis of a shallow strip footing

A shallow and rigid footing has been analysed in plane strain conditions using either the Tresca or the Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan models. Whilst the former is typically used to simulate undrained pore water conditions, the latter set of models is adopted for the drained...

wryness tensor $\chi$ is deviatoric. This is the consequence of the restrained variation along the out of plane direction of the only available component of the rotation vectors (which is along the same direction). Hence the Cosserat elastic parameter $T$ plays no role in the analyses.

### 6.1 Tresca soil

Analyses were conducted for both the Cauchy and the Cosserat continua adopting the Tresca criterion to describe both the yield and the plastic potential surfaces, so that an associated flow occurred. A perfect plastic or a softening behaviour was considered, the latter being defined by a high rate exponential rule as described in Part I of this paper. No lateral surcharge

and a frictionless interface at the soil-footing contact were assumed.

Fig. 8 shows the load-displacement curves for analyses conducted in associated perfect plasticity for the Cauchy and Cosserat continua. The bering pressures \( \bar{q}_b \) and the vertical displacements \( \bar{u} \) have been normalized with respect to the undrained shear strength \( S_u \) and the breath \( B = 2m \) of the foundation, respectively. The dash-dotted line in the diagram shows the theoretical bearing capacity factor

\[
N_c = \bar{q}_f S_u = 2 + \pi
\]

of the Prandtl’s solution [13] valid for associated perfect plasticity in the absence of a lateral surcharge.

Fig. 9 shows the load-displacement curves of the analyses conducted in
associated plasticity and exponential softening, for the Cauchy and Cosserat continua using both coarse and fine meshes.

As expected, Fig. 8 clearly indicates that there is no appreciable mesh dependency when analyses are conducted adopting perfect and associated plasticity. The result is confirmed for both the Cauchy and the Cosserat continua.

However when softening is included in the Cauchy continuum different load-displacement curves are obtained for the coarse and fine meshes, showing as expected the existence of strong mesh dependencies (Fig. 9). No such effect exists for the Cosserat continuum, since the curves of the two analyses conducted with the coarse and the fine meshes perfectly coincide, confirming the effectiveness of such a continuum to provide a mesh independent solution.

In the case of perfect associated plasticity the results of the analyses provide a bearing capacity factor very close to $N_c = 2 + \pi$ of the theoretical Prandtl solution. As expected both the Cauchy and the Cosserat continua slightly overestimate that value by 1.1% and 2.4% respectively (Fig. 8).

When an exponential softening is included (Fig. 9) all four analyses for the coarse and fine meshes and for the Cauchy and the Cosserat are very close to one another until a peak is attained. Thereafter they diverge, the latter continuum exhibiting the least reduction in bearing capacity factor. The reduction in bearing capacity is presumably associated to a progressive failure effect caused by the exponential reduction in the undrained strength.
6.2 Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan soils

The so-called pure $N_\gamma$ problem was investigated. The yield and the plastic potential surfaces were defined by the Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan criteria, both in associated and non-associated plasticity, the latter being achieved by using a different set of parameters for the plastic potential. No hardening/softening behaviour was included. The horizontal displacement of the footing nodes was restrained to simulate a perfect rough interface.

Figure 10 shows a comparison between analyses conducted on the Cauchy and the Cosserat continua, in associated perfect plasticity. Theoretical values of $N_\gamma$ for the three constitutive models are also shown for comparison. These were obtained by means of the limit analyses using the $ABC$ software [7] in combination with the findings of Lagioia and Panteghini [5]. Results indicate that the bearing capacity in Cauchy perfect plasticity coincides with that obtained from the limit analyses for all three failure criteria, whilst for the Cosserat continuum consistently larger values for all models were observed. However for the Mohr-Coulomb criterion the difference between the Cauchy and the Cosserat bearing capacity was not significant.

The same set of analyses was also conducted with an extreme non-associated plastic flow, by setting the angle $\phi_g$ of the plastic potential virtually to zero ($\phi_g = 0.5^\circ$). As expected, the analyses on the Cauchy continuum crushed straight away, without performing even the first load step. On the contrary no problems were encountered with the Cosserat material. Moreover all analyses were concluded in just a few minutes on a portable
Figure 10: Strip footing on Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan soils in associated plasticity.

A final set of analyses was conducted on the Matsuoka-Nakai soil, with the aim of comparing associated and non-associated plasticity for both the Cauchy and the Cosserat continuum. In order to manage to avoid crushing of the analyses involving the former medium, a moderate non-associativity was used, setting the difference between the angles $\phi$ and $\phi_g$ to 15°. As this remedy alone was not enough, an effective cohesion was also introduced in the yield surface (see Table 2).

