SATO–TATE GROUPS OF ABELIAN THREEFOLDS

FRANCESC FITÉ, KIRAN S. KEDLAYA, AND ANDREW V. SUTHERLAND

Abstract. Given an abelian variety over a number field, its Sato–Tate group is a compact Lie group which conjecturally controls the distribution of Euler factors of the $L$-function of the abelian variety. It was previously shown by Fité, Kedlaya, Rotger, and Sutherland that there are 52 groups (up to conjugation) that occur as Sato–Tate groups of abelian surfaces over number fields; we show here that for abelian threefolds, there are 410 possible Sato–Tate groups, of which 33 are maximal with respect to inclusions of finite index. We enumerate candidate groups using the Hodge-theoretic construction of Sato–Tate groups, the classification of degree-3 finite linear groups by Blichfeldt, Dickson, and Miller, and a careful analysis of Shimura’s theory of CM types that rules out 23 candidate groups; we cross-check this using extensive computations in GAP, SAGEMath, and Magma. To show that these 410 groups all occur, we exhibit explicit examples of abelian threefolds realizing each of the 33 maximal groups; we also compute moments of the corresponding distributions and numerically confirm that they are consistent with the statistics of the associated $L$-functions.

1. Introduction

1.1. Sato–Tate groups of abelian varieties. Let $A$ be an abelian variety of dimension $g$ defined over a number field $k$. Associated to $A$ is the $L$-function

$$L(A, s) = \prod_{p} L_p(Norm(p)^{-s})^{-1}$$

where for each prime ideal $p$ of the ring of integers $\mathcal{O}_k$ of $k$ at which $A$ has good reduction, $L_p(T)$ is the reverse characteristic polynomial of Frobenius acting on the $\ell$-adic Tate module of $A$ for any prime $\ell$ coprime to $p$. The polynomial $L_p(T)$ has integer coefficients and its roots in $\mathbb{C}$ all lie on the circle $|T| = Norm(p)^{-1/2}$; if one rescales these roots to have norm 1, it is then meaningful to ask whether the resulting polynomials are equidistributed with respect to some measure.

When $A$ is an elliptic curve, the answer to this question is well-known (although partially conjectural). For $A$ with complex multiplication, one can show using Hecke’s theory of Großencharacters that one of exactly two distributions occurs, depending on whether or not the field of complex multiplication is contained in $k$. By contrast, for $A$ without complex multiplication, the Sato–Tate conjecture predicts that exactly one distribution occurs, and this is known when $k$ is a totally real field [HSBT10], [BLGG11] or a CM field [AAC...18].

These equidistribution assertions can be made in a somewhat more robust fashion, which generalizes to $A$ of arbitrary dimension: one can define a certain compact Lie subgroup of $USp(2g)$ associated to $A$ and a sequence of conjugacy classes therein whose characteristic polynomials are the normalized $L$-polynomials, which are equidistributed for the image of Haar measure. The only dependence on $A$ is then in the value of this group; for $g = 1$, it is $USp(2) = SU(2)$ for $A$ without complex multiplication, and otherwise is either $SO(2)$ or its...
normalizer in SU(2). Following a recipe of Serre [Ser12] (as expanded upon in [BaK15]), one can give a uniform definition of the group (and the sequence of conjugacy classes therein) applicable in cases where the Mumford–Tate conjecture is known, including all cases with \( g \leq 3 \); we call this group the \emph{Sato–Tate group} of \( A \). One then conjectures a corresponding equidistribution statement, which can be shown (as in [Ser68, §I.A.2]) to follow from the analytic continuation of the \( L \)-functions associated to the various representations of the group; this is the approach taken in the results for elliptic curves cited above. The equidistribution statement can be thought of as an analogue of the Chebotarev density theorem, with the Sato–Tate group playing the role of the Galois group; this analogy can be built out by defining a Galois group associated to an arbitrary motive, as in [Ser94].

Since the Sato–Tate group of a motive is a compact Lie group, one can retain much (but not all) of the same information by keeping track of the identity component and of the group of connected components. The identity component turns out to be invariant under base extension, and so can be interpreted over \( \overline{\mathbb{Q}} \) or even \( \mathbb{C} \); it is closely related to the \emph{Mumford–Tate group} of \( A \). By contrast, the component group is not invariant under base extension: it is canonically isomorphic to the Galois group of a certain extension of the base field, which in many cases (including all of dimension at most 3) is the \emph{endomorphism field} of \( A \), defined as the minimum field of definition of all endomorphisms of the base extension of \( A \) to \( \overline{\mathbb{Q}} \).

1.2. \textbf{Abelian surfaces.} While [Ser94] includes a general form of the Sato–Tate conjecture, it sheds very little light on the set of possible groups or measures that can occur for a particular class of motives. Building on some initial investigations by Kedlaya and Sutherland [KS08, KS09], a comprehensive analysis of Sato–Tate groups of abelian surfaces was undertaken by Fité, Kedlaya, Rotger, and Sutherland [FKRS12]. The Sato–Tate group of an abelian surface is a closed subgroup of USp(4), with equality in the generic case; the classification of [FKRS12] shows that there are 52 conjugacy classes of groups that can occur in general. If one restricts to abelian surfaces over \( \mathbb{Q} \), then by analogy with the case of elliptic curves (where one cannot have complex multiplication defined over the base field) one expects to find somewhat fewer groups, and indeed only 34 of the 52 groups occur over \( \mathbb{Q} \) (but it is possible to find a single number field over which all 52 groups occur; see [FG18].)

We note in passing that potential modularity for abelian surfaces over totally real fields is now known [BCGP18], but this is not enough to prove equidistribution for a generic abelian surface (one with trivial endomorphism ring over \( \overline{\mathbb{Q}} \)); one needs potential modularity also for symmetric powers and other functorial transfers, which seems to be out of reach at the moment. By contrast, for nongeneric abelian surfaces equidistribution results are known in many cases due to work of Fité and Sutherland [FS14], Johansson [Joh17], and Taylor [Tay20], which together cover all nongeneric abelian surfaces over \( \overline{\mathbb{Q}} \); see [Tay20, Remark 3.5].

1.3. \textbf{Abelian threefolds.} We turn now from surfaces to threefolds and state our main result, which was previously announced in [FKS19]. The proof of this theorem occupies most of the present work, which has no logical dependence on [FKS19].

\textbf{Theorem 1.1.} The following statements hold:

\begin{itemize}
  \item[(a)] There are exactly 410 conjugacy classes of closed subgroups of USp(6) that occur as Sato–Tate groups of abelian threefolds over number fields. This includes 14 distinct options for the identity component.
  \item[(b)] Of the groups in (a), 33 are maximal for inclusions of finite index.
\end{itemize}
A corollary of the analysis is that the component group orders which are maximal for divisibility are \(192 = 2^6 \times 3\), \(432 = 2^4 \times 3^3\), and \(336 = 2^4 \times 3 \times 7\). As noted above, these translate into bounds on the degree of the minimal field of definition of all endomorphisms defined over \(\mathbb{Q}\); these are consistent with the upper bounds on this degree given by Silverberg [Sil92] and Guralnick and Kedlaya [GK17], the latter being a sharp bound on the least common multiple of the endomorphism field degrees in a given dimension.

Compared to the case of abelian surfaces, Theorem 1.1 exhibits two notable deficiencies whose resolution we leave to future work. One is that we do not perform an analysis of Galois types as in [FKRS12], and so we make no statements about realizability of particular Sato–Tate groups over particular number fields. The other is that we do not determine which Sato–Tate groups can be realized by Jacobians of genus 3 curves over number fields, or even by principally polarized abelian threefolds; there is some reason to believe that there is a genuine distinction to be made here, in contrast with what happens for abelian surfaces.

1.4. Applying the classification. We insert here a few words about how to apply the classification to determine the Sato–Tate group of a given abelian threefold \(A\). For this discussion, we conflate the Sato–Tate group with its associated distribution; this is harmless in dimension 2, but in dimension 3 this loses a small amount of information (see the discussion of new phenomena below).

As noted above, the Sato–Tate group controls the distribution of normalized \(L\)-polynomials of \(A\), so one can make an empirical determination of the Sato–Tate group by compiling data about normalized \(L\)-polynomials. For the Jacobians of hyperelliptic curves of genus \(\leq 3\), this is done very effectively by Sutherland’s SMALLJAC package [KS08]; this incorporates the technique described in [HS14, HS16] to compute the \(L\)-polynomials in average polynomial time. Similar approaches apply in other cases; see [HMS16] for double covers of pointless conics, [Sut20] for other cyclic covers of \(P^1\), and [CKR20] for hypergeometric motives.

In order to discretize the problem of comparing the observed Sato–Tate distribution of \(A\) to the known candidates, we employ the usual device of working with moment statistics. For the random matrix distribution associated to a linear group \(G\), these statistics carry an additional representation-theoretic meaning: computing a moment statistic amounts to computing the average value of some symmetric polynomial of the eigenvalues of a random matrix from \(G\), and for a polynomial with integer coefficients this corresponds to taking the multiplicity of the trivial character in a certain virtual character of \(G\). In particular, this quantity is necessarily an integer; for Sato–Tate groups, even averaging over any one component of \(G\) yields an integer value (see Definition 3.12).

While in principle moments are sufficient to completely distinguish distributions, for Sato–Tate distributions it is more useful in practice to supplement this data with some additional measurements of the \(L\)-polynomials. In particular, for disconnected groups it is quite common that certain functions of the eigenvalues are constant on certain nonidentity components. A familiar example is that of an elliptic curve with complex multiplication: every prime which is inert in the CM field gives a Frobenius trace of 0, corresponding to the fact that the trace is identically 0 on the nonidentity component of the normalizer of \(SO(2)\) in \(SU(2)\). By tracking these statistics in addition to moments, one can make a much more rapid putative determination of the Sato–Tate group than with moments alone.

With the empirical problem well understood, we now turn to the question of making a rigorous determination of the Sato–Tate group of \(A\). One cannot hope to do this purely
from computed \(L\)-polynomials except conditionally on the assumption that various motivic \(L\)-functions admit analytic continuation, functional equation, and the Riemann hypothesis, as these are needed to make the error term effective in the convergence to the Sato–Tate distribution. (see [BFK20, BuK16]). Instead, we propose to compute the endomorphism algebra of \(A\) over \(\mathbb{Q}\), which together with its Galois action completely determines the Sato–Tate group. (Without the Galois action, one only recovers the identity component of the Sato–Tate group.) A good practical approach to this problem has been introduced by Costa, Mascot, Sijsling, and Voight [CMSV19], building on earlier work of van Wamelen; see [CS19] for an implementation of this approach.

Finally, note that any \textit{a priori} knowledge about the structure of \(A\) can potentially be fed into the previous calculations. In particular, if \(A\) is the Jacobian of a curve, then the automorphisms of the curve generate a subalgebra of the endomorphism algebra of \(A\) which restricts the Sato–Tate group to a certain subgroup of \(\text{USp}(6)\); see Proposition 7.1. For example, if \(A\) is the Jacobian of a Picard curve, then its Sato–Tate group is contained in the normalizer of \(\text{U}(3)\) in \(\text{USp}(6)\).

1.5. \textbf{New phenomena.} We mention some examples of phenomena that appear for abelian threefolds but not for abelian surfaces.

- In dimension 3, one finds component groups that are not solvable, namely the simple group of order 168 and its double cover. These appeared previously in the analysis of Sato–Tate groups of twists of the Klein quartic [FLS18].
- One also finds for the first time component groups which are too big to be explained by twisting curves, notably the Hessian group of order 216 (which exceeds the Hurwitz bound of 168 for the automorphism group of a genus 3 curve) and its double cover.
- While in dimension 2 it is nearly automatic that every Sato–Tate group that can be realized occurs for the Jacobian of a curve, this is less clear in dimension 3. In some cases, there appears to be an obstruction even to constructing a realization that admits a principal polarization, although we do not attempt to prove this here.
- On a further related note, for abelian threefolds, we expect (but have not yet confirmed) that certain Sato–Tate groups can only occur in cases where the abelian threefold is isogenous to the cube of a \textit{particular} CM elliptic curve; in particular, the CM field of this curve must occur within the endomorphism field of the threefold. The corresponding phenomenon for abelian surfaces is precluded by the work of Fité and Guitart [FG18, Theorem 1.6], who exhibit a single number field over which all 52 possible Sato–Tate groups occur.
- Whereas the 52 Sato–Tate groups of abelian surfaces correspond to 52 distinct distributions of normalized \(L\)-polynomials, there is one pair of Sato–Tate groups of abelian threefolds which give rise to identical distributions of \(L\)-polynomials, but are not isomorphic as abstract groups; in fact, their component groups are not isomorphic (see Proposition 6.16). One might compare this to the phenomenon of nonisomorphic number fields with the same zeta function [Per77]; see Remark 6.19.
- In dimension 3, the joint coefficient distribution of the normalized \(L\)-polynomials is not determined by the individual coefficient distributions of the normalized \(L\)-polynomials, as is the case in dimension 2. This was already reported in [FLS18].
1.6. **Ingredients of the classification: upper bound.** The proof of Theorem 1.1 involves an upper bound, to show that every Sato–Tate group occurs among our 410 candidates, and a lower bound, to show that each of these candidates can occur. We summarize here the key ingredients in the upper bound.

- The classification of identity components follows from the classification of endomorphism algebras of abelian threefolds over $\mathbb{C}$ (§3.5).

- For the classification of component groups, we use the “Sato–Tate axioms” from [FKRS12] (§3.4) to compile a list of candidate extensions of each of the 14 possible identity components (see §4 for all cases except $\text{U}(1)_3$). In the cases where the identity component has dimension at least 2, this is mostly straightforward given the results of [FKRS12]. One key exception is that when the identity component is $\text{U}(1) \times \text{U}(1) \times \text{U}(1)$, a direct enumeration of groups yields 33 candidates, but a more refined analysis of CM types in the sense of Shimura [Shi71] reduces this list to 13 groups. This is comparable to a feature of [FKRS12]: there the direct group-theoretic classification yields 55 groups, of which 8 have identity component $\text{U}(1)_3$, but only 5 of the latter survive the matching of Galois types.

- As one might guess from the case of abelian surfaces, the classification of component groups is by far the most complicated when the identity component is the one-dimensional diagonal torus $\text{U}(1)_3$ (§5). To make this classification, we use the description of (and to some extent the notation for) finite subgroups of $\text{PGL}_3(\mathbb{C})$ given by Blichfeldt, Dickson, and Miller [MBD61, Chapter XII]. Since $\text{U}(1)_3$ has index 2 in its normalizer in $\text{USp}(6)$, we must also figure out what double covers arise from a given subgroup of $\text{PGL}_3(\mathbb{C})$; this is a rather delicate calculation involving the normalizers of these groups in $\text{PGL}_3(\mathbb{C})$.

- In light of the complexity of the argument, we make a number of computer calculations to verify some key steps. It would be desirable to give a computer verification of the entire classification, but we are not aware of any software that can handle compact Lie groups at the necessary level of generality.

1.7. **Ingredients of the classification: lower bound.** We now summarize the ingredients of the lower bound aspect of Theorem 1.1. A complete proof of this direction was already included in the announcement in [FKS19], but our approach here contains some new features.

- To show that the candidate Sato–Tate groups all occur, we restrict attention to the 33 maximal groups in the classification. Of these, about half arise from products of elliptic curves with abelian surfaces, for which we may rely on the analysis from [FKRS12] to obtain examples. Most of the others have identity component $\text{U}(1)_3$ (the diagonal torus in $\text{U}(1) \times \text{U}(1) \times \text{U}(1)$) and can be obtained by twisting the cube of a CM elliptic curve, using a similar framework as has been used previously for curves [FS14] and more recently for abelian varieties [GK17].

- We compute moments for the random matrix distribution corresponding to each possible Sato–Tate group, using the Weyl character formula (§6). As noted above, there is one pair of groups (neither maximal) that give rise to identical distributions, so there are only 409 possible distributions for normalized $L$-polynomials of an abelian threefold over a number field.
• For each of the 33 maximal groups, we select an explicit example realizing this Sato–Tate group (Table 11) and compare the distribution arising from its \( L \)-function to the predicted one (§7.4). This provides an empirical confirmation of the lower bound. In some cases we provide multiple examples of distinct shapes, such as a product construction and a genus 3 Jacobian.

• We also confirm the matching of examples with Sato–Tate groups rigorously (§8). Here we build upon existing analyses of twists of genus 3 curves with extremal automorphism groups [ACLLM18, FLS18, FS16] (§7.1); we also find some novel examples of genus 2 curves whose Jacobians have quaternionic multiplication (Example 8.11).

1.8. Tables, code, and data. Given the complexity of the classification of Sato–Tate groups of abelian threefolds, it would be neither practical nor useful to include tables at the same level of detail as in [FKRS12, §6]. We have elected instead to present the relevant data in several alternate forms.

• Table 8 lists the possible identity components of Sato–Tate groups of abelian threefolds, as they correspond to real geometric endomorphism algebras, and indicates how many Sato–Tate groups appear in the classification for a given identity component. This table also introduces a shorthand notation by which each identity component is labeled by a letter called its absolute type; for instance, the generic case \( \text{USp}(6) \) corresponds to absolute type \( A \).

• Table 9 lists, for each possible connected Sato–Tate group of an abelian threefold, a certain numerical statistic called the 3-diagonal (see Definition 6.2). For disconnected groups, see instead the LMFDB (see below).

• Table 10 lists the possible automorphism groups of genus 3 curves and, for each of these groups, the identity component of the Sato–Tate group of a generic curve with this automorphism group. These assignments are verified in Proposition 7.1. Table 11 lists, for each of the 33 maximal groups in Theorem 1.1(ii), the identity component and component group, and one or more examples of abelian threefolds realizing this group as a Sato–Tate group. These assignments have been verified both empirically by comparison of moment statistics, and rigorously by analysis of endomorphism algebras; see §7.4 for the latter. For endomorphism fields, see Table 12.

• We have gathered code referenced in this paper in a GitHub repository [FKS21]. This code depends on GAP [GAP20], MAGMA [Magma], and SAGEMath [Sage]; the latter also uses functionality derived from PARI [Pari]. Components include: presentations of the groups with identity component \( U(1)_3 \) (§5); consistency checks for the classification of groups with identity component \( U(1)_3 \) (§5.13); computation of moment statistics and other numerical invariants (§6); verification of the explicit realizations needed for the lower bound aspect of Theorem 1.1(a) (§8).

• We have created a web site with animated histograms that allow one to observe the convergence of various moment statistics for an explicit realization of each of the 410 groups in Theorem 1.1(a).

• Each of the 410 groups in Theorem 1.1(a) has its own home page in the L-Functions and Modular Forms Database (LMFDB). These pages include explicit generators,
subgroups and supergroups, moment statistics (including the 3-diagonals), and point densities for each group.

1.9. **Abelian varieties of higher dimension.** With the classification of Sato–Tate groups complete for abelian varieties of dimension at most 3, it is natural to ask about additional cases, and in particular abelian fourfolds. Going from threefolds to higher-dimensional abelian varieties brings several new difficulties.

- In order to get started one needs a classification of identity components, or equivalently of Mumford–Tate groups. This has been done for dimension up to 5 by Moonen and Zarhin [MZ99].
- For fourfolds, the number of groups resulting in the classification will run into the thousands, so some additional automation of the classification will be required; in particular, when the identity component is a one-dimensional torus, computing double covers by hand is quite laborious and prone to errors. Such automation should be possible, but will require new ideas.
- Starting in dimension 4, the possible components of the real endomorphism algebra include matrix algebras not only over $\mathbb{R}$ and $\mathbb{C}$, but also over the quaternions.
- Starting in dimension 4, one encounters cases where the Mumford–Tate group is not determined solely by endomorphisms; this phenomenon was first observed by Mumford [Mum69] for simple abelian fourfolds and by Shioda [Shi81, Example 6.1] for nonsimple abelian fourfolds. A related issue is that the Mumford–Tate conjecture is not known for arbitrary fourfolds (see [Zha14] for discussion of the absolutely simple case). Consequently, one must be careful when passing between the Hodge-theoretic and Galois-theoretic definitions of the Sato–Tate group of an abelian fourfold.
- In order to determine the Sato–Tate groups whose identity components are tori, one must extend the analysis of CM types to higher dimensions, where new combinatorial possibilities emerge; for instance, in dimension 4 it is possible to have a CM abelian variety over $\mathbb{Q}$ whose CM field is not a cyclic Galois extension of $\mathbb{Q}$ (it can also be a $D_4$-octic). We give some initial analysis here, but some additional work is needed to extract a precise answer in any given dimension.
- It is possible that the rationality condition is not sufficient due to phenomena involving Schur indices (i.e., the distinction between a representation having traces in $\mathbb{Q}$ versus being defined over $\mathbb{Q}$), which have not appeared in dimensions up to 3.
- In sufficiently large dimensions, certain product groups may be obstructed by the failure of the corresponding endomorphism fields to be linearly disjoint. For instance, this may happen because both factors require complex multiplication by a particular imaginary quadratic field. (That said, the result of [FG18] suggests that this may not occur in dimension 4.)
- In dimension 4, there is no reason to expect that all Sato–Tate groups can be realized using Jacobians of curves. (As a reminder, it remains unclear whether this holds even in dimension 3.) Consequently, some new work would be needed in order to compute the $L$-functions of sufficiently many abelian fourfolds to have a reasonable chance of finding examples of all possible groups; reasonably good algorithms and implementations now exist for general curves [Tui16, Tui18, CT18], but applying these
to an abelian variety would require relating that variety to a Jacobian in some fashion that does not blow up the dimension too much (e.g., using the Prym construction).

- Expanding on the previous point, it is not even clear whether all Sato–Tate groups of abelian fourfolds can be realized using principally polarized abelian fourfolds.

It should be noted that it may be feasible to identify the Sato–Tate groups of individual abelian varieties of a given dimension without a full classification of all Sato–Tate groups that occur in that dimension, thanks to work of Zywina [Zyw20].

In another direction, one can consider motives of weight greater than 1, although this requires some extra care with the foundations (see [BaK16] for odd weight and [BaK21] for even weight). For example, [FKS18] gives a classification of Sato–Tate groups associated to motives of weight 3 with Hodge vector \((1,1,1,1)\) (e.g., the symmetric cube of an elliptic curve). A natural next step would be to consider motives of weight 2 associated to K3 surfaces, starting with those of high Picard number; this can be viewed as including the case of abelian surfaces via the Kummer construction of K3 surfaces. See [EJ21] for some work in this direction.

One can also ask similar questions for abelian varieties (or other motives) over function fields. In this case, the equidistribution problem can be settled using the known analytic properties of \(L\)-functions, as originally observed by Deligne [Del80, Théorème 3.5.3]; the combinatorial problem of classifying images of monodromy representations remains to be settled, but the exact constraints are slightly different due to the absence of archimedean places. This means that Hodge theory no longer plays a role, although \(p\)-adic Hodge theory continues to do so.

1.10. Acknowledgments. Thanks to Armand Brumer, Daniel Bump, Edgar Costa, John Cremona, Everett Howe, Alexander Hulpke, Pınar Kılıçer, Jeroen Hanselman, Elisa Lorenzo García, Jennifer Paulhus, Jean-Pierre Serre, Jeroen Sijsling, Liang Xiao, and David Zywina for helpful discussions. Kedlaya also thanks the organizers of AGCCT 2019 for the invitation to present [FKS19].

Financial support was received as follows: Fité: DGICYT (grants MTM2009-13060-C02-01, MTM2015-63829-P), German Research Council (SFB 701, SFB/TR 45), IAS (NSF grant DMS-1638352 plus additional funds), ERC (grant 682152); Kedlaya: NSF (grants DMS-0545904, DMS-1101343, DMS-1501214, DMS-1802161), DARPA (grant HR0011-09-1-0048), MIT (NEC Fund, Cecil and Ida Green professorship), UC San Diego (Stefan E. Warschawski professorship), Guggenheim Fellowship (fall 2015), IAS (visiting professorship 2018–2019); Sutherland: NSF (grants DMS-1115455, DMS-1522526), Google Cloud Platform (GCP Research Credit Program). All three authors were supported by the Simons Collaboration on Arithmetic Geometry, Number Theory, and Computation (Simons Foundation grant 550033).

Additional hospitality was received as follows: Fité: UC San Diego (February–March 2012); Kedlaya: MSRI (spring 2011, fall 2014, spring 2019), IPAM (spring 2014); Kedlaya and Sutherland: ICERM (fall 2015).

2. Conventions

We start by establishing some conventions that we follow throughout the text.

Throughout, we write \(A\) to denote an abelian variety of dimension \(g \geq 1\) over a number field \(k\). We consistently consider abelian varieties without a preferred choice of polarization,
as the Sato–Tate group does not depend on the choice; but see §7.2 for some discussion of polarizations in the context of twisting powers of elliptic curves.

For \( \ell \) a field extension of \( k \) (not necessarily a number field), write \( A_\ell \) for the base extension of \( A \) from \( k \) to \( \ell \). We commonly use this notation with \( \ell \) being the minimal field of definition of all endomorphisms of \( A_k \); we call this the "endomorphism field" of \( A \) and denote it by \( K \).

We write \( \text{End}(A) \) for the endomorphism ring of \( A \) over \( k \); to denote endomorphisms of a base extension we indicate this explicitly (so \( \text{End}(A_{\mathbb{Q}}) \) is the geometric endomorphism ring). We write \( \text{End}(A)_{\mathbb{Q}} \) and \( \text{End}(A)_{\mathbb{R}} \) for the tensor products \( \text{End}(A) \otimes_{\mathbb{Z}} \mathbb{Q} \) and \( \text{End}(A) \otimes_{\mathbb{Z}} \mathbb{R} \).

For \( C \) a curve over a field, we write \( \text{Jac}(C) \) rather than \( J(C) \) to denote the Jacobian of \( C \). This makes the letter \( J \) available for other uses, such as in the notation for Sato–Tate groups. We use \( \text{Aut}(C) \) to denote the automorphism group of \( C \), and define the "reduced automorphism group" \( \text{Aut}'(C) \) as the quotient of \( \text{Aut}(C) \) by the hyperelliptic involution if one exists and define \( \text{Aut}'(C) := \text{Aut}(C) \) otherwise.

We write \( C_n, D_n, A_n, S_n \) for the cyclic, dihedral, alternating, and symmetric groups of respective orders \( n, 2n, n!/2, n! \) (that is, \( n \) is the degree of the standard permutation representation). In some cases, we will follow the practice of GAP and MAGMA and use the unique (but opaque) compact labels for isomorphism classes of finite groups from the Small Groups library [BEO01]; the label for a group \( G \) always has the form \( (n,i) \) where \( n = \#G \). We hyperlink small group labels to their pages in the GroupNames database [Group] whenever they are available; these pages provide an explicit description of each group.

We present hyperelliptic curves (of any genus) as affine curves in lowercase variables (typically \( y^2 = P(x) \)) and plane quartics as projective curves in uppercase variables (i.e., \( P(X,Y,Z) = 0 \)). We will exploit this typographic choice in order to commingle equations of the two types without risk of confusion. In rare cases, we extend the hyperelliptic convention to other cyclic covers of \( \mathbb{P}^1 \), such as Picard curves. In curve equations, we sometimes write \( P_d(...) \) to indicate an unspecified homogeneous polynomial of degree \( d \) over \( k \) in the indicated variables.

We write \( \text{spl}(f) \) for the splitting field of \( f \in \mathbb{Q}[x] \). Note that \( f \) need not be irreducible; if \( f = f_1 f_2 \), we also denote this field by \( \text{spl}(f_1, f_2) \).

We will make frequent references into the L-Functions and Modular Forms Database (LMFDB) [LMFDB]. We remind the reader to consult the LMFDB for more details about the computation of data computed therein; see in particular the following pages for attributions related to the corresponding object types.

- Number fields: https://www.lmfdb.org/NumberField/Source.
- Elliptic curves over \( \mathbb{Q} \): http://www.lmfdb.org/EllipticCurve/Q/Source.
- Elliptic curves over other number fields: https://www.lmfdb.org/EllipticCurve/Source.
- Genus 2 curves over \( \mathbb{Q} \): http://www.lmfdb.org/Genus2Curve/Source.
- Automorphism groups of curves over \( \mathbb{C} \): http://www.lmfdb.org/HigherGenus/C/Aut/Source.

In addition, the LMFDB includes a database of Sato–Tate groups combining the results of [FKRS12] with the classification for abelian threefolds made in this paper:

https://www.lmfdb.org/SatoTateGroup/.

In most cases, we have formatted labels of Sato–Tate groups of abelian varieties as hyperlinks to the home pages of these groups. We also format labels of other objects found in the
LMFDB, such as elliptic curves over number fields and genus 2 curves over \( \mathbb{Q} \), as hyperlinks. In addition, when we write \( \text{spl}(f) \) for \( f \in \mathbb{Q}[x] \) irreducible, if the number field defined by \( f \) (not the splitting field) is found in the LMFDB, then we format \( f \) as a hyperlink to this field.

3. Background on Sato–Tate groups

In this section, we recall some of the theoretical results from \([FKRS12]\) which therein provide the basis for the classification of Sato–Tate groups of abelian surfaces, and herein do likewise for abelian threefolds. We then classify the possible identity components of Sato–Tate groups of abelian threefolds. See also \([Sut16]\) for an overview of this circle of ideas.

3.1. The Mumford–Tate group. We begin by recalling the definition of the Mumford–Tate group of an abelian variety over the number field \( k \). This construction carries the same information as the identity component of the Sato–Tate group.

**Definition 3.1.** Fix an embedding of \( k \) into \( \mathbb{C} \) and set \( V := H^1(A_{\text{top}}^\text{crys}, \mathbb{Q}) \); it carries an alternating pairing \( \psi \) given by the cup product. Via the description of \( A_{\text{top}}^\text{crys} \) as a complex torus, we obtain an \( \mathbb{R} \)-linear identification of \( V \otimes \mathbb{Q} \otimes \mathbb{R} \) with the tangent space of \( A_{\mathbb{C}} \) at the origin (or equivalently, the dual of the space of holomorphic differentials on \( A_{\mathbb{C}} \)). The Mumford–Tate group of \( A \), denoted \( \text{MT}(A) \), is the smallest \( \mathbb{Q} \)-algebraic subgroup of \( \text{GL}(V) \) whose base extension to \( \mathbb{R} \) contains the scalar action of \( \mathbb{C}^\times \) on \( V \otimes \mathbb{Q} \otimes \mathbb{R} \); this group is contained in the symplectic group \( \text{GSp}(V, \psi) \). It follows from Deligne’s theorem on absolute Hodge cycles (see \([DM82]\)) that the definition of \( \text{MT}(A) \) does not depend on the choice of the embedding of \( k \) into \( \mathbb{C} \); it is also clearly invariant under enlarging \( k \).

**Definition 3.2.** The Hodge group \( \text{Hg}(A) \) is the intersection \( \text{MT}(A) \cap \text{Sp}(V, \psi) \). The Lefschetz group \( L(A) \) is the identity connected component of the centralizer of \( \text{End}(A_k) \otimes \mathbb{Q} \) in \( \text{Sp}(V, \psi) \). There is an obvious inclusion \( \text{Hg}(A) \subseteq L(A) \).

**Proposition 3.3.** For \( g \leq 3 \), we have \( \text{Hg}(A) = L(A) \). (That is, the Mumford–Tate group is completely controlled by endomorphisms.)

**Proof.** See \([FKRS12, \text{Theorem 2.16}]\). \( \square \)

3.2. Definition of the Sato–Tate group. We continue with the definition of the algebraic Sato–Tate group and Sato–Tate group of an abelian variety over a number field in terms of \( \ell \)-adic monodromy, and the statement of the refined Sato–Tate conjecture. This material is taken from \([FKRS12, \S 2.1]\); see also \([BaK15, \S 2]\), \([BaK16]\).

**Definition 3.4.** For each \( \tau \in G_k \), define

\[
L(A, \tau) := \{ \gamma \in \text{Sp}(V, \psi) : \gamma^{-1} \alpha \gamma = \tau(\alpha) \text{ for all } \alpha \in \text{End}(A_{\mathbb{F}}) \}. \]

The twisted Lefschetz group \( \text{TL}(A) \) is the union of \( L(A, \tau) \) over all \( \tau \).

**Proposition 3.5.** For \( g \leq 3 \), for any prime \( \ell \), \( \text{TL}(A) \otimes \mathbb{Q} \otimes \mathbb{Q}_{\ell} \) is the kernel of the symplectic character on the Zariski closure of the image of \( \rho_{\ell} : G_k \to H^1_{\text{et}}(A_{\mathbb{F}}, \mathbb{Q}_{\ell}) \).

**Proof.** This amounts to the statement that the Mumford–Tate conjecture holds for \( A \) whenever \( g \leq 3 \). See for example \([BaK15, \text{Theorem 6.11}]\). \( \square \)
Definition 3.6. In light of Proposition 3.3 and Proposition 3.5, for \( g \leq 3 \), we define the Sato–Tate group \( \text{ST}(A) \) to be a maximal compact subgroup of \( \text{TL}(A) \otimes \mathbb{Q} \mathbb{C} \). For \( C \) a curve, we define the Sato–Tate group of \( C \) to be that of its Jacobian \( \text{Jac}(C) \).

Lemma 3.7. For \( g \leq 3 \), there is a canonical isomorphism \( \text{ST}(A)/\text{ST}(A)^0 \to \text{Gal}(K/k) \) where \( K \) is the endomorphism field of \( A \). In particular, this isomorphism is compatible with base change: for any finite extension \( k' \) of \( k \), \( \text{ST}(A_{k'}) \) is the inverse image of the subgroup \( \text{Gal}(k'K/k') \subseteq \text{Gal}(K/k) \) in \( \text{ST}(A) \).

Proof. This is again a consequence of [BaK15, Theorem 6.11].

Remark 3.8. In the definition of the Sato–Tate group, we are implicitly using the fact that for \( g \leq 3 \), the Mumford–Tate group of \( A \) is determined by endomorphisms. For general \( g \), it is expected that the role of \( \text{TL}(A) \) in Proposition 3.5 can be filled by a certain algebraic group over \( \mathbb{Q} \), the motivic Sato–Tate group, whose definition involves algebraic cycles on \( A \times A \) of all codimensions, not just endomorphisms [BaK16]. There is still a canonical surjection \( \text{ST}(A)/\text{ST}(A)^0 \to \text{Gal}(K/k) \), but it is not in general an isomorphism.

3.3. Twisting and the Sato–Tate group.

Definition 3.9. For \( L/k \) a finite Galois extension and \( \xi \) a 1-cocycle of \( \text{Gal}(L/k) \) valued in \( \text{Aut}(A_L) \), there exists a unique (up to unique isomorphism) abelian variety \( A_\xi \) over \( k \) and an isomorphism \( \theta : A_{\xi,L} \to A_L \) such that
\[ \xi_\sigma = \theta^\sigma \circ \theta^{-1} \quad (\sigma \in \text{Gal}(L/k)). \]
Moreover, \( A_\xi \) depends only on the class of \( \xi \) in the pointed set \( H^1(\text{Gal}(L/k), \text{Aut}(A_L)) \).

Definition 3.10. As described in [FS14, Lemma 2.3], there is an inclusion
\[ \text{TL}(A_\xi) \subseteq \text{TL}(A) \cdot \text{Aut}(A_L) \]
in \( \text{Sp}(V, \psi) \). Taking a maximal compact subgroup of \( (\text{TL}(A) \cdot \text{Aut}(A_L)) \otimes \mathbb{C} \) gives the twisting Sato–Tate group of \( A \) [FS14, Definition 2.2]. Achieving this group as a Sato–Tate group of \( A \) amounts to solving a certain Galois embedding problem for the component group of the twisting Sato–Tate group.

Remark 3.11. If \( A \) is equipped with a polarization, then we may similarly consider twisting by a cocycle \( \xi \) valued in automorphisms of \( A_L \) as a polarized abelian variety, and then \( A_\xi \) will acquire a polarization with respect to which \( \theta \) is an isomorphism of polarized abelian varieties. In particular, if \( A \) is the Jacobian of the curve \( C \) equipped with the corresponding principal polarization, then by the Torelli theorem, twisting \( A \) as a polarized abelian variety corresponds to twisting \( C \) as a curve.

3.4. Axioms for Sato–Tate groups. A key tool used to classify Sato–Tate groups in [FKRS12] is a list of necessary conditions called the Sato–Tate axioms. The formulation in [FKRS12, Definition 3.1] is applicable to arbitrary motives; we state here a restricted form of the three original Sato–Tate axioms applicable only to the 1-motives associated to abelian threefolds. We also add a fourth axiom coming from the fact that the Sato–Tate group of an abelian threefold is determined by endomorphisms (Proposition 3.3).

Definition 3.12. For a group \( G \) with identity connected component \( G^0 \), the Sato–Tate axioms (for abelian threefolds) are as follows.
The group $G$ is a closed subgroup of $\text{USp}(6)$. For definiteness, we take the latter to be defined with respect to the symplectic form given by the block matrix

$$J = \begin{pmatrix} 0 & I_3 \\ -I_3 & 0 \end{pmatrix}$$

unless otherwise specified.

(Hodge condition) There exists a homomorphism $\theta : U(1) \to G^0$ such that $\theta(u)$ has eigenvalues $u, u^{-1}$ each with multiplicity 3; the image of $\theta$ is called a Hodge circle. Moreover, the Hodge circles generate a dense subgroup of $G^0$.

