Kanev and Todorov type surfaces in toric 3-folds

Julius Giesler
University of Tübingen
June 29, 2021

Abstract

In the first part of this article we show for some examples of surfaces of general type in toric 3-folds how to construct minimal and canonical models by toric methods explicitly. The examples we study will turn out to be so called Kanev surfaces and surfaces similar to Todorov surfaces. In the second part of this article we study further properties of these examples of surfaces by toric methods: We compute the singularities of the canonical models and compute the generic Picard numbers.

1 Introduction

In this article we study some surfaces of general type that arise as hypersurfaces in toric 3-folds. This article illustrates results from the article ([Bat20]) via concrete examples.

In the latter article it was shown quite generally how to construct minimal and canonical models for nondegenerate hypersurfaces in toric varieties. In other words: Given a nondegenerate Laurent polynomial $f$ with associated hypersurface $Z_f := \{ f = 0 \} \subset (\mathbb{C}^*)^n$ in the torus, it is answered in which toric variety we may take the closure of $Z_f$ in order to get a minimal or canonical model in the sense of Mori theory.

In this situation first the Newton polytope $\Delta$ of $f$ (Definition 2.1) plays an important role. It has some advantages to take the closure $Z_\Delta$ of $Z_f$ in the toric variety $\mathbb{P}_\Delta$ associated to the Newton polytope. But $Z_\Delta$ might have
bad singularities. In ([Bat20]) it was shown, that via natural operations on the polytope $\Delta$ we can partially resolve the singularities of $Z_\Delta$ and make the canonical divisor of the hypersurface nef. In particular the Fine interior $F(\Delta)$ of $\Delta$ is important within this context: If $\Delta$ is defined by the equations

$$\Delta = \{ x \in M_R \mid \langle x, \nu_i \rangle \geq \text{ord}_\Delta(\nu_i), \; i = 1, \ldots, s \}$$

(1)

then $F(\Delta)$ is defined by

$$F(\Delta) := \{ x \in M_R \mid \langle x, \nu \rangle \geq \text{ord}_\Delta(\nu) + 1, \; \nu \in N \setminus \{0\} \}$$

where

$$\text{ord}_\Delta(\nu) := \min_{m \in \Delta \cap M} \langle m, \nu \rangle.$$ 

See section (2.1) for some properties of the Fine interior.

Now in this article we carry out the program of constructing minimal/ canonical models essentially by modifying the Newton polytope $\Delta$ for some examples. The examples rely on an exact classification of 3-dimensional canonical Fano polytopes $\Delta$ in ([Kas10]) with

$$\dim F(\Delta) = 3$$

(see section 2.1). We will see (theorem (3.10)) that this condition on the dimension of $F(\Delta)$ implies that the hypersurface is of general type. There are 49 such polytopes. We bring them onto a normal form and show that there are only 5 types for the Fine interior among them.

This divides the 49 polytopes into 5 classes $a), b), c), d)$ and $e)$ which could be studied separately. We show that in every class there is exactly one maximal polytope with respect to inclusion of sets. For these maximal polytopes $Z_\Delta$ does already get a canonical model of a surface of general type and we do not have to modify the polytope first.

In the classes $a)$ and $b)$ for $Y$ the minimal model or the canonical model, $Y$ has the following invariants:

$$p_g(Y) = 1, \quad K_Y^2 = 1.$$ 

Such surfaces are called Kanev, Kunev or Kynev surfaces in the literature. They were studied in ([Cat78], [Us87], [Tod80]) and became interesting from the point of view of Torelli type theorems: Some of them for example fail the infinitesimal Torelli theorem.
In the classes $c), d)$ and $e)$ the minimal or canonical model $Y$ has the similar invariants
\[ p_g(Y) = 1, \quad q(Y) = 0, \quad K_Y^2 = 2. \]
These surfaces are studied in ([CD89]). For both types of surfaces the bi-
canonical map $\psi_{2K_Y}$ from the canonical model $Y$ defines a branched covering:
\[ \psi_{2K_Y} : Y \to Z \]
where $Z \cong \mathbb{P}^2$ in the case of Kanev surfaces and $Z \subset \mathbb{P}^3$ in the other case. Sometimes it happens that this bicanonical map factors through a K3-surface and in this case the Kanev surfaces are called special and the second type of surfaces are called Todorov surfaces. We thus also call our surfaces in the class $c), d)$ and $e)$ surfaces of Todorov type.

Special Kanev and Todorov surfaces are better understood, since they are closely related to K3-surfaces. The Kanev surfaces and surfaces of Todorov type which we construct in this article are not all special (Todorov surfaces) but still admit a good description, namely via toric geometry.

In section (2.1) we introduce the general background on toric geometry and toric hypersurfaces, which we will need. In section (2.2) we refine the classification of the 49 polytopes found in ([Kas10]) and define the necessary modifications $F(\Delta)$, $C(\Delta)$, $\tilde{\Delta}$ of $\Delta$ and a fan $\Sigma$. We picture the 49 polytopes in figure (2), (3) and (10).

In section (3.1) we deal with the general framework from ([Bat20]) of constructing minimal and canonical models of toric hypersurfaces. The main results of this section are

**Theorem 1.1.** ([Bat20, Thm.5.4])
The closure $Z_\Sigma$ of $Z_f$ in $\mathbb{P}_\Sigma$ gets a minimal model, the closure $Z_{\tilde{\Delta}}$ of $Z_f$ lies between a minimal and a canonical model, i.e. the morphism $\phi$ from the minimal to the canonical model factors through $Z_{\tilde{\Delta}}$.

**Theorem 1.2.** The composition $Z_\Sigma \to Z_{\tilde{\Delta}} \to Z_{F(\Delta)}$ is induced by $m(Z_\Sigma + K_{F_\Sigma})$ where
\[ m = \min\{n \in \mathbb{N}_{\geq 1} | n \cdot F(\Delta) \text{ is a lattice polytope}\}. \]

In our 49 examples $Z_{F(\Delta)}$ gets a canonical model and the morphism $Z_\Sigma \to Z_{F(\Delta)}$ coincides with the birational morphism $\phi$ from the minimal to the canonical model.
In section (3.2) we draw the consequences of this program on our 49 polytopes and in section (3.3) we compute the singularities of \( Z_\Delta \) and \( Z_{F(\Delta)} \). The singularities of \( Z_\Delta \) are of type \( A_k \), whereas on \( Z_{F(\Delta)} \) at one torus fixed points other rational double points might occur.

We picture a refinement of the 3-dimensional cone \( \sigma \) to this torus fixed point in figures (6), (7) and (10). In theorem (3.22) we show that we can read off the Dynkin diagram of the singularity at the torus fixed point from these pictures. Chapter (4) deals with Kanev surfaces and surfaces of Todorov type in general. In chapter (5) we degenerate our examples of surfaces by subdividing the polytopes. In this way we prove:

**Proposition 1.3.** A sufficiently nondegenerate canonical Kanev surface \( Y := X_t, t \neq 0 \), in the maximal families a) or b) can be degenerated into two weak del-Pezzo surfaces \( \bar{Y}_1, \bar{Y}_2 \) of degree 2 that meet transversally in an elliptic curve.

with an analogous result for surfaces of Todorov type degenerating into weak del-Pezzo surfaces of degree 1. These results enables us to compute the generic Picard number for our families of surfaces, by looking for Picard classes in the degenerate fibre that continue to nontrivial Picard classes on the generic fibre. Since all Kanev surfaces and all surfaces of Todorov type are deformation equivalent we may also compute the generic Picard number of an arbitrary Kanev surface or surface of Todorov type to be equal to 1. In the tables (1) and (2) we summarize our results on the polytopes, the singularities and the Picard numbers in a table.

2 Combinatorial classification of 49 canonical Fano polytopes \( \Delta \) with \( \dim F(\Delta) = 3 \)

2.1 General background and the Fine interior

**Notation** (Toric setting):

- \( M \cong \mathbb{Z}^3 \): A 3-dimensional lattice with dual lattice \( N, T := \text{Hom}(M, \mathbb{C}^*) \cong (\mathbb{C}^*)^3 \) the torus. We identify \( M \) with the lattice of characters of \( T \).
- \( \Delta \subset M_\mathbb{R} := M \otimes \mathbb{R} \): A full-dimensional lattice polytope.
- \( \Sigma_\Delta \): The normal fan to the polytope \( \Delta \).
• For Σ a fan in \( \mathbb{R} \) let \( \Sigma[i] \) denote the set of \( i \)-dimensional cones of \( \Sigma \) or for \( i = 1 \) also the set of generators of the 1-dimensional cones.