Figure 12 shows that no mesh sensitivity occurs with the Cosserat continuum since the analyses of the coarse and the fine meshes yielded identical results both in associated and non-associated plasticity. As expected, the same conclusion can be drawn for the Cauchy medium in associated plasticity. However mesh sensitivity and structural softening emerged when the flow was non associated.

7 Conclusions

A Finite Element procedure for the integration of the elastoplastic constitutive model described in part I of this paper for the Cosserat continuum has been implemented using a full backward Euler predictor/corrector scheme into a proprietary Finite Element program. The integration algorithm is an extension to the Cosserat medium of that proposed by Panteghini and Lagioia [11] for the classical Cauchy/Maxwell continuum.

At variance with other approaches available in the literature, which
Figure 11: Strip footing on Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncans Cosserat soils with a limit non-associated plasticity.

adopt as principal variables either the six components of the strain tensor or its principal values, the Panteghini and Lagioia scheme is based on invariants and results in a number of important benefits. First of all the integration requires the solution of a single equation in a single unknown, which brings considerable speed improvements as compared to the system of seven by seven and four by four equations and unknowns necessary for the other two approaches. Moreover no difficulties are encountered when two and/or three of the principal stresses coincide. Finally the use of invariants enables the adoption of the technique proposed by De Souza Neto et al. [3] to deal with the singularity at the apex of the yield and plastic potential surfaces.

The drawback of the adoption of an implicit integration with the Cosserat continuum is the large amount of calculations required, since nine consistent tangent operators needs to be derived. However since the constitutive model proposed in part I of this paper was formulated to allow the use of multiple classical yield criteria, which are relevant in both research and engineering practice, and since these criteria are highly non-linear, the choice of an implicit algorithm is recommended. This is in fact the only one which ensures unconditional stability with highly non-linear surfaces. Moreover the use of consistent tangent operators results in a quadratic convergence of the structural Newton loop.

The reward of the adoption of the proposed integration scheme is considerable. Analyses with a large number of elements and nodes were completed within a couple of minutes and no numerical difficulties were ever encountered, despite the fact that a very demanding boundary value problem was
Figure 12: Strip footing on Matsuoka-Nakai soil with moderate non-associativity and cohesion.

investigated.

A first set of analyses was conducted to model a biaxial compression test in plane strain conditions on a Mohr-Coulomb elastic-perfect plastic material with non-associated flow. A defect inclusion was included in the middle of the specimen. The comparison of the Cauchy and Cosserat continua, clearly confirm the capability of the latter to remove mesh sensitivity.

A plane strain shallow footing problem has been considered next, the soil behaviour being reproduced either with a Tresca or with a Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan models. The analyses conducted with the latter model indicate that the Cauchy and the Cosserat continuum exhibit the same load-displacement curves, with no mesh sensitivity, when a perfect plastic and associated behaviour is considered. However the introduction of a very non linear softening results in mesh sensitivity for the Cauchy medium, whilst the such effect emerges for the Cosserat.

The set of analyses performed with the Mohr-Coulomb, Matsuoka-Nakai and Lade-Duncan materials shows that the Cosserat continuum is effective in removing mesh sensitivity, structural softening and early crush of the analyses when non associated flow is considered.

Appendix A Finite Elements formulation

The proposed Finite Elements (FE) formulation is based on a spatial discretization of the fields $\mathbf{u}$ and $\mathbf{\theta}$, whose nodal values are contained in the vector of the generalized displacements $\hat{\mathbf{u}}_g$. In the general three-dimensional case it is a vector of $6\hat{n}$ components, $\hat{n}$ being the total number of nodes of the element, which reduces to $3\hat{n}$ for planar problems.

The spatial discretization is based on the choice of the shape functions $N^{(i)}(\xi, \eta, \zeta)$, where $i = 1, \ldots, \hat{n}$, with $\xi = [-1, 1], \eta = [-1, 1], \zeta = [-1, 1]$ indicate the intrinsic parent element coordinates. The same shape functions are adopted to discretize both the geometry (i.e., to map the real coordinates $\mathbf{x}$ with respect to the intrinsic coordinates $\mathbf{\xi}$) and the generalized displacements $\mathbf{u}_g$. It is then assumed:

$$\mathbf{x}(\xi, \eta, \zeta) = \sum_{i=1}^{\hat{n}} N^{(i)}(\xi, \eta, \zeta) \hat{\mathbf{x}}^{(i)}$$