(Rationality condition) For each component $H$ of $G$ and irreducible character $\chi$ of $\text{GL}(\mathbb{C}^6)$, the expected value (under the Haar measure) of $\chi(\gamma)$ over $\gamma \in H$ is an integer. In particular, $E[\text{Trace}(\gamma, \wedge^m \mathbb{C}^6)^n : \gamma \in H] \in \mathbb{Z}$ for all integers $m, n > 0$.

(Lefschetz condition) The subgroup of $\text{USp}(6)$ fixing $\text{End}(\mathbb{C}^6)^{G^0}$ is equal to $G^0$.

**Proposition 3.13.** Let $A$ be an abelian threefold over $k$. Then $G = \text{ST}_A$ satisfies the Sato–Tate axioms.

**Proof.** For (ST1), (ST2), (ST3), this is [FKRS12, Proposition 3.2] except that the last condition in (ST2) is not stated therein; that statement is a consequence of the definition of the Mumford–Tate group [FKRS12, Definition 2.11]. For (ST4), apply Proposition 3.3. □

### 3.5. Endomorphism rings of abelian threefolds

We next recall the classification of geometric endomorphism rings of abelian threefolds, then record the effect of this classification on the identity components of Sato–Tate groups. See [FKS21, §3.1] for an alternate argument based on Lie algebras.

For $A$ simple of dimension $g \geq 3$, the work of Albert and Shimura leaves the following possibilities for the $\mathbb{Q}$-algebra of endomorphisms $\text{End}(A_K)_{\mathbb{Q}}$. (See for example [Oor87].)

- If $g = 1$: $\mathbb{Q}$ (non-CM type), or a quadratic imaginary field (CM type).
- If $g = 2$: $\mathbb{Q}$ (type I(1)), a real quadratic field (type I(2)), an indefinite quaternion algebra over $\mathbb{Q}$ (type II(1)), or a quartic CM field (type IV(2,1)).
- If $g = 3$: $\mathbb{Q}$ (type I(1)), a totally real cubic field (type I(3)), an imaginary quadratic field (type IV(1,1)), or a CM field of degree 6 over $\mathbb{Q}$ (type IV(3,1)).

It easily follows that for $A$ of dimension 3, not necessarily simple, there are 14 possibilities for the real endomorphism algebra $\text{End}(A_K)_{\mathbb{R}}$, as listed in [Sut16, §4, Table 2]:

- (A) $\mathbb{R}$, when $A_K$ is simple of type I(1);
- (B) $\mathbb{C}$, when $A_K$ is simple of type IV(1,1);
- (C) $\mathbb{R} \times \mathbb{R}$, when $A_K$ is isogenous to the product of an elliptic curve without CM and a simple abelian surface of type I(1);
- (D) $\mathbb{C} \times \mathbb{R}$, when $A_K$ is isogenous to the product of an elliptic curve with CM and a simple abelian surface of type I(1);
- (E) $\mathbb{R} \times \mathbb{R} \times \mathbb{R}$, when either
  - $A_K$ is simple of type I(3), or
  - $A_K$ is isogenous to the product of an elliptic curve without CM and a simple abelian surface of type I(2), or
• $A_K$ is isogenous to the product of three pairwise nonisogenous elliptic curves without CM;

(F) $\mathbb{C} \times \mathbb{R} \times \mathbb{R}$, when either
  • $A_K$ is isogenous to the product of an elliptic curve with CM and two nonisogenous elliptic curves without CM, or
  • $A_K$ is isogenous to the product of an elliptic curve with CM and a simple abelian surface of type I(2);

(G) $\mathbb{C} \times \mathbb{C} \times \mathbb{R}$, when either
  • $A_K$ is isogenous to the product of an elliptic curve without CM and two nonisogenous elliptic curves with CM, or
  • $A_K$ is isogenous to the product of an elliptic curve without CM and a simple abelian surface of type IV(2,1);

(H) $\mathbb{C} \times \mathbb{C} \times \mathbb{C}$, when either
  • $A_K$ is simple of type IV(3,1), or
  • $A_K$ is isogenous to the product of an elliptic curve with CM and a simple abelian surface of type IV(2,1), or
  • $A_K$ is isogenous to the product of three pairwise nonisogenous elliptic curves with CM;

(I) $\mathbb{R} \times M_2(\mathbb{R})$, when either
  • $A_K$ is isogenous to the product of an elliptic curve without CM and a simple abelian surface of type II(1), or
  • $A_K$ is isogenous to the product of an elliptic curve without CM and the square of an elliptic curve without CM nonisogenous to $E$;

(J) $\mathbb{C} \times M_2(\mathbb{R})$, when either
  • $A_K$ is isogenous to the product of an elliptic curve with CM and the square of an elliptic curve without CM, or
  • $A_K$ is isogenous to the product of an elliptic curve with CM and a simple abelian surface of type II(1);

(K) $\mathbb{R} \times M_2(\mathbb{C})$, when $A_K$ is isogenous to the product of an elliptic curve without CM and the square of an elliptic curve with CM;

(L) $\mathbb{C} \times M_2(\mathbb{C})$, when $A_K$ is isogenous to the product of an elliptic curve $E$ with CM and the square of an elliptic curve with CM nonisogenous to $E$;

(M) $M_3(\mathbb{R})$, when $A_K$ is isogenous to the cube of an elliptic curve without CM;

(N) $M_3(\mathbb{C})$, when $A_K$ is isogenous to the cube of an elliptic curve with CM.

Each option for $\text{End}(A_K)_\mathbb{R}$ corresponds to a unique option for the connected part $\text{ST}(A)_0$ of the Sato–Tate group of $A$. These are listed in Table 8, together with the letters A–N used in the above table; we refer to this letter as the absolute type of $A$. Each group comes equipped with a 6-dimensional representation, which may be inferred from the table using the following considerations.

• The groups $\text{SU}(2)$, $\text{USp}(4)$, $\text{USp}(6)$ carry their standard representations.

• Products of groups correspond to direct sums of representations, in which we interlace coordinates to match up the symplectic forms. That is, a product $G_1 \times G_2$ is
represented using block matrices

\[
\begin{pmatrix}
  * & 0 & * & 0 \\
  0 & * & 0 & * \\
  * & 0 & * & 0 \\
  0 & * & 0 & *
\end{pmatrix}
\]

where the blocks labeled * represent an element of $G_1$ and the blocks labeled ⋆ represent an element of $G_2$, and similarly for a threefold product. (Beware that other orderings of coordinates can be found in some presentations constructed in our code, in the computation of moments in §6, and in the LMFDB.)

- The groups $U(1), U(3)$ are embedded into $SU(2), USp(6)$ by the formula

\[A \mapsto \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}.
\]

- For $d = 2, 3$, $U(1)_d, SU(2)_d$ refer to the $d$-fold diagonal representations of $U(1), SU(2)$; in terms of block matrices, this means that

\[
\begin{pmatrix}
  A_{11} & A_{12} \\
  A_{21} & A_{22}
\end{pmatrix} \mapsto \begin{pmatrix} A_{11}I_d & A_{12}I_d \\ A_{21}I_d & A_{22}I_d \end{pmatrix}.
\]

We note in passing that $SO(3)$ and $SU(3)$ (embedded via $U(3)$) satisfy (ST1), (ST2), (ST3) but not (ST4); this explains their absence above. Note also that $U(1)_2 \times SU(2)$ and $U(1) \times SU(2)_2$ are isomorphic but nonconjugate in $USp(6)$.

4. The classification upper bound, part 1

In this section and the next, we establish the “upper bound” assertion of Theorem 1.1, by showing that there are at most 410 conjugacy classes of subgroups of $USp(6)$ that can occur as the Sato–Tate groups of abelian threefolds over number fields. We organize the discussion in terms of the identity component, making an analogue in each case of the group-theoretic classification from [FKRS12, §3]; the case where this equals $U(1)_3$ requires more analysis than all of the others combined, and so is treated separately in §5. In addition, when the identity component contains $U(1) \times U(1)$ as a factor, we refine the group-theoretic argument by making a further analysis of CM types; this adapts a key component of the analysis of Galois types from [FKRS12, §4], which we otherwise do not reproduce.

Along the way, we identify those conjugacy classes of subgroups that are maximal with respect to inclusions of finite index, which is to say inclusions that preserve the identity component. We say for short that such conjugacy classes are maximal.

Throughout §4, let $G$ denote a closed subgroup of $USp(6)$ satisfying the Sato–Tate axioms (Definition 3.12); let $G^0$ denote the identity connected component of $G$; and let $Z$ and $N$ denote the centralizer and normalizer, respectively, of $G^0$ within $USp(6)$.

4.1. Basic cases. We start with two of the least complicated options for $G^0$. In the case $G^0 = USp(6)$ (type A), it is clear that $G = G^0$. In the case $G^0 \simeq U(3)$ (type B), we have $Z = U(1)_3 \subset G^0$ and $N = G^0 \cup JG^0$. Consequently, $N/G^0 \simeq C_2$, so $G$ is equal to either $G^0$ or $N$. In both cases, $N$ is the unique maximal subgroup.
4.2. Split products. We next analyze the cases in which $G^0$ splits as a product $H_1 \times H_2$ in which $H_1$ and $H_2$ have no common factor; this rules out the cases $G^0 = U(1) \times U(1)$ and $G^0 = SU(2) \times SU(2) \times SU(2)$, for which see below. In the remaining cases, $G$ must belong to a subgroup of the form $G_1 \times G_2$ for some groups $G_1, G_2$ with connected parts $H_1, H_2$.

We start with the cases where we must have $G_i = H_i$ for one $i$, in which case the options come directly from the other factor.

- In the case $G^0 = SU(2) \times USp(4)$ (type C), we must have $G_i = H_i$ for $i = 1, 2$, so $G = G^0$.
- In the case $G^0 = U(1) \times USp(4)$ (type D), we must have $G_2 = H_2$, so $G = G_1 \times USp(4)$ for $G_1 \in \{U(1), N(U(1))\}$.
- In the case $G^0 = SU(2) \times SU(2)$ (type I), we must have $G_1 = H_1$, so $G = SU(2) \times G_2$ for some $G_2$ among the groups with $d = 3$ in [FKRS12, Table 8].
- In the case $G^0 = SU(2) \times U(1)_2$ (type K), we must have $G_1 = H_1$, so $G = SU(2) \times G_2$ for some $G_2$ among the groups with $d = 1$ in [FKRS12, Table 8].
- In the case $G^0 = U(1) \times U(1) \times SU(2)$ (type G), take $H_1 = U(1) \times U(1)$ and $H_2 = SU(2)$; we must have $G_2 = H_2$, so $G = G_1 \times SU(2)$ for some $G_1$ among the groups with $d = 2$ in [FKRS12, Table 8]. Note that $A$ must split up to isogeny as the product of an elliptic curve without CM and an abelian surface whose Sato–Tate group has identity component $U(1) \times U(1)$; consequently, of the 8 options for $G_1$, we may omit the 3 that cannot occur for abelian surfaces.

We next consider cases where $H_1 = U(1)$. In such cases, $G_1 \in \{U(1), N(U(1))\}$, so for any given $G$ there exists a group $G_2$ with connected part $H_2$ such that either $G = U(1) \times G_2$, $G = N(U(1)) \times G_2$, or $G$ is the fiber product $N(U(1)) \times \times G_2$ with respect to the unique nontrivial homomorphism $N(U(1)) \to C_2$ and some nontrivial homomorphism $G_2 \to C_2$. The latter may be characterized by the group $G_2$ and the index-2 subgroup $K$ which is the kernel of the homomorphism.

- In the case $G^0 = U(1) \times SU(2) \times SU(2)$ (type F), we may take $H_1 = U(1)$ and $H_2 = SU(2) \times SU(2)$; then $G_2 \in \{SU(2) \times SU(2), N(SU(2) \times SU(2))\}$ and there is a unique fiber product in the latter case.
- In the case $G^0 = U(1) \times SU(2)_2$ (type J), $G_2$ must be taken from the groups with $d = 3$ in [FKRS12, Table 8]. Unique fiber products occur for $G_2 = E_2, E_4, E_6, J(E_4), J(E_6)$. Multiple fiber products occur for $G_2 = J(E_{2n})$ for $n = 1, 2, 3$, as we may take the kernel to be either $E_{2n}$ or one of the two copies of $J(E_n)$. (The latter are conjugate to each other via the normalizer of $J(E_{2n})$, and so give rise to conjugate fiber products.)
- In the case $G^0 = U(1) \times U(1)_2$ (type L), $G_2$ must be taken among the groups with $d = 1$ in [FKRS12, Table 8]. Unique fiber products occur for

$$G_2 = C_2, C_4, C_6, D_3, O, J(C_1), J(C_3), J(T), C_{2,1}, C_{4,1}, C_{6,1}, D_{3,2}, O_1.$$  

Multiple fiber products occur as in Table 1. It is clear that subgroups $K$ with distinct labels correspond to distinct fiber products up to conjugation; we claim that conversely, subgroups with the same label always correspond to conjugate fiber products, which is to say that there is a group of outer automorphisms induced by the
normalizer in USp(4) acting transitively on each collection of subgroups sharing a
common label.

- For $D_2$ and $J(D_2)$, this group is $S_3$. The image of $D_2$ in SO(3) is the group
generated by the half-turns about three orthogonal axes; $S_3$ acts permuting these.

- For $D_4, D_6, J(D_4), J(D_6), D_{2,1}, D_{4,2}, D_{6,2}$, this group is $C_2$
interchanging the two conjugacy classes of reflections. (Note that in contrast with
$D_2$, in $D_{2,1}$ the subgroup $C_2$ is distinguished from the others.)

</table>

Table 1. Subgroups of dimension $d = 1$ in [FKRS12, Table 8] that have
multiple index-2 subgroups; the notation $H^{\times n}$ indicates that $n$
subgroups of $G$
(up to conjugacy in $G$) are conjugate to $H$ in USp(4).

**Remark 4.1.** We checked in Magma that for each choice of $G_2$, running over all possible
index-2 subgroups $K$ of $G_2$ gives no new distributions (as measured by moments; see §6)
other than the ones listed. This corroborates (but does not independently confirm) the claim
that subgroups with the same label correspond to conjugate fiber products.

In this analysis, the group $G$ is maximal if and only if $G_1$ and $G_2$ are both maximal. To
tabulate maximal subgroups, it thus suffices to recall the maximal subgroups in genus 2.
With notation as in [FKRS12, Table 8], these are as follows:

<table>

4.3. **Triple products.** We next classify the options for \( G \) when \( G^0 \simeq SU(2) \times SU(2) \times SU(2) \) (type \( E \)). In this case, \( N/G^0 \simeq S_3 \); more precisely, \( N \) is generated by \( G^0 \) plus the permutation matrices. The options for \( G \) in this case thus correspond to the subgroups of \( S_3 \) up to conjugacy, which we may identify with \( S_1, S_2, A_3, S_3 \). The unique maximal case is \( S_3 \).

We now classify the options for \( G \) in the case \( G^0 \simeq U(1) \times U(1) \times U(1) \) (type \( H \)). In this case, \( Z = G^0 \) and \( N/G^0 \) is isomorphic to the wreath product \( C_2 \wr S_3 \). Let \( a, b, c \) be representatives of the nontrivial cosets in the three factors of \( N(U(1)) \), and set \( t, s \) correspond to the permutations \((1 2), (1 2 3) \) in \( S_3 \).

If \( A \) is not simple, then it splits as a product of a CM elliptic curve and a CM abelian surface; this means that up to conjugation, \( ST(A) \) is contained in the product of a subgroup of \( \langle a, b, t \rangle \) and a subgroup of \( \langle c \rangle \). By the analysis from [FKRS12, §4.3], the former must be a subgroup of either \( \langle a, b \rangle \) or \( \langle at \rangle \).

To handle the case where \( A \) is simple, we recall some facts about abelian varieties with complex multiplication, following [Dod84, §1] and [Kil16, §1] (and ultimately, [Shi71, §5.5]). For future reference, we temporarily allow \( A \) to have arbitrary dimension.

**Definition 4.2.** A **CM field** is a totally imaginary quadratic extension of a totally real number field. A **CM type** is a pair \( (M, \Phi) \) consisting of a CM field \( M \) and a section \( \Phi \) of the map grouping the complex embeddings of \( M \) into conjugate pairs.

Given a CM type \( (M, \Phi) \), for any \( \mathbb{Z} \)-lattice \( m \) in \( M \), we may use \( \Phi \) to specify a complex structure on \( M \otimes \mathbb{Q} \mathbb{R} \), and thus view \( (M \otimes \mathbb{Q} \mathbb{R})/m \) as a complex torus. Changing the choice of \( m \) gives rise to an isogenous torus [Shi71, Proposition 5.13]; consequently, we may associate a polarization to this torus using the trace pairing on \( M \), and thus obtain an abelian variety over \( \mathbb{C} \) with complex multiplication by some order in \( M \).

**Definition 4.3.** Given a CM type \( (M, \Phi) \), let \( L \) be the Galois closure of \( M \) in \( \mathbb{C} \), which is again a CM field. The action of \( \text{Gal}(L/\mathbb{Q}) \) on the complex embeddings of \( M \) by postcomposition acts on the CM types for \( M \). The **reflex field** of \( (M, \Phi) \) is the fixed field \( M^* \) of the stabilizer of \( \Phi \) in \( \text{Gal}(L/\mathbb{Q}) \); note that \( M^* \) is defined as a subfield of \( L \) (and hence of \( \mathbb{C} \) ), whereas \( M \) does not come with a distinguished embedding into \( L \). (There is also a CM type associated to \( M^* \), the **reflex type**, which we will not discuss here.)

**Lemma 4.4.** Fix an embedding of \( k \) into \( \mathbb{C} \). Let \( A \) be a simple polarized abelian variety of dimension \( n \) over \( k \) with CM type \( (M, \Phi) \).

(a) The field \( M^* \) is Galois over \( k \cap M^* \).

(b) The field \( kM^* \) equals the endomorphism field of \( A \).

(c) The group \( \text{Gal}(kM^*/k) \) is canonically isomorphic to a subgroup of \( \text{Aut}(M/\mathbb{Q}) \).

**Proof.** For (a), (b), see [Shi71, Theorem 5.15, Proposition 5.17]. For (c), we obtain the action from (b), which gives an action of \( \text{Gal}(kM^*/k) \) on \( \text{End}(A_{\mathbb{C}})_{\mathbb{Q}} = M \). \( \square \)

**Remark 4.5.** To trace the effect of the previous discussion on Sato–Tate groups, we identify \( ST(A)/ST(A)^0 \) with a subgroup of \( C_2 \wr S_3 \) using the embedding of \( M \) into \( \text{End}(A_K)_{\mathbb{R}} \) to fix the identification of \( U(1) \times \cdots \times U(1) \) with \( \prod_{\tau \in \Phi} \mathbb{C}^\times \). Then the subgroup \( ST(A)/ST(A)^0 \) is contained in \( \text{Gal}(L/(k \cap M^*)) \) and the composition

\[
ST(A)/ST(A)^0 \to \text{Gal}(L/(k \cap M^*)) \to \text{Gal}(M^*/(k \cap M^*)) \cong \text{Gal}(kM^*/k)
\]

is the canonical map (see Remark 3.8).
We now specialize back to the case where $A$ is a simple CM abelian threefold. In this case, by [Dod84, §5.1.1], the sextic field $M$ must be one of the following.

- A cyclic Galois extension of $\mathbb{Q}$. In this case, we must have $G/G^0 \subseteq \langle abc, s \rangle$ as this is the unique copy of $C_6$ in $C_2 \wr S_3$.
- A compositum of an imaginary quadratic field $M_0$ and a non-Galois totally real cubic field $M_1$. In this case, $\text{Aut}(M/\mathbb{Q}) = \text{Gal}(M_0/\mathbb{Q})$ and so $G/G^0 \subseteq \langle abc \rangle$.
- A non-Galois extension of $\mathbb{Q}$ whose Galois closure has group $C_2 \wr A_3$ or $C_2 \wr S_3$. In this case, $\text{Aut}(M/\mathbb{Q})$ is trivial, as then is $G/G^0$.

To summarize, we list the 33 conjugacy classes of subgroups of $N/G^0$ (as may be verified using GAP or Magma) in Table 2. In the table, an underline denotes a group that is permitted by the previous analysis to occur as a Sato–Tate group of an abelian threefold.

Table 2. Conjugacy classes of subgroups of $N/G^0$ for $G^0 \simeq U(1) \times U(1) \times U(1)$. The underlined groups can be realized by Sato–Tate groups.

4.4. **The case $G^0 = SU(2)_3$.** We next classify the options for $G$ assuming that $G^0 \simeq SU(2)_3$ (type $M$). In this case, $Z$ equals the group $O(3)$ realized as a block matrix with scalar entries, $Z \cap G^0 = \{ \pm 1 \}$, and $N = ZG^0$, so $N/G^0 \simeq SO(3)$.

At this point, we must make the rationality condition explicit for the first time in this discussion (though it intervened implicitly in the discussion of products). Any cyclic subgroup
of SO(3) of order \(n\) is conjugate to the group generated by
\[
A = \begin{pmatrix}
1 & 0 & 0 \\
0 & \cos 2\pi/n & \sin 2\pi/n \\
0 & -\sin 2\pi/n & \cos 2\pi/n
\end{pmatrix}.
\]
For the representation \(\wedge^2 \mathbb{C}^6\), the average of the trace of the coset of \(G^0\) containing \(A\) equals the trace of \(A\) on the \(G^0\)-fixed subspace of \(\wedge^2 \mathbb{C}^6\). The latter equals \((1 + 2 \cos 2\pi/n)^2\); this is an integer if and only if \(n \in \{1, 2, 3, 4, 6\}\). Since every subgroup of SO(3) is either cyclic, dihedral, or one of the three exceptional groups (tetrahedral, octahedral, icosahedral), we obtain component groups isomorphic to
\[
C_1, C_2, C_3, C_4, C_6, D_2, D_3, D_4, D_6, A_4, S_4.
\]
By realizing these groups over \(\mathbb{Z}\), one may see that they satisfy the rationality condition for all representations of GL(\(\mathbb{C}^6\)). The maximal cases are \(D_6, S_4\).

5. The classification upper bound, part 2: the case \(G^0 = U(1)_3\)

Retaining notation as in §4, we classify (up to conjugation) the subgroups \(G\) of USp(6) that satisfy the Sato–Tate axioms in the case where \(G^0 \simeq U(1)_3\). The reader familiar with [FKRS12, §3] may have anticipated that this is the richest and most difficult case; indeed, the analysis is very loosely parallel with that of [FKRS12, §3], with the role of the classification of finite subgroups of SU(2) played instead by the classification of finite subgroups of SU(3) containing \(\mu_3\) by Blichfeldt, Dickson, and Miller [MBD61, Chapter XII]. The main technical difficulty is in filtering candidate groups for the rationality condition.

It will be helpful to record explicit presentations for the groups in question, both to aid with some aspects of the classification and for the computation of moments. These presentations are implemented in accompanying SageMath and Magma scripts; note that the SageMath computations depend heavily on GAP, which ships as a standard component of SageMath.

5.1. Overview. We start with a high-level description of the classification for \(G^0 = U(1)_3\), whose results are summarized in Table 3.

For \(G^0 \simeq U(1)_3\), the centralizer and normalizer of \(G^0\) in USp(6) are respectively \(Z \simeq U(3)\) and \(N = Z \cup JZ\); conjugation by \(J\) acts on \(Z\) via complex conjugation. We thus have an exact sequence
\[
1 \to \text{PSU}(3) \to N/G^0 \to C_2 \to 1
\]
which splits because \(J^2 = -1 \in G^0\); we may thus identify \(N/G^0\) with the semidirect product \(\text{PSU}(3) \rtimes C_2\) via the outer\(^1\) action of \(C_2\) on \(\text{PSU}(3)\) via complex conjugation.

Let \(J(\text{SU}(3))\) be the subgroup of USp(6) generated by \(\text{SU}(3)\) and \(J\). There is now a bijection between conjugacy classes of subgroups \(G\) of USp(6) with \(G^0 \simeq U(1)_3\) satisfying the Sato–Tate axioms and finite subgroups \(\tilde{H}\) of \(J(\text{SU}(3))\) containing \(\mu_6\) and satisfying a corresponding rationality condition.

\(^1\)A comparison to [FKRS12, (3.2)] may be misleading: for \(n \geq 3\), complex conjugation acts on \(\text{PSU}(n)\) as an outer automorphism corresponding to the nontrivial automorphism of the Dynkin diagram; however, for \(n = 2\), the Dynkin diagram has only one node, and so this automorphism becomes inner.
Our methodology will be to proceed through the Blichfeldt–Dickson–Miller (BDM) classification of finite subgroups of SU(3). At each step, we will identify subgroups satisfying a restricted form of the rationality condition (see §5.2); this will yield a finite list of conjugacy classes of subgroups of SU(3). We will then compute the normalizer of a representative of each of these classes, and use this to count extensions from SU(3) to J(SU(3)) (see §5.10).

In principle, this yields only an upper bound on the set of conjugacy classes of groups G satisfying the Sato–Tate axioms with G0 ∼= U(1)3, rather than the exact value; this is because we do not check that our candidate groups satisfy the rationality condition (ST3) at its full strength. In practice, we will see that all of these groups can be realized as Sato–Tate groups (§8), which will imply a posteriori that they satisfy the full rationality condition. For the same reason, we do not need to check that the groups we write down satisfy the restricted rationality condition (although we did verify this using the SAGEMATH and MAGMA scripts); rather, we only need to check that the groups we have excluded do not satisfy (ST3).

Table 3. Numbers of finite subgroups of SU(3) ⋊ C_2 accounted for at the various stages of the classification. The columns H, J, J_s, J_n count subgroups of SU(3), standard extensions, split nonstandard extensions, and nonsplit nonstandard extensions; see §5.10 for explanation of how extensions are classified.

To conclude this overview, we record some running notations and general remarks.

**Definition 5.1.** To lighten notation, we use e(x) to denote e^{2πix} and D(u,v,w) to denote the diagonal matrix Diag(e(u), e(v), e(w)).

**Definition 5.2.** Following [MBD61, Chapter XII], we use the symbol φ as a synonym for the number 3; specifically, we write nφ to refer to the order of a finite subgroup of SU(3) containing µ_3 whose image in PSU(3) has order n. When including φ in a label for such a subgroup, we remove φ to indicate the image of this group in PSU(3) and (by abuse of notation) the resulting Sato–Tate group.

**Remark 5.3.** For a group G occurring as the Sato–Tate group of an abelian threefold, the main theorem of [GK17] implies that |G : G^0| divides 2^6 × 3^3 × 7. We will not use this bound explicitly (as it does not directly apply to groups satisfying the Sato–Tate axioms but not yet known to be realizable), but we do wish to point out its consistency with our results.

5.2. **The rationality condition.** We next specialize the Sato–Tate axiom (ST3) to the representation \wedge^3 C^6 of GL(C^6) to obtain a restriction on subgroups of SU(3) ⋊ C_2 containing µ_3. As noted above, this is a priori weaker than the full statement of (ST3), which is quantified
over arbitrary representations of GL($\mathbb{C}^6$); however, it will suffice for the identification of Sato–Tate groups.

The formulation of (ST3) refers to individual connected components of $G$, so it translates into a condition on individual elements of $\text{SU}(3) \rtimes \mathbb{Z}_2$, which depends only on the conjugacy classes of these elements. For elements in $\text{SU}(3)$, we may represent any conjugacy class by a $3 \times 3$ diagonal matrix $A$; we then want to ensure that the average over $r \in [0, 1]$ of the trace of the block matrix

$$
\begin{pmatrix}
e^{(2r)\wedge^2 A} & 0 & 0 \\
0 & A \otimes \overline{A} & 0 \\
0 & 0 & e^{(-2r)\wedge^2 \overline{A}}
\end{pmatrix}
$$

is an integer. This average equals $|\text{Trace}(A)|^2$, yielding the following definition.

**Definition 5.4.** We say that a subgroup $H$ of $\text{SU}(3)$ satisfies the restricted rationality condition if $|\text{Trace}(A)|^2 \in \mathbb{Z}$ for all $A \in H$. We impose the restricted rationality condition on a subgroup of $\text{SU}(3) \rtimes \mathbb{Z}_2$ by imposing it on the intersection with $\text{SU}(3)$.

To make the rationality condition explicit, we identify the conjugacy classes of elements of $\text{SU}(3)$ which can appear in a subgroup satisfying the condition, that is, we find the diagonal matrices $A = \text{Diag}(z_1, z_2, z_3)$ such that $z_1, z_2, z_3$ are roots of unity, $z_1 z_2 z_3 = 1$, and $|z_1 + z_2 + z_3|^2 \in \mathbb{Z}$. To do this, we first extract from the literature the solution of a closely related problem.

**Lemma 5.5.** Suppose that $x, y, z$ are roots of unity in $\mathbb{C}$ such that

$$(x + x^{-1}) + (y + y^{-1}) + (z + z^{-1}) \in \mathbb{Z}.$$

Then at least one of the following holds. (In the following discussion, the equivalence relation is generated by permutations, inversion of any one term, or negation of all terms at once.)

(i) All three summands are in $\mathbb{Z}$. In this case, up to equivalence, we have $x, y, z \in \{\pm 1, \pm i, \pm e^{(\frac{1}{3})}\}$.

(ii) Two summands sum to zero but are not in $\mathbb{Z}$. In this case, up to equivalence, we have $x \in \{\pm 1, \pm i, \pm e^{(\frac{1}{3})}\}$, $z = -y$.

(iii) Exactly one summand is in $\mathbb{Z}$ and the other two do not sum to zero. In this case, up to equivalence, we have $x \in \{\pm 1, \pm i, \pm e^{(\frac{1}{3})}\}$, $(y, z) = (e^{(\frac{1}{3})}, e^{(\frac{2}{3})})$.

(iv) No summand is in $\mathbb{Z}$ and the sum of all three is zero. In this case, up to equivalence, we have $(y, z) = (e^{(\frac{1}{3})}x, e^{(\frac{2}{3})}x)$.

(v) No summand is in $\mathbb{Z}$ and the sum of all three is nonzero. In this case, up to equivalence, we have $(x, y, z) \in \{(e^{(\frac{1}{3})}, e^{(\frac{2}{3})}, e^{(\frac{1}{3})}), (e^{(\frac{1}{10})}, e^{(\frac{1}{5})}, e^{(\frac{3}{10})}), (e^{(\frac{1}{10})}, e^{(\frac{2}{15})}, e^{(\frac{7}{15})})\}$.

**Proof.** This can be read off from [CJ76, Theorem 7]. Alternatively, we have a sum of at most 12 roots of unity equal to 0, and such sums are classified by [PR98, Theorem 3.1] (see also [CMS11, Theorem 4.1.2] or [KKPR20, Theorem 5.1]).
Definition 5.6. Define an equivalence relation on triples of rational numbers by setting \((u_1, u_2, u_3) \sim (v_1, v_2, v_3)\) if the multisets \(\{e(u_j)\}_{j=1}^3\) and \(\{e(v_j)\}_{j=1}^3\) are Galois conjugate over \(\mathbb{Q}\). In other words, there must exist a permutation \(\sigma\) of \(\{1, 2, 3\}\) and a positive integer \(n\) coprime to the least common denominator of \(u_1, u_2, u_3\) such that
\[
v_j - nu_{\sigma(j)} \in \mathbb{Z} \quad (j = 1, 2, 3).
\]

Proposition 5.7. Let \(a, b, c\) be roots of unity in \(\mathbb{C}\) such that \(abc = 1\). Then \(|a + b + c|^2 \in \mathbb{Z}\) if and only if either \((a + b)(b + c)(c + a) = 0\) or \((a, b, c) = (e(u), e(v), e(w))\) for some triple \((u, v, w)\) equivalent to one of the following:
\[
\begin{align*}
(0, 0, 0), & \quad \left(0, \frac{1}{3}, \frac{2}{3}\right), \quad \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right), \quad \left(\frac{1}{4}, \frac{1}{4}, \frac{1}{2}\right), \quad \left(0, \frac{1}{6}, \frac{5}{6}\right), \quad \left(\frac{1}{6}, \frac{1}{3}, \frac{1}{2}\right), \\
\left(\frac{1}{7}, \frac{1}{7}, \frac{4}{7}\right), & \quad \left(\frac{1}{7}, \frac{1}{8}, \frac{1}{2}\right), \quad \left(\frac{1}{9}, \frac{7}{9}, \frac{7}{9}\right), \quad \left(\frac{1}{12}, \frac{1}{12}, \frac{6}{7}\right), \quad \left(\frac{1}{12}, \frac{1}{6}, \frac{4}{7}\right), \quad \left(\frac{1}{12}, \frac{1}{12}, \frac{2}{7}\right), \\
\left(\frac{1}{18}, \frac{1}{18}, \frac{8}{9}\right), & \quad \left(\frac{1}{21}, \frac{1}{21}, \frac{16}{21}\right), \quad \left(\frac{1}{24}, \frac{1}{6}, \frac{19}{24}\right), \quad \left(\frac{1}{90}, \frac{90}{90}, \frac{7}{9}\right).
\end{align*}
\]

Proof. For
\[
x = \frac{a}{b}, \quad y = \frac{b}{c}, \quad z = \frac{c}{a},
\]
we have
\[
|a + b + c|^2 = x + x^{-1} + y + y^{-1} + z + z^{-1} + 3;
\]
consequently, \((x, y, z)\) must be as described in Lemma 5.5. Conversely, given \(x, y, z\) as above, we may solve for \(a, b, c\) by writing
\[
a = \left(\frac{y}{x}\right)^{1/3}, \quad b = \left(\frac{z}{y}\right)^{1/3}, \quad c = \left(\frac{x}{z}\right)^{1/3}
\]
and choosing cube roots consistently. Enumerating cases of Lemma 5.5 yields the following.

(i) Each of \(x, y, z\) has order dividing 4 or 6, so each of \(a, b, c\) has order dividing 12 or 18. Excluding cases where \((a + b)(b + c)(c + a) = 0\), we obtain the possibilities
\[
(u, v, w) = (0, 0, 0), \quad \left(0, \frac{1}{3}, \frac{2}{3}\right), \quad \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right), \quad \left(\frac{1}{4}, \frac{1}{4}, \frac{1}{2}\right), \quad \left(0, \frac{1}{6}, \frac{5}{6}\right), \\
\left(\frac{1}{6}, \frac{1}{3}, \frac{1}{2}\right), & \quad \left(\frac{1}{9}, \frac{7}{9}, \frac{7}{9}\right), \quad \left(\frac{1}{12}, \frac{1}{12}, \frac{6}{7}\right), \quad \left(\frac{1}{12}, \frac{1}{6}, \frac{4}{7}\right), \quad \left(\frac{1}{12}, \frac{1}{12}, \frac{2}{7}\right), \\
\left(\frac{1}{21}, \frac{1}{21}, \frac{16}{21}\right), & \quad \left(\frac{1}{24}, \frac{1}{6}, \frac{19}{24}\right), \quad \left(\frac{1}{90}, \frac{90}{90}, \frac{7}{9}\right).
\]

(ii) Up to equivalence, \(x = a/b\) has order dividing 4 or 6 and \(z = -y\); the latter forces \(b \in \{e(1/6), e(1/2), e(5/6)\}\). This yields the additional cases
\[
(u, v, w) = \left(\frac{1}{8}, \frac{1}{8}, \frac{1}{2}\right), \quad \left(\frac{1}{12}, \frac{1}{12}, \frac{3}{4}\right), \quad \left(\frac{1}{12}, \frac{5}{12}, \frac{1}{2}\right), \quad \left(\frac{1}{24}, \frac{1}{6}, \frac{19}{24}\right).
\]

(iii) In this situation, there is no way to have \(xyz = 1\).

(iv) In this situation, we have \(x^3 = y^3 = z^3 = 1\) and so no new cases occur.

(v) From the listed options for \((x, y, z)\), we obtain the additional cases
\[
(u, v, w) = \left(\frac{1}{7}, \frac{1}{7}, \frac{4}{7}\right), \quad \left(\frac{1}{21}, \frac{1}{21}, \frac{16}{21}\right), \quad \left(\frac{1}{90}, \frac{90}{90}, \frac{7}{9}\right).
\]

The proposition follows. \(\square\)
Remark 5.8. Proposition 5.7 is a special case of the general problem of finding solutions in roots of unity to a system of polynomial equations (i.e., the multiplicative Manin-Mumford problem). The approach used in [CJ76] yields an algorithm for the more general problem, as described by Leroux [Ler12].

Another algorithm has been given by Beukers and Smyth [BS02] in the case of a single polynomial of two variables, and generalized by Aliev and Smyth [AS08] to a system. See Remark 5.40 for an explanation of how the Beukers–Smyth algorithm can be used to confirm Proposition 5.7.

It might appear that the result of Proposition 5.7 violates [FKRS12, Remark 3.3] by failing to limit $A$ to a finite set. This discrepancy disappears when we impose the rationality condition not on individual group elements, but on entire cyclic subgroups.