• \( \mathbb{P}_\Delta \): The toric variety to the polytope \( \Delta \), defined via its normal fan, more generally \( \mathbb{P}_\Sigma \): The toric variety to a fan \( \Sigma \).

• \( \langle v_0, ..., v_n \rangle \): The convex span of the lattice points \( v_0, ..., v_n \).

Recall that to a ray \( \nu_i \in \Sigma\Delta[1] \) is associated a torus invariant divisor \( D_i \) and that the canonical divisor of \( \mathbb{P}_\Delta \) is given by

\[
K_{\mathbb{P}_\Delta} = - \sum_{\nu_i \in \Sigma\Delta[1]} D_i.
\]  

(2)

In this article we just deal with integral divisors. The results of this section remain true in arbitrary dimensions. We are mainly interested in hypersurfaces in toric varieties and for this we take \( \Delta \) to be the Newton polytope of a Laurent polynomial \( f \):

**Definition 2.1.** Let \( f \) be a Laurent polynomial with presentation

\[
f = \sum_{m \in A} a_m z^m, \quad a_i \in \mathbb{C}
\]

for some finite set \( A \subset M \). The convex span of the \( m \in A \) with \( a_m \neq 0 \) is called the Newton polytope of \( f \).

\( L(\Delta) \) denotes the set of Laurent polynomials \( f \) as in (3) with Newton polytope \( \Delta \) and

\[
l(\Delta) := \dim_{\mathbb{C}} L(\Delta) = |M \cap \Delta|
\]

the number of lattice points in \( \Delta \). Let \( l^*(\Delta) \) be the number of interior lattice points of \( \Delta \) and \( Z_f \) the zero set \( \{ f = 0 \} \subset T \).

**Definition 2.2.** In the above situation \( f \) is called \( \Delta \)-regular if \( Z_f \) is smooth and for every face \( \Gamma \subset \Delta \) the variety \( Z_f|_{\Gamma} \) is smooth as well, where

\[
f|_{\Gamma} := \sum_{m \in \Gamma \cap M} a_m z^m.
\]

For \( f \in L(\Delta) \) we denote the closure of \( Z_f \) in the toric variety \( \mathbb{P}_\Delta \) by \( Z_\Delta \). For \( f \) nondegenerate we sometimes also call \( Z_\Delta \) nondegenerate. We just write \( Z_\Delta \) instead of \( Z_{f,\Delta} \) since many geometric properties of \( Z_\Delta \) are independent
of a chosen nondegenerate $f \in L(\Delta)$. Given a birational map $\phi : \mathbb{P}_{\Delta^*} \dashrightarrow \mathbb{P}_{\Delta}$ (in our case $\Delta^*$ will be typically $C(\Delta)$, $\tilde{\Delta}$ or $F(\Delta)$, see section [3.1]) we write $Z_{\Delta^*}$ for the proper transform, or equivalently the pullback $\phi^*(Z_\Delta)$ of $Z_\Delta$ in $\mathbb{P}_{\Delta^*}$. In fact we should write $Z_{f,\Delta^*}$ or else we might come into conflict with our notation. But in this article, the Newton polytope is always $\Delta$ and we omit the $f$ in order to shorten the notation.

**Remark 2.3.** The nondegeneracy means that the hypersurface $Z_\Delta$ intersects the toric strata in $\mathbb{P}_\Delta$ transversally in a codimension one subvariety. By Bertini’s theorem a general member of the linear system $|Z_\Delta| := \mathbb{P}H^0(\mathbb{P}_\Delta, Z_\Delta)$ is nondegenerate. Under the nondegeneracy condition the singularities of $Z_\Delta \subset \mathbb{P}_\Delta$ all come from singularities of the surrounding toric variety. Besides we may resolve the singularities of $Z_\Delta$ by choosing a toric resolution of those singularities of $\mathbb{P}_\Delta$ that lie on $Z_\Delta$. This follows easily from the transversal intersection of $Z_\Delta$ with the toric strata.

Another point is that $Z_\Delta$ gets an ample divisor on $\mathbb{P}_\Delta$ ([CLS11, Prop.6.1.4]).

**Construction 2.4.** If

$$\Delta = \{x \in M_\mathbb{R} | \langle x, \nu_i \rangle \geq r_i, i = 1, \ldots, s\}$$

(4)

is the facet presentation of $\Delta$ with $\nu_1, \ldots, \nu_s \in \Sigma_\Delta[1]$ the inner facet normals and $r_1, \ldots, r_s \in \mathbb{Z}$, then the hypersurface $Z_\Delta$ is linear equivalent to the following torus invariant divisor (compare [Bat20, Prop.5.1]):

$$Z_\Delta \sim_{\text{lin}} - \sum_{i=1}^{s} r_i D_i.$$  

(5)

A torus invariant divisor $D = \sum_{i=1}^{s} a_i D_i \subset \mathbb{P}_\Delta$ is Cartier if and only if for every $\sigma \in \Sigma_\Delta[3]$ there exists an $m_\sigma \in M$ with

$$\langle m_\sigma, \nu_i \rangle = -a_i \quad \text{for all } \nu_i \in \sigma[1].$$

(see [CLS11, Thm.4.2.8d]). The $(m_\sigma)_{\sigma \in \Sigma_\Delta[3]}$ are unique and the function $x \mapsto \langle m_\sigma, x \rangle$ for $x \in \sigma$ induces a well defined support function $N_\mathbb{R} \to \mathbb{R}$. Q-Cartier divisors, i.e. divisors for which an integral multiple is Cartier, could be described similarly.
There is a close relationship between torus invariant Cartier divisors on \( \mathbb{P}_\Delta \) and lattice polytopes ([CLS11, Prop.4.3.2]): To every Cartier divisor \( D = \sum_{i=1}^s a_i D_i \) is associated the polytope

\[
P_D := \{ x \in M_\mathbb{R} | \langle x, \nu_i \rangle \geq -a_i \},
\]

that counts the global sections of \( D \), that is

\[
H^0(\mathbb{P}_\Delta, D) \cong \bigoplus_{m \in M \cap P_D} \mathbb{C} \cdot \chi^m
\]

with the character \( \chi^m \) to \( m \in M \). For ample Cartier divisors on \( \mathbb{P}_\Delta \) the operation of assigning a polytope to a divisor is invertible: To every polytope \( P \) as in (6) corresponds the unique ample Cartier divisor \( D_P := D \). In this sense by formula (5) to \( Z_\Delta \) there is associated the polytope \( \Delta \).

A Cartier divisor \( D \) with associated Cartier data \( \{m_\sigma\}_{\sigma \in \Sigma_\Delta[3]} \) is basepoint-free if and only if \( m_\sigma \in P_D \) for all \( \sigma \in \Sigma_\Delta[3] \) ([CLS11, Prop.6.1.2]). For a basepointfree Cartier divisor \( D \) on \( \mathbb{P}_\Delta \) with associated polytope \( P := P_D \) by ([CLS11 Thm.6.2.8]) \( \Sigma_\Delta \) gets a refinement of the normal fan \( \Sigma_P \) of \( P \) and induces a toric morphism \( \theta : \mathbb{P}_\Delta \to \mathbb{P}_P \) with \( \theta^*(D_P) = D \), i.e. \( D \) is the pullback of an ample divisor on the toric variety to the polytope \( P_D \).

We will further need the following classical notions and relations: On a toric variety \( \mathbb{P}_\Delta \) defined via the normal fan of \( \Delta \), a Cartier divisor \( D \) is basepoint-free if and only if it is nef ([CLS11 Thm.6.3.12]). The pullback of a nef divisor under a morphism is nef again.

Thus for a birational morphism \( \rho : \mathbb{P}_\Sigma \to \mathbb{P}_\Delta \) inducing a resolution of singularities \( Z_\Sigma \to Z_\Delta \) the pullback \( Z_\Sigma = \rho^*(Z_\Delta) \) is nef, though it need not be ample. In fact \( Z_\Sigma \) is a nef and big divisor ([Laz00 Def.2.2.1]).