$$\mathbf{u}_g(\xi, \eta, \zeta) = \begin{bmatrix} \mathbf{u}(\xi, \eta, \zeta) \\ \mathbf{\theta}(\xi, \eta, \zeta) \end{bmatrix} = \sum_{i=1}^{\hat{n}} N^{(i)}(\xi, \eta, \zeta) \hat{\mathbf{u}}^{(i)}_g$$ (40)
where \( \hat{x} \) and \( \hat{u}_g \) are respectively the vectors of the coordinates and of the
generalized displacements of the \( i \)-th node. Once this discretization
has been adopted, the vectors \( \hat{x}(\xi, \eta, \zeta) \), \( \hat{u}(\xi, \eta, \zeta) \) and \( \hat{u}_g(\xi, \eta, \zeta) \)
containing the components of the tensors \( \hat{x}(\xi, \eta, \zeta) \), \( \hat{u}(\xi, \eta, \zeta) \) and \( \hat{u}_g(\xi, \eta, \zeta) \)
respectively can be computed as a function of the nodal values of the
generalized displacements \( \hat{u}_g \) as:

\[
\begin{align*}
\hat{x}(\xi, \eta, \zeta) &= B(\xi, \eta, \zeta) \hat{u}_g \\
\hat{u}(\xi, \eta, \zeta) &= W(\xi, \eta, \zeta) \hat{u}_g \\
\hat{u}_g(\xi, \eta, \zeta) &= M(\xi, \eta, \zeta) \hat{u}_g
\end{align*}
\]

where the matrices \( B(\xi, \eta, \zeta) \), \( W(\xi, \eta, \zeta) \) and \( M(\xi, \eta, \zeta) \) are functions of the
assumed shape functions and of their spatial derivatives. The complete
description of these matrices for the plane strain case is reported in Appendix
D.

Substituting Eqs. (41) into the internal energy,

\[
\Psi = \int d\Psi = \int (\sigma_{sym} : \hat{e} + s_{skw} : \hat{w} + \mu : \hat{\chi})
\]

yields

\[
W_{int} = \int_{\Omega} (B^T \hat{\sigma}_{sym} + W^T \hat{s}_{skw} + M^T \hat{\mu}) \delta \hat{u}_g dV
\]

where \( \hat{\sigma}_{sym} \), \( \hat{s}_{skw} \) and \( \hat{\mu} \) are the vectors containing the components of the
tensors \( \sigma_{sym} \), \( s_{skw} \) and \( \mu \) respectively. To obtain the internal nodal forces
\( \hat{F}_{int} \) one must differentiate this last expression with respect to the variation
of the nodal variables \( \delta \hat{u}_g \)

\[
\hat{F}_{int} = \int_{\Omega} (B^T \hat{\sigma}_{sym} + W^T \hat{s}_{skw} + M^T \hat{\mu}) dV
\]

The integration of this last equation requires the transformation between
real and intrinsic coordinate system, following the standard approach (see
for instance [17]) and is here omitted for sake of brevity. The consistent
stiffness matrix \( K \) is necessary in a FE approach, and it is specifically
required to assure second-order convergence of the Newton-Raphson scheme
employed to solve the nonlinear algebraic system \( \hat{F}_{int} = \hat{F}_{ext} \). It is obtained
differentiating Eq. (44) with respect to the nodal variables \( \hat{u}_g \), and it is
equal to:

\[
K = \int_{\Omega} \left[ B^T \left( \frac{\partial \sigma_{sym}}{\partial \hat{e}} B + \frac{\partial \sigma_{sym}}{\partial \hat{w}} W + \frac{\partial \sigma_{sym}}{\partial \hat{\chi}} M \right) \\
+ W^T \left( \frac{\partial s_{skw}}{\partial \hat{e}} B + \frac{\partial s_{skw}}{\partial \hat{w}} W + \frac{\partial s_{skw}}{\partial \hat{\chi}} M \right) \\
+ M^T \left( \frac{\partial \mu}{\partial \hat{e}} B + \frac{\partial \mu}{\partial \hat{w}} W + \frac{\partial \mu}{\partial \hat{\chi}} M \right) \right] dV
\]