Proposition 5.9. Let $a, b, c$ be roots of unity in $\mathbb{C}$ with $abc = 1$. Then $|a^n + b^n + c^n|^2 \in \mathbb{Z}$ for all positive integers $n$ if and only if $(a, b, c) = (e(u), e(v), e(w))$ for some triple $(u, v, w)$ equivalent to one of the following:

$$(0, 0, 0), \left(\frac{1}{2^2}, \frac{1}{2^2}\right), \left(0, \frac{1}{3^2}, \frac{1}{3^2}\right), \left(\frac{1}{3^2}, \frac{1}{3^2}, \frac{1}{3^2}\right), \left(0, \frac{1}{4^2}, \frac{1}{4^2}\right), \left(\frac{1}{4^2}, \frac{1}{4^2}, \frac{1}{4^2}\right),$$

$$(\frac{1}{6^2}, \frac{1}{6^2}, \frac{1}{6^2}), \left(\frac{1}{6^2}, \frac{1}{6^2}, \frac{1}{6^2}\right), \left(\frac{1}{7^2}, \frac{1}{7^2}, \frac{1}{7^2}\right), \left(\frac{1}{8^2}, \frac{1}{8^2}, \frac{1}{8^2}\right), \left(\frac{1}{9^2}, \frac{1}{9^2}, \frac{1}{9^2}\right),$$

$$(\frac{1}{12^2}, \frac{1}{12^2}, \frac{1}{12^2}), \left(\frac{1}{12^2}, \frac{1}{12^2}, \frac{1}{12^2}\right), \left(\frac{1}{18^2}, \frac{1}{18^2}, \frac{1}{18^2}\right), \left(\frac{1}{18^2}, \frac{1}{18^2}, \frac{1}{18^2}\right),$$

$$(\frac{1}{21^2}, \frac{1}{21^2}, \frac{1}{21^2}), \left(\frac{1}{21^2}, \frac{1}{21^2}, \frac{1}{21^2}\right), \left(\frac{1}{24^2}, \frac{1}{24^2}, \frac{1}{24^2}\right), \left(\frac{1}{24^2}, \frac{1}{24^2}, \frac{1}{24^2}\right),$$

$$(\frac{1}{36^2}, \frac{1}{36^2}, \frac{1}{36^2}), \left(\frac{1}{36^2}, \frac{1}{36^2}, \frac{1}{36^2}\right).$$

(Each listed triple is lexicographically first in its equivalence class; the list is sorted first by multiplicative order, and then lexicographically.)

Proof. We first check that the complete list of triples $(u, v, w)$ for which some two of $u, v, w$ are equal is

$$(0, 0, 0), \left(\frac{1}{2^2}, \frac{1}{2^2}\right), \left(\frac{1}{3^2}, \frac{1}{3^2}, \frac{1}{3^2}\right), \left(\frac{1}{4^2}, \frac{1}{4^2}, \frac{1}{4^2}\right),$$

$$(\frac{1}{6^2}, \frac{1}{6^2}, \frac{1}{6^2}), \left(\frac{1}{7^2}, \frac{1}{7^2}, \frac{1}{7^2}\right), \left(\frac{1}{8^2}, \frac{1}{8^2}, \frac{1}{8^2}\right), \left(\frac{1}{9^2}, \frac{1}{9^2}, \frac{1}{9^2}\right).$$

Up to equivalence we have $(u, v, w) = (\frac{1}{n}, \frac{1}{n}, \frac{n-2}{n})$ for some $n$. Since $b = a, c = a^{-2}$ we have

$$|a + b + c| = 2(a^3 + a^{-3}) + 5 \in \mathbb{Z};$$

this holds if and only if $a^3$ has order dividing 4 or 6. This yields the options

$$n \in \{1, 2, 3, 4, 6, 9, 12, 18\}$$

and moreover confirms that they all work (because this list is closed under taking divisors).
We next check that the complete list of triples \((u, v, w)\) for which some two of \(u, v, w\) differ by \(\frac{1}{2}\) modulo \(\mathbb{Z}\) is
\[
\begin{align*}
(0, \frac{1}{2}, \frac{1}{2}), & \quad (0, \frac{1}{4}, \frac{3}{4}), & \quad (\frac{1}{6}, \frac{1}{6}, \frac{1}{3}), & \quad (\frac{1}{8}, \frac{1}{4}, \frac{5}{8}), \\
(\frac{1}{12}, \frac{1}{3}, \frac{7}{12}), & \quad (\frac{1}{18}, \frac{1}{18}, \frac{5}{9}), & \quad (\frac{1}{24}, \frac{1}{12}, \frac{13}{24}), & \quad (\frac{1}{36}, \frac{1}{9}, \frac{36}{36}).
\end{align*}
\]
We may assume without loss of generality that \(u \) and \(v\) differ by \(\frac{1}{2}\) modulo \(\mathbb{Z}\) and that \(a\) has even order; then \(a\) generates the group \(\langle a, b, c \rangle\), and therefore up to equivalence we have \((u, v, w) = (\frac{1}{2n}, \frac{n-2}{2n}, \frac{n+1}{2n})\) for some \(n\). Since \(b = -a, c = -a^{-2}\), we have
\[
|a^2 + b^2 + c^2| = 2(a^6 + a^{-6}) + 5 \in \mathbb{Z};
\]
this holds if and only if \(a^6\) has order dividing 4 or 6. This yields the options
\[
\begin{align*}
& n \in \{2, 4, 6, 8, 12, 18, 24, 36\} \\
\end{align*}
\]
and also confirms that they all work (because this list is closed under taking even divisors).

We finally check that the complete list of triples \((u, v, w)\) for which no two of \(u, v, w\) differ by 0 or \(\frac{1}{2}\) modulo \(\mathbb{Z}\) is
\[
\begin{align*}
(0, \frac{1}{3}, \frac{2}{3}), & \quad (0, \frac{1}{6}, \frac{5}{6}), & \quad (\frac{1}{6}, \frac{1}{3}, \frac{1}{2}), & \quad (\frac{1}{7}, \frac{2}{7}, \frac{4}{7}), \\
(\frac{1}{8}, \frac{1}{8}, \frac{3}{2}), & \quad (\frac{1}{12}, \frac{1}{6}, \frac{3}{4}), & \quad (\frac{1}{12}, \frac{1}{12}, \frac{1}{2}), & \quad (\frac{1}{21}, \frac{4}{21}, \frac{16}{21}), & \quad (\frac{1}{24}, \frac{1}{6}, \frac{19}{24}).
\end{align*}
\]
Note that for each positive integer \(n\), the triple \((nu, nv, nw)\) must either be equivalent to an entry in (5.2) or must have two terms which differ by \(\frac{1}{2}\) modulo \(\mathbb{Z}\). Already for \(n = 1\), this criterion eliminates all cases except the listed ones plus \((\frac{1}{90}, \frac{19}{90}, \frac{7}{9})\); the latter case is eliminated by taking \(n = 2\). The remaining cases persist for all \(n\) (see Remark 5.11 for an easy way to check this).

\begin{corollary}
Let \(n\) be a positive integer, and let \(H\) be the subgroup of \(SU(3)\) consisting of those diagonal matrices of order dividing \(n\). Then \(H\) satisfies the restricted rationality condition if and only if \(n \in \{1, 2, 3, 4, 6\}\).
\end{corollary}

\begin{remark}
One way to cross-check (5.3) is to verify the following statements about each triple \((u, v, w)\) appearing therein.
\begin{itemize}
  \item[(a)] Either two of \(u, v, w\) differ by \(\frac{1}{2}\), or \((u, v, w)\) appears in (5.2).
  \item[(b)] Let \(n\) denote the least common denominator of \(u, v, w\). Then for each prime divisor \(p\) of \(n\), the triple \((pu, pv, pw)\) is equivalent to an earlier triple in (5.3).
\end{itemize}
This confirms that each triple \((u, v, w)\) in the list defines a triple \((a, b, c)\) with the desired properties.
\end{remark}

\section{Abelian groups}
For the remainder of §5, let \(H\) denote a finite subgroup of \(SU(3)\) containing \(\mu_3\) that satisfies the restricted rationality condition; we identify the possibilities for \(H\) of various types according to the BDM classification. We start with abelian groups, which occur in type (A) of the BDM classification. We represent these groups as groups of diagonal matrices, which are then stable under complex conjugation. (Recall that \(\phi := 3\), per Definition 5.2.)
Lemma 5.12. For \( H \) abelian, there exist diagonal matrices \( g_1 \) and \( g_2 \) of orders \( m \) and \( n\phi \), with \( m|n\phi \), such that \( H \) is conjugate to
\[
\langle g_1, g_2 \rangle \cong \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\phi\mathbb{Z}
\]
and \( \mu_3 \) is contained in \( \langle g_2 \rangle \).

**Proof.** Since \( H \) is abelian, its elements can be diagonalized simultaneously. Since it injects into \( U(1) \times U(1) \), it is generated by just two elements; we can thus find matrices \( g_1 \) and \( g_2 \) of respective orders \( m \) and \( n\phi \), with \( m|n\phi \), such that \( H \) is equal to
\[
\langle g_1, g_2 \rangle \cong \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\phi\mathbb{Z}.
\]
It remains to check that these can be chosen so that \( \mu_3 \subseteq \langle g_2 \rangle \). For this, we may ignore the prime-to-3 parts of \( m \) and \( n \), and thus reduce to the case where \( m \) and \( n \) are powers of 3. If \( m = 1 \), then \( \mu_3 \subseteq H = \langle g_2 \rangle \) and we are done. If \( n > 1 \), then by Proposition 5.9 we must have \( g_2^{n/9} \) conjugate to \( D(\frac{1}{3}, \frac{1}{3}, \frac{7}{9}) \), and therefore \( \mu_3 \subseteq \langle g_2 \rangle \). This leaves only the case \((m, n) = (3, 1)\), in which case \( H \) is the full 3-torsion subgroup of \( SU(3) \); in this case, we may take \( g_2 \) to be a generator of \( \mu_3 \) and \( g_1 \) to be a complementary generator. \( \square \)

**Proposition 5.13.** Suppose that \( H \) is an abelian group. Then \( H \) is conjugate to exactly one of the 22 groups listed in Table 4.

**Proof.** In Table 4, the cyclic groups are precisely the ones arising from Proposition 5.9 which contain \( \mu_3 \). (The labels \( A(m, n\phi) \) are chosen to preserve the order from (5.3), but the generators themselves are not preserved; see Remark 5.15.) In particular, this implies that any group that appears has order divisible by only the primes 2, 3, 7; moreover, since \( A(1, 7\phi) \) is the only cyclic group that occurs with order divisible by 7, no noncyclic group with order divisible by 7 can occur.

Any noncyclic group that occurs must have the form \( \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\phi\mathbb{Z} \) where \( m, n' \) are divisible only by the primes 2 and 3. Since there is no entry \( A(1, 9\phi), A(1, 16\phi), \) or \( A(1, 24\phi) \) in Table 4, neither \( m \) nor \( n' \) can be divisible by 9, 16, or 24.

We next note that for
\[
(m, n') \in \{ (2, 2), (3, 1), (4, 4), (6, 6) \}
\]
the group \( A(m, n') \) can occur in only one way: it must be generated by \( \mu_3 \) and the maximal elementary abelian subgroup of the diagonal torus of exponent \( m \). In particular, this group is stable under the action of \( S_3 \) on diagonal matrices (see Remark 5.15 for more on this point).

We next note that for
\[
(m, n') \in \{ (3, 3), (6, 6) \},
\]
the group \( A(m, n') \) can again occur in only one way: it must be generated by \( A(m, (n'/3)\phi) \) and \( A(1, 3\phi) \). This group is again stable under the action of \( S_3 \).

We next rule out the cases
\[
(m, n') \in \{ (2, 8), (2, 12), (3, 8), (3, 12), (6, 4) \}.
\]
In each case, we do so by identifying the candidate groups, then identify a witness in each group which does not appear in Proposition 5.9.
To achieve \((m, n') = (2, 8)\), we would have to take the group generated by \(A(2,2\phi)\) and one of \(A(1,8\phi)_1\) or \(A(1,8\phi)_2\). We take as witnesses
\[
D(\frac{1}{2}, 0, \frac{1}{2}) \cdot D(\frac{1}{6}, \frac{1}{24}, \frac{10}{24}) = D(\frac{2}{3}, \frac{1}{24}, \frac{7}{24}), \quad D(\frac{1}{2}, 0, \frac{1}{2}) \cdot D(\frac{1}{12}, \frac{1}{12}, \frac{5}{6}) = D(\frac{7}{12}, \frac{5}{24}, \frac{5}{24}).
\]

To achieve \((m, n') = (2, 12)\), we would have to take the group generated by \(A(2,2\phi)\) and \(A(1,12\phi)\). We take as witness
\[
D(\frac{1}{2}, 0, \frac{1}{2}) \cdot D(\frac{1}{9}, \frac{7}{36}, \frac{25}{36}) = D(\frac{11}{18}, \frac{7}{36}, \frac{7}{36}).
\]
• To achieve \((m, n') = (3, 8)\), we would have to take the group generated by \(A(3, 1\phi)\) and one of \(A(1, 8\phi)_1\) or \(A(1, 8\phi)_2\). We take as witnesses
\[
D(\frac{2}{3}, 0, \frac{1}{3}) \cdot D(\frac{1}{3}, \frac{1}{12}, \frac{7}{12}) = D(0, \frac{1}{12}, \frac{11}{12}), \quad D(\frac{2}{3}, 0, \frac{1}{3}) \cdot D(\frac{1}{12}, \frac{5}{24}, \frac{17}{24}) = D(\frac{2}{3}, \frac{5}{24}, \frac{1}{24});
\]
the first witness also rules out the group generated by \(A(3, 1\phi)\) and \(A(1, 4\phi)_2\).

• To achieve \((m, n') = (3, 12)\), we would have to take the group generated by \(A(3, 1\phi)\) and \(A(1, 12\phi)\). We take as witness
\[
D(\frac{1}{3}, 0, \frac{2}{3}) \cdot D(\frac{1}{3}, \frac{7}{12}, \frac{25}{36}) = D(\frac{4}{3}, \frac{7}{36}, \frac{12}{36}).
\]

• To achieve \((m, n') = (6, 4)\), we would have to take the group generated by \(A(6, 2\phi)\) and one of \(A(1, 4\phi)_1\) or \(A(1, 4\phi)_2\). The latter case is ruled out above; for the former, we take as witness
\[
D(\frac{1}{6}, 0, \frac{2}{3}) \cdot D(\frac{1}{6}, \frac{5}{12}, \frac{5}{12}) = D(\frac{1}{3}, \frac{5}{12}, \frac{1}{4}).
\]

We finally show that in the cases
\[
(m, n') \in \{(2, 4), (2, 6), (3, 2), (3, 4), (3, 6)\},
\]
at most one group occurs.

• For \((m, n') = (2, 4)\), we would have to take the group generated by \(A(2, 2\phi)\) and one of \(A(1, 4\phi)_1\) or \(A(1, 4\phi)_2\). The resulting groups are conjugate because the group generated by \(A(2, 2\phi)\) and \(A(1, 4\phi)_1\) contains a conjugate of \(A(1, 4\phi)_2\).

• For \((m, n') = (2, 6)\), we must take the group generated by \(A(2, 2\phi)\) and \(A(1, 3\phi)\).

• For \((m, n') = (3, 2)\), we must take the group generated by \(A(3, 1\phi)\) and \(A(1, 2\phi)\).

• For \((m, n') = (3, 4)\), we would have to take the group generated by \(A(3, 1\phi)\) and one of \(A(1, 4\phi)_1\) or \(A(1, 4\phi)_2\); the latter case is ruled out above.

• For \((m, n') = (3, 6)\), we must take the group generated by \(A(3, 3\phi)\) and \(A(1, 2\phi)\).

This leaves the options enumerated in Table 4.

\[\square\]

**Remark 5.14.** Recall that we do not need to check that the groups listed in Table 4 satisfy the rationality condition, as this will be confirmed \textit{a posteriori} by the realizability of these groups as Sato–Tate groups. If one did want to do this by hand for the noncyclic groups, it would suffice to do for the maximal noncyclic groups in the table, namely

\[A(3, 4\phi), A(4, 4\phi), A(6, 6\phi)\].

**Remark 5.15.** In Table 4, the “Symmetries” column indicates the subgroup of permutation matrices which normalize the image of the group in \(\text{PSU}(3)\); this data is needed for the analysis of the remaining types in the BDM classification. When the group is given as \(C_2\), the presentation has been chosen so that the normalizing transposition is \((2, 3)\).

**Remark 5.16.** Note that certain pairs of groups in Table 4 give rise to isomorphic but non-conjugate pairs or triples of subgroups of \(\text{PSU}(3)\):

\[A(1, 3) \simeq A(3, 1), \quad A(1, 4)_1 \simeq A(1, 4)_2, \quad A(1, 6)_1 \simeq A(1, 6)_2 \simeq A(3, 2), \quad A(1, 8)_1 \simeq A(1, 8)_2, \quad A(1, 12) \simeq A(3, 4).\]

Some differences between these groups will appear as we continue the classification.
5.4. **Extensions by** $C_2$. Type (B) in the BDM classification consists of nonabelian groups contained in $SU(3) \cap (U(1) \times U(2))$. Note that $U(1) \times SU(2)$ surjects onto $SU(3) \cap (U(1) \times U(2))$ via the map

$$\pi: U(1) \times SU(2) \to SU(3) \cap (U(1) \times U(2)), \quad (u, A) \mapsto (u^2, u^{-1}A)$$

with kernel of order 2 generated by $\{(-1, -1)\}$; the groups in question thus correspond to finite subgroups of $U(1) \times SU(2)$ containing both $(-1, -1)$ and $(e^{i\pi/4}, 1)$.

For the moment, we focus on groups which are (nonabelian) extensions of abelian groups by $C_2$; this amounts to requiring that they have dihedral image in $PSU(2) \cong SO(3)$. This includes products of cyclic groups with dihedral groups, but also some nonsplit extensions such as the quaternion group of order 8. The remaining cases are groups which project to one of the exceptional subgroups of $SU(2)$; we classify those in §5.5.

For $\xi, \alpha \in \mathbb{C}^\times$ of norm 1, let

$$R_{\xi,\alpha} := \begin{pmatrix} -\bar{\xi} & 0 & 0 \\ 0 & 0 & -\bar{\alpha} \\ 0 & -\xi \alpha & 0 \end{pmatrix} \in SU(3);$$

note that

$$R_{\xi,\alpha}^2 = \text{Diag}(\xi^{-2}, \xi, \xi), \quad R_{\xi,\alpha}^{-1} = R_{\xi^{-1},\xi\alpha}.$$

In particular, if $\xi \alpha = \bar{\alpha}$, then $R_{\xi,\alpha} = R_{\xi,\alpha}^{-1}$; this will ensure that any presentation using this matrix is invariant under complex conjugation. With this in mind, we set

$$(5.4) \quad T_1 = R_{1,1}, \quad T_2 = R_{-1,i}, \quad T_4 = R_{i,e^{i\pi/8}}.$$ 

**Lemma 5.17.** Let $H$ be an extension of an abelian group by $C_2$. Then there is a group $H'$ of order $\frac{1}{2}|H|$ in Table 4 with at least $C_2$ symmetries such that $H$ is conjugate to one of:

(i) $(H', T_1)$; or

(ii) $(H', T_2)$ and then $H'$ contains $T_2^2 = D(0, \frac{1}{2}, \frac{1}{2})$; or

(iii) $(H', T_4)$ and then $H'$ contains $T_4^2 = D(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}).$

**Proof.** Write $H$ as an extension of $H'$ by $C_2$; by Proposition 5.13, we may conjugate $H'$ into one of the forms listed in Table 4, in such a way that the action of $C_2$ is given by interchanging the second and third coordinates. Consequently, the nontrivial class in $C_2$ is represented by $R_{\xi,\alpha}$ for some $\xi, \alpha$. The element $R_{\xi,\alpha}^2 = \text{Diag}(\xi^{-2}, \xi, \xi)$ must belong to $H'$, so $\xi$ must be a root of unity; by replacing $R_{\xi,\alpha}$ with $R_{\xi,\alpha}^s = R_{\xi,\xi^{(1-s)/2}\alpha}$ for a suitable odd integer $s$, we may ensure that $\xi = e^{i/2^h}$ for some $h$. Since $R_{\xi,\alpha}^2$ must satisfy the restricted rationality condition, we see from Proposition 5.13 that $\xi$ has order at most 4; hence $\xi \in \{1, -1, i\}$. We may then rescale $\alpha$ (by conjugating by a matrix of the form $\text{Diag}(1, \beta, \beta^{-1})$ for suitable $\beta$) to ensure that $R_{\xi,\alpha} \in \{T_1, T_2, T_4\}$, from which the claim follows. \hfill \square

**Remark 5.18.** In case (ii) of Lemma 5.17, if $H'$ contains an element $g$ of the form $D(\frac{1}{2}, *, *)$, then it also contains

$$gT_2 = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & * \\ 0 & * & 0 \end{pmatrix};$$

by conjugating by a suitable matrix in the diagonal torus, we see that $(H', gT_2)$ is conjugate to $(H', T_2)$. By the same token, in case (iii) of Lemma 5.17, if $H'$ contains an element $g$ of the form $D(\frac{1}{4}, *, *)$, then $(H', gT_4)$ is conjugate to $(H', T_4)$. 

28
Proposition 5.19. Suppose that $H$ is an extension of an abelian group by $C_2$ and is not abelian. Then $H$ is conjugate to exactly one of the 18 groups listed in Table 5.

Proof. Write $B(m, n\phi; t)_*$ for the group $\langle A(m, n\phi)_*, T_t \rangle$, omitting $t$ when it equals 1. By Lemma 5.17, it suffices to include the following entries.

(i) The group $B(m, n\phi)_*$ for each group $A(m, n\phi)_*$ of Table 4 with at least $C_2$ symmetries, excluding $A(1, 1\phi), A(1, 2\phi), A(1, 3\phi), A(1, 4\phi)_1, A(1, 6\phi)_1$ which give rise to abelian groups; this exhausts all cases where $H$ is a semidirect product of an abelian group by $C_2$. Of these, $B(2, 2\phi)$ is conjugate to $B(1, 4\phi)_2$ (by writing it as the semidirect product of a cyclic subgroup by $C_2$) and has thus been omitted; similarly, $B(2, 6\phi)$ is conjugate to $B(1, 12\phi)$ and has thus been omitted. We also omit $B(1, 8\phi)_2$ because it will be redundant with (iii). This yields 12 entries.

(ii) The group $B(m, n\phi; 2)_*$ for each group $A(m, n\phi)_*$ in (i) containing $D(0, \frac{1}{2}, \frac{1}{2})$ but not containing any element of the form $D(\frac{1}{2}, *, *)$ (see Remark 5.18). This yields 4 entries.

(iii) The group $B(m, n\phi; 4)_*$ for each group $A(m, n\phi)_*$ listed in (i) containing $D(\frac{1}{2}, \frac{1}{4}, \frac{1}{4})$ but not containing any element of the form $D(\frac{1}{4}, *, *)$ (see Remark 5.18). This yields 2 entries; the group $B(2, 4\phi; 4)$ is conjugate to $B(1, 8\phi)_2$ (with the cyclic subgroup of order 8 being generated by $T_4$), justifying the omission of the latter.

The results of this tabulation are shown in Table 5 below.

| $B(1, 4\phi)_2$ | $B(3, 3\phi)$ | $B(1, 4\phi; 2)_2$ | $B(2, 4\phi; 4)$ | $B(1, 8\phi)_2$ |
| $B(1, 8\phi)_1$ | $B(3, 4\phi)$ | $B(1, 12\phi; 2)$ | $B(3, 4\phi; 4)$ |
| $B(1, 12\phi)_2$ | $B(3, 6\phi)$ | $B(3, 2\phi; 2)$ | $B(3, 6\phi; 2)$ |
| $B(2, 4\phi)$ | $B(4, 4\phi)$ | $B(3, 6\phi; 2)$ |
| $B(3, 1\phi)$ | $B(6, 2\phi)$ |
| $B(3, 2\phi)$ | $B(6, 6\phi)$ |

Table 5. Finite subgroups of SU(3) containing $\mu_3$ that satisfy the restricted rationality condition which are extensions of an abelian group by $C_2$. The group $B(m, n\phi; t)_*$ denotes the group $\langle A(m, n\phi)_*, T_t \rangle$, with $t = 1$ omitted.

5.5. Exceptional groups from SU(2). We now finish off type (B) of the BDM classification, which consists of groups contained in SU(3) \( \cap (U(1) \times U(2)) \). In what follows, it will be convenient to identify SU(2) with the group of unit quaternions via the isomorphism

\[ a + bi + cj + dk \mapsto \begin{pmatrix} a + bi & c + di \\ -c + di & a - bi \end{pmatrix}. \]

As in §5.4, we work with the surjection

\[ \pi: U(1) \times SU(2) \to SU(3) \cap (U(1) \times U(2)), \quad (u, A) \mapsto (u^2, u^{-1}A) \]

and look for finite subgroups $\tilde{H}$ of $U(1) \times SU(2)$ containing both $(-1, -1)$ and $(e^{\frac{i}{4}}, 1)$. Any such group whose image in SU(2) is cyclic or dihedral gives rise to a subgroup $H$ of SU(3) which is either abelian, or an extension of an abelian group by $C_2$; these cases have
already been accounted for by Proposition 5.13 and Proposition 5.19. It thus remains to consider cases where the image in SU(2) is one of the three exceptional finite subgroups: the binary tetrahedral, octahedral, and icosahedral groups. We may immediately rule out the case where \( \tilde{H} \) projects to the binary icosahedral group: in any such case, the component group of \( H \) has order divisible by 5, and so \( H \) cannot satisfy the restricted rationality condition.

We next consider the case where \( \tilde{H} \) projects onto the binary tetrahedral group, presented as

\[
2T = \{ \pm 1, \pm i, \pm j, \pm k, \frac{1}{2}(\pm 1 \pm i \pm j \pm k) \} = \langle j, \frac{1}{2}(1 + i + j + k) \rangle;
\]

this presentation is invariant under complex conjugation, as are all of the presentations we will derive from it, with one exception; see Proposition 5.34. The only nontrivial cyclic quotient of \( 2T \) is

\[
2T/Q \simeq C_3, \quad Q = \{ \pm 1, \pm i, \pm j, \pm k \}.
\]

**Proposition 5.20.** Suppose that \( H \) is the image of a finite subgroup \( \tilde{H} \) of \( U(1) \times SU(2) \) containing \((-1, -1)\) and \((e(\frac{1}{2}), 1)\) which projects to the subgroup \( 2T \) of \( SU(2) \). Then \( H \) is conjugate to one of

\[
B(T, 1\phi), \quad B(T, 2\phi), \quad B(T, 3\phi), \quad B(T, 1\phi; 1).
\]

Here \( B(T, n\phi) \) denotes \( \pi(C_{2n\phi} \times 2T) \), while \( B(T, 1\phi; 1) \) denotes \( \pi(C_{6\phi} \times C_3, 2T) \) where the fiber product is via the nontrivial homomorphism \( C_6 \to C_3 \) and one of the two nontrivial homomorphisms \( 2T/Q \to C_3 \).

**Proof.** Let \( C \) be the kernel of the map \( \tilde{H} \to 2T \), identified with a subgroup of \( U(1) \). Then \( \tilde{H} \) in \( U(1)/C \times 2T \) is the graph of a homomorphism \( 2T \to U(1)/C \). If this homomorphism is trivial, then \( \tilde{H} = C \times 2T \). Because \((-1, -1)\) and \((e(\frac{1}{2}), 1)\) belong to \( \tilde{H} \), the order of \( C \) can be written as \( 2n\phi \); the group \( C \) projects to the subgroup of \( SU(3) \) generated by \( D(\frac{1}{n\phi}, -\frac{1}{2n\phi}, -\frac{1}{2n\phi}) \). By Proposition 5.9, the latter satisfies the restricted rationality condition if and only if \( n \in \{1, 2, 3\} \).

For all such \( n \), the image of \( C \times 2T \) in \( SU(3) \) satisfies the restricted rationality condition.

Suppose now that \( 2T \to U(1)/C \) is nontrivial; it must then have image \( C_3 \). Since \(-1 \in Q \), we must have \(-1 \in C \); hence the order of \( C \) must again be of the form \( 2n\phi \). As above, we must have \( n \in \{1, 2, 3\} \). When \( n = 1 \), we see from above that \( H \) satisfies the restricted rationality condition (the two possible groups of this form are conjugate to each other). In the other two cases, \( \tilde{H} \) must contain an element of the form \((u, \frac{1}{2}(1 + i + j + k))\) where \( u \in U(1) \) has order \( 12\phi \) (if \( n = 2 \)) or \( 18\phi \) (if \( n = 3 \)). The latter case is impossible, as it would imply that \( H \) contains an element of order \( 9\phi \) and this is inconsistent with Table 4. As for the former case, projecting the element in question to \( H \) yields a matrix conjugate in \( SU(3) \) to \( \text{Diag}(u^2, u^{-1}e(\frac{j}{6}), u^{-1}e(-\frac{j}{6})) \); the three components of this diagonal matrix have orders \( 6\phi, 12\phi, 12\phi \), so this matrix does not generate a group conjugate to \( A(1, 12\phi) \) (in which the component orders of a generator are \( 3\phi, 12\phi, 12\phi \)) and therefore cannot satisfy the restricted rationality condition. \( \square \)

We finally consider the case where \( \tilde{H} \) projects to the binary octahedral group, presented as

\[
2O = 2T \cup S_4 \left( \frac{1}{\sqrt{2}}(\pm 1 \pm i) \right);
\]

this presentation is invariant under complex conjugation, as are all of the presentations we will derive from it. The only nontrivial cyclic quotient of \( 2O \) is \( 2O/2T \simeq C_2 \).
Proposition 5.21. Suppose that $H$ is the image of a finite subgroup $\tilde{H}$ of $U(1) \times SU(2)$ containing $(-1, -1)$ and $(e(\frac{1}{3}), 1)$ which projects to the subgroup $2O$ of $SU(2)$. Then $H$ is conjugate to one of

$$B(O, 1\phi), \quad B(O, 2\phi),$$

where $B(O, n\phi)$ denotes the nontrivial fiber product $\pi(C_{4n\phi} \times C_2 2O)$. (Beware that $B(O, 1\phi)$ is not conjugate to a subgroup of $B(O, 2\phi)$.)

Proof. Let $C$ be the kernel of the map $\tilde{H} \to 2O$, identified with a subgroup of $U(1)$. Then $\tilde{H}$ in $U(1)/C \times 2O$ is the graph of a homomorphism $2O \to U(1)/C$. If this homomorphism is trivial, then $\tilde{H} = C \times 2O$; however, already the image of $C_{n\phi} \times 2O$ fails to satisfy the restricted rationality condition due to the presence of the matrix $D(0, \frac{1}{8}, \frac{7}{8})$.

If the homomorphism is nontrivial, then it must map $2O$ to its only nontrivial cyclic quotient, namely $2O/2T \cong \mathbb{Z}/2\mathbb{Z}$; in particular, we have $C \times 2T \subset \tilde{H}$, so the order of $n$ of $C$ must be in $\{2\phi, 4\phi, 6\phi\}$ by Proposition 5.20. Then $\tilde{H}$ must contain an element of the form $(u, \frac{1}{\sqrt{2}}(1 + i))$ where $u \in U(1)$ has order $4\phi$ (if $n = 2\phi$), $8\phi$ (if $n = 4\phi$), or $12\phi$ (if $n = 6\phi$). If $n = 6\phi$, then projecting the element in question to $H$ yields $\text{Diag}(u^2, u^{-1}e(\frac{1}{3}), u^{-1}e(-\frac{1}{3}))$, whose diagonal components have orders $6\phi, 24\phi, 24\phi$; however, there is no cyclic group of order $24\phi$ satisfying the restricted rationality condition. In the other two cases, one does get groups satisfying the restricted rationality condition. □

5.6. Extensions by $A_3$. Type (C) in the BDM classification consists of semidirect products of abelian groups, represented as diagonal matrices, with the cyclic group $A_3$, represented as cyclic permutation matrices. (In particular, we need not consider nonsplit extensions by $A_3$; this will be apparent from the proof of Lemma 5.22.) Let

$$S = \begin{pmatrix}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{pmatrix};$$

since this matrix is real, the following presentations are again invariant under complex conjugation.

Lemma 5.22. Suppose that $H$ is an extension of an abelian group by $A_3$. Then there exists an abelian group $H'$ of order $\frac{1}{3}|H|$ in Table 4 with at least $A_3$ symmetries such that $H$ is conjugate to $\langle H', S \rangle$; in particular, $H \cong H' \rtimes A_3$.

Proof. By conjugating suitably, we may ensure that $H$ is generated by a diagonal abelian subgroup $H'$ and a matrix of the form

$$S_{\zeta, \mu} = \begin{pmatrix}
0 & 0 & \zeta^{-1}\mu^{-1} \\
\zeta & 0 & 0 \\
0 & \mu & 0
\end{pmatrix}$$

for some $\zeta, \mu \in \mathbb{C}^\times$. Since

$$S_{\zeta, \mu} \cdot \text{Diag}(d_1, d_2, d_3) \cdot S_{\zeta, \mu}^{-1} = \text{Diag}(d_3, d_1, d_2),$$

the group $H'$ is invariant under a cyclic permutation of the diagonal elements of its constituting matrices; we can thus conjugate it into a form appearing in Table 4.
Write $\tilde{S} = S_{2/3, \mu^{2/3}, \kappa^{-1/3}}$. Since
\[ \tilde{S} \cdot S_{\xi, \mu} \cdot \tilde{S}^{-1} = S, \]
and conjugation by $\tilde{S}$ preserves $H'$ (as in 5.8), we see that $H$ is conjugate to $\langle H', S \rangle$. □

**Proposition 5.23.** Suppose that $H$ is the semidirect product of an abelian group by $A_3$ and is not abelian. Then $H$ is conjugate to exactly one of the 7 following groups:
\[
C(1, 7\phi), C(2, 2\phi), C(3, 1\phi), C(3, 3\phi), C(4, 4\phi), C(6, 2\phi), C(6, 6\phi).
\]
Here $C(m, n\phi)$ denotes the group $\langle A(m, n\phi), S \rangle \simeq (\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\phi \mathbb{Z}) \rtimes A_3$.

Proof. By Lemma 5.22, the given list includes all possibilities; note that the group $C(1, 1\phi)$ is abelian and are hence omitted. (By contrast, $C(3, 1\phi)$ is not abelian, but its image in $\text{PSU}(3)$ is abelian.) It is automatic that these groups satisfy the restricted rationality condition because the product of $S$ with any matrix in $A(m, n\phi)$ has eigenvalues $1, e^{\frac{\pi i}{3}}, e^{\frac{2\pi i}{3}}$. □

5.7. **Extensions by $S_3$.** Type (D) in the BDM classification consists of extensions of abelian groups, represented as diagonal matrices, by the symmetric group $S_3$, represented as scaled permutation matrices.

Define the matrices $S, T_1$ as in (5.6) and (5.5). Since these matrices are real, the following presentations are again invariant under complex conjugation.

**Lemma 5.24.** Suppose that $H$ is an extension of an abelian group by $S_3$. Then there exists an abelian group $H'$ of order $\frac{1}{6}|H|$ in Table 4 with $S_3$ symmetries such that $H$ is conjugate to $\langle H', S, T_1 \rangle$. In particular, $H \simeq H' \rtimes S_3$.

Proof. As in Lemma 5.22, we may assume that $H$ is conjugate to $\langle H', S, R_{\xi, \alpha} \rangle$, where $H'$ is one of the abelian groups of order $\frac{1}{6}|H|$ of Table 4, and $R_{\xi, \alpha}$ is defined as in (5.4) for some $\xi, \alpha \in \mathbb{C}^\times$. Since
\[
R_{\xi, \alpha}^2 = \text{Diag}(\xi^{-2}, \xi, \xi), \quad (S \cdot R_{\xi, \alpha})^2 = \text{Diag}(\alpha, \alpha, \alpha^{-2}),
\]
$\xi$ and $\alpha$ are roots of unity. Moreover, for $n$ the least common multiple of the orders of $\xi$ and $\alpha$, the $S_3$-symmetry of $H'$ implies that $H'$ contains the full $n$-torsion subgroup of $\text{SU}(3)$. We can thus rescale to force $\xi = \alpha = 1$, yielding the desired result. □

**Proposition 5.25.** Suppose that $H$ is an extension of an abelian group by $S_3$, but not an extension of an abelian group by $C_2$. Then $H$ is conjugate to one of the 6 following groups:
\[
D(2, 2\phi), \ D(3, 1\phi), \ D(3, 3\phi), \ D(4, 4\phi), \ D(6, 2\phi), \ D(6, 6\phi).
\]
Here $D(m, n\phi)$ denotes the group $\langle A(m, n\phi), S, T_1 \rangle \simeq (\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\phi \mathbb{Z}) \rtimes S_3$.