Somehow the most easy situation in (5) is achieved if \( \Delta \) is reflexive:

**Definition 2.5.** ([Bat94 Def.4.1.5])

A lattice polytope \( \Delta \subset \mathbb{M}_\mathbb{R} \) is called reflexive, if it contains a unique interior lattice point and every facet has lattice distance 1 to the interior point, that is, \( \Delta \) admits a presentation

\[
\Delta = \{ x \in \mathbb{M}_\mathbb{R} | \langle x, \nu_i \rangle \geq -1, \quad i = 1, \ldots, s \} \quad \nu_i \in \mathbb{N}
\]

where the interior lattice point is assumed to be zero.
More generally for $\Delta$ a polytope and $\Gamma \subset \Delta$ a facet we define the distance of $\Gamma$ to zero as follows:

**Definition 2.6.** If $\Gamma$ is defined by the hyperplane $\{x | \langle x, n \rangle = l\}$ where $n \in N$, $l \in Z$ then the integer $l$ is called the (integral) distance of $\Gamma$ to 0.

**Remark 2.7.** Now for reflexive polytopes we obtain with formula 5

$$Z_{\Delta} \sim_{\text{lin}} \sum_{i=1}^{s} D_i$$

and by formula 2 and the adjunction formula ([KM98, Prop.5.73])

$$K_{Z_{\Delta}} = (K_{P_{\Delta}} + Z_{\Delta})|_{Z_{\Delta}}$$

we get $K_{Z_{\Delta}} = \mathcal{O}_{Z_{\Delta}}$. The polytopes we consider in this article constitute the next more difficult situation:

**Definition 2.8.** A lattice polytope $\Delta \subset M_\mathbb{R}$ is said to be

- canonical, if $l^*(\Delta) = 1$,
- Fano, if the vertices of $\Delta$ are primitive lattice vectors.

By the classification in ([Kas10]) there are still 674,688 canonical Fano 3-topes, but these polytopes could be further divided into classes in terms of their Fine interior:

**Definition 2.9.** ([Rei87, Appendix to §4])

Let $\Delta \subset M_\mathbb{R}$ be a full-dimensional lattice polytope with facet presentation (4). For $\nu \in N$ let

$$\text{ord}_\Delta(\nu) := \min_{m \in \Delta \cap M} \langle m, \nu \rangle.$$ 

Note that $\text{ord}_\Delta(\nu_i) = r_i$. The Fine interior of $\Delta$ is defined as

$$F(\Delta) := \{x \in M_\mathbb{R} | \langle x, \nu \rangle \geq \text{ord}_\Delta(\nu) + 1, \nu \in N \setminus \{0\}\}$$

**Remark 2.10.** In order to construct the Fine interior $F(\Delta)$ of $\Delta$ we have to move every hyperplane which touches some face of $\Delta$ one into the interior of $\Delta$. In general it is not enough to move just the hyperplanes defining facets one into the interior (see figure 1). However finitely many hyperplanes will always be enough. In fact define the support $S_F(\Delta)$ of $F(\Delta)$ to $\Delta$ as follows:
Figure 1: Illustration of the construction of the Fine interior $F(\Delta)$ from $\Delta$.

**Definition 2.11.** The set of lattice points $\nu \in N \setminus \{0\}$ with

$$\text{ord}_{F(\Delta)}(\nu) = \text{ord}_\Delta(\nu) + 1$$

is called the support of $F(\Delta)$ to $\Delta$ and is denoted by $S_F(\Delta)$. Then we have

**Proposition 2.12.** ([Bat20, Prop.1.11])

$$S_F(\Delta) \subset \langle \nu_i | \nu_i \in \Sigma_\Delta[1] \rangle$$

In particular there are only finitely many hyperplanes touching $\Delta$ and after moving into the interior also touching $F(\Delta)$.

**Remark 2.13.** For $n = 2$ the Fine interior of $\Delta$ always equals the convex span of the interior lattice points of $\Delta$, but for $n \geq 3$ the Fine interior $F(\Delta)$ is in general only a rational polytope, i.e. the vertices have rational coordinates ([Bat17, Prop.2.9, Rem. 2.10]). But still we can define $\text{ord}_{F(\Delta)}$ just as above and may construct the normal fan to $F(\Delta)$.

**Remark 2.14.** We note that formula (5) admits a generalization, which is expressible via the “ord” function (see again [Bat20, Prop.5.1]). Namely if we take the closure of $Z_f$ in an arbitrary normal toric variety $\mathbb{P}_\Sigma$, then we get for the closure $Z_{\Sigma}$ of $Z_f$: 

$$Z_{\Sigma} \sim_{\text{lin}} - \sum_{\nu_i \in \Sigma[1]} \text{ord}_\Delta(\nu_i) D_i$$

with $\Delta$ the Newton polytope of $f$. This reduces to (5) in case $\Sigma = \Sigma_\Delta$. We will need this general form later.
Construction 2.15. We restrict in this article to canonical Fano 3-topes $\Delta$ with

$$\dim F(\Delta) = 3.$$ 

There are just 49 such polytopes left, listed in ([Sch18 Appendix A.3]) and they share the following properties:

- Every facet of $\Delta$ has distance 1 to the origin (=unique interior lattice point) except from one facet, which we call $\Delta_{\text{can}}$, and which has distance 2 to the origin.
- The Fine interior has 0 as a vertex (this follows from the first point) and exactly one facet, which we call $F(\Delta)_{\text{can}}$, opposite to 0.
- There are 46 polytopes $\Delta$ with $l^*(\Delta_{\text{can}}) = 2$ and 3 polytopes with $l^*(\Delta_{\text{can}}) = 3$.

Thus in all these cases we get with formula (5)

$$Z_{\Delta} \sim_{\text{lin}} \sum_{i: D_i \neq D_{\text{can}}} D_i + 2D_{\text{can}},$$

with $D_i$ the torus invariant divisor to the facet $\Delta_i$ and $D_{\text{can}}$ the one to $\Delta_{\text{can}}$, and thus $D_{\text{can}} = Z_{\Delta} + K_{\mathbb{P}\Delta}$ becomes the „adjoint divisor“, i.e. the divisor used in the adjunction formula

$$(Z_{\Delta} + K_{\mathbb{P}\Delta})|_{Z_{\Delta}} = K_{Z_{\Delta}},$$

therefore we chose the name $D_{\text{can}}$ for this divisor. The adjoint divisor will be of great importance for us, and the fact that it corresponds in our cases to a torus invariant divisor or equivalently to a facet $\Delta_{\text{can}}$ of $\Delta$, makes the geometry of the surfaces easier to deal with from the toric point of view.

### 2.2 Further classification of the 49 polytopes

We brought the 49 polytopes onto a normal form and showed by observation the following:

Theorem 2.16. Among the 49 polytopes there are just 5 isomorphy types for the Fine interior. For all 49 examples

$$2 \cdot F(\Delta)_{\text{can}} := \{ 2 \cdot t | t \in F(\Delta)_{\text{can}} \}$$

is inscribed into $\Delta_{\text{can}}$ with the same shape as $\Delta_{\text{can}}$ (see the pictures below). Thus the 5 different types of $F(\Delta)$ correspond to 5 different types of $\Delta_{\text{can}}$. 

10
For the first 46 polytopes $\Delta$ with $l^*(\Delta_{can}) = 2$ there are two types of $\Delta_{can}$: For 20 polytopes the facet $\Delta_{can}$ looks like in picture a) and for 26 polytopes the facet looks like in picture b). We list these polytopes in the tables (1) and (2).

![Diagram](image1)

**a)** $\Delta_{can}$ and $2 \cdot F(\Delta)_{can}$  
**b)** $\Delta_{can}$ and $2 \cdot F(\Delta)_{can}$

For the remaining 3 polytopes with $l^*(\Delta) = 3$ the facet $\Delta_{can}$ looks like in the pictures c), d) and e).

![Diagram](image2)

c): $\Delta_{can}$, $2F(\Delta)_{can}$  
d): $\Delta_{can}$, $2F(\Delta)_{can}$  
e): $\Delta_{can}$, $2F(\Delta)_{can}$

This result suggests to consider all polytopes $\Delta$ among the 49 with given $F := F(\Delta)$ at once. It is natural to ask: How are they related? Are there some minimal/maximal polytopes among them with respect to inclusion of sets? In fact we found by observation:

**Theorem 2.17.** In each of the 5 classes there is exactly one maximal polytope.

**Remark 2.18.** This maximal polytope $\Delta$ with given Fine interior $F(\Delta)$ is gotten by moving just the facets of $F(\Delta)$ by one outwards. Then it is easy to see that up to translation $\Delta$ coincides with $6 \cdot F(\Delta)$ in the cases a) an b)
and with $4 \cdot F(\Delta)$ in the cases $c), d) and e$).