28
where the matrices \((\partial \bar{\sigma}_{\text{sym}}/\partial \bar{\varepsilon}), (\partial \bar{\sigma}_{\text{sym}}/\partial \bar{\omega}), (\partial \bar{\sigma}_{\text{sym}}/\partial \bar{\chi}), (\partial \bar{s}_{\text{skw}}/\partial \bar{\varepsilon}), (\partial \bar{s}_{\text{skw}}/\partial \bar{\omega}), (\partial \bar{s}_{\text{skw}}/\partial \bar{\chi}), (\partial \bar{\mu}/\partial \bar{\varepsilon}), (\partial \bar{\mu}/\partial \bar{\omega}), (\partial \bar{\mu}/\partial \bar{\chi})\) contain the components of the fourth-order tensors \((\partial \tilde{\sigma}_{\text{sym}}/\partial \tilde{\varepsilon}), (\partial \tilde{\sigma}_{\text{sym}}/\partial \tilde{\omega}), (\partial \tilde{\sigma}_{\text{sym}}/\partial \tilde{\chi}), (\partial \tilde{s}_{\text{skw}}/\partial \tilde{\varepsilon}), (\partial \tilde{s}_{\text{skw}}/\partial \tilde{\omega}), (\partial \tilde{s}_{\text{skw}}/\partial \tilde{\chi}), (\partial \tilde{\mu}/\partial \tilde{\varepsilon}), (\partial \tilde{\mu}/\partial \tilde{\omega})\) and \((\partial \tilde{\mu}/\partial \tilde{\chi})\), respectively. These tensors are the jacobians of the stresses with respect to the strains and, in order to achieve quadratic convergence, they must be computed consistently with the stress integration algorithm.

\]

\[
\frac{\partial q}{\partial \theta} = \frac{\partial r}{\partial \theta_s} - 3G \left( \hat{\Gamma} \frac{\partial \Delta \lambda}{\partial \theta_s} + \Delta \lambda \hat{\Gamma}' \right) \tag{49}
\]

\[
\frac{\partial f}{\partial \theta} = \left( \Gamma' q + \Gamma \frac{\partial q}{\partial \theta} \right) + M \frac{\partial p}{\partial \theta_s} - \frac{\partial \sigma_0}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \theta_s} \tag{50}
\]

**Appendix C** Consistent Jacobian operators

**C.0.1** Consistent operator for the linear elastic response

In case of linear elastic response, the stresses \(\tilde{\sigma}\) and couple-stresses \(\tilde{\mu}\) at the end of the increment coincide with their respective elastic predictors \(\tilde{\sigma}^*\) and \(\tilde{\mu}^*\) and the consistent tangent operators coincide with the elastic fourth order stiffness tensors.

**C.0.2** Consistent operator for the first return algorithm

By differentiating Eqs. \((31)\)

\[
\frac{\partial \sigma_{\text{sym}}}{\partial \varepsilon} = \frac{1}{q^*} \left( s^*_{\text{sym}} \otimes \frac{\partial q}{\partial \varepsilon} \right) - 3G \frac{q^3}{q^*} \left( s^*_{\text{sym}} \otimes s^*_{\text{sym}} \right) + 2G \frac{q^3}{q^*} \tilde{I}_d + \left( I \otimes \frac{\partial p}{\partial \varepsilon} \right) \tag{51}
\]

\[
\frac{\partial \sigma_{\text{sym}}}{\partial \omega} = \frac{1}{q^*} \left( s^*_{\text{sym}} \otimes \frac{\partial q}{\partial \omega} \right) - 3G \frac{q^3}{q^*} \left( s^*_{\text{sym}} \otimes s^*_{\text{skw}} \right) + \left( I \otimes \frac{\partial p}{\partial \omega} \right) \tag{52}
\]

\[
\frac{\partial \sigma_{\text{sym}}}{\partial \chi} = \frac{1}{q^*} \left( s^*_{\text{sym}} \otimes \frac{\partial q}{\partial \chi} \right) - 3G \frac{q^3}{q^*} \left( s^*_{\text{sym}} \otimes \mu^* \right) + \left( I \otimes \frac{\partial p}{\partial \chi} \right) \tag{53}
\]
and by differentiating Eq. [32], using the second, third and forth of Eq. 30