Proof. By Lemma 5.24, the given list includes all possibilities. As in the proof of Proposition 5.23, the restricted rationality condition is automatic in these cases. □

5.8. **Solvable exceptional subgroups.** Types (E), (F), (G) in the BDM classification are exceptional groups whose images in $\text{SU}(3)/\mu_3$ have orders 36, 72, 216, respectively; we denote these by $E(36\phi), E(72\phi), E(216\phi)$. The group $E(216)$ is the Hessian group.
Define the matrices
\[(5.9) \quad g_1 = D(0, \frac{1}{3}, \frac{2}{3}), \quad g_2 = \frac{1}{e(\frac{1}{3}) - e(\frac{2}{3})} \begin{pmatrix} 1 & 1 & 1 \\ 1 & e(\frac{1}{3}) & e(\frac{2}{3}) \\ 1 & e(\frac{2}{3}) & e(\frac{1}{3}) \end{pmatrix}, \quad g_3 = D(\frac{2}{3}, \frac{2}{3}, \frac{5}{3}).\]

Then \(E(36\phi), E(72\phi), E(216\phi)\) are the respective groups
\[\langle g_1, g_2 \rangle, \quad \langle g_1, g_2, g_3 g_2 g_3^{-1} \rangle, \quad \langle g_1, g_2, g_3 \rangle.\]
(The presentations given in [MBD61, Chapter XII] include the matrix \(S\) of (5.6), but this is unnecessary because \(S = g_2^{-1}g_1g_2\).)

Note that \(g_2^2 = g_3^3\) and that the complex conjugate of \(g_3 g_2 g_3^{-1}\) belongs to \(\langle g_1, g_2, g_3 g_2 g_3^{-1} \rangle\); since \(S \in \langle g_1, g_2 \rangle\), we can see the latter by writing the conjugate as
\[g_2(g_3 g_2 g_3^{-1}) D(\frac{2}{3}, \frac{2}{3}, \frac{2}{3})\]
and observing that \(D(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}) = g_1 S g_1^{-1} S^{-1}\). This means that all three of these presentations are invariant under complex conjugation; these groups also satisfy the restricted rationality condition.

**Remark 5.26.** As an aside, we note that for \(S_{\zeta, \mu}\) as in (5.7), the group \(E(216\phi)\) contains the subgroup \(\langle A(1, 1\phi), S e(\zeta/9), e(\zeta/9) \rangle\) which is conjugate to \(C(3, 1\phi)\) in \(SU(3)\) (by Lemma 5.22) but not in \(E(216\phi)\).

5.9. **Simple exceptional groups.** The final types (H), (I), (J) in the BDM classification are exceptional groups whose images in \(SU(3)/\mu_3\) have orders 60, 360, 168, respectively. These are the unique simple groups of these orders: \(A_5, A_6,\) and \(PSL(3, \mathbb{F}_2) \simeq PSL(2, \mathbb{F}_7)\).
We may immediately rule out the groups of order 60 and 360 because any groups made from them contain elements of order 5 and thus cannot satisfy the restricted rationality condition.

We denote the group of order 168 by \(E(168\phi)\); it admits the presentation
\[(5.10) \quad \langle D(\frac{1}{3}, 2, 4), S, D(\frac{1}{3}, 2, 7), \frac{1}{\sqrt{-7}} \begin{pmatrix} e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) \\ e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) \\ e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) & e(\frac{2}{3}) - e(\frac{3}{3}) \end{pmatrix} \rangle.\]

Since the latter matrix has real entries, the presentation is invariant under complex conjugation; it also satisfies the restricted rationality condition. (Note that omitting \(D(\frac{1}{3}, 2, 7)\) yields a group which projects isomorphically onto \(E(168)\).)

5.10. **Standard and nonstandard extensions: overview.** At this point, we have completed the classification of finite subgroups of \(SU(3)\) containing \(\mu_3\) and satisfying the restricted rationality condition, and it remains to classify the extensions of such subgroups to \(J(SU(3))\). Before embarking on the specific calculations, we read off some general features of the situation and set some terminology.

**Definition 5.27.** Let \(H\) be a subgroup of \(SU(3)\) which is stable under complex conjugation. (See Remark 5.31 for the changes that need to be made to handle more general \(H\).) Write \(\pm H\) for the group \(\langle H, -1 \rangle\). For any subgroup \(\tilde{H}\) of \(J(SU(3))\) with \(H = \tilde{H} \cap SU(3)\), we have an exact sequence
\[(5.11) \quad 1 \to \pm H \to \tilde{H} \to C_2 \to 1.\]
One candidate for $\tilde{H}$ is the group $\langle H, J \rangle$; we denote it by $J(H)$ and call it the **standard extension** of $H$, and characterize any other $\tilde{H}$ as a **nonstandard extension**.

Let $N_H$ denote the normalizer of $H$ in SU(3) (which is itself stable under complex conjugation); then any extension of $H$ must have the form $\langle H, Jg \rangle$ for some $g \in U(3)$ whose image in SU(3) belongs to $N_H$ and satisfies $JgJg \in \pm H$ (so that $[\tilde{H} : H] \leq 2$). This last condition is equivalent to requiring that the image of $g$ in $N_H/H$ maps to its inverse under complex conjugation; let $I_H$ be the set of elements of $N_H/H$ with this property.

Conjugation by $h \in N_H$ takes $Jg$ to

$$h^{-1}(Jg)h = J\overline{h}^{-1}gh,$$

and in particular $N_H/H$ acts on $I_H$. We thus have a bijection between the set of extensions of $H$ and the quotient set of $I_H$ by the action of $\langle N_H/H \rangle$ where $h$ acts as $g \mapsto \overline{h}^{-1}gh$. (It is not necessary to record the conjugation action of $J$: if $g \in N_H$ represents a class in $I_H$, then the actions of $J$ and $g^{-1}$ on this class coincide.)

**Definition 5.28.** Consider the nonstandard extension defined by the class in $I_H$ of some $g \in N_H$. We further classify the extension according to the following criteria.

- A **split** nonstandard extension, denoted $J_s(H)$, is one where $\overline{g} = \overline{h}$ for some $h \in H$. Such an extension is still a semidirect product by $C_2$, but via a different action.

- A **nonsplit** nonstandard extension, denoted $J_n(H)$, is one corresponding to the class in $I_H$ of some $g \in N_H$ such that $\overline{g} \neq \overline{h}$ for any $h \in H$. Such an extension is not a semidirect product by $C_2$.

While this is not clear *a priori*, it will turn out that every group $H$ we consider has at most one nonstandard extension of each type. Consequently, the notations $J_s(H)$ and $J_n(H)$ will be completely unambiguous.

**Lemma 5.29.** Let $N^0_H$ denote the identity component of $N_H$, which centralizes $H$ since $H$ is finite. Let $N'_H := N_H/\langle N^0_H, H \rangle$ be the component group of $N_H/H$. Then the action of $N'_H/H$ on $I_H$ (where $h$ acts as $g \mapsto \overline{h}^{-1}gh$) induces an action of $N'_H$ on the set of connected components of $I_H$, with corresponding orbits.

*Proof.* Note that the action in question has only finitely many orbits: given $H$ there are finitely many isomorphism classes of groups $\tilde{H}$ as in (5.11), and each occurs for finitely many conjugacy classes of subgroups of $J(SU(3))$, by [FKRS12, Remark 3.3]. If we restrict the action from $N_H/H$ to its identity component $\langle N^0_H, H \rangle/H$, we still have only finitely many orbits (because this subgroup is of finite index), but now the orbits are connected and closed (because they are images of a continuous map between compact topological spaces); these orbits must thus be entire connected components of $I_H$. This yields the desired result. \[\square\]

**Remark 5.30.** Suppose that $N^0_H$ is contained in the diagonal torus and centralizes not only $H$, but all of $N_H$ (this will only fail for some abelian groups). Then $I_H$ is the image of a set of connected components of $N_H$: if $g \in N_H$, $h \in N^0_H$, then $\overline{g} = \overline{gh}gh$. As a consequence, the set of connected components of $I_H$ is in bijection with the set $I'_H$ of elements of $N'_H$ which map to their inverses under complex conjugation.

The computation of the orbits of $I'_H$ under the action of $N'_H$ will be further facilitated by the following general observations. (In this discussion, we do not differentiate between
split and nonsplit nonstandard extensions; we make this distinction by inspection in each individual case.)

- If $N'_H$ is trivial, then $H$ admits no nonstandard extension.
- If $N'_H \simeq C_2$, then $I'_H = N'_H$, the action of $N'_H$ on $I'_H$ is trivial, and so $H$ admits a nonstandard extension.
- Suppose that $N'_H$ has a normal subgroup $N''_H$ stable under complex conjugation, such that $N'_H/N''_H$ is cyclic of odd prime order. Let $I''_H$ be the set of elements of $N''_H$ which map to their inverses under complex conjugation; then we have a canonical bijection $I'_H/N'_H \to I''_H/N''_H$ (regardless of the action of complex conjugation on $N'_H$). In particular, if $N'_H$ is of odd order (e.g., $C_3$), then $I'_H/N'_H$ is a singleton set and so $H$ admits no nonstandard extension.
- The set of orbits of $N'_H$ acting on $I'_H$ is invariant under twisting the action of complex conjugation by an element of $N'_H$ (compare Remark 5.31 below). In particular, if $N'_H \simeq S_3$, then $N'_H$ has only inner automorphisms, so by Remark 5.31 the number of extensions does not depend on the action of complex conjugation on $N'_H$. For the trivial action, we see that $I'_H$ is the set of transpositions with the action of $N'_H$ by conjugation, so $H$ admits one nonstandard extension.

**Remark 5.31.** Without the assumption that $H$ is stable under complex conjugation (but still assuming that $N'_H$ is contained in the diagonal and centralizes all of $N_H$), the analysis of Remark 5.30 remains valid if we replace $J$ with $Jg$ for some $g \in SU(3)$ for which $Jg$ normalizes $H$, and define the action of $N_H/H$ on $I_H$ by replacing complex conjugation with the automorphism induced by $Jg$ (that is, complex conjugation composed with the ordinary conjugation by $g$). In particular, the number of extensions of $H$ depends only on the group $N'_H$ and the element represented by complex conjugation in the outer automorphism group of $N'_H$; this observation is useful even if $H$ is stable under complex conjugation, as it saves us the trouble of having to completely pin down the action of complex conjugation on $N'_H$.

5.11. **Standard and nonstandard extensions: computations.** We now recapitulate the classification of finite subgroups $H$ of $SU(3)$ containing $\mu_3$ and satisfying the restricted rationality condition, determining the standard and nonstandard extensions in each case.

**Proposition 5.32.** Of the 23 groups listed in Table 4, each admits a standard extension; the 15 groups

$A(1,4\phi)_2$, $A(1,8\phi)_1$, $A(1,8\phi)_2$, $A(1,12\phi)$, $A(2,2\phi)$, $A(2,6\phi)$,
$A(3,1\phi)$, $A(3,2\phi)$, $A(3,3\phi)$, $A(3,4\phi)$, $A(3,6\phi)$, $A(4,4\phi)$, $A(6,2\phi)$, $A(6,6\phi)$

admit split nonstandard extensions; and the 9 groups

$A(1,2\phi)$, $A(1,4\phi)_1$, $A(1,4\phi)_2$, $A(1,6\phi)_1$, $A(1,12\phi)$, $A(2,4\phi)$, $A(3,2\phi)$, $A(3,4\phi)$, $A(3,6\phi)$

admit nonsplit nonstandard extensions.

**Proof.** These groups are all invariant under complex conjugation, and so admit standard extensions. To identify nonstandard extensions, we cannot apply Remark 5.30 because $N'_H$ does not centralize $N_H$ in most cases; we thus make a direct analysis. To begin with, for $H = A(1,1\phi)$, $N_H = N'_H = SU(3)$ and $I_H$ consists of all symmetric matrices in $SU(3)$; thus $I_H$ is connected and $H$ admits no nonstandard extension.
For the groups
\[ H = A(1, 2\phi), A(1, 3\phi), A(1, 4\phi)_1, A(1, 6\phi)_1, \]
we have \( N_H = N^0_H = SU(3) \cap (U(1) \times U(2)) \). For any \( g \in N_H \), the top-left entry of \( \overline{gg} \) is 1; consequently, if \( \overline{gg} \in H \) then \( \overline{gg} \in \{ D(0, 0, 0), D(0, \frac{1}{2}, \frac{1}{2}) \} \subseteq A(1, 2\phi) \) and each option accounts for a single connected component of \( I_H \). For \( H = A(1, 3\phi) \), the second component does not occur because \( D(0, \frac{1}{2}, \frac{1}{2}) \notin H \); consequently, \( H \) admits no nonstandard extension.

In the other three cases, \( I_H \) contains a second connected component, so \( H \) admits a nonsplit nonstandard extension corresponding to the class of

\[
(5.12) \quad g = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}.
\]

In the remaining cases, \( N^0_H \) is the diagonal torus, and \( N_H \) is generated by \( N^0_H \) plus a group of symmetries contained in \( S_3 \) and isomorphic to \( N_H/H \). Note that the entire image of \( N_H \) in \( I_H \) is a single orbit, corresponding to the standard extension; moreover, the image in \( I_H \) of an element of \( N_H \) in the coset of an order-3 symmetry in \( S_3 \) cannot map to its inverse under complex conjugation. Consequently, if the group of symmetries is either trivial or equal to \( A_3 \), then \( H \) admits no nonstandard extensions; this covers the cases \( H = A(1, 6\phi)_2, A(1, 7\phi) \). In all other cases, every nonstandard extension arises from a matrix of the form

\[
g = \begin{pmatrix} -a & 0 & 0 \\ 0 & 0 & -c \\ 0 & -b & 0 \end{pmatrix},
\]

where \( abc = 1 \); this matrix satisfies

\[
\overline{gg} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & b\overline{c} & 0 \\ 0 & 0 & \overline{cb} \end{pmatrix}.
\]

It follows that the connected components of \( I_H \) are in bijection with the quotient of the group \( H \cap \{ D(0, u, -u) : u \in \mathbb{Q} \} \) by the image of \( H \) under the map \( D(u, v, w) \mapsto D(0, v - w, w - v) \). In particular, we always get a split nonstandard extension by taking \( g \) to be the matrix \( T_1 \) of (5.5); in addition, we obtain nonsplit nonstandard extensions for

\[ H = A(3, 2\phi), A(3, 4\phi), A(3, 6\phi). \]

by taking \( g \) as in (5.12), so that \( u = \frac{1}{2} \), and for

\[ H = A(1, 4\phi)_2, A(1, 12\phi), A(2, 4\phi), \]

by taking

\[
g = \begin{pmatrix} i & 0 & 0 \\ 0 & 0 & i \\ 0 & 1 & 0 \end{pmatrix},
\]

so that \( u = \frac{1}{4} \). \( \square \)
Proposition 5.33. Of the 18 groups appearing in Table 5, each admits a standard extension; the 12 groups

\[ B(1, 4\phi)_2, \; B(1, 12\phi), \; B(2, 4\phi), \; B(3, 2\phi), \; B(3, 4\phi), \; B(3, 6\phi), \]
\[ B(1, 4\phi; 2)_2, \; B(1, 12\phi; 2), \; B(3, 2\phi; 2), \; B(3, 6\phi; 2), \; B(2, 4\phi; 4), \; B(3, 4\phi; 4) \]

admit split nonstandard extensions; and none admits a nonsplit nonstandard extension.

Proof. These groups are invariant under complex conjugation and admit standard extensions. For each group \( H = B(m, n\phi; k)_* \) in the list, \( \langle m, n\phi; k \rangle \) is the torus \( \{ D(2u, -u, -u) : u \in \mathbb{Q} \} \); this torus is the image of \( \mathbb{U}(1) \times \{ 1 \} \) under \( \pi \). Moreover, \( \langle m, n\phi; k \rangle \) contains \( \langle \tau, 1 \rangle \mathbb{U}(2) \) and thus centralized by \( \langle m, n\phi; k \rangle \); we may therefore apply Remark 5.30.

We first treat the exceptional cases

\[ H = B(2, 4\phi), \; B(1, 4\phi; 2), \; B(1, 12\phi; 2). \]

These groups all project to the subgroup \((i, k)\) of \( \mathbb{U}(2) \), which has normalizer \( 2O \); it follows that in all three cases, \( \langle m, n\phi; k \rangle \) is a characteristic subgroup of \( H \). (Note that this does not apply to the alternate presentations \( B(2, 2\phi), B(2, 6\phi), B(1, 8\phi) \) of the groups \( B(1, 4\phi)_2, B(1, 12\phi), B(2, 4\phi; 4) \); this explains our choice of labels in these cases.)

By the previous paragraph, \( \langle m, n\phi; k \rangle \) is contained in the subgroup of \( \mathbb{U}(3) \) generated by the diagonal torus and the symmetries listed in Table 4. (Note that all cases where the connected part of the normalizer of \( A(m, n\phi)_* \) in \( \mathbb{U}(3) \) is larger than the diagonal torus fail to contribute to Table 5, because the resulting groups are all abelian.) Moreover, symmetries in \( S_3 \) but not in \( C_2 \) fail to normalize \( T_j \) up to scalars. It follows that \( \langle m, n\phi; k \rangle \) is generated by the intersection of \( \langle m, n\phi; k \rangle \) with the diagonal torus.

An element \( g = D(u, v, w) \in \mathbb{U}(3) \) belongs to \( \langle m, n\phi; k \rangle \) if and only if \( H \) contains

\[ T_j^{-1} g^{-1} T_j g = D(-u, -w, -v) D(u, v, w) = D(0, v - w, w - v); \]

moreover, this element is trivial in \( H \) if and only if \( g \in \langle m, n\phi; k \rangle \). Consequently, \( \langle m, n\phi; k \rangle \) is equal to the intersection of \( H \) with the torus \( \{ D(0, u, -u) : u \in \mathbb{Q} \} \) modulo the image of \( A(m, n\phi)_* \) under \( D(u, v, w) \mapsto D(0, v - w, w - v) \).

If \( A(m, n\phi)_* \) has symmetries by \( S_3 \), then \( \langle m, n\phi; k \rangle \) is trivial because \( D(0, u, -u) \) is the image of \( D(-u, u, 0) \); consequently, the groups

\[ H = B(3, 1\phi), \; B(3, 3\phi), \; B(4, 4\phi), \; B(6, 2\phi), \; B(6, 6\phi), \]

admit no nonstandard extension. For \( H = B(1, 8\phi)_1, \) \( \langle m, n\phi; k \rangle \) is trivial because the image of

\[ D(\frac{1}{2}, \frac{1}{8}, \frac{3}{8}) \in H \]

is \( D(0, \frac{3}{4}, \frac{1}{4}) \), which generates the intersection of \( A(1, 8\phi)_1 \) with the torus \( \{ D(0, u, -u) : u \in \mathbb{Q} \} \). Hence \( H \) admits no nonstandard extension.

The groups

\[ H = B(1, 4\phi)_2, \; B(1, 12\phi), \; B(2, 4\phi; 4) \]
all contain $D(0, \frac{1}{4}, \frac{3}{4})$ (whose image is $D(0, \frac{1}{4}, \frac{1}{2})$) but not $D(0, \frac{1}{2}, \frac{7}{8})$, and $N'_H \simeq C_2$ generated by the image of $D(\frac{1}{2}, 0, \frac{1}{2})$; hence $H$ admits a split nonstandard extension. The groups

$$H = B(3, 2\phi), B(3, 4\phi), B(3, 6\phi), B(3, 2\phi; 2), B(3, 6\phi; 2), B(3, 4\phi; 4),$$

all contain $D(0, \frac{1}{2}, \frac{1}{2})$ but not $D(0, \frac{1}{2}, \frac{3}{4})$, so $N'_H \simeq C_2$ generated by the image of $D(\frac{1}{2}, 0, \frac{1}{2})$; hence $H$ admits a split nonstandard extension.

**Proposition 5.34.** Of the 6 groups listed in Proposition 5.20 and Proposition 5.21, all except $B(T, 1\phi; 1)$ admit standard extensions; the 4 groups

$$B(T, 1\phi), B(T, 2\phi), B(T, 3\phi), B(T, 1\phi; 1)$$

admit split nonstandard extensions; and none admits a nonsplit nonstandard extension.

**Proof.** As in Proposition 5.33, $N^0_H$ is the image of $U(1) \times \{1\}$ under $U(1) \times SU(2) \to SU(3)$ and $N_H$ is contained in $SU(3) \cap (U(1) \times U(2))$; we may thus apply Remark 5.30.

For each of the groups

$$H = B(T, 1\phi), B(T, 2\phi), B(T, 3\phi)$$

listed in Proposition 5.20, $H$ maps to the subgroup $2T$ of $SU(2)$, so $N_H = \langle N^0_H, 2O \rangle$ and $N'_H \simeq C_2$. Consequently, each of these 3 groups admits a split nonstandard extension corresponding to the class of $D(\frac{1}{4}, \frac{1}{4}, \frac{1}{2})$ in $I_H$. By the same token, for each of the groups

$$H = B(O, 1\phi), B(O, 2\phi)$$

listed in Proposition 5.21, $H$ maps to the subgroup $2O$ of $SU(2)$, so $N_H = \langle N^0_H, 2O \rangle$ and $N'_H$ is trivial. Consequently, neither of these 2 groups admits a nonstandard extension.

The case $H = B(T, 1\phi; 1)$ is anomalous; see Remark 5.35 below.

**Remark 5.35.** In Proposition 5.34, the case $H = B(T, 1\phi; 1)$ requires special dispensation because the given presentation of $H$ is not stable under complex conjugation, so there is no standard extension. (The action of $J$ is nontrivial on $C_3$ but trivial on $2T/Q$, so the two possible fiber products are interchanged by conjugation.)

That aside, $N^0_H$ is the image of $U(1) \times \{1\}$ under the map $U(1) \times SU(2) \to SU(3)$ and $N_H$ is contained in $SU(3) \cap (U(1) \times U(2))$, so Remark 5.31 applies with $g = D(\frac{1}{4}, \frac{1}{4}, \frac{1}{2})$. However, in this case, the projection of $N_H$ to $SU(2)$ does not hit the nontrivial coset of $T$ in $O$, so $N'_H$ is trivial. Consequently, $H$ admits a unique extension; since $(Jg)^2$ is the identity, we categorize this as a split nonstandard extension of $H$.

**Proposition 5.36.** Of the 7 groups appearing in Proposition 5.23, each admits a standard extension; the 5 groups

$$C(2, 2\phi), C(3, 3\phi), C(4, 4\phi), C(6, 2\phi), C(6, 6\phi)$$

admit split nonstandard extensions; and none admits a nonsplit nonstandard extension.

**Proof.** For each group $H = C(m, n\phi)$ in the list, $A(m, n\phi)$ is centralized only by the diagonal torus, so the centralizer of $H$ in $SU(3)$ is $\mu_3$. In particular, $N^0_H$ is trivial, so Remark 5.30 applies with $N'_H = N_H/H$.

To analyze the case $H = C(3, 1\phi)$, we first note that $H$ coincides with the subgroup $\langle g_1, g_3^3, S = g_2^{-1}g_1g_2 \rangle$ of $E(216\phi)$. By checking that $g_2^{-1}Sg_2 = g_1$ and $g_1^{-1}Sg_1 = g_3^3S$, we see that $N_H = E(216\phi)$ and $N'_H \simeq 2T$; since $2T/Q \simeq C_3$, we may reduce consideration from $N'_H$.
to $N_H'' \simeq Q$ via Remark 5.30. If we normalize the latter identification so that $g_2$ corresponds to $i$ and $g_3 g_2 g_3^{-1}$ maps to $j$, then complex conjugation acts on $N_H''$ by

$$i \mapsto -i, \quad j \mapsto k, \quad k \mapsto j;$$

hence $I_H'' = \{ \pm 1, \pm i \}$ and the action is transitive. (More precisely, $j$ interchanges $\pm 1$ with $\pm i$ while $k$ interchanges $\pm 1$ with $\mp i$.) We conclude that $H$ admits no nonstandard extension.

In the remaining cases, $A(m, n\phi)$ is normalized by $N_H$. To see this, note that in the case $H = C(1, 7\phi)$, the group $A(1, 7\phi)$ is the unique Sylow 7-subgroup; for $H = C(3, 3\phi)$, we see that $A(3, 1\phi)$ is the unique index-9 normal subgroup (it being the inverse image of the center of $A(3, 1)$) and not central, so its centralizer in $H$ equals $A(m, n\phi)$; while for

$$H = C(2, 2\phi), C(4, 4\phi), C(6, 2\phi), C(6, 6\phi),$$

the Sylow 2-subgroup of $H$ is unique and not central, so its centralizer in $H$ equals $A(m, n\phi)$. It follows that $N_H$ is contained in the subgroup of SU(3) generated by the diagonal torus, $S$, and $T_1$.

An element $g = D(u, v, w) \in \text{SU}(3)$ belongs to $N_H$ if and only if $H$ contains

$$S^{-1}g^{-1}Sg = D(-v, -w, -u)D(u, v, w) = D(u - v, v - w, w - u);$$

note that any element of the diagonal torus can be represented in this fashion. Moreover, $D(u, v, w) \mapsto D(u - v, v - w, w - u)$ defines a homomorphism from $A(m, n\phi)$ to itself with kernel $\langle D(1/3, 1/3, 1/3) \rangle$; hence $N_H'$ consists of a copy of $C_3$, times a copy of $C_2$ generated by $T_1$ in all cases except $H = C(1, 7\phi)$. Per Remark 5.30, the factor of $C_3$ may be ignored; consequently, $H$ admits a standard extension in all of the cases except $H = C(1, 7\phi)$. These extensions are all represented by the class of $T_1$ in $I_H$, and so are split. \hfill $\square$

**Proposition 5.37.** Of the 6 groups appearing in Proposition 5.25, each admits a standard extension, and none admits a (split or nonsplit) nonstandard extension.

**Proof.** For each group $H = D(m, n\phi)$ in the list, $A(m, n\phi)$ is centralized only by the diagonal torus, so the centralizer of $H$ in SU(3) is $\mu_3$. In particular, $N_H''$ is trivial, so Remark 5.30 applies with $N_H' = N_H/H$.

For $H = D(3, 1\phi)$, we again use the presentation of the group $E(216\phi)$ described in §5.8. In this case, $N_H = E(216\phi)$, $N''_H \simeq BT'/\{ \pm 1 \} \simeq A_4$, and $A_4/(Q/\{ \pm 1 \}) \simeq C_3$, so we may reduce consideration from $N_H''$ to $N_H' \simeq Q/\{ \pm 1 \} = \{ 1, i, j, k \}$ via Remark 5.30. With notation as in Proposition 5.36, the action of complex conjugation on $N_H''$ fixes $i$ and interchanges $j$ with $k$; consequently, $I''_H = \{ 1, \bar{i} \}$ and the action on this set is again transitive. It follows that $H$ admits no nonstandard extension.

For the groups

$$H = D(2, 2\phi), D(3, 3\phi), D(4, 4\phi), D(6, 2\phi), D(6, 6\phi),$$

the unique index-2 subgroup of $H$ is $C(m, n\phi)$, so from Proposition 5.36 we see that $N_H$ normalizes both $A(m, n\phi)$ and $C(m, n\phi)$, and that $N_H' \simeq C_3$. By Remark 5.30, $H$ admits no nonstandard extension. \hfill $\square$

**Proposition 5.38.** Of the 4 groups

$E(36\phi), E(72\phi), E(216\phi), E(168\phi),$

each admits a standard extension, none admits a split standard extension, and the group $E(36\phi)$ admits a nonsplit standard extension.
Proof. For $H = E(36\phi), E(72\phi), E(216\phi)$, $N_H^0$ is trivial and so Remark 5.30 applies with $N_H' = N_H/H$. For $H = E(36\phi)$, $N_H = E(72\phi)$ and so $N_H' \simeq C_2$; thus $H$ admits a nonstandard extension corresponding to $g_3g_2g_3^{-1}$, which turns out to be nonsplit. For $H = E(72\phi)$, $N_H = E(216\phi)$ and so $N_H' \simeq C_3$; consequently, $H$ admits no nonstandard extension. For $H = E(216\phi)$, $N_H'$ is trivial; thus $H$ admits no nonstandard extension.

For $H = E(168\phi)$, $N_H^0$ is trivial (so Remark 5.30 applies with $N_H' = N_H/H$) and $N_H = H$, so $H$ admits only its standard extension. \hfill \square

5.12. **Maximal subgroups.** We now go back through the classification to identify maximal subgroups. Recall that dropping $\phi$ from a group label corresponds to passing from SU(3) to PSU(3). (Note that in the LMFDB, the entry for each Sato–Tate group includes the maximal subgroups and minimal supergroups of that group with respect to inclusions of finite index.)

**Proposition 5.39.** Among the possible component groups of a group satisfying the Sato–Tate axioms with connected part $U(1)_3$, the maximal subgroups that occur are

$$J(B(3, 4; 4)), \ J_s(B(1, 12)), \ J(B(3, 4)), \ J_s(B(3, 4)), \ J(B(T, 3)), \ J_s(B(T, 3)),$$

$$J(B(O, 1)), \ J(B(O, 2)), \ J(D(4, 4)), \ J(D(6, 6)), \ J(E(216)), \ J(E(168)).$$

**Proof.** As may be confirmed by a simple SAGEMath calculation (see [FKS21]), in most cases our presentations have been chosen so that there is an inclusion into one of the listed subgroups, without any conjugation required. The remaining cases are handled as follows.

- The group $B(1, 8)_1$ is conjugate to a subgroup of $B(O, 1)$ containing $A(1, 8)_1$. This induces embeddings of $B(1, 8)_1, J(B(1, 8)_1), J_s(A(1, 8)_1)$ into $J(B(O, 1))$.

- The group $B(3, 4; 4)$ is conjugate to a subgroup of $B(O, 2)$. This induces an embedding of $J_s(B(3, 4; 4))$ into $J(B(O, 2))$. (However, $J(B(3, 4; 4))$ does not embed into $J(B(O, 2))$; it stands as a maximal subgroup.)

- The group $B(2, 4; 4)$ is conjugate to a subgroup of $B(4, 4)$ by Remark 5.18. This induces embeddings of $B(2, 4; 4), J(B(2, 4; 4)), J_s(B(2, 4; 4))$ into $J(D(4, 4))$.

- Combining the previous point with the isomorphism $B(1, 8)_2 \simeq B(2, 4; 4)$ from the proof of Proposition 5.19, we obtain embeddings of $A(1, 8)_2, J(A(1, 8)_2), J_s(A(1, 8)_2)$ into $J(D(4, 4))$. (These groups also embed into $J(B(O, 2))$.)

- The group $B(3, 6; 2)$ is conjugate to a subgroup of $B(6, 6)$ by Remark 5.18. This induces embeddings of $B(3, 6; 2), J(B(3, 6; 2)), J_s(B(3, 6; 2))$ into $J(D(6, 6))$.

- The group $B(1, 12)$ is conjugate to a subgroup of $B(6, 6)$; this follows from the isomorphism $B(1, 12) \simeq B(2, 6)$ given in the proof of Proposition 5.19. This induces embeddings of $J_s(A(1, 12)), J(B(1, 12))$ into $J(D(6, 6))$. (However, $J_s(B(1, 12))$ does not embed into $J(D(6, 6))$; it stands as a maximal subgroup.)

It remains to check that the list of maximal subgroups is irredundant; that is, no group in the list is conjugate to a subgroup of any other group in the list. This may be checked by using GAP to identify conjugacy classes of subgroups of each listed group, then checking that there is not even an abstract isomorphism between a representative of each class and any other listed group. (This must be done at the level of subgroups of $J(SU(3))$, as there are some spurious isomorphisms among the resulting subgroups of $J(PSU(3))$; for example, $J(B(3, 4; 4))$ and $J_s(B(1, 12))$ are isomorphic as abstract groups, but $J(B(3, 4\phi; 4))$ and $J_s(B(1, 12\phi))$ are not.) \hfill \square
5.13. **Consistency checks.** Given the intricacies of the preceding classification, it is reasonable to ask for ways to corroborate the result. We conclude this section with some discussion of these; see [FKS21] for relevant code.

**Remark 5.40.** Picking up on Remark 5.8, we describe an implementation in SAGEMATH of the algorithm of Beukers and Smyth [BS02] that verifies Proposition 5.7. (See also [KKPR20, Algorithm 7.5, Theorem 7.6] for a robust generalization of this algorithm.)

Suppose that \(a, b, c\) are roots of unity such that \(abc = 1\) and \(|a + b + c|^2 = n\) for some integer \(n\). We must then have \(n \in \{0, \ldots, 9\}\) and \(f_n(a, b) = 0\) for

\[
f_n(x, y) = (x^2 y + xy^2 + 1)(x + y + x^2 y^2) - nx^2 y^2.
\]

Note that \(f_1\) factors as \((x + y)(x^2 y + 1)(xy + 1)\), so its zeroes correspond precisely to the cases where \((a + b)(b + c)(c + a) = 0\); we may thus assume hereafter that \(n \neq 1\).

Define the set

\[
S_n = \{f_n(s_1 x^e, s_2 y^e) : s_1, s_2 \in \{\pm 1\}; e \in \{1, 2\}; (s_1, s_2, e) \neq (1, 1, 1)\}.
\]

By [BS02, Lemma 1], there exist \(n \in \{0\} \cup \{2, \ldots, 9\}\) and \(g \in S_n\) such that \(g(a, b) = 0\). For each choice of \(n\) and \(g\), we performed a resultant computation to eliminate \(y\); made a similar computation to pick out the roots of the resulting polynomial in \(x\) which are roots of unity; then for each option for \(x\), substituted back into \(f_n(x, y)\) and found the roots of the resulting polynomial in \(y\) which are roots of unity.

**Remark 5.41.** For each listed subgroup \(H\) of SU(3), it is easy to verify the restricted rationality condition directly; we checked this in SAGEMATH. Conversely, we also checked in SAGEMATH that there are no counterexamples \((a, b, c)\) to Proposition 5.7 for which \(a, b, c\) generate a group of order dividing \(2^4, 3^3, 7^2,\) or \(2^3 \times 3^2 \times 7\).

**Remark 5.42.** Proposition 5.9 implies that every finite cyclic subgroup of SU(3) containing \(\mu_3\) and satisfying the restricted rationality condition has order dividing one of \(7\phi, 8\phi, 12\phi\). Given only this fact, one can check in SAGEMATH that Table 4 is complete, and that the lists in Proposition 5.23 and Proposition 5.25 are complete.

**Remark 5.43.** To verify that there are no redundancies in the classification, for each listed subgroup \(H\) of SU(3) \(\rtimes\) \(C_2\), we used GAP to compute the isomorphism class of the image of \(H\) in PSU(3) \(\rtimes\) \(C_2\); in cases where this does not suffice to separate groups, we also computed the isomorphism class of \(H\) itself. This computation separates all groups except for the pairs

\[
\{A(1, 4\phi)_1, A(1, 4\phi)_2\}, \quad \{A(1, 6\phi)_1, A(1, 6\phi)_2\}, \quad \{A(1, 8\phi)_1, A(1, 8\phi)_2\},
\]

and the corresponding pairs of standard extensions. Since these groups are all cyclic, they are easily distinguished based on their eigenvalues (or by the computation of moments in §6, which provides another proof of irredundancy).

**Remark 5.44.** Recall that according to Proposition 5.39, there are 12 maximal groups occurring in the classification. We used GAP to compute the isomorphism classes of each conjugacy class of subgroups of each of the maximal groups. This confirms that every group is abstractly isomorphic to a subgroup of one of these groups, and conversely that every subgroup of one of these groups is abstractly isomorphic to one listed in the classification.
Our primary purpose for computing Sato–Tate groups of abelian threefolds is to use the associated distributions to explain the observed statistical behavior of their $L$-polynomials. To this end, we describe some statistics on these distributions and how we computed them for the groups in the classification. For this discussion, we work with the longer list of 433 groups rather than the list of 410 specified in Theorem 1.1. For short, we refer to the groups in this longer list as groups of the extended classification.

6.1. Group invariants. We first recall the definition of the two sets of invariants that we will primarily use to distinguish the groups in the extended classification. These are the simplex of moments and the character norms.

**Definition 6.1.** Let $a_1, a_2, a_3 : \text{USp}(6) \to \mathbb{R}$ be the functions computing the coefficients of $T_1, T_2, T_3$ in the characteristic polynomial of an element of USp(6). For $G$ a closed subgroup of USp(6) and $(e_1, e_2, e_3)$ a triple of nonnegative integers, let $M_{e_1, e_2, e_3}(G)$ denote the average value of $a_1^{e_1} a_2^{e_2} a_3^{e_3}$ on $G$, that is, if $\mu_G$ denotes the Haar measure of $G$, then

$$M_{e_1, e_2, e_3}(G) = \int_G a_1(\gamma)^{e_1} a_2(\gamma)^{e_2} a_3(\gamma)^{e_3} \mu_G(\gamma).$$

This number can be interpreted as the multiplicity of the trivial representation within the representation

$$\left(\mathbb{C}^6\right)^{\otimes e_1} \otimes \left(\Lambda^2 \mathbb{C}^6\right)^{\otimes e_2} \otimes \left(\Lambda^3 \mathbb{C}^6\right)^{\otimes e_3}$$

of $G$, and is thus a nonnegative integer.

To convert this infinite collection of integers into a finite computable invariant, we must choose an appropriate truncation. For $m$ a nonnegative integer, we define the $m$-simplex of moments associated to $G$ as the collection of moments $M_{e_1, e_2, e_3}(G)$ for all tuples $(e_1, e_2, e_3)$ with $e_1 + 2e_2 + 3e_3 \leq m$.