There are also minimal polytopes with respect to inclusion of sets: With the notation as in table (1), (2) or figure (3) the following polytopes (with the number of lattice points below) are minimal:

<table>
<thead>
<tr>
<th></th>
<th>$\langle \Delta_{\text{can}}, a_2 \rangle$, $\langle \Delta_{\text{can}}, b_1, a_1, d_1 \rangle$, $\langle \Delta_{\text{can}}, c_2 \rangle$</th>
<th>$l(\Delta)$:</th>
<th>11</th>
<th>15</th>
<th>11</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a$</td>
<td>$\langle \Delta_{\text{can}}, b_1, d_1 \rangle$, $\langle \Delta_{\text{can}}, c_2 \rangle$, $\langle \Delta_{\text{can}}, a_2 \rangle$</td>
<td>$l(\Delta)$:</td>
<td>13</td>
<td>11</td>
<td>11</td>
</tr>
</tbody>
</table>

The polytopes $c), d)$ and $e)$ are both maximal and minimal. Note that every lattice polytope $\Delta$ with

$$\Delta_{\text{min}} \subset \Delta \subset \Delta_{\text{max}}$$

for some minimal and maximal polytope $\Delta_{\text{min}}$ and $\Delta_{\text{max}}$ is also a canonical Fano polytope with the same Fine interior as $\Delta_{\text{max}}$ (or $\Delta_{\text{min}}$), since the operation 

"taking Fine interior" respects inclusions.

It is easy to see that for a 2-dimensional lattice polytope $\Delta$ there is a unique maximal lattice polytope $\Delta_{\text{max}}$ with $F(\Delta_{\text{max}}) = F(\Delta)$. This situation has already been investigated in ([Koe91]). But from dimension 3 on it is not clear whether in general there exists exactly one maximal polytope containing a given Fine interior.

We picture the polytopes in the classes $a)$ and $b)$ in figures (2) and (3).

**Definition 2.19.** [Bat20, Def.1.9, Prop.1.11, Def.1.13]

The polytope

$$C(\Delta) := \{ x \in M_{\mathbb{R}} \mid \langle x, \nu \rangle \geq \text{ord}_\Delta(\nu) \ \forall \nu \in S_F(\Delta) \}$$

is called the canonical closure of $\Delta$. We call $\Delta$ canonically closed if $C(\Delta) = \Delta$.

**Remark 2.20.** One motivation for this definition is that there might be some lattice points $\nu \in N \setminus \{0\}$ with associated hyperplane that does not touch the Fine interior after moving by one, since other lattice vectors have more restrictive hyperplanes. In this case we have

$$\text{ord}_{F(\Delta)}(\nu) \neq \text{ord}_\Delta(\nu) + 1.$$
But certainly the canonical closure $C(\Delta)$ contains $\Delta$ and for $\dim(\Delta) = 2$ with $F(\Delta) \neq \emptyset$ we even have equality $C(\Delta) = \Delta$ (see [Bat20, Prop.2.4]). In general we have ([Bat20, Prop.1.17(b), Cor.1.19]):

$$F(C(\Delta)) = F(\Delta), \quad C(C(\Delta)) = C(\Delta),$$

(7)

i.e. $C(\Delta)$ is canonically closed and still has the same Fine interior as $\Delta$. Note that a toric birational morphism $\mathbb{P}_{\tilde{\Delta}} \to \mathbb{P}_\Delta$ is given by a refinement of the fan $\Sigma_{\Delta}$ within the same lattice $N$. In particular we may consider the torus invariant divisors $D_i \subset \mathbb{P}_\Delta$, which correspond to rays of $\Sigma_{\Delta}$, also as torus invariant divisors on $\mathbb{P}_{\tilde{\Delta}}$. The following construction appeared first in ([Bat20, Cor.4.4]):

**Construction 2.21.** We have the following general framework: Let $\Delta \subset M_\mathbb{R}$ be a 3-dimensional lattice polytope with Fine interior $F(\Delta) \neq \emptyset$. Let

$$\tilde{\Delta} := C(\Delta) + F(\Delta)$$

be the Minkowski sum. In this way the normal fan $\Sigma_{\tilde{\Delta}}$ gets the coarsest refinement of $\Sigma_{C(\Delta)}$ and $\Sigma_{F(\Delta)}$ ([CLS11, Prop.6.2.13]) and thus we get birational morphisms

$$\begin{array}{ccc}
\mathbb{P}_{\tilde{\Delta}} & \xrightarrow{\rho} & \mathbb{P}_C(\Delta) \\
\downarrow \theta & & \downarrow \\
\mathbb{P}_{F(\Delta)} & & \mathbb{P}_\Delta
\end{array}$$

(8)

We proof by observation

**Proposition 2.22.** Let $\Delta$ be a canonically closed polytope out of the 49 polytopes. Then $\Sigma_{\Delta}[1] = \Sigma_{\tilde{\Delta}}[1]$, i.e. $\rho : \mathbb{P}_{\tilde{\Delta}} \to \mathbb{P}_\Delta$ is an isomorphism in codimension 1.

**Theorem 2.23.** For $\Delta$ one of the 5 maximal lattice polytopes among the 49 polytopes we have

$$\mathbb{P}_{F(\Delta)} \cong \mathbb{P}_{\tilde{\Delta}} \cong \mathbb{P}_\Delta.$$  

Proof. The reason for this is that by remark 2.18 for $\Delta$ maximal $C(\Delta) = \Delta$ and $C(\Delta)$ and $F(\Delta)$ have the same normal fan. □
Figure 2: The 11 canonically closed polytopes out of 20 polytopes in the first class a). The polytopes in the i-th row have $18 - i$ lattice points (The maximal polytope $i = 0$ is additionaly put in the first row on the left).
Figure 3: The 15 canonically closed polytopes out of 26 polytopes in the second class b) with the same convention on the rows as in case a) beginning with $l(\Delta) = 18$ for $i = 0$. 
3 Construction of some minimal/canonical surfaces of general type in toric 3-folds

3.1 A toric framework for constructing canonical models of hypersurfaces

In this section we summarize some results from ([Bat20]). The results of this section stay true in any dimension. In order to speak about minimal (canonical) models, we should give here a definition of terminal (canonical) singularities of algebraic varieties. But we will just need this notions for toric varieties (in fact toric 3-folds) and algebraic surfaces. In these two cases the situation could be simplified:

Definition 3.1. ([Rei83, (1.11)])
Consider a fan $\Sigma$ and a cone $\sigma$ of $\Sigma$. Then $\sigma$ is called canonical (of index $j \in \mathbb{N}$), if there exists a primitive vector $m \in M$ such that

$$\langle m, \nu_i \rangle = j \text{ for } \nu_i \in \sigma[1]$$

and

$$\langle m, n \rangle \geq j \text{ for } n \in \sigma \cap N, n \notin \{0\} \cup \sigma[1] \quad (9)$$

$\sigma$ is called terminal if we have strict inequality in (9). The fan $\Sigma$ is called canonical (terminal) if all its cones are canonical (terminal).

According to [Rei83, (1.12)] we have the following result:

Theorem 3.2. The toric variety $\mathbb{P}_\Sigma$ has at most canonical (terminal) singularities if and only if the fan $\Sigma$ is canonical (terminal).

For normal algebraic surfaces we have

Proposition 3.3. ([KM98, Thm.4.5])
A normal algebraic surface $Y$ has canonical (terminal) singularities if and only if it has at most rational double points (=R.D.P.) (is smooth).

Definition 3.4. A (partial) resolution of singularities $\pi : X \to Y$ is called crepant if

$$K_X = \pi^*(K_Y).$$
Given a normal algebraic surface $Y$, we write $\kappa(Y)$ for the Kodaira dimension of $Y$. In this sense given $Y$ with $\kappa(Y) \geq 0$, $Y$ is called a minimal model if $Y$ is smooth and $K_Y$ is nef. If $\kappa(Y) = 2$, the surface $Y$ is called of general type and is called a canonical model if $Y$ has at most R.D.P. and $K_Y$ is ample.

**Remark 3.5.** If $\kappa(Y) = 2$ there is a birational morphism $\phi : Y_{\text{min}} \to Y_{\text{can}}$ from the minimal model $Y_{\text{min}}$ to the canonical model $Y_{\text{can}}$, given by contracting every curve $C$ with $K_Y.C = 0$ ([BHPV04, Ch.7, Cor.2.3]).