\[
\frac{\partial \mathbf{s}_{\text{skw}}}{\partial \varepsilon} = \frac{1}{q^\ast} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \frac{\partial q}{\partial \varepsilon} \right) - 3G \frac{q}{q^\ast} \frac{\partial}{\partial \varepsilon} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \mathbf{s}^\ast_{\text{sym}} \right) \\
\frac{\partial \mathbf{s}_{\text{skw}}}{\partial \omega} = \frac{1}{q^\ast} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \frac{\partial q}{\partial \omega} \right) - 3G \frac{q}{q^\ast} \frac{\partial}{\partial \omega} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \mathbf{s}^\ast_{\text{skw}} \right) + 2G_c \frac{q}{q^\ast} \mathbf{I} \\
(52) \\
\frac{\partial \mathbf{s}_{\text{skw}}}{\partial \chi} = \frac{1}{q^\ast} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \frac{\partial q}{\partial \chi} \right) - 3G \frac{q}{q^\ast} \frac{\partial}{\partial \chi} \left( \mathbf{s}^\ast_{\text{skw}} \otimes \mathbf{\mu}^\ast \right) \\
\frac{\partial \mathbf{s}_{\text{skw}}}{\partial \chi} = \frac{1}{q^\ast} \left( \mathbf{\mu}^\ast \otimes \frac{\partial q}{\partial \chi} \right) - 3G \frac{q}{q^\ast} \left( \mathbf{\mu}^\ast \otimes \mathbf{\mu}^\ast \right)
\]

\[
\frac{\partial \mathbf{\mu}}{\partial \varepsilon} = \frac{1}{q^\ast} \left( \mathbf{\mu}^\ast \otimes \frac{\partial q}{\partial \varepsilon} \right) - 3G \frac{q}{q^\ast} (\mathbf{\mu}^\ast \otimes \mathbf{s}^\ast_{\text{sym}}) \\
\frac{\partial \mathbf{\mu}}{\partial \omega} = \frac{1}{q^\ast} \left( \mathbf{\mu}^\ast \otimes \frac{\partial q}{\partial \omega} \right) - 3G \frac{q}{q^\ast} (\mathbf{\mu}^\ast \otimes \mathbf{s}^\ast_{\text{skw}}) \\
\frac{\partial \mathbf{\mu}}{\partial \chi} = \frac{1}{q^\ast} \left( \mathbf{\mu}^\ast \otimes \frac{\partial q}{\partial \chi} \right) - 3G \frac{q}{q^\ast} (\mathbf{\mu}^\ast \otimes \mathbf{\mu}^\ast) \\
(53)
\]

Where the required derivatives are

\[
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \varepsilon} = \frac{\partial p(\varepsilon, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \varepsilon} = \frac{\partial p}{\partial \varepsilon} + \frac{\partial p}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \varepsilon} = K \left( \mathbf{I} - \mathbf{M} \frac{\partial \Delta \lambda}{\partial \varepsilon} \right) \\
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \omega} = \frac{\partial p(\varepsilon, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \omega} = \frac{\partial p}{\partial \omega} + \frac{\partial p}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \omega} = -K M \frac{\partial \Delta \lambda}{\partial \omega} \\
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \chi} = \frac{\partial p(\varepsilon, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \chi} = \frac{\partial p}{\partial \chi} + \frac{\partial p}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \chi} = -K M \frac{\partial \Delta \lambda}{\partial \chi} \\
(54)
\]

\[
\frac{\partial q(\varepsilon, \omega, \chi)}{\partial \varepsilon} = \frac{\partial q(\varepsilon, \omega, \chi, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \varepsilon} = \frac{\partial q}{\partial \varepsilon} + \frac{\partial q}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \varepsilon} = 3G \left( \frac{s_{\text{sym}}}{q^\ast} - \hat{\Gamma} \frac{\partial \Delta \lambda}{\partial \varepsilon} \right) \\
\frac{\partial q(\varepsilon, \omega, \chi)}{\partial \omega} = \frac{\partial q(\varepsilon, \omega, \chi, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \omega} = \frac{\partial q}{\partial \omega} + \frac{\partial q}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \omega} = 3G \left( \frac{s_{\text{skw}}}{q^\ast} - \hat{\Gamma} \frac{\partial \Delta \lambda}{\partial \omega} \right) \\
\frac{\partial q(\varepsilon, \omega, \chi)}{\partial \chi} = \frac{\partial q(\varepsilon, \omega, \chi, \Delta \lambda(\varepsilon, \omega, \chi))}{\partial \chi} = \frac{\partial q}{\partial \chi} + \frac{\partial q}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \chi} = 3G \left( \frac{\mu^*}{q^\ast} - \hat{\Gamma} \frac{\partial \Delta \lambda}{\partial \chi} \right) \\
(55)
\]
\[ \frac{\partial p}{\partial \Delta \lambda} = -K \dot{M} \]  
\[ \frac{\partial q}{\partial \Delta \lambda} = -3\dot{G} (\theta^*_s) \]  
\[ \frac{\partial \Delta \lambda}{\partial \xi} = -\frac{\partial f}{\partial \Delta \lambda} = \frac{3G \frac{s^*_{sym}}{q^*} \Gamma (\theta^*_s) + MKI}{3G \dot{\Gamma} (\theta^*_s) \Gamma (\theta^*_s) + K \dot{M} + \frac{\partial \sigma_0}{\partial \Delta \lambda}} \]  
\[ \frac{\partial \Delta \lambda}{\partial \omega} = -\frac{\partial f}{\partial \omega} = \frac{3G \frac{s^*_{skw}}{q^*} \Gamma (\theta^*_s)}{3G \dot{\Gamma} (\theta^*_s) \Gamma (\theta^*_s) + K \dot{M} + \frac{\partial \sigma_0}{\partial \Delta \lambda}} \]  
\[ \frac{\partial \Delta \lambda}{\partial \chi} = -\frac{\partial f}{\partial \chi} = \frac{3G \frac{\mu^*}{q^*} \Gamma (\theta^*_s)}{3G \dot{\Gamma} (\theta^*_s) \Gamma (\theta^*_s) + K \dot{M} + \frac{\partial \sigma_0}{\partial \Delta \lambda}} \]  
\[ \frac{\partial f}{\partial \Delta \lambda} = -3\dot{G} (\theta^*_s) \Gamma (\theta^*_s) - K \dot{M} - \frac{\partial \sigma_0}{\partial \Delta \lambda} \]  