Ordered triples $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq 0$ of nonnegative integers (referred to as partitions from now on) stand in bijection with the highest weights of irreducible representations of USp(6), and we will freely identify both sets. We will denote by $\chi_\lambda$ the irreducible character of USp(6) with highest weight associated to the partition $\lambda$. Following [Shi16], we make the following definition.

**Definition 6.2.** For $G$ a closed subgroup of USp(6) and partitions $\lambda$ and $\mu$, let $N_{\lambda, \mu}(G)$ denote the average of $\chi_\lambda \cdot \chi_\mu$ on $G$, that is

$$N_{\lambda, \mu}(G) = \int_G \chi_\lambda(\gamma) \chi_\mu(\gamma) \mu_G(\gamma).$$

For $m$ a nonnegative integer, we define the $m$-orthogonality matrix of characters associated to $G$ as the collection of averages $N_{\lambda, \mu}(G)$ for all subpartitions $\lambda, \mu$ of the rectangular partition $m \geq m \geq m$. By the $m$-diagonal of character norms we refer to the collection of norms $N_{\lambda, \lambda}(G)$ for all subpartitions $\lambda$ of $m \geq m \geq m$.

The irreducible characters $\chi_\lambda$ can be expressed in terms of the functions $a_1, a_2, a_3$ by means of the Brauer–Klimyk formula (see [Shi16, §4]). In Table 6, we have carried out this computation for the first few values of $\lambda$. 

42
it will become apparent the necessity to describe the methods for a third approach to this problem).

\[ \chi \mid \lambda = 0 \]

\[ \chi \mid \lambda = 1 \]

\[ \chi \mid \lambda = 2 \]

\[ \chi \mid \lambda = 3 \]

\begin{tabular}{|c|c|c|}
\hline
\( \lambda \) & \( \chi \lambda \) & \( \lambda \) & \( \chi \lambda \) \\
\hline
(0, 0, 0) & 1 & (3, 0, 0) & \( -a_1^3 + 2a_1a_2 - a_3 \) \\
(1, 0, 0) & \( -a_1 \) & (3, 1, 0) & \( a_1^2a_2 - a_1^2 - a_1a_3 - a_2^2 + 2a_2 \) \\

Table 6. Some irreducible characters of USp(6) in terms of coefficients of characteristic polynomials.

Remark 6.3. If \( H \subseteq G \) is an inclusion of groups (not necessarily of finite index), then for any representation of USp(6), the multiplicity of the trivial representation within the restriction to \( G \) is less than or equal to the multiplicity within the restriction to \( H \). This means in particular that for any \((e_1, e_2, e_3)\) or \((\lambda, \mu)\) we have

\[ M_{e_1,e_2,e_3}(H) \geq M_{e_1,e_2,e_3}(G), \quad N_{\lambda,\mu}(H) \geq N_{\lambda,\mu}(G). \]

Conversely, if any one of these equalities fails, then \( H \) is not conjugate to a subgroup of \( G \) within USp(6). This can be used, for instance, to give another consistency check of the group inclusions in Proposition 5.39.

In the next sections we will explain the methods used to compute moments and character norms for the groups in the extended classification. Although the character norms can be recovered from the moments, we develop a (more efficient) method to compute them directly (except for the group \( N(U(3)) \); see §6.4).

6.2. Averages over connected groups. Let \( G \) be one of the 14 connected Sato–Tate groups of the extended classification, and let \( F \) be a virtual character of \( G \), that is, a finite \( \mathbb{C} \)-linear combination of irreducible characters of \( G \). Although we are primarily interested in the case where \( F \) is the restriction to \( G \) either of the character \( a_1^e a_2^e a_3^e \) or of an irreducible character of USp(6), in §6.3 it will become apparent the necessity to describe the methods of this section for general virtual characters.

To compute the average of \( F \) over \( G \) we can either use the Weyl integration formula [Wey46] or the Weyl character formula [FH91, §24] (see §6.4 for a third approach to this problem).

In order to apply the Weyl integration formula, we may express \( F \) in terms of the eigenangles \( \theta_1, \theta_2, \theta_3 \) of an element of \( G \). The measures \( \mu \) that we need are listed below in terms of the eigenangles \( \theta_i \).
In each case we are embedding these groups (or products of them) in USp(6) as elements with three conjugate pairs of eigenvalues $e^{±iθ_1}, e^{±iθ_2}, e^{±iθ_3}$. In the case of diagonally embedded groups, some or all of the $θ_i$ may coincide; in the case of $G = U(1)_d$, for example, we have $θ_1 = θ_2 = θ_3$ and simply integrate $F$ against the measure for $U(1)$. In the more complicated cases, however, computing the resulting integrals becomes quite burdensome in practice. There is however a more algorithmic approach to compute these integrals. Let $T ∼ U(1)^r$ denote a maximal torus in $G$, $Φ$ the set of roots of the semisimple part of $\text{Lie}(G)$, and $W$ the Weyl group of $G$. By abuse of notation, we may regard each $α ∈ Φ$ as a function on $U(1)^r$, and therefore there exist integers $e_i(α)$ such that $α(t) = \prod_i t_i^{e_i(α)}$ for $t = (t_1, \ldots, t_r) ∈ U(1)^r$.

The Weyl integration formula establishes that the average of $F$ over $G$ is

$$\frac{1}{|W|} \int_{U(1)^r} F(t) \prod_{α ∈ Φ} (1 - α(t)) dt.$$

Computing the above integral reduces to computing integrals of the form $\int_{U(1)^r} t_i^{e} dt_i$, which are 1 if $e = 0$ and 0 otherwise.

An alternative way to compute the average of $F$ on $G$ is by determining, via the Weyl character formula, the (virtual) multiplicity of the trivial representation in $F$. We now explain how to do this concretely, and note that this is the method that we used in our computations. The virtual character $F$ gives rise to an element $F$ in $\mathbb{C}[u_1^{±1}, \ldots, u_r^{±1}]$, where $r ≤ 3$ denotes the rank of $G$. For an integer $k$, let $[u_i^k] F$ denote the coefficient of $u_i^k$ in the Laurent polynomial $F$ (as a Laurent polynomial in the remaining variables).

Let us start by making three elementary observations.

- Suppose that $G = H × U(1)_d$ for some positive integer $d$, and that the variable $u_r$ corresponds to the factor $U(1)_d$. Then it is apparent that the multiplicity of the trivial representation in $F$ is the multiplicity of the trivial representation in the virtual character of $H$ associated with $[u_r^0] F$.
- Suppose that $G = H × SU(2)_d$ for some positive integer $d$, and that the variable $u_r$ corresponds to the factor $SU(2)_d$. Using that the irreducible representations of $SU(2)$ are the symmetric powers $\text{Sym}^m \mathbb{C}^2$ of the standard representation $\mathbb{C}^2$, one easily sees that the multiplicity of the trivial representation in $F$ is the multiplicity of the trivial representation in the virtual character of $H$ associated with $[u_r^0] F - [u_r^2] F$.
- Suppose that $G = U(3)$. Via the substitution $u_1 = uv$, $u_2 = vw$, $u_3 = w^{-1}v^{-1}w$, we see that $F$ gives rise to an element $F$ in $\mathbb{C}[u^{±1}, v^{±1}, w^{±1}]$. Then the multiplicity of the trivial representation in $F$ is the multiplicity of the trivial representation of the virtual character of $SU(3)$ associated with $[w^0] F$.

</table>
These observations allow us to reduce the problem to determining the multiplicity of the trivial representation in a virtual character $F$ of $G$ for some $G \in \{\text{USp}(4), \text{SU}(3), \text{USp}(6)\}$. To determine this multiplicity, we apply the theory of representations of the complex Lie algebras attached to these classical groups. That is, the multiplicity of the trivial representation is recovered by successively applying the following steps:

- First identify a highest weight $\lambda$ in $F$.
- Then subtract from $F$ the character $\chi_\lambda$ attached to $\lambda$.

The Weyl character formula provides a way to compute $\chi_\lambda$. Let $\tilde{\chi}_\lambda$ be the element in $\mathbb{C}[u_1^\pm, \ldots, u_r^\pm]$ associated with $\chi_\lambda$. Suppose that the variable $u_i$ corresponds to the weight $w_i$, and let $\lambda_i$ denote the coordinates of $\lambda$ written with respect to the basis formed by the weights $w_i$. Let $u^\lambda$ denote $u_1^{\lambda_1} \cdots u_r^{\lambda_r}$ and write

$$D_\lambda = \sum_{w \in W} \text{sign}(w)u^{w(\lambda)},$$

where $\rho$ is the half-sum of the positive roots of the Lie algebra of $G$. The Weyl character formula expresses $\tilde{\chi}_\lambda$ as the quotient $D_\lambda + \rho/D_\rho$.

Table 9 in §9 lists the 3-diagonals of character norms for each of the possible connected Sato–Tate groups $G = G^0$ in USp(6).

6.3. Averages over disconnected groups of central type. Let $F$ be a character of USp$(2g)$, and let $G$ be a closed subgroup of USp$(2g)$ (not necessarily connected). Computing the average of $F$ over $G$ reduces to computing the average of $F$ over every connected component $C$ of $G$. We will show that this computation can be carried out using the methods of §6.2 when $G$ is a group of central type in the extended classification. Let $\varphi : G \to \mathbb{R}[T]$ denote the map that sends $g$ to its reverse characteristic polynomial $\det(1 - gT)$.

Definition 6.4. Let $G$ be a closed subgroup of USp$(2g)$ and let $H$ be a finite subgroup of $G$. We will say that $G$ is of central type relative to $H$ if $G$ is generated by $G^0$ and $H$, and for every $h \in H$ the map

$$\Phi := \Phi^h : G^0 \xrightarrow{\cdot h} G^0 h \xrightarrow{\varphi|_{G^0 h}} \mathbb{R}[T], \quad \Phi(g) = \det(1 - ghT)$$

is a class function of $G^0$. We say that $G$ is of central type if it is of central type relative to some finite subgroup of itself.

Let $G$ be of central type relative to $H$, and let $h$ denote an element of $H$. Let $P$ denote the set of characteristic polynomials of elements of $G^0 h$. The restriction of $F$ to $G^0 h$ factors through $P$ as

$$G^0 h \xrightarrow{\varphi|_{G^0 h}} P \xrightarrow{F^h} \mathbb{R},$$

for a certain map $F^h$. We will denote by $\Phi^h_F$ the composition $F^h \circ \Phi^h$. It is a virtual character of $G^0$. Moreover, the invariance of the Haar measure under translation immediately implies the following lemma.

Lemma 6.5. If $G$ is of central type relative to $H$, then for every $h$ in $H$ the average of $F$ over $G^0 h$ equals the average of $\Phi^h_F$ over $G^0$.
If $G$ is a group of central type in the extended classification, the above lemma reduces the computation of the average of $F$ over a connected component $C$ to the problem considered in §6.2. Fortunately, most of the groups in the extended classification turn out to be of central type. Before considering this question, let us fix presentations for the groups of absolute type $E$ or $F$ (these do not follow the conventions given in §3.5, but rather coincide with the presentations given in the LMFDB). Consider the matrices
\[ I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad J_2 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \]
We fix the symplectic form $\text{Diag}(J_2, J_2, J_2)$ and consider the groups $\text{SU}(2) \times \text{SU}(2) \times \text{SU}(2)$ and $\text{U}(1) \times \text{SU}(2) \times \text{SU}(2)$ embedded in $\text{USp}(6)$ as 3-diagonal block matrices. Set
\[ t = \begin{pmatrix} I_2 & 0 & 0 \\ 0 & I_2 & 0 \\ 0 & 0 & I_2 \end{pmatrix}, \quad s = \begin{pmatrix} I_2 & 0 & 0 \\ 0 & I_2 & 0 \\ 0 & 0 & I_2 \end{pmatrix}, \quad a = \begin{pmatrix} J_2 & 0 & 0 \\ 0 & I_2 & 0 \\ 0 & 0 & I_2 \end{pmatrix}. \]
Denote by $E_*$ the group generated by $\ast \subseteq \{s, t\}$ and $\text{SU}(2) \times \text{SU}(2) \times \text{SU}(2)$. The groups of absolute type $E$ are
\[ E, \quad E_t, \quad E_s, \quad E_{s,t}. \]
Denote by $F_*$ the group generated by $\ast \subseteq \{a, t\}$ and $\text{U}(1) \times \text{SU}(2) \times \text{SU}(2)$. The groups of absolute type $F$ are
\[ F, \quad F_a, \quad F_t, \quad F_{at}, \quad F_{a,t}. \]
The following lemma is an immediate consequence of the multiplicativity of the determinant.

**Lemma 6.6.** Let $G$ be a closed subgroup of $\text{USp}(2g)$. Suppose that:

(i) $G^0 = G_1^0 \times G_2^0$, where $G_i^0$ is a subgroup of $\text{USp}(2g_i)$ and $g = g_1 + g_2$.

(ii) $G$ is generated by $G^0$ and a finite subgroup $H$ of $\text{USp}(2g_1) \times \text{USp}(2g_2)$.

Let $H_i$ be the image of $H$ under the projection onto the factor $\text{USp}(2g_i)$. If $G_1$ and $G_2$ are of central type relative to $H_1$ and $H_2$, respectively, then $G$ is of central type relative to $H$.

**Proposition 6.7.** Let $G$ be a group of the extended classification distinct from
\[ N(\text{U}(3)), \quad E_t, \quad E_s, \quad E_{s,t}, \quad F_t, \quad F_{at}, \quad F_{a,t}. \]
Then $G$ is of central type.

**Proof.** The proposition is trivially true when $G$ is connected or $G^0$ is abelian. Taking into account the restrictions on $G$, this implies that the proposition holds when the absolute type of $G$ is one of $A, B, E, H, L, N$. Suppose next that $G$ is a split product (under the restrictions on $G$, this covers the cases in which $G$ has absolute type $C, D, F, G, I, J, K, L$). In this case, $G$ satisfies the hypotheses of Lemma 6.6 for $g_1 = 1$ and $g_2 = 2$. Moreover, by the restrictions on $G$, if $G^0_2 = \text{SU}(2) \times \text{SU}(2)$, then we may assume that $H_2$ is trivial. The proposition then immediately follows from Lemma 6.8 below.

It remains only to consider the case that $G$ has absolute type $M$, that is, $G^0 = \text{SU}(2)_3$. In §4.4 we have shown that in this case $G$ can be generated by $G^0$ and a finite subgroup $H$ centralizing $G^0$. Therefore for every $f, g \in G^0$ and $h \in H$ we have
\[ \det(1 - f^{-1}gfhT) = \det(1 - f^{-1}ghfT) = \det(1 - ghT), \]
which concludes the proof of the proposition. \qed
The following lemma is used in the proof of Proposition 6.7.

Lemma 6.8. If $G$ is the Sato–Tate group of an elliptic curve or an abelian surface and $G$ is not the group $N(SU(2) \times SU(2))$, then $G$ is of central type.

Proof. The three groups arising for $g = 1$ are either connected or have abelian identity component, so the claim follows trivially. For $g = 2$, having ruled out $N(SU(2) \times SU(2))$, the only nonabelian connected groups that arise as subgroups of disconnected groups are the groups $G^0 = U(1) \times SU(2)$ and $G^0 = SU(2)^2$. In the former case, the lemma follows from Lemma 6.6. As for $G^0 = SU(2)_2$, we recall from [FKRS12, §3.4] that there exists a subgroup $H \subseteq \langle Diag(e^{i\pi/n}, e^{i\pi/n}, e^{-i\pi/n}, e^{-i\pi/n}), J_4 \rangle$, where $J_4 = \begin{pmatrix} 0 & J_2 \\ -J_2 & 0 \end{pmatrix}$, such that $G$ is generated by $H$ and $G^0$. Any such $H$ centralizes $G^0$ (see [FKRS12, p. 1404]), so the argument at the end of the proof of Proposition 6.7 also applies here. □

6.4. Averages over disconnected groups not of central type. Let $F$ be a character of $USp(6)$. We now consider the problem of computing the average of $F$ over the connected components of the seven groups listed in (6.1). For the three groups of absolute type $F$, those for which $G^0 = U(1) \times SU(2) \times SU(2)$, these can be computed using data in the row $JG_{3,3}$ in [FKRS12, Table 6].

For the three groups of absolute type $E$ with $G^0 = SU(2) \times SU(2) \times SU(2)$, the computation of the average of $F$ for the connected component $s^jts^{-j}G^0$ follows again from data in the row $JG_{3,3}$ of [FKRS12, Table 6]. Let us now consider the connected component $sG^0$ (the case of the connected component $s^2G^0$ being analogous). We claim that the distribution of $\det(1 - sgT)$ as $g$ runs over $G^0$ with respect to the Haar measure of $G^0$ is the same as the distribution of the polynomials

$$1 - \text{Trace}(a)T^3 + T^6,$$

as $a$ runs over $SU(2)$ with respect to the Haar measure of $SU(2)$. Let $\varphi$ be any continuous function on the set of polynomials $\det(1 - sgT)$ for $g \in G^0$. If $g = \text{Diag}(a, b, c)$, let us write $\mu(a, b, c)$ for the Haar measure of $G^0$ at $g$. Then an elementary calculation gives

$$\int_{G^0} \varphi\left(\det(1 - \text{Diag}(a, b, c) \cdot s \cdot T)\right) \mu(a, b, c) = \int_{G^0} \varphi\left(\det(1 - acb \cdot T^3)\right) \mu(a, b, c).$$

By the invariance of the Haar measure under translations, the right-hand side of the above equality is

$$\int_{SU(2)} \varphi\left(\det(1 - a \cdot T^3)\right) \mu_{SU(2)}(a) = \int_{SU(2)} \varphi\left(1 - \text{Trace}(a)T^3 + T^6\right) \mu_{SU(2)}(a),$$

and the claim follows.

We are left with the group $N(U(3))$. In this case we focus on the computation of the moments, which will suffice for our purposes. Since none of the elementary approaches used so far seems to work to compute $M_{e_1, e_2, e_3}(JU(3))$, we will instead take an approach recently introduced by Lee and Oh [LO20]. We have not attempted to apply this method to the other groups in the extended classification, although this seems an interesting problem. While successful with $N(U(3))$, we point out that this method has some limitations on the computational side; we will return to this question below.
Let us describe this method for an arbitrary closed subgroup $G$ of USp(6). Observe first that the moments of $G$ are encoded in the integrals

$$
\int_{G} \prod_{j=1}^{m} \det(1 - u_j \gamma) \mu_G(\gamma) \in \mathbb{Z}[u_1, \ldots, u_m].
$$

More precisely, for $m = e_1 + e_2 + e_3$ the moment $M_{e_1, e_2, e_3}(G)$ is the coefficient of the monomial

$$
\prod_{j=1}^{e_1} u_j \prod_{j=e_1+1}^{e_1+e_2} u_j^2 \prod_{j=e_1+e_2+1}^{m} u_j^3
$$

in (6.2). For $G = \text{USp}(6)$ a formula of Bump and Gamburd [BG06], derived from the dual Cauchy identity (see [How95] and [JM85]), expresses the integral (6.2) in terms of the irreducible characters of USp(2m).

Let us recall an extension of this formula, due to Lee and Oh [LO20, Prop. 3.3], which applies to any closed subgroup $G$ of USp(6) (and in fact to any closed subgroup of USp(2g) for any $g$). Let $\chi_3$ denote the irreducible character of USp(2m) of highest weight $\lambda$. It defines an element $\tilde{\chi}_\lambda \in \mathbb{Z}[u_1^{\pm 1}, \ldots, u_m^{\pm 1}]$. Given a subpartition $\lambda$ of the rectangular partition $3 \geq \ldots \geq 3$, let $\lambda^*$ denote the partition $m - \lambda_3' \geq m - \lambda_2' \geq m - \lambda_1'$,

where $\lambda_1' \geq \lambda_2' \geq \lambda_3'$ denotes the transpose partition of $\lambda$. Given a character $\chi$ of USp(6), denote by $m_G(\chi)$ the multiplicity of the trivial representation of $G$ in the restriction of $\chi$ to $G$. The Lee–Oh formula establishes

$$
\int_{G} \prod_{j=1}^{m} \det(1 - u_j \gamma) \mu_G(\gamma) = (u_1 \ldots u_m)^3 \sum_{\lambda} m_G(\chi_{\lambda^*}) \tilde{\chi}_\lambda,
$$

where the sum runs over subpartitions $\lambda$ of the rectangular partition $3 \geq \ldots \geq 3$. The Weyl character formula together with (6.3) reduces the problem of computing $M_{e_1, e_2, e_3}(G)$ for $e_1 + e_2 + e_3 \leq m$ to computing the multiplicities $m_G(\chi_{\lambda^*})$ for every subpartition $\lambda^*$ of the rectangular partition $m \geq m \geq m$.

**Remark 6.9.** From a theoretical point of view, formula (6.3) makes it conceivable to obtain closed formulas for $M_{e_1, e_2, e_3}(G)$. In fact in dimension 2, Lee and Oh [LO20] derive closed formulas for $m_{H}(\chi_{\lambda^*})$ for each possible Sato–Tate group $H$ of an abelian surface. From a computational perspective, however, computing the right-hand side of (6.3) is extremely expensive as the number of terms of $\tilde{\chi}_\lambda$ grows very rapidly in $m$, and in fact (6.3) is the result of an almost miraculous cancellation.

The next lemma explains how to compute $m_{\text{SU}(3)}(\chi_{\lambda^*})$.

**Lemma 6.10.** Let $\lambda^*$ be the partition $(a, b, c)$. Then:

(a) $m_{\text{SU}(3)}(\chi_{\lambda^*})$ is 1 if $a, b, c$ are all even, and it is 0 otherwise.

(b) $m_{\text{SU}(3)}(\chi_{\lambda^*})$ is 1 if $a, b, c$ are even and $a + b + c \equiv 0 \pmod{4}$, and it is 0 otherwise.

**Proof.** We check (a) using the branching rule for the inclusion $\text{GL}_3 \subset \text{Sp}_6$ of algebraic groups as formulated in [HTW05, (2.3.2)] (see also [Kin75]). For a representation of $\text{GL}_3$ indexed
by a pair of nonnegative partitions \((\mu^+, \mu^-)\), its multiplicity in the restriction of \(\chi_{\lambda^*}\) is given by a sum of Littlewood–Richardson numbers:

\[
\sum_{\delta, \gamma} C_{\mu^+, \mu^-}^{\gamma} \lambda^*_{\gamma, 2\delta}
\]

where \(\delta\) and \(\gamma\) run over nonnegative partitions. To evaluate \(\mathfrak{m}_{U(3)}(\chi_{\lambda^*})\) we take \(\mu^+ = \mu^- = 0\), in which case \(C_{\mu^+, \mu^-}^{\gamma} = 1\) if \(\gamma = 0\) and \(C_{\mu^+, \mu^-}^{\gamma} = 0\) otherwise. Meanwhile, for \(\gamma = 0\), \(\lambda^*_{\gamma, 2\delta} = 1\) if \(\lambda^* = 2\delta\) and \(\lambda^*_{\gamma, 2\delta} = 0\) otherwise. This proves the claim.

We now prove (b). We may assume that \(a, b, c\) are all even, since otherwise the statement follows from (a). Recall that the irreducible representation \(V_{\lambda^*}\) of USp(6) with highest weight \(\lambda^*\) is a subrepresentation of

\[
\text{Sym}^{a-b}(V) \otimes \text{Sym}^{b-c}(W) \otimes \text{Sym}^c(U) \subseteq V \otimes (a+b+c),
\]

where \(V\) is the standard representation of USp(6), \(W\) is \(\wedge^2 V \setminus 1\), and \(U\) is \(\wedge^3 V \setminus V\). Let \(v\) be an element of \(V_{\lambda^*}\) spanning the line which is fixed under the action of \(U(3)\). On the one hand, this implies that \(v\) is an element of weight \((0,0,0)\). On the other hand, since \(J\) normalizes \(U(3)\), we see that \(U(3)\) fixes \(Jv\) and \(Jv\) is thus a scalar multiple of \(v\).

Let \(v_1, \ldots, v_6\) denote the standard basis of \(V\). Since \(v \in V \otimes (a+b+c)\) is of weight \((0,0,0)\), it is a nonzero linear combination of vectors of the form

\[
w = \bigotimes_{j=1}^{a+b+c} w_j,
\]

where \(\{w_j\}\), as a multiset, contains \(r\) copies of \(v_1\) and \(v_4\), \(s\) copies of \(v_2\) and \(v_5\), and \(t\) copies of \(v_3\) and \(v_6\), where \(2(r + s + t) = a + b + c\). Let \(\hat{v}_j\) denote \(v_{j+3}\) if \(j = 1, 2, 3\), and \(v_{j-3}\) if \(j = 4, 5, 6\). Note that \(Jv_j = -\hat{v}_j\) for \(j = 1, 2, 3\) and \(Jv_j = \hat{v}_j\) for \(j = 4, 5, 6\), and therefore

\[
Jw = (-1)^{r+s+t} \bigotimes_{j=1}^{a+b+c} \hat{w}_j.
\]

The fact that \(Jv\) is a scalar multiple of \(v\) implies that \(v\) is a nonzero linear combination of vectors of the form

\[
u = \bigotimes_{j=1}^{a+b+c} w_j + (-1)^{(a+b+c)/2} \bigotimes_{j=1}^{a+b+c} \hat{w}_j
\]

But \(J\) acts trivially on \(u\) if and only if \(a + b + c \equiv 0 \pmod{4}\).

\[\square\]

**Remark 6.11.** The Weyl character formula admits an extension to disconnected compact Lie groups due to Kostant [Kos61, §7]. It should be possible to use Kostant’s formula to compute moments of disconnected groups, but we have not attempted this.

6.5. **Point densities.** For \(G\) a connected closed subgroup of USp(6), the distributions associated to \(a_1, a_2, a_3\) are continuous; in particular, no single value occurs with positive probability. By contrast, if \(G\) is disconnected, then it is possible for one or more of \(a_1, a_2, a_3\) to take a constant value on a connected component of \(G\).
Lemma 6.12. Let \( G \) be a group satisfying (ST1), (ST2), and (ST3). Let \((i, t)\) be a pair in which \( i \in \{1, 2, 3\} \) and \( t \) is a real number with the property that the function \( a_i : G \to \mathbb{R} \) is identically equal to the constant function \( t \) on some connected component \( C \) of \( G \). Then

\[
(i, z) \in \{(1, 0)\} \cup \{(2, t) : t \in \{-1, 0, 1, 2, 3\}\} \cup \{(3, 0)\}.
\]

Proof. Since \( G \) satisfies (ST2), \( G^0 \) contains \(-1\). For \( i = 1, 3 \), the presence of \(-1\) in \( G^0 \) implies that the only possible constant value is 0. Now suppose \( i = 2 \). Since \( G \) satisfies (ST3), \( t \) must be an integer. Choose \( g_0 \in C \) so that \( a_1(g_0) = 0 \); such a \( g_0 \) exists, since if \( a_1 \) is not identically zero on \( C \), then \( a_1(g) < 0 < -a_1(g) = a_1(-g) \) for some \( g \in C \), and \( g_0 \) exists by continuity (note \(-C = C\)). We have \(-1 \leq a_2(g_0) \leq 3\) by [KS08, Prop. 4], and therefore \(-1 \leq t \leq 3\). \( \Box \)

Remark 6.13. Lemma 6.12 can be generalized to any closed subgroup of \( \text{USp}(2g) \) that satisfies (ST2) and (ST3). The same argument shows that if \( a_2 \) takes the constant value \( t \) on a component, then \( t \) is an integer in \([2 - g, g]\) when \( g \) is odd, and in \([-g, g]\) when \( g \) is even.

The previous lemma suggests the following definition.

Definition 6.14. Let \( G \) be a group of the extended classification. If \( S \) is a string of digits and \( t \) is a real number, let \( z^t_S \in \mathbb{Q} \) denote the proportion of connected components \( C \) of \( G \) with all of the following properties: \( a_1 \) is identically 0 on \( C \) if 1 appears in \( S \), \( a_2 \) is identically \( t \) on \( C \) if 2 appears in \( S \), and \( a_3 \) is identically 0 on \( C \) if 3 appears in \( S \). If 2 does not appear in \( S \) we omit the superscript \( t \). If 2 does appear in \( S \), let \( z^t_S \) denote the sum of all \( z^t_S \) for all possible values of \( t \). We define the matrix of point densities associated to \( G \) as

\[
Z(G) = \begin{bmatrix}
1 & z_2 & z_2^{-1} & z_2^0 & z_2^1 & z_2^2 & z_2^3 \\
z_1 & z_{12} & z_{12}^{-1} & z_{12}^0 & z_{12}^1 & z_{12}^2 & z_{12}^3 \\
z_3 & z_{23} & z_{23}^{-1} & z_{23}^0 & z_{23}^1 & z_{23}^2 & z_{23}^3 \\
z_{13} & z_{123} & z_{123}^{-1} & z_{123}^0 & z_{123}^1 & z_{123}^2 & z_{123}^3
\end{bmatrix}.
\]

6.6. A Magma computation. For each group \( G \) in the extended classification, we have implemented MAGMA code that gives matrix generators for the group of components of \( G \), and using the methods of the previous sections, computes:

- the 12-simplex of moments of \( G \);
- the 3-diagonal of character norms of \( G \);
- the matrix of point densities \( Z(G) \);
- the averages of \( a^e_i \) over \( G \) for \( i \in \{1, 2, 3\} \) and \( 1 \leq e \leq 12 \) (except for \( N(U(3)) \) we only compute \( a^e_2 \) for \( 1 \leq e \leq 6 \));
- the group of connected components of \( G \);
- the lattice of finite index subgroups of \( G \).

This code may be found in the GitHub repository [FKS21]. The output it produces is included in the LMFDB home page for each of the 410 groups realized by abelian threefolds.

Remark 6.15. Each group \( G \) of central type in the extended classification is of central type relative to the finite group \( H \) specified in §4 or §5 in order to construct it. For each such \( G \) and specific choice of \( H \), the MAGMA code constructs the Laurent polynomials

\[
\Phi^h_F \in \mathbb{C}[u_1^{\pm 1}, \ldots, u_r^{\pm 1}],
\]

for each \( F \in \{1, 2, 3\} \) and \( h \in H \).
where \( h \) runs over \( H \), and \( F \) is either \( a_1^e a_2^e a_3^e \) for \( e_1 + 2e_2 + 3e_3 \leq 12 \), \( a_i^e \) for \( 1 \leq e \leq 12 \), or \( \chi^2 \) for \( \lambda \) a subpartition of \( 3 \). In fact, the explicit presentations of the finite subgroups \( H \) show that the coefficients of \( \Phi^h_F \) always belong to the cyclotomic field generated by a primitive root of unity of order 504. The problem of computing the average of \( F \) over \( G^0 h \) is then resolved as explained in §6.2.

Computing moments of the group \( N(U(3)) \) via the Lee–Oh formula required the implementation of the Weyl character formula for unitary symplectic groups of arbitrary degree. Obtaining the 12-simplex of moments requires considering the characters of \( USp(2m) \) for \( 1 \leq m \leq 6 \), which entails a significant computational effort (and this is precisely what limits our computation of the average of \( a_e^e \) to \( 1 \leq e \leq 6 \)). For \( N(U(3)) \), the 3-diagonal of character norms can be easily recovered from the 12-simplex of moments using the additional input that \( a_1 = a_3 = 0 \) on \( J(U(3)) \). The remaining groups not of central type are treated using the results of §6.4.

Our MAGMA computation yields the following proposition; see Theorem 6.22 for a sharper result regarding the 410 groups that arise for abelian threefolds.

**Proposition 6.16.** The following statements hold:

(a) The 433 groups in the extended classification give rise to 432 distinct 14-simplices of moments (resp. 3-diagonals of character norms).

(b) For the groups

\[
G_1 = J(C(3,3)), \quad G_2 = J_s(C(3,3)),
\]

the pushforward measures from \( G_1, G_2 \) to conjugacy classes in \( USp(6) \) coincide. In particular, we have \( M_{e_1, e_2, e_3}(G_1) = M_{e_1, e_2, e_3}(G_2) \) for all nonnegative integers \( e_1, e_2, e_3 \).

**Proof.** The statement about the 3-diagonals is direct result of the MAGMA computation, which also shows that the 433 groups appearing in the classification give rise to 431 distinct 12-simplices of moments. The two absolute type \( N \) groups \( J(C(3,3)) \) and \( J_s(C(3,3)) \) share the same 12-simplex of moments, and so do the absolute type \( L \) groups \( G_3 = L(J(D_6), J(C_6)) \) and \( G_4 = L(J(D_6), D_6) \). The latter two groups are respectively the fiber product of \( N(U(1)) \) and \( J(D_6) \) along \( J(C_6) \), and the fiber product of \( N(U(1)) \) and \( J(D_6) \) along \( D_6 \). By slightly extending the MAGMA computation, one finds \( M_{0,4,2}(G_3) = 98083 \) and \( M_{0,4,2}(G_4) = 98082 \), showing that there are at least 432 distinct 14-simplices.

For \( i = 1, 2 \), let \( H_i \) be the finite group described in §5 which generates \( G_i \) together with \( G^0_i \). Let \( S_i \) denote the multiset of triples

\[
(\Phi^h_{a_1}, \Phi^h_{a_2}, \Phi^h_{a_3})
\]

as \( h \) runs in \( H_i \). Since both \( G_1 \) and \( G_2 \) are of central type, the multiset \( S_i \) determines the pushforward measure from \( G_i \) to conjugacy classes in \( USp(6) \) as discussed in §6.2 and §6.3. The MAGMA computation verifies that the multisets \( S_1 \) and \( S_2 \) coincide, proving (b), and this completes the proof of (a) and the proposition. \( \square \)

**Remark 6.17.** Let \( G \) be a group in the extended classification, and let \( F \) be a character of \( USp(6) \). If \( h \) and \( h' \) are conjugate in \( G \), then the average of \( F \) over \( G^0 h \) coincides with that over \( G^0 h' \). This implies that many of the Laurent polynomials \( \Phi^h_F \) of (6.4) computed by the MAGMA code coincide. This naturally raises the problem of studying the 3-diagonals of the connected components of the groups in the extended classification. By computation, we
have observed that there are only 82 distinct 3-diagonals of connected components, while, as observed in the previous lemma, their appropriate combination gives rise up to 432 distinct 3-diagonals for entire groups. This discrepancy is particularly remarkable for the groups of absolute type $N$, whose connected components give rise to just 19 distinct 3-diagonals.

**Remark 6.18.** Data inspection shows that, uniformly over the groups, the size of the entries of the 3-diagonal of character norms is much smaller than that of the entries of the 14-simplex of moments (in addition to having just 20 nonzero entries rather than 81). As already suggested in [Shi16], this makes the 3-diagonal of character norms a more desirable invariant to identify Sato–Tate groups from a computational perspective. To illustrate this point, we list in Table 9 the 3-diagonals for the connected groups in the extended classification; these values are all at most $10^5$, whereas the 14-simplices include values that exceed $10^8$.

**Remark 6.19.** Despite inducing the same measures on the set of conjugacy classes of USp(6) by Proposition 6.16, the groups $J(C(3, 3))$ and $J_s(C(3, 3))$, which are not conjugate inside USp(6), do not even have isomorphic groups of connected components. Although the group-theoretic mechanism at work is somewhat different, this phenomenon is loosely analogous to the phenomenon of Gassmann equivalence, in which nonconjugate subgroups of an ambient group give rise to isomorphic permutation representations. See [Sut18, Sut21] for a modern survey of this topic and some recent results.

**Remark 6.20.** The computation of the lattice of subgroups of finite index of a given group relies on Proposition 6.16. This ensures that any two groups in the extended classification are uniquely distinguished by the pair formed by the group of components and the 3-diagonal of character norms. Given $G$, we compute its set of maximal subgroups of finite index up to conjugacy and identify each of them by computing the previous pair of invariants.

**Remark 6.21.** In principle, the point densities do not carry any additional information beyond that of the moments. (In particular, by Proposition 6.16, the point densities cannot be used to separate the groups $J(C(3, 3)), J_s(C(3, 3))$.) However, in practice it is much easier to measure point densities on experimental data than very high moments, so including them in the statistical profile when matching $L$-functions to Sato–Tate groups yields better results.

**Theorem 6.22.** The following statements hold:

(a) The 2-simplex of moments distinguishes the 14 connected Sato–Tate groups that arise for abelian threefolds over number fields.

(b) The 3-diagonal of character norms distinguishes the 409 Sato–Tate distributions that arise for abelian threefolds over number fields. In fact, the same holds if we replace the 3-diagonal with the list of $N_{\lambda,\lambda}(G)$ for $\lambda \in \{(3, 2, 2), (3, 3, 0), (3, 3, 1)\}$.

(c) The isomorphism class of $G/G_0$ together with the matrix of point densities and the 2-diagonal of character norms distinguishes the 410 Sato–Tate groups $G$ that arise for abelian threefolds over number fields. In fact, the same holds if we replace the 2-diagonal with the list of $N_{\lambda,\lambda}(G)$ for $\lambda \in \{(1, 1, 0), (1, 1, 1), (2, 0, 0)\}$.