Back to our hypersurfaces: They will turn out to be surfaces of general type (theorem 3.10), but if we just take the closure $Z_\Delta$ of $Z_f$ in $\mathbb{P}_\Delta$, $Z_\Delta$ might have bad singularities, in particular non-canonical. We ask the following:

- In which toric variety sits the minimal/canonical model?
- Is the morphism $\phi : Y_{\text{min}} \to Y_{\text{can}}$ induced by some toric morphism?

Recall the diagram (8) in construction (2.21) with $\tilde{\Delta} = C(\Delta) + F(\Delta)$. The following result is the crucial combinatorial input to answer these questions:

**Theorem 3.6.** [Bat20, Thm.4.3]
We have $\Sigma[1] \subset S_F(\Delta)$. In particular we may choose a simplicial refinement $\Sigma$ of $\Sigma[1]$ with $\Sigma[1] = S_F(\Delta)$.

Following ([Bat20, Proof of Cor.4.4]) we consider the following support function on $\Sigma[1]$

$$\delta_{C(\Delta)}(\nu) := \text{ord}_{F(\Delta)}(\nu) - \text{ord}_{C(\Delta)}(\nu), \quad \nu \in N \setminus \{0\}.$$ 

This function is linear on every cone of $\Sigma[1]$ and defines a $\mathbb{Q}$-Cartier divisor on $\mathbb{P}_\Delta$ by construction (2.4). Since for $\nu \in S_F(\Delta)$

$$\text{ord}_{F(\Delta)}(\nu) - \text{ord}_{C(\Delta)}(\nu) = 1$$

we get by formula (2) and theorem 3.6 that $\delta_{C(\Delta)}$ defines exactly the canonical divisor $K_{\mathbb{P}_\Delta}$. Further we have

$$\delta_{C(\Delta)}(\nu) \geq 1 \quad (10)$$

for all $\nu \in N \setminus \{0\}$ and it thus follows from Definition 3.1 that $\mathbb{P}_\Delta$ has at most canonical singularities.

In the equation (10) we have by definition of $S_F(\Delta)$ equality if and only if
\( \nu \in S_F(\Delta) \). Thus choosing a simplicial fan \( \Sigma \) refining \( \tilde{\Sigma} \) with \( \Sigma[1] = S_F(\Delta) \), the toric variety \( \mathbb{P}_\Sigma \) has at most terminal singularities. Besides it follows easily that the induced morphism

\[ \pi : \mathbb{P}_\Sigma \to \mathbb{P}_\Delta \]

is crepant. Of course \( \Sigma \) is again a normal fan of some polytope but we do not need this polytope and thus use the notation with the fan. We summarize:

**Consequence 3.7.** The toric variety \( \mathbb{P}_\Delta \) has at most canonical singularities and \( \mathbb{P}_\Sigma \) has at most terminal singularities. The morphism \( \mathbb{P}_\Sigma \to \mathbb{P}_\Delta \) is crepant.

Note that for \( \Delta \) reflexive \( F(\Delta) = \{0\} \) and thus \( \mathbb{P}_\Delta \cong \mathbb{P}_\Delta \). We pictured the polytopal complexes on which \( \delta_{C(\Delta)} \) attains the value 1 in figure (1).

**Construction 3.8.** But in fact the situation is much better: By construction (2.4) on \( \mathbb{P}_{C(\Delta)} \) there is an ample divisor \( D_{C(\Delta)} \) and on \( \mathbb{P}_{F(\Delta)} \) there is an ample divisor \( D_{F(\Delta)} \). Their pullbacks \( \rho^*(D_{C(\Delta)}) \) and \( \theta^*(D_{F(\Delta)}) \) define two nef divisors, such that

\[ D_\Delta = \rho^*(D_{C(\Delta)}) + \theta^*(D_{F(\Delta)}) \]

is ample. We claim that

\[ m(Z_\Delta + K_{\mathbb{P}_\Delta}) \]

is a basepointfree Cartier divisor, and thus so is its restriction \( mK_{Z_\Delta} = m(Z_\Delta + K_{\mathbb{P}_\Delta})|_{Z_\Delta} \), where \( m \) is the index of \( F(\Delta) \) in \( M \), i.e. the smallest positive integer such that \( m \cdot F(\Delta) \) is a lattice polytope.

To see this first note that to the closure \( Z_\Sigma \subset \mathbb{P}_\Sigma \) of \( Z_f \) is associated the polytope \( \Delta \), since by Remark 2.14

\[ Z_\Sigma \sim_{lin} - \sum_{\nu_i \in \Sigma[1]} \text{ord}_\Delta(\nu_i)D_i. \]

But \( \Sigma[1] = S_F(\Delta) \) and thus

\[ Z_\Sigma + K_{\mathbb{P}_\Sigma} \sim_{lin} - \sum_{\nu_i \in S_F(\Delta)} (\text{ord}_\Delta(\nu_i) + 1)D_i = - \sum_{\nu_i \in S_F(\Delta)} \text{ord}_{F(\Delta)}(\nu_i)D_i \]

by the definition of \( S_F(\Delta) \). In other words \( \Sigma \) has enough rays such that to the divisor \( Z_\Sigma + K_{\mathbb{P}_\Sigma} \) is associated the polytope \( F(\Delta) \). Then

\[ m \cdot \text{ord}_{F(\Delta)}(\nu_i) = \min_{w \in F(\Delta) \cap M} \langle m \cdot w, \nu_i \rangle \in \mathbb{Z}, \quad \nu_i \in \Sigma[1] \]
Figure 4: The polytopal complexes for the polytopes in the class $a$.
We use the following notations: $n_0 := n_{abd} = (-1, 0, 0)$, $n_1 := n_{pab} = (-1, 3, 1)$, $n_2 := n_{pad} = (2, -3, 1)$, $n_3 := n_{pbd} = (0, 0, -1)$. The convention on the rows is the same as in figure 2.
so that we find a support function \( x \mapsto \langle m_\sigma, x \rangle \) for \( m(Z_\Sigma + K_{\mathbb{P}_\Sigma}) \) with \( m_\sigma \in m \cdot F(\Delta) \), i.e. \( m(Z_\Sigma + K_{\mathbb{P}_\Sigma}) \) is a basepointfree Cartier divisor by construction \(^2\).

With a bit more work it could be shown that \( Z_\Delta \) and \( V \) inherit at most the mild (canonical/terminal) singularities of \( \mathbb{P}_\Sigma \) and \( \mathbb{P}_\Delta \). Thus we have the following theorem:

**Theorem 3.9.** ([Bat20, Thm.5.4])
The closure \( Z_\Sigma \) of \( Z_f \) gets a minimal model and the closure \( Z_\Delta \) of \( Z_f \) lies between a minimal and a canonical model, i.e. the morphism \( \phi \) from the minimal to the canonical model factors through \( Z_\Delta \).

Now that we know the singularities of \( Z_\Sigma \) and \( Z_\Delta \), we state the following result, relating the Kodaira dimension of \( Z_\Delta \) to the dimension of the Fine interior, which is interesting in its own right:

**Theorem 3.10.** ([Bat20, Thm.6.2])
Given a 3-dimensional lattice polytope \( \Delta \subset M_\mathbb{R} \) with \( k := \dim(F(\Delta)) \geq 0 \), the Kodaira dimension of \( Z_\Delta \) equals

\[
\kappa(Z_\Delta) = \min(k, 2).
\]

This means that for our 49 polytopes \( \Delta \) with \( \dim F(\Delta) = 3 \) we have \( \kappa(Z_\Delta) = 2 \). Further we can understand the morphism \( \theta \circ \pi : \mathbb{P}_\Sigma \to \mathbb{P}_{F(\Delta)} \) now even better: By the last point in construction \(^2\) \( m(Z_\Sigma + K_{\mathbb{P}_\Sigma}) \) induces the birational toric morphism \( \theta \circ \pi \) and thus

\[
(\theta \circ \pi)^*(D_{F(\Delta)}) = m(Z_\Sigma + K_{\mathbb{P}_\Sigma}).
\]

Since \( \pi : \mathbb{P}_\Sigma \to \mathbb{P}_\Delta \) is crepant, we also get

\[
m(Z_\Delta + K_{\mathbb{P}_\Delta}) \sim_{\text{lin}} \theta^*(D_{F(\Delta)}).
\]

The birational morphism \( \theta : \mathbb{P}_\Delta \to \mathbb{P}_{F(\Delta)} \) induces now a birational morphism

\[
\theta : Z_\Delta \to Z_{F(\Delta)}, \quad \text{with } \theta^*(D_{F(\Delta)}|_{Z_{F(\Delta)}}) = m(Z_\Delta + K_{\mathbb{P}_\Delta})|_{Z_\Delta} = mK_{Z_\Delta}.
\]

Since \( D_{F(\Delta)} \) is ample we get for a curve \( C \subset Z_\Delta \):

\[
\theta(C) = \text{pt.} \iff 0 = \theta^*(D_{F(\Delta)}|_{Z_{F(\Delta)}}).C = mK_{Z_\Delta}C
\]

i.e. we get
Theorem 3.11. The composition \( Z_\Sigma \to Z_\Delta \to Z_{F(\Delta)} \) is induced by \( m(Z_\Sigma + K_{F_\Sigma}) \) where
\[
m = \min\{n \in \mathbb{N} \mid n \cdot F(\Delta) \text{ is a lattice polytope}\}.
\]
In our 49 examples \( Z_{F(\Delta)} \) gets a canonical model and the morphism \( Z_\Sigma \to Z_{F(\Delta)} \) coincides with the birational morphism \( \phi \) from the minimal to the canonical model.