C.0.3 Consistent operator for the second return algorithm

The construction of the consistent tangent operator in the general case of the second return algorithm requires the evaluation of the derivative of Eq. (34) with respect to \( \tilde{\epsilon} \)

\[ \frac{\partial \sigma_{sym}}{\partial \xi} = \sum_{i=I,II,III} \left( b_i^* \otimes \frac{\partial \sigma_i}{\partial \xi} \right) + \sigma_i \Omega^*_i \]  

where \( \Omega^*_i = \left( \frac{\partial b^*_i}{\partial \xi} \right) \) is the spin of the principal directions. Since, at variance with standard approaches, all principal stresses in the general case of the second return algorithm are distinct, and the principal directions of the symmetric stress state \( \sigma_{sym} \) at time \( t_{n+1} \) coincide with those of its predictor \( \sigma_{sym}^* \) or, equivalently, of \( \xi^* \), the evaluation of \( \Omega^*_i \) following Miehe [8] is simply

\[ \Omega^*_i = \frac{\partial b^*_i}{\partial \epsilon} = \frac{\partial b^*_i}{\partial \epsilon^*} = \frac{\partial \epsilon^*_i}{\partial \epsilon^*_i \otimes \epsilon^*_i} \]  

The derivatives of \( \sigma_{sym} \) with respect the other Cosserat strain tensors is similarly obtained from Eq. (34)

\[ \frac{\partial \sigma_{sym}}{\partial \omega} = \sum_{i=I,II,III} \left( b_i^* \otimes \frac{\partial \sigma_i}{\partial \omega} \right) \]  
\[ \frac{\partial \sigma_{sym}}{\partial \chi} = \sum_{i=I,II,III} \left( b_i^* \otimes \frac{\partial \sigma_i}{\partial \chi} \right) \]
The others consistent jacobians operators are constructed by deriving the third, fourth and fifth of Eqs. (23) with respect to each of the Cosserat strain tensors

\[
\frac{\partial s_{skw}}{\partial \varepsilon} = s_{skw}^* \otimes \left( \frac{1}{r} \frac{\partial q}{\partial \varepsilon} - \frac{q}{r^2} \frac{\partial r}{\partial \varepsilon} \right)
\]

\[
\frac{\partial s_{skw}}{\partial \omega} = s_{skw}^* \otimes \left( \frac{1}{r} \frac{\partial q}{\partial \omega} - \frac{q}{r^2} \frac{\partial r}{\partial \omega} \right) + 2G_c q I
\]

\[
\frac{\partial s_{skw}}{\partial \chi} = s_{skw}^* \otimes \left( \frac{1}{r} \frac{\partial q}{\partial \chi} - \frac{q}{r^2} \frac{\partial r}{\partial \chi} \right) - 2G_c q I
\]

whilst all required derivatives are

Let consider that the three invaria

\[
\frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} = 3G \cos^2(\theta_s^* - \theta_s) s_{sym}^* \frac{\partial q}{\partial \varepsilon} - \frac{\partial r}{\partial \theta_s} \frac{\partial \theta_s^*}{\partial \varepsilon}
\]