**Proof.** This is verified by computing these invariants for the 14 Sato–Tate groups that appear in Table 8 and the 410 Sato–Tate groups admitted by Theorem 1.1 using the Magma scripts in [FKS21].
7. Methods for explicit realizations of abelian threefolds

In preparation for our treatment of the lower bound aspect of Theorem 1.1, we document some strategies for constructing abelian threefolds with particular Sato–Tate groups. These include consideration of curves with various automorphism groups and Galois twisting of abelian varieties. We also discuss how to compute the $L$-functions of these abelian threefolds, so as to give an empirical corroboration of the assignment of Sato–Tate groups. Recall that $\text{Aut}'(C)$ denotes the reduced automorphism group of a curve $C$, as defined in §2.

7.1. Curves with automorphisms.

Proposition 7.1. Let $C$ be a curve of genus 3 over $\overline{\mathbb{Q}}$ (or equivalently $\mathbb{C}$).

(a) The group $\text{Aut}'(C)$ takes one of the values listed in Table 10.

(b) For each option for $\text{Aut}'(C)$, the models listed give the generic hyperelliptic or non-hyperelliptic curves realizing that option.

(c) For each option for $\text{Aut}'(C)$, the absolute type of a generic curve realizing that option is as listed.

Proof. For (a) and (b), see [Sha06] or [MP17, Table 1] in the hyperelliptic case and [LRRS14, Theorem 3.1] or [Dol12, Theorem 6.5.2] in the nonhyperelliptic case. (See also [OS20] for an extension of [MP17] to superelliptic curves.)

For (c), we may confirm the decomposition into Jacobians using the LMFDB, which implements the method of [Pau08]; it then remains to identify cases where one or more factors has extra endomorphisms. (See also [LLRS20, Proposition 1.1, Proposition 1.2].)

- For $\text{Aut}'(C) = C_2$, there are two distinct possibilities for $\text{Aut}(C)$ in case $C$ is hyperelliptic. In the case $\text{Aut}(C) \cong C_4$, we have a single factor with an action of $\mathbb{Z}[i]$.
- For $\text{Aut}'(C) = C_3$, we have a single factor with an action of $\mathbb{Z}[\zeta_3]$.
- For $\text{Aut}'(C) = C_n$ with $n \in \{7, 9\}$, we have a single factor with CM by $\mathbb{Z}[\zeta_n]$.
- For $\text{Aut}'(C) = C_6$, we have a 1-dimensional factor with CM by $\mathbb{Z}[\zeta_3]$ and a 2-dimensional factor with an action by an index-2 order in the quaternion algebra of discriminant 6 over $\mathbb{Q}$.
- For $\text{Aut}'(C) = D_6$, we have three one-dimensional factors with CM by $\mathbb{Z}[i]$.
- For $\text{Aut}'(C) = D_8$, we have a 1-dimensional factor with CM by $\mathbb{Z}[i]$ and two 1-dimensional factors with CM by $\mathbb{Z}[^{\sqrt{-2}}]$.
- For $\text{Aut}'(C) = \langle 16, 13 \rangle$, we have a 1-dimensional factor and two 1-dimensional factors with CM by $\mathbb{Z}[i]$.
- For $\text{Aut}'(C) = \langle 48, 33 \rangle$, we have a 1-dimensional factor with CM by $\mathbb{Z}[\zeta_3]$ and two 1-dimensional factors with CM by $\mathbb{Z}[i]$.
- For $\text{Aut}'(C) = \langle 96, 64 \rangle$, we have three 1-dimensional factors with CM by $\mathbb{Z}[i]$.
- For $\text{Aut}'(C) = \text{PSL}_2(\mathbb{F}_7)$, we have three 1-dimensional factors with CM by $\mathbb{Z}[\frac{1+\sqrt{-7}}{2}]$.

□

We make a few cases more explicit, starting with that of a single extra involution on a hyperelliptic curve.
Lemma 7.2. Let \( P(x) \in k[x] \) be a polynomial of degree 4 such that \( xP(x) \) has no repeated roots. Then the genus 3 curve
\[
C : y^2 = P(x^2)
\]
maps to the curves
\[
C_1 : y^2 = P(x), \quad C_2 : y^2 = xP(x)
\]
of respective genera 1 and 2, and the Prym variety of \( C \to C_1 \) is 2-isogenous to \( \text{Jac}(C_2) \).

Proof. The map \( C \to C_1 \) is \((x, y) \mapsto (x^2, y)\). The map \( C \to C_2 \) is \((x, y) \mapsto (x^2, xy)\). □

Remark 7.3. The general form of a plane quartic with an involution defined over \( k \) is
\[
C : Y^4 - P_2(X, Z)Y^2 + P_4(X, Z) = 0.
\]
The quotient by the involution is the genus 1 curve
\[
C_1 : y^2 - P_2(x, 1)y + P_4(x, 1) = 0.
\]
A formula for the genus 2 quotient has been given by Ritzenthaler and Romagny [RR18]. Note that it depends on a factorization of \( P_4(x, 1) \) as a product of two quadratic polynomials that are either Galois invariant or Galois conjugates, which in general does not exist over \( k \) (when it does not one can work over the extension defined by the cubic resolvent of \( P_4(x, 1) \)).

One can effectively reverse this construction by gluing curves of genus 1 and 2 along their 2-torsion; see [HSS20].

Remark 7.4. The general form of a hyperelliptic curve over \( k \) with reduced automorphism group \( C_2 \times C_2 \) (where all three automorphisms are defined over \( k \)) is
\[
y^2 = ax^8 + bx^6 + cx^4 + bx^2 + a
\]
with the three involutions
\[
(x, y) \mapsto (-x, y), \quad (x, y) \mapsto (1/x, y), \quad (x, y) \mapsto (-1/x, y).
\]
The general form of a plane quartic over \( k \) with reduced automorphism group \( C_2 \times C_2 \) is
\[
P_2(X^2, Y^2, Z^2) = 0
\]
with the three involutions
\[
(X : Y : Z) \mapsto (-X : Y : Z), \quad (X : Y : Z) \mapsto (X : -Y : Z), \quad (X : Y : Z) \mapsto (X : Y : -Z).
\]
A result of Howe, Leprévost, and Poonen [HLP00, Proposition 14, Proposition 15] gives a recipe for reconstructing a genus 3 curve with reduced automorphism group containing \( C_2 \times C_2 \) from these quotients (this imposes a matching condition on 2-torsion).

The following is a variant of [Lor18, Example 3.4].

Lemma 7.5. Let \( C \) be a smooth plane quartic curve over \( k \) of the form
\[
X^3Z + bY^3Z + cX^2Y^2 + dXYZ^2 + eZ^4 = 0.
\]
Over \( L = \mathbb{Q}(\zeta_3, b^{1/3}) \), \( C \) admits the group of automorphisms \( S_3 \) generated by
\[
s : [X : Y : Z] \mapsto [\zeta_3 X : \zeta_3^2 Y : Z], \quad t : [X : Y : Z] \mapsto [b^{1/3} Y : b^{-1/3} X : Z].
\]
The quotient \( C_1 = C_L/\langle s \rangle \) has the form
\[
C_1 : y^2 + bx^3 + cx^2y + dxy + ey = 0,
\]

where \( \zeta_3 \) is a primitive cube root of unity and \( b, c, d, e \) are constants determined by the curve \( C \).
and the projection $C \to C_1$ is a degree-3 map defined over $k$. The associated Prym variety is 3-isogenous over $L$ to $\text{Jac}(C_2)^2$ where $C_2$ has the form

$$C_2 : x^3 - 3b^{1/3}xy + cy^2 + dy + e = 0.$$  

Proof. Note that $C_2$ is the quotient of $C$ by $t$. □

The following is a variant of entry V of [Lor18, Proposition 2.1].

Lemma 7.6. Let $C$ be a smooth plane quartic over $k$ of the form

$$Y^4 = X^3Z + aX^2Z^2 + bXZ^3.$$  

Over $L = k(i, b^{1/2})$, $C$ admits the group of automorphisms $D_4$ given by

$$r : [X : Y : Z] \mapsto [X : iY : Z], \quad s : [X : Y : Z] \mapsto [b^{1/2}Z : Y : b^{-1/2}X].$$  

Then the quotient $C_L/\langle r^2 \rangle$ is the genus 1 curve

$$C_1 : y^2 = x(x^2 + ax + b),$$  

and the projection $C \to C_1$ is a degree-2 map defined over $k$. The associated Prym variety is 2-isogenous over $L$ to $\text{Jac}(C_2)^2$ where $C_2$ is the genus 1 curve

$$C_2 : y(x^2 + (a - 2b^{1/2})y) = 1.$$  

(Note that $\text{Jac}(C_2)$ has CM by $\mathbb{Q}(i)$.)

Proof. This can be treated as a special case of Remark 7.4: $C_2$ is the quotient of $C$ by $s$. □

Remark 7.7. It is also useful to consider twists of curves with extremal automorphism groups. In lieu of analyzing such cases here, we will draw on prior results from [ACLLLM18], [FLS18], [FS16].

7.2. Twisting constructions. In [FKS19, §4.2.5], a number of examples of abelian three-folds with particular Sato–Tate groups were constructed by twisting abelian varieties which are $\mathbb{Q}$-isogenous to an elliptic curve with complex multiplication. We make this construction more explicit so that we can confirm numerically that the resulting $L$-functions agree with the computed Sato–Tate groups. In these cases, equidistribution is known unconditionally by an application of Hecke’s theory of Großencharacters (see [Joh17, Proposition 16], for example).

Definition 7.8. Let $E$ be an elliptic curve over $k$ with CM by the maximal order of an imaginary quadratic field $M \not\subseteq k$ of class number 1 and discriminant $-D$. Let $r$ be a positive integer. Let $\rho_M : G_{kM} \to \text{GL}_r(\mathcal{O}_M)$ be a representation with kernel $G_L$. Let $\rho^e_M$ be the representation obtained from $\rho_M$ by precomposing with the action of $\text{Gal}(kM/k)$ on $G_{kM}$ and postcomposing with the action of $\text{Gal}(kM/k)$ on $\text{GL}_r(\mathcal{O}_M)$ via conjugation of matrix entries. By an isogeny twist of $E^r$ by $\rho_M$, we will mean an abelian variety $A_\rho$ over $k$ of dimension $r$ for which $A^e_{\rho_L}$ admits an isogeny to $E^e_L$ and the representation of $G_{kM}$ on $\text{Hom}(A^e_{\rho_L}, E^e_L)_\mathbb{Q} \cong M^r$ is $M$-equivalent to $\rho_M$. Note that the existence of an isogeny twist implies that $\rho^e_M$ is also $M$-equivalent to $\rho_M$.

Remark 7.9. In Definition 7.8, the field $L$ is not the endomorphism field of $A_\rho$ but of $E \times A_\rho$; the endomorphism field of $A_\rho$ is rather the kernel field of the projectivization of $\rho_M$ (as in [FS14, Remark 4.4]).
On a related note, the isogeny class of an isogeny twist is not in general uniquely determined by the image of the representation $\rho_M$ and the extension $L/k$; the choice of the isomorphism of $\text{Gal}(L/kM)$ with the image of $\rho_M$ also has an effect. However, by the previous paragraph these data do suffice to determine the Sato–Tate group.

In order to construct isogeny twists, it is not enough to have equivalence of $\rho_M$ with $\rho'_M$ over $M$. But when we have equivalence over $O_M$, the situation is relatively straightforward.

Remark 7.10. In Definition 7.8, take $k = \mathbb{Q}$ and suppose that the representations $\rho_M$ and $\rho'_M$ are isomorphic (that is, $O_M$-equivalent, not just $M$-equivalent). We can then express this isomorphism via some matrix $V \in \text{GL}_r(O_M)$ (we may omit mention of $V$ when it is the identity matrix).

In this case, we can construct an isogeny twist as follows: take $A_{\rho,M}$ to be the twist of $E_{kM}^2$ by $\rho_M$, then use $V$ to define a descent datum on $A_{\rho,M}$ from $M$ to $\mathbb{Q}$ to obtain an abelian variety $A_{\rho}$ over $\mathbb{Q}$.

We next consider what happens in some cases where Remark 7.10 does not apply. In these cases, we can replace $E_{kM}^2$ with an isogenous variety so as to replace $\rho'_M$ with a different integral model.

Remark 7.11. In Definition 7.8, take $r = 2$, fix a positive integer $m$, and suppose that $\rho_M$ is valued in the subring $R = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(O_M) : b \in mO_M \right\} \subseteq \text{End}(E_{kM}^2)$.

Let $\rho'_M$ be the representation obtained from $\rho_M$ by precomposing the action of $\text{Gal}(kM/k)$ on $G_{kM}$ and postcomposing with the involution of $R$ given by $u \mapsto g^{-1}u g$, $g = \begin{pmatrix} 0 & m \\ 1 & 0 \end{pmatrix}$.

Suppose that $\rho_M$ is $O_M$-equivalent to $\rho'_M$. Then the twist $A_{\rho,M,0}$ of $E_{kM}^2$ by $\rho_M$ contains a subscheme $G$ isomorphic to $E_{kM}[m]$. If $E$ admits a cyclic $m$-isogeny, we can identify its kernel with a subgroup of $G$ and then quotient $A_{\rho,M,0}$ by this subgroup to obtain an abelian variety $A_{\rho,M}$ isomorphic to its conjugate by $\text{Gal}(kM/k)$. In this way, we obtain an abelian variety $A_{\rho}$ over $k$.

Remark 7.12. An important case of Remark 7.11 that can be carried out with $k = \mathbb{Q}$ is $M = \mathbb{Q}(\sqrt{-3})$, $m = 2$. In this case, we may take $E$ to be the curve $y^2 = x^3 - 1$.

Remark 7.13. An important case of Remark 7.11 that cannot be carried out with $k = \mathbb{Q}$ is $M = \mathbb{Q}(i)$, $m = 3$. In this case, the best we can do is to take $k = \mathbb{Q}(\sqrt{3})$, in which case we may take $E$ to be the curve $y^2 = x^3 - 1$. To keep notation somewhat uniform across different twisting constructions, we only apply this construction in the case where $\rho_M$ is the restriction of a representation $G_M \to \text{GL}_r(O_M)$ whose kernel field is linearly disjoint from $k$, and write $\rho_M$ also for the latter representation.

Remark 7.14. When applying Remark 7.13, we will obtain an $L$-function which “looks like” the $L$-function of an abelian surface over $\mathbb{Q}$. In particular, $A_{\rho}$ will be $(2,2)$-isogenous to its Galois conjugate (because $9.1$-a3 is $2$-isogenous to its conjugate), but it is unclear whether it can be chosen to be isomorphic to its Galois conjugate.
It is possible that Sato–Tate groups realized in this manner do occur for K3 surfaces over \( \mathbb{Q} \), rather than abelian surfaces: a given K3 surface can sometimes be realized in multiple ways as the Kummer surface of an abelian surface, using the criterion of Nikulin [Nik75].

Since twisting is not guaranteed to give a Jacobian or even a principally polarizable abelian variety, we include a brief discussion of polarizations of twists.

**Remark 7.15.** Suppose that \( \rho_M \) is absolutely irreducible; then \( A_{\rho,M} \) will admit an invariant polarization which is unique up to rescaling. We may compute this polarization as follows. Let \( L \) be the kernel field of \( \rho_M \) and let \( U \in M_r(\mathcal{O}_M) \) be a \( \mathbb{Q} \)-scalar multiple of the matrix

\[
\sum_{g \in \text{Gal}(L/kM)} \rho_M(g)^* \rho_M(g) \in M_r(M)
\]

(where \( * \) denotes the Hermitian transpose). Then for \( \psi : E^r \to E^r \) the product polarization, \( U \circ \psi \) is a polarization on \( A_{\rho,M} \) whose degree equals \( d = \det(U) \); more precisely, the polarization type can be read off from the elementary divisors of \( U \).

In Remark 7.10, \( A_\rho \) also carries a polarization of type \((1, d)\) or \((1, 1, d)\). In Remark 7.12, \( A_\rho \) carries a polarization of type \((1, d/2)\) provided that \( U \) is chosen to have top-right entry divisible by 2. In Remark 7.13, \( A_\rho \) carries a polarization of type \((1, d/3)\) provided that \( U \) is chosen to have top-right entry divisible by 3.

**Remark 7.16.** In our applications, the polarizations given by Remark 7.15 will have degrees in \( \{1, 2, 3, 6\} \) (see Table 11). In particular, we obtain some examples of abelian surfaces over \( \mathbb{Q} \) which carry a \((1, 6)\)-polarization, and which we believe (but have not checked) admit no isogeny defined over \( \mathbb{Q} \) to an abelian surface carrying a polarization of lower degree.

### 7.3. Exhaustive searches.

In addition to the explicit constructions described in the next section, we conducted several large scale enumerations of genus 3 curves in an effort to realize as many Sato–Tate groups as possible using Jacobians of curves defined over \( \mathbb{Q} \); these enumerations were part of a larger project to construct a database of genus 3 curves to be incorporated into the LMFDB. See [Sut19] for a description of the enumeration of all smooth plane quartics over \( \mathbb{Q} \) defined by models with integer coefficients of absolute value at most 9; this amounts to more than \( 10^{17} \) curves, of which only those with absolute discriminant at most \( 10^9 \) (about 80,000 curves) were retained. Based on an analysis of this dataset we constructed a larger dataset of about a million curves using a similar enumeration that retained smooth plane quartics whose discriminants are 7-smooth (divisible only by primes \( p \leq 7 \)), or of absolute value at most \( 10^9 \).

The motivation for imposing a smoothness constraint is that it substantially increases the likelihood of finding exceptional Sato–Tate groups. If \( S \) denotes the set of \( \mathbb{Q} \)-isomorphism classes of smooth plane quartics represented by integral models with coefficients of absolute value at most 9, the proportion of elements of \( S \) with non-generic Sato–Tate group is much higher in the subset with 7-smooth discriminants than it is in the subset with absolute discriminants bounded by \( 10^9 \). Indeed, among the approximately 2.6 million elements of \( S \) with absolute discriminant bounded by \( 10^9 \), more than 98 percent have Sato–Tate group USp(6), while less than half of the approximately 1.0 million elements of \( S \) with 7-smooth minimal discriminants have Sato–Tate group USp(6).

We also constructed a large database of hyperelliptic curves of genus 3 over \( \mathbb{Q} \) using a generalization of the method described in [BSSVY16] for genus 2 curves. This dataset
includes approximately 4.9 million genus 3 curves defined by an integral model of the form $y^2 = f(x)$ with coefficients of absolute value at most 48 and 7-smooth discriminants.

To analyze the Sato–Tate groups of these curves we first filtered out those we could easily prove have generic Sato–Tate group $\text{USp}(6)$ by computing the reductions modulo $\ell = 2, 3, 5$ of $L$-polynomials $L_\rho(T)$ at small primes $p$. The set of characteristic polynomials that arise in $\text{GSp}_6(\mathbb{F}_\ell)$ is strictly larger than the sets that arise in any of its maximal subgroups, and it suffices to collect a subset of characteristic polynomials that rule out any maximal subgroup. By the Chebotarev density theorem, this approach is guaranteed to eventually identify any abelian threefold $A/\mathbb{Q}$ whose mod-$\ell$ Galois image is equal to $\text{GSp}_6(\mathbb{F}_\ell)$, and on average one expects this to happen quite quickly: for $\ell = 2, 3, 5$ respectively, approximately 8, 5, 4 random elements of $\text{GSp}_6(\mathbb{F}_\ell)$ suffice, on average, to rule out every maximal subgroup. In the typical case where $A$ has surjective mod-$\ell$ representation for $\ell = 2, 3, 5$ one heuristically expects to be able to prove this for at least one of these $\ell$ by computing $L$-polynomials $L_\rho(T)$ for just the first three primes $p > 5$ of good reduction, on average. It follows from Proposition 7.18 below that an abelian threefold that has a surjective mod-$\ell$ image for any prime $\ell$ necessarily has large monodromy and Sato–Tate group $\text{USp}(6)$.

**Remark 7.17.** For $\ell = 2, 3$ there are maximal subgroups of $\text{GSp}_4(\mathbb{F}_\ell)$ in which every characteristic polynomial of $\text{GSp}_4(\mathbb{F}_\ell)$ arises, but one can use $\ell = 5, 7, 11, 13$. Similarly, for $\text{GSp}_2(\mathbb{F}_\ell) = \text{GL}_2(\mathbb{F}_\ell)$ one should avoid $\ell = 2, 3, 5, 7$ and instead use $\ell = 11, 13, 17, 19$.

**Proposition 7.18.** Let $C/\mathbb{Q}$ be a smooth and projective curve of genus $g$, and let $A$ denote its Jacobian. Let $\rho_{A,\ell} : G_k \to \text{Aut}(T_\ell(A)) \cong \text{GSp}_{2g}(\mathbb{Z}_\ell)$ denote the $\ell$-adic representation attached to $A$, and let $\bar{\rho}_{A,\ell}$ denote the mod-$\ell$ representation. If $\ell \neq 2g$ and $\text{Sp}_{2g}(\mathbb{F}_\ell) \subseteq \bar{\rho}_{A,\ell}(G_k)$, then $\text{ST}(A) = \text{USp}(2g)$.

**Proof.** Let $V_\ell(A)$ denote $T_\ell(A) \otimes \overline{\mathbb{Q}}_\ell$, and let $G^{\text{zar}}_\ell$ denote the Zariski closure of the image of $\rho_{A,\ell}$ in $\text{GL}(V_\ell(A))$. It will suffice to show that $G^{\text{zar}}_\ell = \text{GSp}_{2g}(\mathbb{Q}_\ell)$, in which case $G^{\text{zar}}_\ell = \text{GSp}_{2g}(\mathbb{Q}_\ell')$ for every prime $\ell'$. Indeed, if $G^{\text{zar}}_\ell = \text{GSp}_{2g}(\mathbb{Q}_\ell)$, then the inclusions $G^{\text{zar}}_\ell \subseteq \text{MT}(A)_{\mathbb{Q}_\ell'} \subseteq \text{GSp}_{2g}(\mathbb{Q}_\ell')$ provided by [Del82, Prop. 6.2] become equalities. Moreover, by [LP95, Thm. 4.3], if these equalities hold for one prime $\ell$, then they hold for every prime $\ell'$.

Suppose that $g = 1$. If $G^{\text{zar}}_\ell \subseteq \text{GSp}_{2g}(\mathbb{Q}_\ell)$, then $A$ has CM by an order $\mathcal{O}$ in an imaginary quadratic field $M$, and $\bar{\rho}_{A,\ell}(G_M) \subseteq \text{Aut}_\mathcal{O}(A[\ell]) \simeq (\mathcal{O}/\ell\mathcal{O})^\times$ cannot contain any index 2 subgroup of $\text{Sp}_2(\mathbb{F}_\ell) = \text{SL}_2(\mathbb{F}_\ell)$ for $\ell > 2$.

Suppose that $g = 2$ and $\ell = 2$. Then $C$ is given by $y^2 = f(x)$, for some separable polynomial $f \in \mathbb{Q}[x]$ of degree 6. It is well known that the Galois group of $f$ coincides with $\bar{\rho}_{A,2}(G_{\mathbb{Q}})$. Therefore, if $\bar{\rho}_{A,2}(G_{\mathbb{Q}})$ contains $\text{Sp}_4(\mathbb{F}_2) \simeq S_6$, then the Galois group of $f$ must be $S_6$. In this case, by [Zar10, Theorem 1.1], we have $\text{End}(A_{\overline{\mathbb{Q}}}) = \mathbb{Z}$ and therefore $G^{\text{zar}}_\ell = \text{GSp}_{4}(\mathbb{Q}_{\ell'})$.

Finally, if $g \geq 2$ and $\ell \geq 3$ then [Vas04, Theorem 4.1] shows that if $\text{Sp}_{2g}(\mathbb{F}_\ell) \subseteq \bar{\rho}_{A,\ell}(G_{\mathbb{Q}})$, then $\rho_{A,\ell}(G_{\mathbb{Q}}) = \text{GSp}_{2g}(\mathbb{Z}_\ell)$, which clearly implies $G^{\text{zar}}_\ell = \text{GSp}_{2g}(\mathbb{Q}_{\ell'})$. \hfill $\square$

Having filtered out curves that we could easily prove have generic Sato–Tate group we attempted to compute the geometric real endomorphism type of the Jacobian $A$ of each curve using three different software packages, each of which implements a different heuristic algorithm for computing $\text{End}(A_{\overline{\mathbb{Q}}}/\mathbb{R})$ that is practical to apply to millions of curves en masse:

(i) The endomorphisms software repository [CS19] provides a MAGMA implementation that uses a period matrix calculation to compute a numerical approximation of
End(\(A_{\mathbb{Q}}\))\(_{\mathbb{R}}\) to a specified precision; the results are not guaranteed to be correct, but when performed to sufficient precision almost always are. It is possible to certify the results after the fact as described in [CMSV19], but we did not attempt this.

(ii) The monodromy software repository [Zyw21] provides a MAGMA implementation of the algorithm described in [Zyw20], which uses a given set of \(L\)-polynomials at good primes \(p \leq B\) to compute an upper bound on the geometric endomorphism algebra \(\text{End}(A_{\mathbb{Q}})\) (and a lower bound on the Mumford–Tate group) that is guaranteed to be correct for sufficiently large \(B\) (but without an effective bound on such a \(B\)).

(iii) The crystalline obstruction software repository [Cos21] provides a SAGEMath implementation of the algorithm described in [CS20], which uses a \(p\)-adic computation at a prime of good reduction to compute upper bounds on the rank \(r\) of the Néron–Severi group of \(A_{\mathbb{Q}}\) and the dimension \(d\) of the geometric endomorphism algebra \(\text{End}(A_{\mathbb{Q}})\); by varying the choice of \(p\) and taking minima one expects to eventually obtain tight bounds. As shown in [CFS19], the pair \((r, d)\) coincides with the 2-simplex of moments of \(\text{ST}(A_{\mathbb{Q}})\), which by Theorem 6.22 determines \(\text{ST}(A)^0\) and \(\text{End}(A_{\mathbb{Q}})\).

We applied these three methods to each curve in stages, increasing the precision and/or number of primes used in each stage, until all three methods output the same result. We chose bounds on the precision and number of primes so that each method took approximately the same time, with computation times roughly doubling with each stage; the number of curves surviving each stage declined at a much faster rate (roughly a factor of 8), so that the total time was dominated by the first stage, where each method spent 5–10 seconds on each curve. No more than 7 stages were required for any curve. The results are summarized in Table 7 below, in which the notation \(\|f\|\) denotes the maximum of the absolute values of the integer coefficients of a polynomial \(f\).

Remark 7.19. We encountered a small number of genus 3 curves with Sato–Tate group \(\text{USp}(6)\) (as proved by the upper bounds on \(\text{End}(A_{\mathbb{Q}})\) given by methods (ii) and (iii) above), that nevertheless appear to have non-surjective mod-\(\ell\) Galois representations for \(\ell = 2, 3, 5\). One example is the hyperelliptic curve

\[y^2 = 4x^8 - 24x^6 + 45x^4 - 16x^3 - 25x^2 + 16x,\]

for which the \(L\)-polynomials at good primes \(p \leq 2^{24}\) do not imply the surjectivity of \(\bar{\rho}_{A,\ell}\) for any of \(\ell = 2, 3, 5\).

7.4. Explicit computation of \(L\)-functions of abelian threefolds. The explicit realization of abelian threefolds \(A\) matching each of the Sato–Tate groups in our classification was facilitated at several stages by the computation of \(L\)-functions. This was done both in the process of searching for specific examples in large datasets of curves such as those described in the previous section, and also to empirically corroborate our computations of moments and the matrices of point densities for each of the 410 Sato–Tate groups. For each of the 33 maximal Sato–Tate groups whose realizations via explicit abelian threefolds are described in the next section we computed \(L\)-polynomials \(L_p(T)\) for all degree 1 primes of norm bounded by some \(B \geq 2^{30}\) outside of a small excluded set of primes \(S\). The set \(S\) typically consisted of the primes of bad reduction, but in some cases it was convenient to exclude a few others; none of the excluded sets contained more than ten primes, and their exclusion has no impact on the Sato–Tate statistics we are interested in.

Table 7. Counts of heuristically computed absolute types of Sato–Tate groups for Jacobians of genus 3 curves over $\mathbb{Q}$ with 7-smooth discriminants, including hyperelliptic curves $y^2 = f(x)$ with $\|f\| \leq 48$, quartic curves $f(x, y, z) = 0$ with $\|f\| \leq 9$, quartic covers $y^4 + h(x, z)y^2 = f(x, y, z)$ with $\|f\|, \|h\| \leq 64$ and Picard curves $y^3 = f(x)$ with $\|f\| \leq 2187$.

Once computed this data can then be used to compute Sato–Tate statistics for the base change of $A$ to any number field $K$ by including each Euler factor with multiplicity equal to the number of degree 1 primes of $K$ above $p$ (the contribution from primes of higher degree is both asymptotically and practically negligible). For each of the 33 abelian threefolds $A$ realizing one of the maximal Sato–Tate groups, we computed Sato–Tate statistics of the base change of $A$ to every subfield of its endomorphism field, thus obtaining Sato–Tate statistics for all 410 Sato–Tate groups (with multiplicity in cases where maximal Sato–Tate groups with the same identity component have intersection larger than the identity component). Visualizations of these statistics are available at

https://math.mit.edu/~drew/st3/g3SatoTateDistributions.html

We used a wide range of methods to compute the $L$-polynomials of $L_p(T)$ for an abelian variety $A$ over $\mathbb{Q}$ or a quadratic field at degree 1 primes $p$ with $\text{Norm}(p) \leq B$ outside a small set of excluded primes that includes all primes of bad reduction. Several of our explicit realizations of abelian threefolds with maximal Sato–Tate groups involve products of abelian varieties of dimension 1 or 2, which we exploited whenever possible.

The various methods we used are summarized below. For purposes of comparison we give asymptotic time complexity estimates in terms of $p := \text{Norm}(p)$, which should be understood as averages over $p \leq B$ where average polynomial-time algorithms are noted, along with a rough estimate of the total time to compute $L_p(T)$ for all $p \leq B = 2^{30}$ outside the excluded set using a single core of a modern CPU (we used a 3.1GHz Intel i9-9960X CPU in our
computations). In our actual computations we had up to 128 cores working in parallel and were able to extend the computations to $B = 2^{30}$ in most cases.

- For CM elliptic curves $E$ we compute $L_p(T) = 1 - t_p T + pT^2$ at primes that split in the CM field by solving the norm equation $4p = t^2 - v^2 D$ with $D = \text{disc}(\text{End}(E\mathbb{F}_p))$ using Cornachia’s algorithm and determining the Frobenius trace $t_p$ via [RS10], with $t_p = 0$ at inert primes. This has time complexity $(\log p)^{2+o(1)}$ and takes less than a core-minute for $B = 2^{30}$ using the smalljac library [KS08].

- For non-CM elliptic curves $E$ we compute $L_p(T) = 1 - t_p T + pT^2$ by computing $t_p = p + 1 - \#E(\mathbb{F}_p)$ using the optimized baby-step giant-step algorithm implemented in smalljac. This has expected time complexity $p^{1/4+o(1)}$ which is faster than an $(\log p)^{4+o(1)}$ polynomial-time approach for $B = 2^{30}$, taking less than ten core-minutes.

- For Jacobians of generic Picard curves $C/\mathbb{Q}$ that are twists of $y^2 = x^5 - x$ or $y^2 = x^6 + 1$ we compute $L_p(T)$ using the algorithm in [FS14, §5.2.1], which is implemented in smalljac. In the situation where we know the endomorphism field $K$ of the twist (as is the case in all the examples we construct), the ambiguities noted in [FS14, §6.2.1] can be efficiently distinguished by computing Frobenius elements in $\text{Gal}(L/M)$, where $M$ is the CM field of the elliptic curve $E/\mathbb{Q}$ whose square is $\mathbb{Q}$-isogenous to $A$, and $L$ is the minimal field over which all homomorphisms $E_{\mathbb{Q}} \to A_{\mathbb{Q}}$ are defined; the triples $(M, K, L)$ are listed in Tables 6 and 7 of [FS14]. This has time complexity $(\log p)^{2+o(1)}$ and takes less than a core-minute for $B = 2^{30}$ using smalljac.

- For Jacobians of other genus 2 curves $C/\mathbb{Q}$ we use the average polynomial-time algorithm in [HS14, HS16] to compute $L_p(T) = 1 + a_1 T + a_2 T^2 + a_3 pT^3 + p^2 T^4$ modulo $p$, which for $p > 64$ determines $a_1 \in \mathbb{Z}$, leaving at most 5 possibilities for $a_2$; see [KS08, Prop. 4]. All but one possibility can be eliminated in $(\log p)^{2+o(1)}$ expected time by sampling random points $P \in \text{Jac}(C_p)$ and testing if $L_p(1)P = 0$ for each value of $L_p(1)$ implied by the choices for $a_2$ and doing the same on the Jacobian of the quadratic twist of $C_p$ with $a_1$ negated. The average expected time is $(\log p)^{1+o(1)}$, and the total time for $B = 2^{30}$ is about a core-day (less if the curve has rational Weierstrass points, as explained in [HS16, §6.1]).

- For Jacobians of generic Picard curves $y^3 = f(x)$ over $\mathbb{Q}$ we use the algorithm in [Sut20] to compute $L_p(T)$ modulo $p$ and then apply the algorithm in [AFP21] to lift it to $\mathbb{Z}[T]$, which takes negligible time. The average complexity is $(\log p)^{4+o(1)}$ and the time for $B = 2^{30}$ is about 8 core-hours.

- For Jacobians of genus 3 hyperelliptic curves $y^2 = f(x)$ over $\mathbb{Q}$ we compute $L_p(T)$ modulo $p$ using the average polynomial time algorithm of [HS14, HS16]. This leaves $O(p^{1/2})$ possibilities for $L_p(T)$ which we distinguish by performing a baby-step giant-step search along an arithmetic progression determined by $L_p(T)$ modulo $p$ to compute $L_p(1)$ and $L_p(-1)$ using the group computations in the Jacobian of the reduction of the curve and its quadratic twist, which for $p > 1640$ uniquely determines $L_p(T)$ [Sut09, Lemma 4]; see [KS08, Sut09] for details of this computation, which is implemented in smalljac. The average complexity for computing $L_p(T)$ modulo $p$ is $(\log p)^{4+o(1)}$ and the expected cost of lifting to $\mathbb{Z}[T]$ is $p^{1/4+o(1)}$; for $B = 2^{30}$ the time spent on lifting is less than 20 percent of the total time, which is 3 or 4 core-days.
• For Jacobians of genus 3 curves that are degree-2 covers of pointless conics over \(\mathbb{Q}\) (these admit a hyperelliptic model \(y^2 = f(x)\) over a quadratic extension but not over \(\mathbb{Q}\)), we use the average polynomial-time algorithm described in [HMS16] to compute \(L_p(T)\) modulo \(p\), and then lift \(L_p(T)\) to \(\mathbb{Z}[T]\) as above (over \(\mathbb{F}_p\) these curves necessarily admit a hyperelliptic model). The complexity bounds are the same as in the rationally hyperelliptic case but the constant factors are worse. For \(B = 2^{30}\) the total time is one or two core-weeks, of which perhaps a core-day is spent lifting \(L_p(T)\).

• For Jacobians of smooth plane quartic curves over \(\mathbb{Q}\) we compute \(L_p(T)\) modulo \(p\) using the average polynomial time algorithm of [CHS21], which has an average complexity of \((\log p)^{4+o(1)}\) and takes about two core-weeks for \(B = 2^{30}\). We did not implement the lifting phase in the generic case (we can compute trace statistics without this), but in principle it can be done in \(p^{1/4+o(1)}\) time using group operations in the Jacobian of the curve and the corresponding trace zero variety (the kernel of \(\pi + 1\), where \(\pi\) is the Frobenius automorphism) via the addition formulas in [FOR08].

• For smooth plane quartic curves over \(\mathbb{Q}\) that are covers of genus 1 curves, we compute \(L_p(T)\) modulo \(p\) for both curves, leaving at most five options for \(L_p(T) \in \mathbb{Z}[T]\), which we can distinguish in \((\log p)^{2+o(1)}\) expected time using group operations in the Jacobian of the genus 2 curve determined by [RR18, Proposition 2.1] (which may be defined over a cubic extension of \(\mathbb{Q}\), see Remark 7.3). As above, the total time for \(B = 2^{30}\) is one or two core-weeks.

• For Jacobians \(A\) of twists of the Fermat and Klein quartics \(X^4 + Y^4 + Z^4 = 0\) and \(X^3Y + Y^3Z + XZ^3 = 0\), both covers of genus 1 curves, we can compute \(L_p(T)\) modulo \(p\) as above and apply the method described in [FLS18] to lift \(L_p(T)\) to \(\mathbb{Z}[T]\), which takes \((\log p)^{2+o(1)}\) time. Alternatively (and more efficiently), we can compute \(L_p(T)\) using an isogeny twist of \(E^3\) by a 3-dimensional Artin representation \(\rho_M\), where \(E/\mathbb{Q}\) is an elliptic curve with CM by \(M\) whose cube is \(\mathbb{Q}\)-isogenous to \(A\). This has complexity \((\log p)^{2+o(1)}\) following the precomputation of \(\rho_M\). Using a MAGMA implementation of the approach sketched in §7.5 below, it takes a few core-hours for \(B = 2^{30}\); a smalljagc implementation would likely reduce this to a few core-minutes.