By properties of canonical models of surfaces of general type the morphism \( Z_\Sigma \to Z_{F(\Delta)} \) is crepant as well. Parts of the above result generalises the MPCP-desingularization associated to reflexive polytopes (compare [Bat94, Def.2.2.13, Thm.2.2.24]).

3.2 Unravelling the diagram (8)

We have seen in proposition (2.22) that in all 49 examples \( \rho \) is an isomorphism in codimension one and is an isomorphism for \( \Delta \) maximal. It is thus an isomorphism or a so called „small contraction“, that is a nontrivial contraction, which contracts at most finitely many curves. The situation is just interesting if the polytope is not maximal, thus we restrict to the classes \( a \) and \( b \). We further restrict to \( \Delta \) canonically closed.

Proposition 3.12. For \( \Delta \) canonically closed \( \rho : \mathbb{P}_{\Delta} \to \mathbb{P}_{\Delta} \) is an isomorphism if and only if
\[
\{a_1, b_1, (c_1), d_1\} \subset \Delta,
\]
with \( c_1 \) added in the class \( b \).

In figure 2 and figure 3 these are the polytopes

\[
\begin{align*}
a) : \langle \Delta_{can} , p \rangle, & \quad \langle \Delta_{can} , a_2 , b_1 , c_2 , d_1 \rangle, & \quad \langle \Delta_{can} , a_1 , b_1 , c_2 , d_1 \rangle, & \quad \langle \Delta_{can} , a_1 , b_1 , d_1 \rangle \\
b) : \langle \Delta_{can} , p \rangle, & \quad \langle \Delta_{can} , a_2 , b_1 , c_2 , d_1 \rangle, & \quad \langle \Delta_{can} , a_1 , b_1 , c_2 , d_1 \rangle, & \quad \langle \Delta_{can} , a_2 , b_1 , c_1 , d_1 \rangle, & \quad \langle \Delta_{can} , a_1 , b_1 , c_1 , d_1 \rangle
\end{align*}
\]

Proof. If \( \rho \) is a small contraction, then \( K_{F_{\Delta}} \) is not \( \mathbb{Q} \)-Cartier (compare ([KM98 2.6, Case 3])). But \( K_{F_{\Delta}} \) is \( \mathbb{Q} \)-Cartier if and only if \( D_{can} = K_{F_{\Delta}} + Z_{\Delta} \) is \( \mathbb{Q} \)-Cartier.
Figure 5: The polytope $\Delta$ on the left and $\Delta'$ on the right with $\mathbb{P}_{\Delta'} \cong \mathbb{P}_\Delta$

Looking for a support function $x \mapsto \langle m_\sigma, x \rangle$, where $\sigma \in \Sigma_\Delta[3]$, for $mD_{can}$ we get the following conditions

$$\langle m_\sigma, \nu_i \rangle = \begin{cases} -m & n_i = n_{can} \\ 0 & \text{else} \end{cases}$$

(12)

for $n_i \in \sigma[1]$. If condition (11) is fulfilled everything works as on $\mathbb{P}_\Delta$ in construction (3.8), i.e. these equations describe lattice points $m_\sigma \in m \cdot F(\Delta)_{can}$ if $n_{can} \in \sigma[1]$ and $m_\sigma = (0, 0, 0)$ else for $m \in 6\mathbb{Z}$.

But if another facet than the facets to the maximal polytope containing $\Delta$ touches some vertex $m \in \Delta_{can}$, then the normal vector to this facet yields an extra condition on $m_\sigma$, and there is no Cartier data for $mD_{can}$.

\[ \blacksquare \]

**Remark 3.13.** In fact it is easy to see that for $\Delta$ a maximal polytope we have the following Picard groups:

$$a), b) : \text{Pic}(\mathbb{P}_\Delta) \cong \mathbb{Z} \cdot [6D_{can}], \quad c), d), e) : \text{Pic}(\mathbb{P}_\Delta) \cong \mathbb{Z} \cdot [4D_{can}].$$

**Remark 3.14.** We can describe the small contraction $\rho$ at our polytopes: For example for the polytope $\langle \Delta_{can}, a_1, c_2, d_1 \rangle$ remark 3.12 suggests to insert an edge $\langle b', b \rangle$ as in figure (5) and thus obtaining a polytope $\Delta'$. It is easy to see that $\mathbb{P}_{\Delta'} \cong \mathbb{P}_\Delta$ and we omit the proof here.

In all other examples the situation is similar: In order to go from $\mathbb{P}_\Delta$ to $\mathbb{P}_\Delta$ whenever at least one element of $\{a_1, b_1, (c_1), d_1\}$ is missing in $\Delta$, we stretch the facet $\Delta_{can}$ a bit and thus introduce new vertices.
Remark 3.15. It follows easily from this description of $\Sigma_{\Delta}$ that $\Sigma_{\Delta}$ coincides with $\Sigma_{F(\Delta)}$ except that $\Sigma_{\Delta}$ might refine one cone $\sigma \in \Sigma_{F(\Delta)}$, where

$$a), c) : \sigma[1] = \{n_{abp}, n_{bdp}, n_{adp}\}, \quad b), d), e) : \sigma[1] = \{n_{abp}, n_{bcp}, n_{cdp}, n_{adp}\}$$

We also want to take into account the lattice vectors from the support $S_{F(\Delta)}$ which are not in $\Sigma_{\Delta}[1]$. We make the observation that for $\Delta$ maximal they lie on the boundary of the above cone $\sigma$. From the common description of all $\Delta$'s as a pyramid with common base $\Delta_{can}$ we may easily deduce that for every $\Delta$ the vectors in the support lie in the cone $\sigma$.

Construction 3.16. We picture the refinement $\Sigma_{\Delta}$ of $\Sigma_{F(\Delta)}$ in figure (6) and (7) and indicate some of the support vectors.

It is easy to see that a $\Delta$-regular Laurent polynomial is also $\tilde{\Delta}$-regular since $\Sigma_{\Delta}$ is a refinement of $\Sigma_{\Delta}$. Thus the hypersurface $Z_{\Delta}$ does not meet the torus fixed points of $\mathbb{P}_{\Delta}$. Further some of the support vectors might lie in the interior of 3-dimensional cones, which correspond to torus fixed points, through which the hypersurface $Z_{\Delta}$ does not pass. These support vectors are superfluous for constructing a minimal model and we did not pictured them. We are left with the 2-dimensional cones $\tau \in \Sigma_{\Delta}[2]$ which correspond to torus invariant curves meeting the hypersurface in finitely many points.

We use the following notations: In $a$): $n_1 := n_{pab} = (-1, 3, 1), n_2 := n_{pad} = (2, -3, 1), n_3 := n_{pbd} = (0, 0, -1)$, in $b$): $n_1 := n_{pab} = (2, 1, -2), n_2 := n_{pbc} = (0, -1, -1), n_3 := n_{pcd} = (-1, -1, 1), n_4 := n_{pad} = (0, 1, 2)$.

Proposition 3.17. Let $\tau \in \Sigma_{\Delta}[2]$ be a 2-dimensional cone, corresponding to the torus invariant curve $F$. Then if $\tau$ is the normal cone to the edge $\Gamma = \langle s, t \rangle \subset \tilde{\Delta}$, the hypersurface $Z_{\Delta}$ intersect $F$ in $l$ points where

$$s - t = l \cdot (\text{primitive vector}).$$

Proof. The edge $\Gamma$ is the Newton polytope of the zero-dimensional subvariety $Z_{\Delta} \cap F$ and thus just counts the number of points. \qed
Figure 6: A cross-section of the cone $\sigma$ for all canonically closed polytopes in $a$) with the refinement $\Sigma_\Delta$ pictured and the position of the additional vectors from $S_F(\Delta)$ lying on a cone in $\Sigma_\Delta$ and yielding singularities of $Z_\Delta$. The order is the same as in figure (2) except from the maximal polytope written left from the next one.