\[
\frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} = 3G s_{skw}^* \frac{\partial q}{\partial \omega}
\]

\[
\frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} = 3G \mu^* \frac{\partial q}{\partial \chi}
\]

\[
\frac{\partial \Delta \lambda}{\partial \varepsilon} = \Delta \lambda \left[ 6G \frac{s_{sym}^*}{q_s^*} - \frac{1}{r} \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} + \frac{2}{\tan(2\theta_s^* - 2\theta_s)} \frac{\partial \theta_s^*}{\partial \varepsilon} \right]
\]

\[
\frac{\partial \Delta \lambda}{\partial \omega} = -\frac{\Delta \lambda}{r} \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega}
\]

\[
\frac{\partial \Delta \lambda}{\partial \chi} = -\frac{\Delta \lambda}{r} \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi}
\]

\[
\frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} = K \left( I - M \right) \frac{\partial \Delta \lambda}{\partial \varepsilon}
\]

\[
\frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} = -KM \frac{\partial \Delta \lambda}{\partial \omega}
\]

\[
\frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} = -KM \frac{\partial \Delta \lambda}{\partial \chi}
\]
\[
\frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} = \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} - 3G \frac{\partial \Delta \lambda}{\partial \varepsilon} \\
\frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} = \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} - 3G \frac{\partial \Delta \lambda}{\partial \omega} \\
\frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} = \frac{\partial r(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} - 3G \frac{\partial \Delta \lambda}{\partial \chi}
\]

(69)

\[
\frac{\partial \theta_s}{\partial \varepsilon} = -\frac{\frac{\partial f}{\partial \varepsilon}}{\frac{\partial f}{\partial \theta_s}} = -\frac{1}{\frac{\partial f}{\partial \theta_s}} \left( \Gamma \frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} + M \frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \varepsilon} \right) - \frac{\partial \sigma_0}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \varepsilon}
\]

(70)

\[
\frac{\partial \theta_s}{\partial \omega} = -\frac{\frac{\partial f}{\partial \omega}}{\frac{\partial f}{\partial \theta_s}} = -\frac{1}{\frac{\partial f}{\partial \theta_s}} \left( \Gamma \frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} + M \frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \omega} \right) - \frac{\partial \sigma_0}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \omega}
\]

\[
\frac{\partial \theta_s}{\partial \chi} = -\frac{\frac{\partial f}{\partial \chi}}{\frac{\partial f}{\partial \theta_s}} = -\frac{1}{\frac{\partial f}{\partial \theta_s}} \left( \Gamma \frac{\partial q(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} + M \frac{\partial p(\theta_s, \varepsilon, \omega, \chi)}{\partial \chi} \right) - \frac{\partial \sigma_0}{\partial \Delta \lambda} \frac{\partial \Delta \lambda}{\partial \chi}
\]

(71)

\[
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \varepsilon} = \frac{\partial p(\varepsilon, \omega, \chi, \theta_s(\varepsilon, \omega, \chi))}{\partial \varepsilon} = \frac{\partial p}{\partial \varepsilon} + \frac{\partial p}{\partial \theta_s} \frac{\partial \theta_s}{\partial \varepsilon}
\]

\[
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \omega} = \frac{\partial p(\varepsilon, \omega, \chi, \theta_s(\varepsilon, \omega, \chi))}{\partial \omega} = \frac{\partial p}{\partial \omega} + \frac{\partial p}{\partial \theta_s} \frac{\partial \theta_s}{\partial \omega}
\]

\[
\frac{\partial p(\varepsilon, \omega, \chi)}{\partial \chi} = \frac{\partial p(\varepsilon, \omega, \chi, \theta_s(\varepsilon, \omega, \chi))}{\partial \chi} = \frac{\partial p}{\partial \chi} + \frac{\partial p}{\partial \theta_s} \frac{\partial \theta_s}{\partial \chi}
\]

(72)
The computation of the derivatives of the stress invariants $p$, $q$, $\theta_s$ and of the principal stress components with respect to the strain increments is standard, and it is reported in Appendix.