• For abelian threefolds that are the restriction of scalars of a CM elliptic curve defined over a cubic number field we can compute \(L_p(T)\) using the Euler factors of the corresponding Hecke character at the primes above \(p\) in \((\log p)^{2+o(1)}\) time; this takes less than a minute for \(B = 2^{30}\) using smalljagc.

• For abelian surfaces and threefolds \(A\) that are isogeny twists of squares or cubes of CM elliptic curves over \(\mathbb{Q}\) or \(\mathbb{Q}(\sqrt{3})\) by Artin representations \(\rho_M\) of dimension 2 or 3 over the CM field \(M\) we compute \(L_p(T)\) using the Hecke character of the CM elliptic curve and computing Frobenius elements via the algorithm of [DD13] as described below. This has time complexity \((\log p)^{2+o(1)}\) once a suitable precomputation for \(\rho_M\) has been completed, but that precomputation may take a long time when the endomorphism field of \(A\) is large; in the most extreme cases the kernel field of \(\rho_M\) is a degree 1296 extension of \(M\) and it takes about 36 hours, but in most cases only a few minutes (see Remark 7.21 for how this could be improved). Using a MAGMA implementation of the approach sketched in §7.5 below, it takes a few core-hours for \(B = 2^{30}\); as noted above, a smalljagc implementation would likely reduce this to a few core-minutes.
Remark 7.20. All 33 of the maximal Sato–Tate groups can be realized using a construction that does not involve the Jacobian of a generic smooth plane quartic or a hyperelliptic cover of a pointless conic; we give at least one such example for each group in §8. It was thus never necessary to apply the algorithms described above for these cases in order to compute moment statistics with $B = 2^{30}$, although we did perform computations with smaller values of $B$ as a sanity check and to obtain timing estimates. The most time-consuming computations we actually performed were for the generic case $A$, which can be realized by a genus 3 hyperelliptic curve with a rational Weierstrass point; this took less than 3 core-days.

7.5. Computing $L$-polynomials of isogeny twists. As described in the next section, the 12 maximal Sato–Tate groups of type $N$ can all be realized using abelian varieties that are isogeny twists of the cube of a CM elliptic curve. In this section we sketch the method we used to compute $L$-polynomials for these realizations.

Let $E/k$ be an elliptic curve with CM by $M$, and let $A$ be an isogeny twist of $E^r$ by an Artin representation $\rho_M : \text{Gal}(L/M) \to \text{GL}_r(\mathbb{C})$ as in Definition 7.8. We may compute the $L$-polynomials of $A$ using its interpretation as the base change from $kM$ to $k$ of the twist of the Artin $L$-function of $\rho_M$ by one of the Hecke characters $\psi_E$ corresponding to $E$. For the purpose of computing Sato–Tate distributions, we can restrict to degree 1 primes of $k$, since the contribution from other primes is asymptotically negligible. If $p$ is a degree 1 prime of $k$ of good reduction for $E$ that splits as $p = \mathfrak{r} \mathfrak{r}$ in $kM$ and is unramified in $L$, then we may compute the $L$-polynomial of $A$ as

$$L_p(T) = \text{Norm}_{M/Q}f(\psi_E(\mathfrak{r})T),$$

where $f$ is the reverse characteristic polynomial of $\rho_M(\text{Frob}_q)$, with $q := \mathfrak{r} \cap M$, by applying [FS14, Eq. (3-8)]. At degree 1 primes $p$ of $k$ of norm $p$ that are inert in $M$ we have

$$L_p(T) = \begin{cases} 1 + a_2T^2 + p^2T^4 & \text{if } r = 2, \\ 1 + a_2T^2 + po_2T^4 + p^3T^6 & \text{if } r = 3, \end{cases}$$

where $a_2 = r - 4 + (\zeta_s + \zeta_s)^2$ with $s = 2, 4, 6, 8, 12$ the order of $\rho_M(\text{Frob}_p\mathcal{O}_M)$; see [FS14, Prop. 3.3] for $r = 2$ and see [FLS18, Cor. 2.4] for $r = 3$.

To compute $\rho_M(\text{Frob}_q)$ at a degree 1 prime $q$ of $M$ that is unramified in $L$, we use the algorithm of Dokchitser and Dokchitser [DD13], which allows one to very efficiently determine the conjugacy class of $\text{Frob}_q$ in $\text{Gal}(L/M)$ once a suitable precomputation has been done. Given a monic polynomial $f \in \mathcal{O}_M[x]$ with splitting field $L$ and distinct roots $r_1, \ldots, r_d \in \mathcal{O}_L$, one chooses a set of polynomials $h \in \mathcal{O}_M[x]$ of degree less than $d$ such that for each conjugacy class $C$ of $\text{Gal}(L/M)$, the polynomials

$$\Gamma_{C,h}(X) := \prod_{\sigma \in C} \left( X - \sum_{j=1}^d h(r_j)\sigma(r_j) \right) \in \mathcal{O}_M[X]$$

are coprime, and for each prime $q$ of $M$ with residue field $\mathbb{F}_q := \mathcal{O}_M/q$ that is unramified in $L$ the conjugacy class $C$ of $\text{Frob}_q$ is the unique conjugacy class for which

$$(7.1) \quad \Gamma_{C,h} \left( \text{Trace}_{\mathbb{F}_q(x^q)/\mathbb{F}_q}(h(x)x^q) \right) = 0.$$
holds for all of the polynomials $h(x)$ that have been chosen. Any $h$ for which the $\Gamma_{C,h}(X)$ are coprime will already distinguish the conjugacy class of $\text{Frob}_q$ for all but finitely many $q$, by [DD13, Thm. 5.3], and it typically takes only a few $h$ to handle all unramified primes.

The computation of the $\Gamma_{C,h}$ involves explicitly computing the Gal($L/M$)-set $\{r_1, \ldots, r_d\}$ and then trying various $h \in \mathcal{O}_M[x]$ until a suitable set has been found (in our implementation we use sparse $h \in \mathbb{Z}[x]$ with small coefficients). Once this precomputation has been done and the $\Gamma_{C,h}$ are fixed, one can very efficiently compute the conjugacy class of $\text{Frob}_q$ for any prime $q$ of $K$ using arithmetic operations that involve only evaluation of the reduction map $\mathcal{O}_M \rightarrow \mathbb{F}_q$ and arithmetic operations in $\mathbb{F}_q$ (which for us is a prime field).

**Remark 7.21.** The cost of precomputing the polynomials $\Gamma_{C,h}$ is dominated by the time to explicitly compute the roots of a polynomial $f \in \mathcal{O}_M[x]$ in its splitting field $L/M$. This can be quite expensive when $[L : M]$ is large (in our most extreme case $[L : M] = 648$ and it takes about 24 hours). This cost can be dramatically reduced by computing the roots in a suitable $p$-adic field, together with the Gal($L/M$)-action, which is efficiently implemented in MAGMA. This requires recognizing the polynomials $\Gamma_{C,h} \in \mathcal{O}_M[x]$ as polynomials whose coefficients have been embedded in this $p$-adic field. It is in principle feasible to do this efficiently using a $p$-adic LLL computation with explicit height bounds, but we did not attempt this.

We mention here an additional precomputation that can substantially improve the efficiency of computing (7.1) in the cases of relevance to us here, where the groups Gal($L/M$) of interest are not all that much larger than the degree $d$ of $f$ and most of the conjugacy classes have fewer than $d$ elements. In this situation, it is advantageous to avoid computing the cycle type of $\text{Frob}_q$ and to avoid all of the matrix operations suggested in [DD13, §5.9], which lead to an asymptotic complexity dominated by the cost of $O(d \log q)$ multiplications of $d \times d$ matrices over $\mathbb{F}_q$; this has a bit complexity of $O(d^{e+1} \log q \mathcal{M}(\log q))$, where $\omega$ is the exponent of matrix multiplication and $\mathcal{M}(n)$ is the cost of multiplying $n$-bit integers. The values of $d$ and $\log q$ of interest to us are less than 50, and in this range the time to compute $\rho_M(\text{Frob}_q)$ will be proportional to $d^4(\log q)^3$.

Let $A_f \in \mathcal{O}_M^{d \times d}$ be the companion matrix of $f$, so $f(A) = 0$, and let $\pi_q : \mathcal{O}_M \rightarrow \mathcal{O}_M/q = \mathbb{F}_q$ be the reduction map. For any $n \geq 0$ we have

$$\text{Trace}_{\mathbb{F}_q}[\pi_q(A_f)^n] = \text{Trace}(\pi_q(A_f)^n) = \pi_q(\text{Trace}(A_f^n)).$$

If we precompute the vector $v_f := [1, \text{Trace}(A), \text{Trace}(A^2), \ldots, \text{Trace}(A^{d-1})] \in \mathcal{O}_M^d$, we can then compute (7.1) by computing the coefficient vector of $h(x)x^n \mod f(x)$ in $\mathbb{F}_q^d$ and plugging the dot product of this vector with the reduction of $v_f$ to $\mathbb{F}_q^d$ into the reduction of $\Gamma_{C,h}(x)$ to $\mathbb{F}_q$. Assuming the cost of applying the reduction map $\pi_p$ is $O(\mathcal{M}(\log q))$, the asymptotic complexity of this approach is $O(\log q \mathcal{M}(d \log q) + e \mathcal{M}(\log q))$, where $e = [L : M]$. Using naive multiplication, the time to compute $\rho_M(\text{Frob}_q)$ will be proportional to $d^2 (\log q)^3 + e (\log q)^2$.

All of the examples considered in the next section have $e \leq 4d^2$, in which case we save a factor of $d^2$ over the approach above, which is a significant improvement. In practice it takes substantially less time to compute $\rho_M(\text{Frob}_q)$ in our examples than it does to compute the cycle type of $\text{Frob}_q$ in the usual way (by computing $\gcd(x^{d^n} - x, f(x))$ for $n \leq d/2$), which is the first step of the approach in [DD13, §5.9]. But we should note that this will not be true in the generic case where $e$ is exponentially larger than $d$.
A MAGMA implementation of this algorithm is available in our GitHub repository [FKS21], along with scripts that compute \( L \)-polynomials at degree 1 primes for all of the examples that involve isogeny twists.

8. The lower bound via explicit realizations

We now establish the “lower bound” assertion of Theorem 1.1 by establishing that among the 410 groups described in §4 and §5, the 33 maximal groups all occur as the Sato–Tate groups of certain abelian threefolds. This was done in a somewhat abstract fashion in [FKS19] by systematic use of twisting constructions; here, we exhibit explicit examples which may be verified both theoretically (by a rigorous computation of the endomorphism algebra and its Galois action) and empirically (by computing the \( L \)-series as described in Section 7.4 and comparing the resulting distribution to the theoretical prediction given by Section 6).

8.1. Overview of techniques. The examples we will be using are summarized in Table 11. In the notation, we use the following elliptic curves defined over \( \mathbb{Q} \):

\[
E_0: y^2 = x^3 - x + 1 \\
E_1: y^2 = x^3 - 288x - 1872 \\
E_{-3}: y^2 = x^3 - 1 \\
E_{-4}: y^2 = x^3 - x \quad (E_{-4,n}: y^2 = x^3 - nx) \\
E_{-7}: y^2 + xy = x^3 - x^2 - 2x - 1 \\
E_{-8}: y^2 = x^3 + x^2 - 3x + 1.
\]

Note that \( E_0 \) and \( E_1 \) do not have CM, whereas for \( D < 0 \), \( E_D \) and \( E_{D,n} \) have CM by the imaginary quadratic order of discriminant \( D \). We also use the curve \( E_{-4,12-8\sqrt{3}} \) over \( \mathbb{Q}(\sqrt{3}) \), which is a model of the curve 9.1-a3 used in Remark 7.13.

The techniques used are listed below, in our order of preference. Here \( k \) denotes the field of definition (equal to \( \mathbb{Q} \) unless specified) and \( d \) denotes the minimum (known) polarization degree for the resulting abelian threefold.

- The product of three elliptic curves over \( \mathbb{Q} \).
- The Weil restriction of an elliptic curve \( C_{1,3} \) defined over the cubic number field \( L_3 = \mathbb{Q}[\alpha]/(\alpha^3 - \alpha^2 + \alpha - 2) \). The extension \( L_3/\mathbb{Q} \) is not Galois; in the analysis we use \( L_3'/\mathbb{Q} \) to denote its Galois closure and \( \alpha_1, \alpha_2, \alpha_3 \) for the conjugates of \( \alpha \) in \( L_3' \).
- The product of an elliptic curve and the Jacobian of a curve \( C_2 \) of genus 2.
- The Jacobian of a curve \( C_3 \) of genus 3 (preferably hyperelliptic). When one of the previous constructions has been used but a Jacobian is also available, we list both.
- The product of an elliptic curve with an abelian surface of the form \( \text{Prym}(C_3/C_1) = \ker(\text{Jac}(C_3) \rightarrow \text{Jac}(C_1)) \), where \( \pi : C_3 \rightarrow C_1 \) is a degree-2 morphism from a genus 3 curve to a genus 1 curve. In this case, \( d = 2 \).
- The product of an elliptic curve with an abelian surface \( A_D \) obtained as an isogeny twist of \( E_D^2 \) as described in Remark 7.10. In this case, \( d \) is given by Remark 7.15.
- The product of an elliptic curve with an abelian surface \( A_D[m] \) obtained as an isogeny twist of \( E_D^2 \) as described in Remark 7.12 or Remark 7.13 (taking \( k = \mathbb{Q}(\sqrt{3}) \) in the
latter case). In this case, \( d \) is given by Remark 7.15. (We add subscripts \( a \) and \( b \) to distinguish cases.)

- An abelian threefold constructed by twisting as in Remark 7.10. In this case, \( d \) is given by Remark 7.15.

In all cases that do not involve isogeny twists, one may use the methods of [CMSV19], as implemented in [CS19], to verify that the Sato–Tate group is as claimed; however, in all cases we give more direct (if less systematic) verifications. See [FKS21] for code to perform some steps in these verifications.

**Remark 8.1.** The twisting constructions follow the approach described in [FKS19], using group-theoretic considerations (aided by [Group]) to formulate some Galois embedding problems. Unlike in [FKS19], where these embedding problems are (mostly) solved uniformly using the invariant rings of complex reflection groups, here we take a more ad hoc approach in order to produce “small” explicit examples. It would be desirable to find more explicit varieties realizing these Sato–Tate groups; however, the computed values of \( d \) suggest obstructions to realizing certain cases using Jacobians or Pryms of double covers. (To promote these to genuine obstructions, one would need to make a more exhaustive analysis in the style of [FG18] to show that no other twisting constructions are possible.)

For the constructions involving twists of abelian surfaces, it might be preferable to work with the associated Kummer surfaces, which are singular K3 surfaces where more of the polarization-preserving automorphisms can be seen directly. These can be described as elliptic fibrations via a construction of Inose (see [Sch07, Proposition 4.1], for example, or see [Kum08, Theorem 11] for a more general result covering arbitrary genus 2 curves). However, it may be possible to find other models that make the symmetries more easily visible.

### 8.2. Examples: types A to M.**

We remind the reader that the curves \( C_{1,3}, C_2, C_3 \) used in the following examples are listed in Table 11.

**Example 8.2.** The unique maximal group of type A occurs as the Sato–Tate group of \( \text{Jac}(C_3) \) where \( C_3 \) is a hyperelliptic curve whose Jacobian has trivial geometric endomorphism ring, by a theorem of Zarhin [Zar00, Theorem 2.1].

**Example 8.3.** The unique maximal group of type B occurs as the Sato–Tate group of \( \text{Jac}(C_3) \) where \( C_3 \) is a hyperelliptic curve whose Jacobian has geometric endomorphism ring \( \mathbb{Z}[i] \). To confirm this, we check that the mod-5 Galois representation has image \( \text{GL}_3(\mathbb{F}_5) \), which implies that the 5-adic Galois representation has image \( \text{GL}_3(\mathbb{Z}_5) \) (see [Upt09, Prop. 6], for example). The \( L \)-polynomials at 37 and 73 factor modulo 5 as

\[
L_{37}(T) \equiv (1 + 3T + T^2 + T^3)(1 + 2T + 2T^2 + 3T^3) \pmod{5}
\]

\[
L_{73}(T) \equiv (1 + T)(1 + 3T)(1 + 4T + 2T^2)(1 + 4T + T^2) \pmod{5}.
\]

The root sets of these polynomials include elements of multiplicative orders 24 and 124; a short MAGMA computation shows that no proper subgroup of \( \text{GL}_3(\mathbb{F}_5) \) contains elements of both of these orders.

This group also occurs as the Sato–Tate group of the Jacobian of a Picard curve whose Jacobian has geometric endomorphism ring \( \mathbb{Z}[\zeta_3] \). We may take the curve \( y^3 = x^4 + x + 1 \), for example, whose Galois representation surjects onto \( \text{GL}_3(\mathbb{Z}_{67}) \); see [Upt09, §6.1.2]. We will verify later that this curve also has large mod-2 Galois image (see Example 8.34).
Example 8.4. The unique maximal group of type C occurs as the Sato–Tate group of $E_0 \times \text{Jac}(C_2)$ where $C_2$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $\text{USp}(4)$. Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2; the genus 2 quotient is the curve 709.a.709.1 in the LMFDB.

The unique maximal group of type D occurs as the Sato–Tate group of $E_{-3} \times \text{Jac}(C_2)$. Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2; the genus 2 quotient is the curve 836352.a.836352.1 in the LMFDB.

Example 8.5. The unique maximal group of type E occurs as the Sato–Tate group of $\text{Res}
C_{1,3}$; note that 23 splits completely in $L_3$ and the Frobenius traces of $C_{1,3}$ at the primes of $L_3$ above 23 are not all equal up to sign, so $C_{1,3}$ cannot be a $\mathbb{Q}$-curve. (Another way to confirm that $C_{1,3}$ is not a $\mathbb{Q}$-curve is to use the algorithm described in [CN20, §5].) Table 11 also includes an example of a Jacobian. The curve $C_3$ has the form

$$y^2 = (x - 1)(2x^3 + 1)((1 + x)^3 - 2).$$

Over $\mathbb{Q}(2^{1/3})$, $C_3$ acquires the nonhyperelliptic involution

$$(x, y) \mapsto \left(\frac{-x + 4^{1/3}}{2^{1/3}x + 1}, \frac{9}{(2^{1/3}x + 1)^4}\right).$$

Hence over $L = \mathbb{Q}(\zeta_3, 2^{1/3})$, the reduced automorphism group of $C_3$ becomes $C_2 \times C_2$, and the quotients by the three involutions are conjugate over $L$. We may recover the $j$-invariant of one of these quotients by computing that the map

$$x \mapsto x + \frac{-x + 4^{1/3}}{2^{1/3}x + 1}$$

carries the Weierstrass points $1, -2^{-1/3}, -2^{-1/3}\zeta_3, -2^{1/3}\zeta_3^2$ to $2^{1/3}, \infty, 2^{-1/3}(1 + \zeta_3), 2^{-1/3}(1 + \zeta_3^2)$; we find that this quotient does not have CM.

Example 8.6. The unique maximal group of type F occurs as the Sato–Tate group of the product $E_{-8} \times \text{Jac}(C_2)$ where $C_2$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $\text{N}(G_{3,3})$; the endomorphism field of $E_{-8} \times \text{Jac}(C_2)$ is $\mathbb{Q}(\sqrt{-2}, i) = \mathbb{Q}(\zeta_8)$. Table 11 also includes an example of a Jacobian with endomorphism field $\mathbb{Q}(\zeta_8)$ which can be explained using Lemma 7.2; the genus 1 quotient has Jacobian with CM by $\mathbb{Q}(\sqrt{-2})$, while the genus 2 quotient becomes isomorphic over $\mathbb{Q}(\sqrt{2})$ to

$$y^2 = (1 + \sqrt{2})x^6 + (-1 + \sqrt{2})x^4 + (-1 - \sqrt{2})x^2 + (1 - \sqrt{2}).$$

The quotient of this curve by the nonhyperelliptic involution $(x, y) \mapsto (-x, y)$ is the elliptic curve 512.1-h2 in the LMFDB, which does not have CM and is not a $\mathbb{Q}$-curve.

Example 8.7. The maximal group of type G with component group $C_4$ occurs as the Sato–Tate group of $E_0 \times \text{Jac}(C_2)$ where $C_2$: $y^2 = x^5 + 1$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $F_{ac}$ and endomorphism field $\mathbb{Q}(\zeta_5)$. Table 11 also includes an example of a Jacobian with endomorphism field $\mathbb{Q}(\zeta_5)$ which can be explained using Lemma 7.2; the genus 2 quotient is isomorphic to $C_2$.

Example 8.8. The maximal group of type G with component group $C_2 \times C_2$ occurs as the Sato–Tate group of $E_0 \times E_{-4} \times E_{-8}$, which has endomorphism field $\mathbb{Q}(i, \sqrt{2}) = \mathbb{Q}(\zeta_8)$. 67
Table 11 also includes an example of a Jacobian with endomorphism field \( \mathbb{Q}(\zeta_8) \) which can be explained using Lemma 7.2; the genus 2 quotient is isomorphic to

\[
2y^2 = x^6 + x^4 - 3x^2 + 1.
\]

The quotient by the involution \((x, y) \mapsto (-x, y)\) has CM by \( \mathbb{Q}(\sqrt{-2}) \) and the quotient by the involution \((x, y) \mapsto (-x, -y)\) has CM by \( \mathbb{Q}(i) \).

**Example 8.9.** The maximal group of type \( H \) with component group \( C_6 \) occurs as the Sato–Tate group of \( \text{Jac}(C_3) \), where \( C_3 \) is a hyperelliptic curve with endomorphism field \( \mathbb{Q}(\zeta_7) \).

The maximal group of type \( H \) with component group \( C_2 \times C_4 \) occurs as the Sato–Tate group of \( E_{-3} \times \text{Jac}(C_2) \) where \( C_2 \) is as in Example 8.7; note that the endomorphism field of \( \text{Jac}(C_2) \) does not contain \( \mathbb{Q}(\sqrt{-3}) \). Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2; the genus 1 quotient has CM by \( \sqrt{-2} \), while the genus 2 quotient appears in \cite{vW99a}, Table 1] as an example whose Jacobian has CM by the number field \( \text{sp}l(x^4 + 4x^2 + 2) \).

The maximal group of type \( H \) with component group \( C_2 \times C_2 \times C_2 \) occurs as the Sato–Tate group of \( E_{-3} \times E_{-4} \times E_{-8} \). Table 11 also includes an example of a Jacobian (shown to us by Everett Howe) which can be explained using Remark 7.4; it is isogenous to a product of certain twists of \( E_{-3}, E_{-4}, E_{-8} \).

**Example 8.10.** The maximal group of type \( I \) with component group \( D_4 \) occurs as the Sato–Tate group of \( E_0 \times \text{Jac}(C_2) \) where \( C_2 \) occurs in \cite[Table 11]{FKRS12} as an example whose Jacobian has Sato–Tate group \( J(E_1) \) and endomorphism field \( \mathbb{Q}(i, 2^{1/4}) \). Per \cite[Proposicio 8.2.1]{Car01} or \cite[\S 5.3]{GS01}, the \( \mathbb{Q} \)-isogeny factors of \( \text{Jac}(C_2) \) have \( j \)-invariants which are not in \( \mathbb{Q} \). Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2; the genus 2 curve is again \( C_2 \).

Similarly, the maximal group of type \( J \) with component group \( C_2 \times D_4 \) occurs as the Sato–Tate group of \( E_{-3} \times \text{Jac}(C_2) \). Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2: the genus 1 quotient has CM by \( \mathbb{Q}(i) \), while Magma confirms that the genus 2 quotient acquires an action of \( D_4 \) over \( \text{sp}l(x^4 - 6x^2 + 3) \). The endomorphism field of the Jacobian is \( \text{sp}l(x^4 - 6x^2 + 3)(i) = \text{sp}l(x^8 + 30x^4 + 9) \).

**Example 8.11.** The maximal group of type \( I \) with component group \( D_6 \) occurs as the Sato–Tate group of \( E_0 \times \text{Jac}(C_2) \) where \( C_2 \) occurs in \cite[Table 11]{FKRS12} as an example whose Jacobian has Sato–Tate group \( J(E_6) \) and endomorphism field \( \mathbb{Q}(\sqrt{-3}, (-2)^{1/6}) \). Table 11 also includes an example of a Jacobian which can be explained using Lemma 7.2; over the field \( \mathbb{Q}[\alpha]/(\alpha^3 - 2\alpha^2 + \alpha - 16/27) \), \( \text{Jac}(C_2) \) admits a Richelot isogeny to its quadratic twist by \( \alpha \). Hence the endomorphism field contains \( \text{sp}l(x^6 - 2x^4 + x^2 - 16/27) = \text{sp}l(x^6 - 4x^3 + 1) \); the results of \cite{FKRS12} will now force the Sato–Tate group to be \( J(E_6) \) once we check that \( \text{Jac}(C_2) \) cannot have CM in some imaginary quadratic field \( M \). If this were the case, then \( M \) would be unramified away from the primes of bad reduction of \( \text{Jac}(C_2) \), which in this case are 2 and 3; this implies \( M \subseteq \mathbb{Q}(\zeta_24) \). Also, from the proof of \cite[Corollary 3.12]{FS14}, the Frobenius trace of \( \text{Jac}(C_2) \) at every prime that is inert in \( M \) would be 0; by checking this condition for \( p = 5, 13, 17 \), we rule out all possibilities except \( M = \mathbb{Q}(i) \). Finally, note that the \( L \)-polynomial for each prime that is split in \( M \) would factor nontrivially over \( M \); this does not occur for \( p = 5 \). (See also Remark 8.12 below.)

Similarly, the maximal group of type \( J \) with component group \( C_2 \times D_6 \) occurs as the Sato–Tate group of \( E_{-4} \times \text{Jac}(C_2) \). Table 11 also includes an example of a Jacobian which
can be partially explained using Remark 7.3; writing $C_3$ in the form

$$2Y^4 + Y^2(4X^2 - 6Z^2) + 4X^4 + 6X^3Z + XZ^3 + 3Z^4,$$

we see that the genus 1 quotient has CM by $\mathbb{Q}(i)$, while the Prym is 2-isogenous to the Jacobian of a curve $C'_2$ defined over $\mathbb{Q}[\alpha]/(\alpha^3 - \alpha^2 - 2\alpha - 6)$. Using MAGMA to compute a Richelot isogeny, we check that $\text{Jac}(C_2)$ is (2, 2)-isogenous to the Jacobian of

$$C_2 : y^2 = 56x^6 - 144x^5 + 12x^4 + 16x^3 + 90x^2 + 60x + 9$$

$$(2x^2 - 4x - 1)(28x^4 - 16x^3 - 12x^2 - 24x - 9).$$

By computing Igusa invariants, we see that $C_2$ and $C'_2$ are isomorphic over $\overline{\mathbb{Q}}$, but MAGMA confirms that they are not isomorphic over $\mathbb{Q}$. As in the previous paragraph, we can now verify that $\text{Jac}(C_2)$ has Sato–Tate group $J(E_6)$ by checking that $\text{Jac}(C_2)$ cannot have CM in some imaginary quadratic field $M$. In this example, $\text{Jac}(C_2)$ has good reduction away from 2, 3, 7, and so $M \subseteq \mathbb{Q}(\zeta_{68})$. By checking the nonvanishing of Frobenius traces for $p = 5, 11, 31, 53$, we rule out all possibilities except $M = \mathbb{Q}(\sqrt{-6})$; we rule out that case by checking that the $L$-polynomial for $p = 5$ does not factor nontrivially over $\mathbb{Q}(\sqrt{-6})$.

To compute the endomorphism field of $\text{Jac}(C_2)$, note that the field of definition of the Weierstrass points of $C_2$ is an $(C_2 \times S_4)$-extension $L$ of $\mathbb{Q}$ over which the Weierstrass points of $C'_2$ are also defined; therefore $C_2$ and $C'_2$ must be isomorphic over $L$. The only $D_6$-subextension of $L$ is $\text{spl}(x^3 - x^2 - 2x - 6)(\sqrt{-6}) = \text{spl}(x^6 + 7x^4 + 7x^2 - 63)$, which must then be the endomorphism field of $\text{Jac}(C_2)$. Hence the endomorphism field of $\text{Jac}(C_3)$ is

$$\text{spl}(x^6 + 7x^4 + 7x^2 - 63)(i) = \text{spl}(x^{12} + 10x^{10} + 177x^8 + 244x^6 + 172x^4 + 96x^2 + 36).$$

**Remark 8.12.** More generally, the family of genus 2 curves

$$C_t : y^2 = x^5 + 8x^4 + tx^3 + 16x^2 - 4x.$$

has the property that for generic $t$, the endomorphism field $L_t$ of $\text{Jac}(C_t)$ is the splitting field of $x^6 - 2x^4 + x^3 + 64/(t^2 - 432)$ and $\text{End}(\text{Jac}(C_t)_{\overline{L}})$ is an index-2 order of the quaternion algebra over $\mathbb{Q}$ of discriminant 6; that is, $\text{Jac}(C_t)$ is the universal family of quaternionic abelian surfaces over some genus 0 Shimura curve (compare [BG08]). Namely, as pointed out to us by Noam Elkies, this can be confirmed by applying [Kum08, Theorem 11] to compute the associated elliptic K3 surface with fibers of type $E_7$ and $E_8$ at 0 and $\infty$, respectively.

**Example 8.13.** The maximal group of type $K$ with component group $C_2 \times D_6$ occurs as the Sato–Tate group of $E_0 \times \text{Jac}(C_2)$ where $C_2$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $J(D_6)$ and endomorphism field

$$\mathbb{Q}(\zeta_{24})[\alpha]/(\alpha^3 + 3\alpha - 2) = \text{spl}(x^{12} - 4x^9 + 8x^6 - 4x^3 + 1).$$

The maximal group of type $L$ with component group $C_2 \times C_2 \times D_6$ occurs as the Sato–Tate group of $E_{-7} \times \text{Jac}(C_2)$ with endomorphism field $\text{spl}(x^{24} - 660x^{18} + 12134x^{12} - 660x^6 + 1)$. Table 11 also includes an example of a Jacobian for the maximal group of type $K$ with component group $C_2 \times D_6$, which can be explained using Remark 7.3: over $\mathbb{Q}[\alpha]/(\alpha^3 - 3\alpha - 4)$, the Prym of $C_3 \to C_1$ becomes isogenous to $\text{Jac}(C_2)$ for

$$C_2 : y^2 = x^5 + 8x^4 + 16x^2 - 4x.$$
(this is the degenerate specialization $t = 0$ of the family from Remark 8.12). The latter acquires endomorphisms by $C_2 \times C_2$ over $\mathbb{Q}(\zeta_8)$, and the isogeny factors have CM by $\mathbb{Q}(\sqrt{-6})$ (compare [BG08, Proposition 3.7]). The endomorphism field of $\text{Jac}(C_3)$ is

$$\text{spl}(x^3 - 3x - 4)(\zeta_8, \sqrt{-6}) = \text{spl}(x^{12} - 4x^6 + 1).$$

**Example 8.14.** The maximal group of type $K$ with component group $C_2 \times S_4$ occurs as the Sato–Tate group of $E_6 \times \text{Jac}(C_2)$ where $C_2$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $J(O)$ and endomorphism field $\text{spl}(x^6 + 4x^4 - 22)$. Similarly, the maximal group of type $L$ with component group $C_2 \times C_2 \times S_4$ occurs as the Sato–Tate group of $E_{-3} \times \text{Jac}(C_2)$ with endomorphism field $\text{spl}(x^{12} - 9x^8 - 38x^6 - 9x^4 + 1)$.

Table 11 also includes an example of a Jacobian; to analyze this example, let $\alpha_1, \alpha_2, \alpha_3$ be the roots of the polynomial $x^3 + 2x + 1$ in a splitting field $L$. Over $L$, we may change the model to

$$Y^4 = X^3 Z + a_j X^2 Z^2 + b_j X Z^3, \quad (a_j, b_j) = (-4 - 3\alpha_j^2, 2\alpha_j^2 - 3\alpha_j + 4).$$

Using Lemma 7.6, we deduce that the endomorphism field of $\text{Jac}(C_3)$ is

$$K := \mathbb{Q}(i, \sqrt{-59}, \alpha_1, b_1^{1/2}, b_2^{1/2}, b_3^{1/2}) = \text{spl}(x^6 - 4x^4 - 59).$$

**Example 8.15.** The maximal group of type $M$ with component group $D_6$ occurs as the Sato–Tate group of $E_1 \times \text{Jac}(C_2)$ where $C_2$ occurs in [FKRS12, Table 11] as an example whose Jacobian has Sato–Tate group $J(E_3)$ with endomorphism field $\mathbb{Q}(\zeta_3, 2^{1/3})$. We analyze this example following [FKS19, §4.2.4]. Over $\mathbb{Q}(2^{1/3})$, $C_2$ becomes isomorphic to $2y^2 = 2x^6 + x^3 + 2$, whose quotient by the involution $(x, y) \mapsto (1/x, y/x^3)$ may be identified with the curve $C_1 : 2y^2 = (x + 2)(2x^3 - 6x + 1)$ via the map $(x, y) \mapsto (x + 1/x, y(x + 1)/x^2)$. Since $\text{Jac}(C_1)$ is the quadratic twist of $E_1$ over $\mathbb{Q}(i)$, the endomorphism field of $E_1 \times \text{Jac}(C_2)$ is $\mathbb{Q}(\zeta_{12}, 2^{1/3})$.

Table 11 also includes an example of a Jacobian; using Lemma 7.5, we see that all three quotients have $j$-invariant $-216$ and the endomorphism field is $\mathbb{Q}(\zeta_{12}, 2^{1/3})$.

**Example 8.16.** The maximal group of type $M$ with component group $S_4$ occurs as the Sato–Tate group of $\text{Res} C_{1,3}$. The endomorphism field is

$$L_3' [\sqrt{\alpha_1/\alpha_2}, \sqrt{\alpha_2/\alpha_3}] = \text{spl}(x^4 - 4x^2 - 8x - 3).$$

Table 11 includes an example of a Jacobian with endomorphism field $\text{spl}(x^4 - 2x^3 - 6x + 3)$; it is a reduced model of the twist of $y^2 = x^8 + 14x^4 + 1$ listed in [ACLLM18, Table 4, row 11].

**8.3. Examples: type $N$.** In the following examples, we sometimes define a matrix $V$ to specify an isomorphism of $\rho_M$ with $\rho_M^c$ (see Remark 7.10); we also write $U$ for the matrix defining an invariant polarization (see Remark 7.15).

**Example 8.17.** Let $M = \mathbb{Q}(\zeta_3)$. The maximal group $J_4(B(1, 12))$ of type $N$ with component group $(48, 15)$ occurs as the Sato–Tate group of $E_{-3} \times A_{-3|2|a}$ obtained as in Remark 7.12, for a representation $\rho_M : G_M \to \text{GL}_2(\mathcal{O}_M)$ with image isomorphic to $(24, 10)$, generated by

$$\begin{pmatrix} \zeta_3 & 0 \\ 0 & \zeta_3 \end{pmatrix}, \begin{pmatrix} -1 & -2 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}$$

with $U = \begin{pmatrix} 2 & 2 \\ 2 & 4 \end{pmatrix}$. 
(Note that $U$ must have its top-right entry divisible by 2.) To exhibit an explicit example, we must find a Galois extension $L/Q$ with
\[
\begin{align*}
\text{Gal}(L/Q) &
\cong
D_4 \times S_3 \cong (48, 15), \\
\text{Gal}(L/M) &
\cong
D_4 \times C_3 \cong (24, 10).
\end{align*}
\]
We may obtain such an extension by taking the compositum of two Galois extensions $L_1/Q, L_2/Q$ containing $M$ with
\[
\begin{align*}
\text{Gal}(L_1/Q) &
\cong
D_8, &
\text{Gal}(L_1/M) &
\cong
D_4, \\
\text{Gal}(L_2/Q) &
\cong
S_3, &
\text{Gal}(L_2/M) &
\cong
C_3.
\end{align*}
\]
We may satisfy these constraints with
\[
\begin{align*}
L_1 &
= \text{spl}(x^8 - 12x^6 + 12x^4 - 52x^2 - 3), \\
L_2 &
= \text{spl}(x^3 - 2), \\
L &
= L_1L_2 = \text{spl}(x^{24} + 488x^{18} + 63384x^{12} - 5872x^6 + 1372), \\
K &
= L^{C_6} = \text{spl}(x^4 - 4x^2 - 3).
\end{align*}
\]
There are 16 representations $\rho_M$ with kernel field $L$ and image $\rho_M(G_M)$ as above, comprising two complex conjugate $M$-equivalence classes. Of these, 8 are $\mathcal{O}_M$-equivalent (in fact equal) to $\rho_M^*$ as required by Remark 7.11. These $\rho_M$ realize both $M$-equivalence classes and give rise to $(1, 2)$-polarized abelian surfaces $A_{-3[2]a}$ over $Q$ with Sato–Tate group $D_{4,1}$ and endomorphism field $K$ with $\text{Gal}(K/Q) \cong D_4$; they are distinguished by their $L$-polynomials at 13. In both cases the product $E_{-3} \times A_{-3[2]a}$ is an abelian threefold over $Q$ with Sato–Tate group $J_s(B(1, 12))$ and endomorphism field $L$.

**Remark 8.18.** In Example 8.17, based on the polarization type, we expect that the abelian surface can be realized (up to a quadratic twist) as the Prym of a degree 2 morphism from a genus 3 curve to a genus 1 curve, all defined over $Q$.