24
Figure 7: A cross-section of the cone $\sigma$ for all canonical closed polytopes in the class $b)$ with the same convention as in figure (6) and the same order as in figure (3).
3.3 The singularities of $Z_{\tilde{\Delta}}$ and $Z_{F(\Delta)}$

Construction 3.18. The singularities of $Z_{\tilde{\Delta}}$ come from 2-dimensional singular cones $\tau \in \Sigma_{\tilde{\Delta}}[2]$. Locally around a point $x \in F \cap Z_{\tilde{\Delta}}$, the toric variety $\mathbb{P}_{\tilde{\Delta}}$ is isomorphic to the product of the orbit $F$ to $\tau$ and a two-dimensional toric variety $P$. The type of singularity of $Z_{\tilde{\Delta}}$ at $x$ is the same as that of $P$, since both intersect the orbit $F$ transversally. But a normal toric surface has at most $A_k$ singularities ([CLS11, Example 10.1.5]). Thus if $\tau$ has generators $n_i$ and $n_j$ and corresponds to the edge $\langle s, t \rangle$, write

$$n_i - n_j = k \cdot \text{(primitive vector)}$$
$$s - t = l \cdot \text{(primitive vector)}$$

Then $Z_{\tilde{\Delta}}$ intersects $F$ in $l$ singularities of type $A_k$. We listed the singularities in table (1) and (2). In figures (6) and (7) we thus pictured just those vectors in $S_F(\Delta)$ which lie on a cone $\tau \in \Sigma_{\tilde{\Delta}}[2]$ corresponding to an edge $\langle s, t \rangle$ of $\tilde{\Delta}$ such that $s, t \in \Delta$.

Example 3.19. For the polytope $\langle a, b, d, b_1, c_2, d_1 \rangle$ in the class $a$) there are 4 curves whose intersection with $Z_{\tilde{\Delta}}$ will form the singular points on $Z_{\tilde{\Delta}}$: The orbit to the cone spanned by $n_1$ and $n_2$, which corresponds to the edge $\langle a, d \rangle$ yields $A_2$ singularities. But already $a_1 \notin \Delta$, thus this orbit does not intersect $Z_{\tilde{\Delta}}$.

The cones spanned by $n_{14}$, $n_{15}$ ($n_{14}$, $n_3$, and $n_{15}$, $n_3$) also yield $A_2$ singularities and correspond to the edges $\langle a, c_2 \rangle$ ($\langle b_1, c_2 \rangle$, $\langle c_2, d_1 \rangle$). Since $a - c_2$, $b_1 - c_2$, $c_2 - d_1$ are primitive lattice vectors we get one $A_2$ singularity respectively.

Example 3.20. For the maximal polytope in the class $a$) there is just one singular cone with generators $n_1$ and $n_2$ and corresponding to the edge $\langle a, p \rangle$ of $\Delta$. We have

$$n_1 - n_2 = (3, -6, 0) = 3 \cdot \text{(primitive vector)}$$
$$a - p = (6, 3, -3) = 3 \cdot \text{(primitive vector)}$$

Thus we get 3 singularities of type $A_2$ on $Z_{\Delta}$

Construction 3.21. The canonical model $Z_{F(\Delta)}$ might have other singularities if the polytope is not maximal, since $Z_{F(\Delta)}$ is not $F(\Delta)$-regular or in other words $Z_{F(\Delta)}$ passes through the torus fixed point to the vertex $p$. By remark [B.15] only the 3-dimensional cone $\sigma$ to the vertex $p$ gets refined by
rays, thus this is the only extra singularity of \( Z_{F(\Delta)} \).

Figures (6) and (7) tells us how to refine the 3-dimensional cone to the vertex \( p \). For each ray \( \rho \) that gets added we get a toric divisor \( E_\rho \) and the intersection \( Z_\Sigma \cap E_\rho \) defines a \((-2)\)-curve on \( Z_\Sigma \): The intersection consists certainly of a collection of \((-2)\)-curves. It is smooth by nondegeneracy and there is a connected neighborhood \( U \subset Z_\Sigma \) of \( E_\rho \cap Z_\Sigma \) which retracts onto \( E_\rho \cap Z_\Sigma \), thus it is also connected and consists of a single \((-2)\)-curve.

Different \((-2)\)-curves intersect if the corresponding rays are joined by a face, that is in figures (6) and (7) the points are joined by an edge. Thus we get the following result:

**Theorem 3.22.** Let \( \Delta \) be a canonically closed polytope (under the 49 polytopes). Then the diagram with vertices the points in the interior of \( \sigma \) in the figures (6) and (7) constitutes the Dynkin diagram of the singularity of \( Z_{F(\Delta)} \) at the torus fixed point to \( p \).

**Example 3.23.** In figure (6) we get for the right example in the first row an \( A_2 \) singularity at the torus fixed point to \( p \), whereas for the second example from left in the third row we get an \( E_6 \) singularity at the torus fixed point to \( p \).

**Remark 3.24.** We can also verify the types of singularities at \( p \) directly: For example for the class \( a \) let \( \Delta_{\text{max}} \) be the maximal polytope and consider the cone
\[
C := \text{Cone}(\Delta_{\text{max}} \cap M - p).
\]

The affine toric variety \( U_p \) to this cone defines an open neighbourhood of \( p \) within \( \mathbb{P}_{F(\Delta)} \) ([CLST11 Thm.2.3.1]). The vectors \( a_2 - p, b_1 - p, c_2 - p, d_1 - p \) generate all lattice points in the cone \( C \) and fulfill the relation
\[
3(c_2 - p) = (b_1 - p) + (d_1 - p).
\]

We introduce variables \( x_1, \ldots, x_4 \) for these vectors in the same order and get
\[
U_p = \{ x_3^3 = x_2x_4 \} \subset \mathbb{C}^4.
\]

\( U_p \) has the line \( \{ x_2 = x_3 = x_4 = 0 \} \) as singular locus. Now if for example \( \Delta = \langle a, b, d, a_2, b_1, c_2, d_1 \rangle \), then the Laurent polynomial \( f \) will be of the form
\[
f = r_1 x_1 + \text{(other terms)} \quad r_1 \in \mathbb{C} \setminus \{0\}
\]
Figure 8: From the left to the right: The cross-section with all support vectors, the polytope $\Delta'$ (canonically closed) and $\Delta$.

since $a_2 - p$ corresponds to the coordinate $x_1$ and (up to translation) $a_2 - p$ is a vertex of $\Delta$. Thus the hypersurface $\{ f = 0 \} \subset \mathbb{C}^4$ meets the toric variety $U_p$ like the line $\{ x_1 = 0 \}$ in an $A_2$ singularity at $(0, 0, 0, 0)$. For other $\Delta$’s the situation is similar but more complicated.

Let us say a few words to the case if $\Delta$ is not canonically closed:
In this case $\Delta$ has the same support vectors as its canonical closure ([Bat94, Cor.1.18]). But the Laurent polynomial is a priori no longer $\bar{\Delta}$-regular and thus all support vectors in $S_F(\Delta)$ might be relevant. But we see by observation that in all examples both $Z_{\bar{\Delta}}$ and $Z_{F(\Delta)}$ have the same singularities as the hypersurface to the canonical closure. We want to illustrate this at an example:

**Example 3.25.** We take the cross-section of the cone in $a)$ which is represented in figure (6) in the fourth row the second from the left ($\Delta' := \langle a, b, d, a_2, c_1 \rangle$):
There are 2 additional support vectors and these all lie in the 3-dimensional cone to the vertex $a_2$ of $\Delta$ (see figure (8)). There is one polytope $\Delta := \langle a, b, d, a_2 \rangle$ in table (11) which has $\Delta'$ as its canonical closure and this polytope still contains $a_2$ as a vertex, thus the hypersurface $Z_{F(\Delta)}$ does not pass through the torus fixed point to $a_2$ and the singularities of $Z_{\bar{\Delta}}$ ($Z_{F(\Delta')}$) are the same respectively.