### C.0.4 Consistent operator for the third return algorithm

\[
\frac{\partial \sigma_{\text{sym}}}{\partial \varepsilon} = K \left[ 1 - \left( \frac{MMK}{K \Delta \dot{M} + \frac{\partial \sigma_0}{\partial \Delta \lambda}} \right) \right] \tilde{\gamma} \tag{76}
\]

\[
\frac{\partial \sigma_{\text{sym}}}{\partial \omega} = \frac{\partial \sigma_{\text{sym}}}{\partial \chi} = 0, \quad \frac{\partial s_{\text{skw}}}{\partial \varepsilon} = \frac{\partial s_{\text{skw}}}{\partial \omega} = \frac{\partial s_{\text{skw}}}{\partial \chi} = 0, \quad \frac{\partial \mu}{\partial \varepsilon} = \frac{\partial \mu}{\partial \omega} = 0 \tag{77}
\]
\[ \frac{\partial \mu}{\partial \chi} = 0 \]  

(78)

**Appendix D  Matrices for 2D plane strain FE**

By ordering the generalized nodal displacements components in the vector

\[ u_y = [u_x^{(1)} u_y^{(1)} \theta_z^{(1)} \ldots u_x^{(\hat{n})} u_y^{(\hat{n})} \theta_z^{(\hat{n})}]^T \]  

(79)

one can compute the vectors \( \bar{\varepsilon} \) and \( \bar{\omega} \) containing the components of the tensors \( \tilde{\varepsilon} \) and \( \tilde{\omega} \) respectively as:

\[ \bar{\varepsilon} = \begin{bmatrix} \frac{\partial u_x}{\partial x} & \frac{\partial u_y}{\partial y} & 0 & 1 & 2 \left( \frac{\partial u_y}{\partial x} + \frac{\partial u_x}{\partial y} \right) \end{bmatrix}^T = B \bar{u}_g \]  

(80)

\[ \bar{\omega} = \begin{bmatrix} 0 & 0 & 0 & \frac{1}{2} \left( \frac{\partial u_y}{\partial x} - \frac{\partial u_x}{\partial y} \right) - \theta_z & 1 \frac{1}{2} \left( \frac{\partial u_x}{\partial y} - \frac{\partial u_y}{\partial x} \right) + \theta_z \end{bmatrix}^T = W \bar{u}_g \]  

(81)

where:

\[ B = \begin{bmatrix} \frac{\partial N^{(1)}}{\partial x} & 0 & 0 & \ldots & \frac{\partial N^{(\hat{n})}}{\partial x} & 0 & 0 \\ 0 & \frac{\partial N^{(1)}}{\partial y} & 0 & \ldots & 0 & \frac{\partial N^{(\hat{n})}}{\partial y} & 0 \\ 0 & 0 & \ldots & 0 & \frac{\partial N^{(1)}}{\partial y} & \frac{\partial N^{(\hat{n})}}{\partial y} & 0 \\ \frac{1}{2} \frac{\partial N^{(1)}}{\partial x} & \frac{1}{2} \frac{\partial N^{(1)}}{\partial y} & 0 & \ldots & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial x} & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial y} & 0 \\ \frac{1}{2} \frac{\partial N^{(1)}}{\partial y} & \frac{1}{2} \frac{\partial N^{(1)}}{\partial x} & 0 & \ldots & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial y} & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial x} & 0 \end{bmatrix} \]  

(82)

\[ W = \begin{bmatrix} 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\ 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\ 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\ \frac{1}{2} \frac{\partial N^{(1)}}{\partial y} & \frac{1}{2} \frac{\partial N^{(1)}}{\partial x} & -N^{(1)} & \ldots & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial y} & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial x} & -N^{(\hat{n})} \\ \frac{1}{2} \frac{\partial N^{(1)}}{\partial y} & \frac{1}{2} \frac{\partial N^{(1)}}{\partial x} & N^{(1)} & \ldots & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial y} & \frac{1}{2} \frac{\partial N^{(\hat{n})}}{\partial x} & N^{(\hat{n})} \end{bmatrix} \]  

(83)

The vector \( \chi \) containing the components of the tensor \( \chi \) can be computed as:

\[ \chi = \begin{bmatrix} \frac{\partial \theta_z}{\partial x} & \frac{\partial \theta_z}{\partial y} \end{bmatrix}^T = M \bar{u}_g \]  

(84)

\[ M = \begin{bmatrix} 0 & 0 & \frac{\partial N^{(1)}}{\partial x} & \ldots & 0 & 0 & \frac{\partial N^{(\hat{n})}}{\partial x} \\ 0 & 0 & \frac{\partial N^{(1)}}{\partial y} & \ldots & 0 & 0 & \frac{\partial N^{(\hat{n})}}{\partial y} \end{bmatrix} \]  

(85)