**Example 8.19.** Let $M = Q(i)$ and $k = Q(\sqrt{3})$. The maximal group $J(B(3, 4; 4))$ of type $N$ with component group $(48, 15)$ occurs as the Sato–Tate group of $E_{-4,12-8\sqrt{3}} \times A_{-4[3]a}$ obtained as in Remark 7.13, for a representation $\rho_M: G_M \to GL_2(\mathcal{O}_M)$ with image isomorphic to $(24, 1)$, generated by
\[
\begin{pmatrix}
i & 0 \\
0 & i
\end{pmatrix},
\begin{pmatrix}
-1 & -i \\
i & 1 + i
\end{pmatrix},
\begin{pmatrix}
1 & 3 \\
-1 & -2
\end{pmatrix}
\] with $U = \begin{pmatrix} 6 & 3 - 3i \\
3 + 3i & 6 \end{pmatrix}$.
(Note that $U$ must have its top-right entry divisible by 3.) To exhibit an explicit example, we must find a Galois extension $L/Q$ not containing $k$ with
\[
\begin{align*}
\text{Gal}(L/Q) &
\cong
D_4 \times S_3, &
\text{Gal}(L/M) &
\cong
C_3 \times C_8.
\end{align*}
\]
We obtain such an extension as in [FKS19, §4.2.5] by taking the compositum $L$ of two Galois extensions $L_1/Q, L_2/Q$ such that
\[
\begin{align*}
\text{Gal}(L_1/Q) &
\cong
D_8, &
\text{Gal}(L_1/(L_1 \cap L_2)) &
\cong
D_4, &
\text{Gal}(L_1/M) &
\cong
C_8, \\
\text{Gal}(L_2/Q) &
\cong
S_3, &
\text{Gal}(L_2/(L_1 \cap L_2)) &
\cong
C_3.
\end{align*}
\]
We take
\[
\begin{align*}
L_1 &= \text{spl}(x^8 - 7x^4 + 28), \\
L_2 &= \text{spl}(x^3 - x^2 + 2x - 3), \\
K &= L_2M = \text{spl}(x^6 + x^4 + 2x^2 - 7), \\
L &= L_1L_2.
\end{align*}
\]

There are 24 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising two \( M \)-equivalence classes. Of these, 8 are \( \mathcal{O}_M \)-equivalent (in fact equal) to \( \rho'_M \) as required by Remark 7.11. These \( \rho_M \) realize both \( M \)-equivalence classes and give rise to \((1, 6)\)-polarized abelian surfaces \( A_{-4a} \) over \( k \) with Sato–Tate group \( D_{6,1} \) and endomorphism field \( kK \) with \( \text{Gal}(kK/k) \simeq D_6 \simeq \langle 12, 4 \rangle \); they are distinguished by their \( L \)-polynomials at 13. In both cases the product \( E_{-4,12 - 8\sqrt{3}} \times A_{-4a} \) is an abelian threefold over \( k \) with Sato–Tate group \( J(B(3, 4; 4)) \) and endomorphism field \( kL \).

**Example 8.20.** The maximal group \( J(B(3, 4)) \) of type \( N \) with component group \( \langle 48, 38 \rangle \) occurs as the Sato–Tate group of \( \text{Jac}(C_3) \) where \( C_3 \) is the hyperelliptic curve
\[
y^2 = (x^2 + 2x - 1)(x^3 - 3x^2 - 3x - 3)(x^3 + 3x + 2).
\]

Over \( \mathbb{Q}(\sqrt{2}) \), this curve becomes isomorphic to
\[
C'_3: y^2 = (4 - 3\sqrt{2})x^7 + (4 + 3\sqrt{2})x.
\]

Applying [FS16, Lemma 5.6] to the latter, we deduce that the endomorphism field of \( \text{Jac}(C_3) \) is given by
\[
L = \mathbb{Q}(\sqrt{2}, i, (-1 - \sqrt{2})^{1/3}, (-3)^{1/4}) = \text{spl}(x^{12} - 3x^8 + 24x^4 - 48).
\]

This is a Galois extension with Galois group \( \langle 48, 38 \rangle \simeq S_3 \times D_4 \). Moreover, the isogeny factors of \( \text{Jac}(C_3) \) all have CM by \( \mathbb{Q}(i) \), and the Galois group of \( L \) over \( \mathbb{Q}(i) \) is \( \langle 24, 5 \rangle \). The only option for the Sato–Tate group consistent with these observations is \( J(B(3, 4)) \).

This example can also be realized as a product of the form \( E_{-4,2} \times A_{-4a} \), obtained as in Remark 7.10 with \( M = \mathbb{Q}(i) \), for a representation \( \rho_M: G_M \to \text{GL}_2(\mathcal{O}_M) \) with image isomorphic to \( \langle 24, 5 \rangle \), generated by
\[
\begin{pmatrix}
i & 0 \\
0 & i
\end{pmatrix}, 
\begin{pmatrix}0 & 1 \\
1 & 0
\end{pmatrix}, 
\begin{pmatrix}0 & -1 \\
1 & -1
\end{pmatrix}
\text{ with } U = \begin{pmatrix}2 & -1 \\
-1 & 2
\end{pmatrix}.
\]

There are 24 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising two \( M \)-equivalence classes. All 24 are \( \mathcal{O}_M \)-equivalent (in fact equal) to \( \rho'_M \). These \( \rho_M \) realize both \( M \)-equivalence classes and give rise to \((1, 3)\)-polarized abelian surfaces \( A_{-4a} \) over \( \mathbb{Q} \) with Sato–Tate group \( D_{6,1} \) and endomorphism field \( K = \text{spl}(x^6 - 3x^2 - 6) \) with Galois group \( D_6 \simeq \langle 12, 4 \rangle \); they are distinguished by their \( L \)-polynomials at 29:
\[
1 - 20T - 158T^2 - 580T^3 + 841T^4, \\
1 + 20T - 158T^2 + 580T^3 + 841T^4.
\]

In both cases the product \( E_{-4,2} \times A_{-4a} \) is an abelian threefold over \( \mathbb{Q} \) with Sato–Tate group \( J(B(3, 4)) \) and endomorphism field \( L \); for the abelian surface \( A_{-4a} \) with the second \( L \)-polynomial listed above, the product \( E_{-4,2} \times A_{-4a} \) is isogenous to \( \text{Jac}(C_3) \).
**Example 8.21.** Let $M = \mathbb{Q}(i)$ and $k = \mathbb{Q}(\sqrt{3})$. The maximal group $J_s(B(3, 4))$ of type $N$ with component group $(48, 41)$ occurs as the Sato–Tate group of $E_{-4, 12 - 8\sqrt{3}} \times A_{-4[3]b}$ obtained as in Remark 7.13, for a representation $\rho_M : G_M \to \text{GL}_2(\mathcal{O}_M)$ with image isomorphic to $(24, 5)$, generated by

$$\begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ -1 & -1 \end{pmatrix}, \begin{pmatrix} 1 & 3 \\ -1 & -2 \end{pmatrix} \text{ with } U = \begin{pmatrix} 2 & 3 \\ 3 & 6 \end{pmatrix}.$$ 

To exhibit an explicit example, we must find a Galois extension $L/\mathbb{Q}$ not containing $k$ with

$$\text{Gal}(L/\mathbb{Q}) \simeq (48, 41), \quad \text{Gal}(L/M) \simeq (24, 5).$$

We obtain such an extension by taking the compositum of two Galois extensions $L_1/\mathbb{Q}, L_2/\mathbb{Q}$ such that

$$\text{Gal}(L_1/\mathbb{Q}) \simeq (16, 13), \quad \text{Gal}(L_1/M) \simeq C_2 \times C_4, \quad \text{Gal}(L_1/(L_1 \cap L_2)) \simeq (8, 4),$$

$$\text{Gal}(L_2/\mathbb{Q}) \simeq S_3, \quad \text{Gal}(L_2/(L_1 \cap L_2)) \simeq C_3.$$ 

We take

$$L_1 = \text{spl}(x^8 - 8x^4 + 25),$$

$$L_2 = \text{spl}(x^3 - x^2 + 5x + 15),$$

$$K = L_2M = \text{spl}(x^6 - 2x^5 + 2x^4 + 4x^3 + 9x^2 - 30x + 50),$$

$$L = L_1L_2 = \text{spl}(x^{24} - 208x^{20} + 12434x^{16} - 161872x^{12} + 766481x^8 - 5190400x^4 + 10240000).$$

There are 24 representations $\rho_M$ with kernel field $L$ and image $\rho_M(G_M)$ as above, comprising two $M$-equivalence classes. Of these, 8 are $\mathcal{O}_M$-equivalent (in fact equal) to $\rho'_M$ as required by Remark 7.11. These $\rho_M$ realize both $M$-equivalence classes and give rise to principally polarized abelian surfaces $A_{-4[3]b}$ over $k$ with Sato–Tate group $J(D_3)$ and endomorphism field $kK$ with $\text{Gal}(kK/k) \simeq D_6 \simeq (12, 4)$; they are distinguished by their $L$-polynomials at 13. In both cases the product $E_{-4, 12 - 8\sqrt{3}} \times A_{-4[3]b}$ is an abelian threefold over $k$ with Sato–Tate group $J_s(B(3, 4))$ and endomorphism field $kL$.

**Remark 8.22.** In Example 8.21, since $A_{-4[3]b}$ carries an indecomposable principal polarization, it must occur as the Jacobian of a genus 2 curve over $k$. At this time, we have not attempted to identify this curve explicitly.

**Example 8.23.** The maximal group $J(B(O, 1))$ of type $N$ with component group $(96, 193)$ occurs as the Sato–Tate group of $E_{-8} \times \text{Jac}(C_2)$ where $C_2$ is as in Example 8.14; the abelian surface $\text{Jac}(C_2)$ has Sato–Tate group $J(O)$ and endomorphism field $K = \text{spl}(x^6 + 4x^4 - 22)$. From [FS14, Table 4, Table 6], we see that the endomorphism field of $E_{-8} \times \text{Jac}(C_2)$ is

$$L = \text{spl}(x^{16} - 44x^{12} - 308x^{10} - 990x^8 - 1936x^6 - 2662x^4 + 9196x^2 + 20449),$$

which has the desired Galois group $(96, 193)$ and contains $K$ as a subfield of index 2.

This example can also be interpreted (up to isogeny) as a product of the form $E_{-8} \times A_{-8}$ obtained as in Remark 7.10 with $M = \mathbb{Q}(\sqrt{-2})$, for a representation $\rho_M : G_M \to \text{GL}_2(\mathcal{O}_M)$ with image isomorphic to the Shephard–Todd group $G_{12} \simeq (48, 29)$, generated by

$$\begin{pmatrix} -1 & 0 \\ 1 & -\sqrt{-2} \end{pmatrix}, \begin{pmatrix} -1 & -1 \\ 1 & 0 \end{pmatrix}.$$
with
\[ U = \begin{pmatrix} 2 & 1 + \sqrt{-2} \\ 1 - \sqrt{-2} & 2 \end{pmatrix}, \quad V = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \]

There are 48 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising two \( M \)-equivalence classes. Of these, 8 are \( O_M \)-equivalent to \( \rho_M^s \) (via \( V \)). These \( \rho_M \) realize both \( M \)-equivalence classes and give rise to principally polarized abelian surfaces \( A_{-8} \) over \( \mathbb{Q} \) with Sato–Tate group \( J(O) \) and endomorphism field \( K \) with Galois group \( S_4 \times C_2 \simeq \langle 48, 48 \rangle \); they are distinguished by their \( L \)-polynomials at 17:
\[
\begin{align*}
&1 - 8T + 32T^2 - 136T^3 + 289T^4, \\
&1 + 8T + 32T^2 + 136T^3 + 289T^4.
\end{align*}
\]

The abelian surface \( A_{-8} \) with the second \( L \)-polynomial listed above is isogenous to \( \text{Jac}(C_2) \). In both cases the product \( E_{-8} \times A_{-8} \) is an abelian threefold over \( \mathbb{Q} \) with Sato–Tate group \( J(B(O, 1)) \) and endomorphism field \( L \).

**Example 8.24.** Let \( M = \mathbb{Q}(\zeta_3) \). The maximal group \( J_s(B(T, 3)) \) of type \( N \) with component group \( \langle 144, 125 \rangle \) occurs as the Sato–Tate group of \( E_{-3} \times A_{-3} \) obtained as in Remark 7.10, for a representation \( \rho_M: G_M \to \text{GL}_2(O_M) \) with image isomorphic to \( \langle 72, 25 \rangle \), generated by
\[
\left( \begin{array}{cc} \zeta_3 & 0 \\ 0 & \zeta_3 \end{array} \right), \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right), \left( \begin{array}{cc} 1 + \zeta_3 & -1 \\ 0 & -\zeta_3 \end{array} \right)
\]

with
\[ U = \begin{pmatrix} 3 & 1 + 2\zeta_3 \\ -1 - 2\zeta_3 & 3 \end{pmatrix}, \quad V = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \]

To exhibit an explicit example, we must find a Galois extension \( L/\mathbb{Q} \) with
\[
\text{Gal}(L/\mathbb{Q}) \simeq \langle 144, 125 \rangle, \quad \text{Gal}(L/M) \simeq \langle 72, 25 \rangle.
\]

We obtain such an extension by taking the compositum of two Galois extensions \( L_1/\mathbb{Q}, L_2/\mathbb{Q} \) such that
\[
\text{Gal}(L_1/\mathbb{Q}) \simeq \text{GL}(2, 3), \quad \text{Gal}(L_1/\mathbb{Q}(\zeta_3)) \simeq \text{SL}(2, 3),
\]
\[
\text{Gal}(L_2/\mathbb{Q}) \simeq S_3, \quad \text{Gal}(L_2/M) \simeq C_3.
\]

We take
\[
L_1 = \text{spl}(x^8 - 6x^4 + 4x^2 - 3), \\
L_2 = \text{spl}(x^3 - 2), \\
L = L_1L_2, \\
K = L_1^C = \text{spl}(x^4 - 2x^3 - 6x + 3).
\]

There are 144 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising six \( M \)-equivalence classes. Of these, 24 are \( O_M \)-equivalent to \( \rho_M^s \) (via \( V \)). These \( \rho_M \) realize all six \( M \)-equivalence classes and give rise to \( (1, 6) \)-polarized abelian surfaces \( A_{-3} \) over \( \mathbb{Q} \) with Sato–Tate group \( O_1 \) and endomorphism field \( K \) with Galois group \( \text{PGL}(2, 3) \simeq S_4 \simeq \langle 24, 12 \rangle \); they are distinguished by their \( L \)-polynomials at 7 and 13. In every case the product \( E_{-3} \times A_{-3} \) is an abelian threefold over \( \mathbb{Q} \) with Sato–Tate group \( J_s(B(T, 3)) \) and endomorphism field \( L \).
Remark 8.25. In Example 8.24, we may also take $L_1$ to be the 3-division field of any elliptic curve over $\mathbb{Q}$ with surjective mod-3 Galois representation (e.g., curve 24.a5 in the LMFDB).

Remark 8.26. The abelian threefold in Example 8.24 is 2-isogenous to another threefold admitting an indecomposable polarization of type $(1,1,3)$.

Example 8.27. Let $M = \mathbb{Q}(\zeta_3)$. The maximal group $J(B(T,3))$ of type $\mathbb{N}$ with component group $\langle 144,127 \rangle$ occurs as the Sato–Tate group of $E_{-3} \times A_{-3|2}^b$ obtained as in Remark 7.12, for a representation $\rho_M : G_M \to GL_2(\mathcal{O}_M)$ with image isomorphic to $\langle 72,25 \rangle$, generated by
\[
\begin{pmatrix}
\zeta_3 & 0 \\
0 & \zeta_3
\end{pmatrix}, \begin{pmatrix}
-1 & -2 \\
1 & 1
\end{pmatrix}, \begin{pmatrix}
1+\zeta_3 & 2\zeta_3 \\
0 & -\zeta_3
\end{pmatrix} \quad \text{with } U = \begin{pmatrix}
3 & 2-2\zeta_3^2 \\
2 & 6
\end{pmatrix}.
\]
To exhibit an explicit example, we must find a Galois extension $L/\mathbb{Q}$ with
\[\text{Gal}(L/\mathbb{Q}) \simeq \langle 144,127 \rangle, \quad \text{Gal}(L/M) \simeq \langle 72,25 \rangle.\]
We obtain such an extension as in [FKS19, §4.2.5] by taking the compositum of Galois extensions $L_1/\mathbb{Q}$ and $L_2/\mathbb{Q}$ satisfying
\[\text{Gal}(L_1/\mathbb{Q}) \simeq \langle 48,33 \rangle, \quad \text{Gal}(L_1/M) \simeq \text{SL}(2,3),\]
\[\text{Gal}(L_2/\mathbb{Q}) \simeq S_3, \quad \text{Gal}(L_2/M) \simeq C_3.\]
We may take
\[L_1 = \text{spl}(x^{16} - 18x^{12} + 101x^{10} + 99x^8 - 1098x^6 + 3043x^4 - 738x^2 + 81),\]
\[L_2 = \text{spl}(x^3 - 3),\]
\[K = L_1^{C_2} = \text{spl}(x^6 - 3x^5 + 10x^4 - 15x^3 - 41x^2 + 48x + 27),\]
\[L = L_1L_2.\]
There are 144 representations $\rho_M$ with kernel field $L$ and image $\rho_M(G_M)$ as above, comprising six $M$-equivalence classes. Of these, 16 are $\mathcal{O}_M$-equivalent (in fact equal) to $\rho_M^H$, as required by Remark 7.12. These $\rho_M$ realize two $M$-equivalence classes and give rise to $(1,3)$-polarized abelian surfaces $A_{-3|2}^b$ over $\mathbb{Q}$ with Sato–Tate group $J(T)$ and endomorphism field $K$ with Galois group $A_4 \times C_2 \simeq \langle 24,13 \rangle$; they are distinguished by their $L$-polynomials at 7. In both cases the product $E_{-3} \times A_{-3|2}^b$ is an abelian threefold over $\mathbb{Q}$ with Sato–Tate group $J(B(T,3))$ and endomorphism field $L$.

Example 8.28. The maximal group $J(B(O,2))$ of type $\mathbb{N}$ with component group $\langle 192,988 \rangle$ occurs as the Sato–Tate group of $E_{-4} \times \text{Prym}(C_3/C_1)$, where $C_3 : Y^4 = X^4 + 2X^2Z^2 + XZ^3$ as in Example 8.14 and $C_1$ is its quotient by the involution $(X : Y : Z) \mapsto (X : -Y : Z)$. Using Lemma 7.6, we deduce that the endomorphism field $L$ of $E_{-4} \times \text{Prym}(C_3/C_1)$ is obtained by adjoining $(a_1 - 2\sqrt{b_1})^{1/4}$ to the field $K = \text{spl}(x^6 - 4x^4 - 59)$ with $\text{Gal}(K/\mathbb{Q}) \simeq \langle 48,48 \rangle$ from Example 8.14, yielding
\[L = K((a_1 - 2\sqrt{b_1})^{1/4}) = \text{spl}(x^{24} - 40x^{16} + 430x^{12} - 240x^8 + 344x^4 - 59),\]
with $\text{Gal}(L/\mathbb{Q}) \simeq \langle 192,988 \rangle$.

This example can also be realized as a product of the form $E_{-4} \times A_{-4b}$, where $A_{-4b}$ is an abelian surface isogenous to $\text{Prym}(C_3/C_1)$ obtained as in Remark 7.10 with $M = \mathbb{Q}(i)$, for
a representation \( \rho_M : G_M \to \text{GL}_2(O_M) \) with image isomorphic to the Shephard–Todd group \( G_8 \simeq \langle 96, 67 \rangle \), generated by
\[
\begin{pmatrix}
i & 0 \\
-i & 1
\end{pmatrix}, \quad \begin{pmatrix}1 & 1 \\
0 & i
\end{pmatrix}
\]
with
\[
U = \begin{pmatrix}2 & 1 + i \\
1 - i & 2
\end{pmatrix}, \quad V = \begin{pmatrix}0 & 1 \\
1 & 0
\end{pmatrix}.
\]
There are 96 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising four \( M \)-equivalence classes. Of these, 16 are \( O_M \)-equivalent to \( \rho_M^* \) (via \( V \)). These \( \rho_M \) realize all four \( M \)-equivalence classes and give rise to \((1, 2)\)-polarized abelian surfaces \( A_{-4b} \) over \( \mathbb{Q} \) with Sato–Tate group \( J(O) \) and endomorphism field \( K \); they are distinguished by their \( L \)-polynomials at 61:
\[
\begin{align*}
1 - 22T + 242T^2 - 1342T^3 + 3721T^4, \\
1 + 22T + 242T^2 + 1324T^3 + 3721T^4, \\
1 - 2T + 2T^2 - 122T^3 + 3721T^4, \\
1 + 2T + 2T^2 - 122T^3 + 3721T^4.
\end{align*}
\]
The abelian surface \( A_{-4b} \) with the last of these \( L \)-polynomials is isogenous to \( \text{Prym}(C_3/C_1) \), and in every case the product \( E_{-4} \times A_{-4b} \) is an abelian threefold over \( \mathbb{Q} \) with Sato–Tate group \( J(B(O, 2)) \) and endomorphism field \( L \).

**Remark 8.29.** Note that Example 8.28 contradicts [FG18, Table 6], which asserts that \( J(O) \) cannot occur as the Sato–Tate group of an abelian surface with complex multiplication by \( \mathbb{Q}(i) \). In fact this is an omission in the table; it corresponds to a similar omission in [FG18, Proposition 3.5(iv)], which fails to account for the fact that the binary octahedral group has a faithful 2-dimensional representation with traces in \( \mathbb{Q}(i) \). None of this affects the other results of [FG18].

**Example 8.30.** The maximal group \( J(D(4, 4)) \) of type \( N \) with component group \( \langle 192, 956 \rangle \) occurs as the Sato–Tate group of \( \text{Res} C_{1,3} \), where \( C_{1,3} : y^2 = x^3 - \alpha x \) and \( \alpha \) is a root of the cubic \( f(x) = x^3 - x^2 + x - 2 \). The endomorphism field is
\[
K = \mathbb{Q}(\sqrt{-1}, (\alpha_1/\alpha_2)^{1/4}, (\alpha_2/\alpha_3)^{1/4}) = \text{spl}(x^{12} + x^8 + 2x^4 + 4),
\]
where \( \alpha_1, \alpha_2, \alpha_3 \) are the three roots of \( f(x) \).

Table 11 also includes an example of a Jacobian; this is a twist of the Fermat quartic listed in [FLS18, Table 4, row 59] with endomorphism field \( \text{spl}(x^{12} + 3x^4 - 1) \).

This example can also be realized as an isogeny twist of \( E_{-4} \), obtained as in Remark 7.10 with \( M = \mathbb{Q}(i) \), for a representation \( \rho_M : G_M \to \text{GL}_3(O_M) \) with image isomorphic to the wreath product \( \mu_4 \wr S_3 \simeq \langle 384, 5557 \rangle \), generated by
\[
\begin{pmatrix}0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 0
\end{pmatrix}, \quad \begin{pmatrix}0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1
\end{pmatrix}, \quad \begin{pmatrix}i & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}.
\]
The kernel field of \( \rho_M \) is
\[
L = \mathbb{Q}(\sqrt{-1}, \alpha_1^{1/4}, \alpha_2^{1/4}, \alpha_3^{1/4}) = \text{spl}(x^{12} - x^8 + x^4 - 2),
\]
with Galois group \( \langle 768, 1088009 \rangle \); the endomorphism field \( K \) is the kernel field of the projective representation with Galois group \( \langle 192, 956 \rangle \).

There are 768 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising eight \( M \)-equivalence classes. Of these, 192 are \( O_M \)-equivalent (in fact equal) to \( \rho_M^c \). These \( \rho_M \) realize all eight \( M \)-equivalence classes and give rise to abelian threefolds defined over \( \mathbb{Q} \) that are twists of \( E_{-4}^{3} \) with Sato–Tate group \( J(D(4,4)) \) and endomorphism field \( K \). These abelian threefolds are isogenous to the abelian threefolds \( \text{Res} \tilde{C}_{1,3} \) that arise for the eight twists \( \tilde{C}_{1,3} : y^2 = x^3 - \tilde{\alpha} \) of \( C_{1,3} \) with

\[
\tilde{\alpha} \in \{ \alpha, -\alpha, \alpha^3, -\alpha^3, 832\alpha, -832\alpha, 832\alpha^3, -832\alpha^3 \},
\]

which are distinguished by their \( L \)-polynomials at 5 and 29.

**Example 8.31.** The maximal group \( J(E(168)) \) of type \( N \) with component group \( \langle 336, 208 \rangle \) occurs as the Sato–Tate group of \( \text{Jac}(C_3) \) where \( C_3 \) is a twist of the Klein quartic, taken from [FLS18, Table 5, row 14], with endomorphism field \( K = \text{spl}(x^8 + 4x^7 + 21x^4 + 18x + 9) \).

This example can also be realized as an isogeny twist of \( E_{-7}^{3} \) obtained as in Remark 7.10 with \( M = \mathbb{Q}(\zeta_3) \), for a representation \( \rho_M : G_M \to \text{GL}_3(\mathcal{O}_M) \) with image isomorphic to \( \langle 168, 42 \rangle \), generated by the matrices

\[
\begin{pmatrix}
-1 & 0 & \frac{1+\sqrt{-7}}{2} \\
0 & -1 & \frac{1+\sqrt{-7}}{2} \\
0 & 0 & 1
\end{pmatrix},
\begin{pmatrix}
2 & -\frac{1+\sqrt{-7}}{2} & -\frac{3+\sqrt{-7}}{2} \\
1 & 0 & 0 \\
\frac{1+\sqrt{-7}}{2} & -1 & -1
\end{pmatrix},
\]

with

\[
U = \begin{pmatrix}
2 & -\frac{1+\sqrt{-7}}{2} & -\frac{3+\sqrt{-7}}{2} \\
-\frac{1-\sqrt{-7}}{2} & \frac{3+\sqrt{-7}}{2} & -\frac{3-\sqrt{-7}}{2} \\
\frac{3-\sqrt{-7}}{2} & \frac{3-\sqrt{-7}}{2} & 3
\end{pmatrix},
V = \begin{pmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & -1
\end{pmatrix}.
\]

This group is an index-2 subgroup of the Shephard–Todd group \( G_{24} \).

There are 336 representations \( \rho_M \) with kernel field \( K \) and image \( \rho_M(G_M) \) as above, comprising two \( M \)-equivalence classes. Of these, 12 are \( O_M \)-equivalent to \( \rho_M^c \) (via \( V \)). These \( \rho_M \) realize both \( M \)-equivalence classes and give rise to principally polarized abelian threefolds over \( \mathbb{Q} \) that are twists of \( E_{-7}^{3} \) with Sato–Tate group \( J(E(168)) \) and endomorphism field \( K \). These twists are distinguished by their \( L \)-polynomials at 11:

\[
1 - 5T - 3T^2 + 57T^3 - 33T^4 - 605T^5 + 1331T^6,
1 + 9T + 53T^2 + 211T^3 + 583T^4 + 1089T^5 + 1331T^6.
\]

The twist with the second \( L \)-polynomial listed above is isogenous to \( \text{Jac}(C_3) \).

**Example 8.32.** The maximal group \( J(D(6,6)) \) of type \( N \) with component group \( \langle 432, 523 \rangle \) occurs as the Sato–Tate group of \( \text{Res} C_{1,3} \), where \( C_{1,3} : y^2 = x^3 - \alpha \) with \( \alpha \) a root of the cubic polynomial \( f(x) = x^3 - x^2 + x - 2 \). The endomorphism field is

\[
K = \mathbb{Q}(\alpha_1/\alpha_2)^{1/6}, \langle \alpha_2/\alpha_3 \rangle^{1/6}) = \text{spl}(x^{36} + x^{30} + 27x^{24} - 42x^{18} + 28x^{12} - 384x^6 + 4096).
\]

This example can also be realized as an isogeny twist of \( E_{-3}^{3} \) obtained as in Remark 7.10 with \( M = \mathbb{Q}(\zeta_3) \) for a representation \( \rho_M : G_M \to \text{GL}_3(\mathcal{O}_M) \) with image isomorphic to the
wreath product \( \mu_6 \wr S_3 \simeq \langle 1296, 1827 \rangle \), generated by
\[
\begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} \zeta_6 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

The kernel field of \( \rho_M \) is the degree-2592 field
\[
L = \mathbb{Q}(\alpha_1^{1/6}, \alpha_2^{1/6}, \alpha_3^{1/6}) = \text{spl}(x^{18} - x^{12} + x^6 - 2)
\]
whose Galois group is the transitive group \( 18T396 \); \( K \) is the kernel field of the projective representation, with Galois group \( \langle 432, 523 \rangle \).

There are 2592 representations \( \rho_M \) with kernel field \( L \) and image \( \rho_M(G_M) \) as above, comprising twelve \( M \)-equivalence classes. Of these, 288 are \( \mathcal{O}_M \)-equivalent (in fact equal) to \( \rho_M^c \). These \( \rho_M \) realize all twelve \( M \)-equivalence classes and give rise to abelian threefolds over \( \mathbb{Q} \) that are twists of \( E^3 \) with Sato–Tate group \( J(D(6, 6)) \) and endomorphism field \( K \). These abelian threefolds are isogenous to the abelian threefolds \( \text{Res} \tilde{C}_{1,3} \) that arise for the 12 twists \( \tilde{C}_{1,3} : y^2 = x^3 - \tilde{\alpha} \) of \( C_{1,3} \) with
\[
\tilde{\alpha} \in \{ \alpha, 2^2\alpha, 2^4\alpha, 3^3\sqrt[3]{3}\alpha, 2^2\cdot 3\cdot \sqrt[3]{3}\cdot \alpha, 2^4\cdot 3\cdot \sqrt[3]{3}\cdot \alpha, 2^6\cdot 3\cdot \sqrt[3]{3}\cdot \alpha^5, 2^4\cdot 5, 2^4\cdot \sqrt[5]{5}, 3^3\cdot \sqrt[3]{3}\cdot \alpha^5, 2^2\cdot 3^2\cdot \sqrt[3]{3}\cdot \alpha^5, 2^4\cdot 3^2\cdot \sqrt[3]{3}\cdot \alpha^5 \},
\]
which are distinguished by their \( L \)-polynomials at 13.

**Remark 8.33.** Similarly, the group \( J(D(3, 3)) \) occurs as the Sato–Tate group of the Weil restriction of the elliptic curve \( y^2 = x^3 - \alpha^2 \) from \( L_3 \) to \( \mathbb{Q} \). The base extensions of this abelian threefold to the fields \( \mathbb{Q}(\sqrt{-83}) \) and \( \mathbb{Q}(\sqrt{249}) \) have Sato–Tate groups \( J(C(3, 3)) \) and \( J_s(C(3, 3)) \) which have nonisomorphic component groups, but give rise to identical distributions (see Proposition 6.16).

**Example 8.34.** Let \( M = \mathbb{Q}(\zeta_3) \). The maximal group \( J(E(216)) \) of type N with component group \( \langle 432, 734 \rangle \) occurs as the Sato–Tate group of \( E^3 \) obtained as in Remark 7.10, for a representation \( \rho \) whose restriction to \( G_{\mathbb{Q}(\zeta_3)} \) has image equal to the Shephard–Todd group \( G_{25} \), generated by
\[
\begin{pmatrix} 1 & \zeta_3^2 & 0 \\ 0 & \zeta_3^2 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} \zeta_3 & 0 & 0 \\ \zeta_3 & 1 & 0 \\ \zeta_3 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & \zeta_3^2 \\ 0 & 1 & 0 \\ 0 & 0 & \zeta_3 \end{pmatrix},
\]
with
\[
U = \begin{pmatrix} 3 & \zeta_3 - 1 & \zeta_3^2 - 1 \\ \zeta_3 - 1 & 2 & 1 \\ \zeta_3 - 1 & 1 & 2 \end{pmatrix}, \quad V = \begin{pmatrix} 1 & 0 & 0 \\ 1 & -1 & 0 \\ 1 & 0 & -1 \end{pmatrix}.
\]
(The invariant polarization is of type \( 1, 1, 3 \).) To exhibit an explicit example, following a suggestion of Noam Elkies, we construct \( \rho \) by identifying \( G_{25} \rtimes \mathbb{C}_2 \) with \( U(3, 2) \rtimes \text{Gal}(\mathbb{F}_4/\mathbb{F}_2) \) and considering the 2-torsion Galois representation of a generic Picard curve over \( \mathbb{Q} \).

We verify that the Picard curve \( C : y^3 = x^4 + x + 1 \) used in Example 8.3 has maximal mod-2 Galois image. Note that the 64 theta characteristics form a principal homogeneous space for \( \text{Jac}(C)[2] \). The 28 odd theta characteristics correspond to the bitangents of \( C \); for a Picard curve, the line at infinity is a distinguished bitangent, so we have a Galois action on the other 27. We compute this action by following a suggestion from [PSV11, §2]. The bitangents are the lines \( y = ax + b \) for which we have an equality of polynomials in \( x \):
\[
(ax + b)^3 - (x^4 + x + 1) = -(x^2 + \kappa_1 x + \kappa_0)^2
\]
for suitable values of $\kappa_1, \kappa_0$. By comparing the coefficients of $x^3$ and $x^2$, we see that

$$\kappa_1 = -\frac{1}{2}a^3, \quad \kappa_0 = -\frac{1}{2}a^6 + \frac{3}{8}a^2b.$$  

Equating the remaining coefficients yields two additional equations:

$$a^9 + 12a^5b + 24ab^2 - 8 = a^{12} + 24a^8b + 144a^4b^2 + 64b^3 - 64 = 0.$$  

Eliminating $b$ yields an equation in $A = \frac{1}{2}a^3$:

$$A^9 + 168A^6 + 1080A^5 - 636A^3 + 864A^2 - 432A + 8 = 0.$$  

This polynomial in $A$ has Galois group $\langle 432, 734 \rangle$, which is the projective image we seek. Substituting for $a$ yields a polynomial $f(a)$ with Galois group $\langle 1296, 2891 \rangle \cong G_{25} \rtimes C_2$. The kernel field $L$ of $\rho$ is the splitting field of $f(a)$, and the splitting field $K$ of $f(A)$ is the kernel field of the projective representation.

There are 1296 representations $\rho_M$ with kernel field $L$ and image as above, comprising 6 $M$-equivalence classes. Of these, 36 are $\mathcal{O}_M$-equivalent (via $V$) to $\rho_M^*$. These $\rho_M$ realize all six $M$-equivalence classes and give rise to (1, 3)-polarized abelian threefolds over $\mathbb{Q}$ that are isogeny twists of $E^3_{23}$ with Sato–Tate group $J(E(216))$ and endomorphism field $K$. They are distinguished by their $L$-polynomials at 19:

- $1 + T - 7T^2 - 26T^3 - 133T^4 + 361T^5 + 6859T^6$,
- $1 + T + 8T^2 - 11T^3 + 152T^4 + 361T^5 + 6859T^6$,
- $1 + 7T - 7T^2 - 182T^3 - 133T^4 + 2527T^5 + 6859T^6$,
- $1 + 7T + 56T^2 + 259T^3 + 1064T^4 + 2527T^5 + 6859T^6$,
- $1 - 8T + 8T^2 + 88T^3 + 152T^4 - 2888T^5 + 6859T^6$,
- $1 - 8T + 56T^2 - 296T^3 + 1064T^4 - 2888T^5 + 6859T^6$.

The twist with the last $L$-polynomial listed above corresponds to the representation $\rho$ defined by the Galois action on the bitangents of $C$.

8.4. Numerical consistency check. For each of the 33 abelian varieties with maximal Sato–Tate groups described above we used the methods in §7.4 to compute $L$-polynomials for primes of norm up to $B = 2^{30}$ (and in most cases up to $B = 2^{32}$), and computed moment statistics and point densities over every subfield of the corresponding endomorphism field that we compared to the corresponding values predicted by the Sato–Tate group derived in §6. These moment statistics and code that compares them to their predicted values is available in our GitHub repository [FKS21]. Of the 745 sets of statistics computed (covering all 410 Sato–Tate groups, some multiple times), in all but one case they match the predicted values to within one percent; the sole exception matches to within 1.3 percent.
### Table 8. Real endomorphism algebras and connected parts of Sato–Tate groups of abelian threefolds. The column “Moduli” indicates the maximum dimension of a family whose (very) generic member has this form. Extensions satisfying the Sato–Tate axioms are enumerated in §4 (types A–M) and §5 (type N); realizable extensions are enumerated in §8.

Table 10. Reduced automorphism groups of curves of genus 3. In the models, $a, b, c$ are generic constants, $P_n$ is a generic polynomial of total degree $n$, and Cyc is the sum over the cyclic permutations of $X, Y, Z$. The stars denote isolated points in moduli. See Proposition 7.1 for further discussion.

</table>

Table 12. Endomorphism fields of the abelian threefolds listed in Table 11. In the two cases where the threefold is defined over $k \neq \mathbb{Q}$ (Examples 8.19 and 8.21), we give an extension of $\mathbb{Q}$ linearly disjoint from $k$ whose compositum with $k$ is the endomorphism field.