**Remark 3.26.** Note that in diagram (8) it is necessary to use $\mathbb{P}_{C(\Delta)}$ and not $\mathbb{P}_{\Delta}$ since by theorem (3.6) we have $\Sigma_{C(\Delta)}[1] \subset S_F(\Delta)$, i.e. every facet to $C(\Delta)$ touches the Fine interior $F(\Delta)$ after moving into the interior. This property is crucial but need not hold for $\Delta$. 

28
4 Constructing Kanev and generalized Todorov surfaces

Notation: (Complex algebraic)
Let $Y$ be a normal algebraic surface with at most R.D.P., let

- $p_g(Y) := h^0(Y, \mathcal{O}_Y(K_Y))$ the geometric genus of $Y$
- $q(Y) := h^0(Y, \Omega^1_Y)$ the irregularity of $Y$
- $\chi(Y, \mathcal{O}_Y)$: The euler characteristic of the structure sheaf
- $e(Y)$: The topological euler characteristic
- $\mathbb{P}(a_0, \ldots, a_n)$: The weighted projective space with the weights $a_0, \ldots, a_n$

For $Y$ with $p_g(Y) = 1$ we denote by $K_Y$ also the unique curve $C \in |K_Y|$. To compute these invariants for our hypersurfaces we use results from Danilov and Khovanskii:

**Theorem 4.1.** ([DK86, 5.5, Prop.3.4]) Let $\Delta \subset M_{\mathbb{R}}$ be a 3-dimensional lattice polytope, such that $\Sigma_\Delta$ is simplicial. Then the geometric genus $p_g(Z_\Delta)$ may be computed as

$$p_g(Z_\Delta) = l^*(\Delta).$$

In general choose a simplicial refinement $\Sigma$ of $\Sigma_\Delta$, then

$$p_g(Z_\Sigma) = l^*(\Delta).$$

For the irregularity of $Z_\Delta$ we have, even in the non simplicial case $q(Z_\Delta) = 0$.

In particular we obtain in remark (2.7), after resolving singularities, a K3 surface. For our 49 polytopes $\Sigma_F(\Delta)$ need not be simplicial, but $\Sigma$ is and $Z_\Sigma \to Z_F(\Delta)$ is crepant, thus we get

$$p_g(Z_F(\Delta)) = l^*(\Delta) = 1.$$

**Definition 4.2.** ([Cat78]) A Kanev surface is a smooth surface $Y$ with

$$p_g(Y) = 1, \quad K_Y^2 = 1.$$ 

Such surfaces are minimal and of general type: $K_Y$ is nef and $\kappa(Y) = 2$ since additionally $K_Y^2 > 0$ (compare ([Laz00 Thm.2.2.16])). We call the canonical model of $Y$ also a canonical Kanev surface.
Theorem 4.3. For $\Delta$ out of the 46 polytopes with $l^*(\Delta_{\text{can}}) = 2$ the hypersurface $Z_{F(\Delta)}$ gets a canonical Kanev surface, whereas for $\Delta$ from the remaining 3 polytopes $Z_{F(\Delta)}$ gets a canonical surface with $p_g(Z_{F(\Delta)}) = 1$, $q(Z_{F(\Delta)}) = 0$, $K^2_{Z_{F(\Delta)}} = 2$.

Remark 4.4. In order to keep the notation clear we write from now on $Y$ for $Z_\Delta$, $Y_{\text{min}}$ for $Z_\Sigma$ and $Y_{\text{can}}$ for $Z_{F(\Delta)}$. In computing invariants of minimal/canonical surfaces we feel free to work with $Y$, since the morphisms $Y_{\text{min}} \to Y$ and $Y \to Y_{\text{can}}$ are crepant.

Proof. We already showed that $Y$ lies between a minimal and a canonical surface of general type and $p_g(Y) = 1$. Now $\Delta_{\text{can}}$ is exactly the Newton polytope of a curve whose closure defines $K_Y$. Thus we may apply theorem 4.1 to $\Delta_{\text{can}}$ and we obtain in 46 examples

$$p_g(K_Y) = l^*(\Delta_{\text{can}}) = 2$$

and in 3 examples

$$p_g(K_Y) = l^*(\Delta_{\text{can}}) = 3, \quad q(Y) = 0.$$ 

From the adjunction formula $p_g(K_Y) = K_Y^2 + 1$ we obtain that in 46 examples $Y_{\text{can}}$ gets a canonical Kanev surface whereas in the remaining 3 examples $Y_{\text{can}}$ gets a canonical model with $p_g(Y_{\text{can}}) = 1$, $q(Y_{\text{can}}) = 0$, $K^2_{Y_{\text{can}}} = 2$. \qed

4.1 General properties of Kanev surfaces

Lemma 4.5. A Kanev surface $Y$ is simply connected, i.e. $\pi_1(Y) = 0$. The condition $p_g(Y) = 1$ in the definition of Kanev surfaces is equivalent to the condition $\chi(Y, O_Y) = 2$ or $e(Y) = 23$.

Proof. The first assertions follows from the section 8 of the article ([Bomb73]). The other statements follow from this first assertion and Noether’s formula ([BHPV04, Ch.1, Thm.(5.5)])

$$\chi(Y, O_Y) = \frac{1}{12}(K^2_Y + e(Y)).$$ \qed
The lemma allows us to compute the Hodge number $h^{1,1}(Y)$ via the topological euler number: The only nonzero Hodge numbers are

$$h^{0,0} = h^{2,2} = 1, \quad h^{0,2} = h^{2,0} = 1, \quad h^{1,1} = 19$$

The following result is well known ([BHPV04, Ch.7, Cor.(5.4)]).

**Proposition 4.6.** Let $Y$ be a minimal or canonical surface of general type, then we have the following formula for the plurigenera

$$P_n(Y) := h^0(Y, O_Y(nK_Y)) = \chi(Y, O_Y) + \frac{n(n-1)}{2}K_Y^2 \quad \text{for } n \geq 2$$

**Remark 4.7.** In particular for Kanev surfaces we have the following dimensions:

$$P_2(Y) = 3, \quad P_3(Y) = 5.$$ 

The pluricanonical maps $\phi_{nK_Y}$ from the minimal model $Y_{min}$ factor through the canonical model (compare [BHPV04, Ch.7, discussion before Thm 5.1]) with induced maps $\psi_{nK_Y}$ from $Y_{can}$. The bicanonical map $\psi_{2K_Y}$ is basepoint-free (compare ([Cat78 Thm.1])) and defines a branched covering of degree 4, since

$$(2K_Y)^2 = 4.$$ 

Further $Y_{can}$ may be realized as a projective variety by embedding it as a complete intersection of type $(6,6)$ into $\mathbb{P}(1,2,2,3,3)$ by using sections of $|K_Y|$, $|2K_Y|$, and $|3K_Y|$ at once (compare ([Cat78 Prop.6])), but in this article we will not need this.

For some Kanev surfaces an interesting phenomenon occurs:

**Definition 4.8.** ([Cat78, Def.9, Thm.3])

A canonical Kanev surface $Y$ is called special if $\psi_{2K_Y} : Y \to \mathbb{P}^2$ factors through a K3-surface $Z$ with R.D.P.:

$$\begin{align*}
Y \xrightarrow{\psi_{2K_Y}} \mathbb{P}^2 \\
\downarrow & \quad \downarrow \\
Z & 
\end{align*}$$

**Remark 4.9.** Special Kanev surfaces are better understood than general Kanev surfaces. For example for special Kanev surfaces the branch locus of $\psi_{2K_Y}$ could be further specified ([Cat78 Prop.10]). These special Kanev surfaces build a 12-dimensional family, whereas all Kanev surfaces build an 18-dimensional family ([Cat78 Proof of Thm.4]).
4.2 Surfaces with $K^2 = 2$, $p_g = 1$, $q = 0$ in general

In this short section we summarize results from (CD89) concerning minimal surfaces $Y$ with

$$K_Y^2 = 2, \quad p_g(Y) = 1, \quad q(Y) = 0.$$  \hfill (13)

The topological Euler number is given by $e(Y) = 22$ by Noether’s formula as in lemma 4.5. Thus the only nonzero Hodge numbers are

$$h^{0,0} = h^{2,2} = 1, \quad h^{2,0} = h^{0,2} = 1, \quad h^{1,1} = 18.$$  

By Proposition 4.6 we have $h^0(Y, \mathcal{O}_Y(2K_Y)) = 4$.

**Proposition 4.10.** (CD89, Prop.1.1)

For a surface with invariants as in (13) the linear system $|2K_Y|$ has no base points. It defines a finite morphism $\psi_{2K_Y} : Y_{\text{can}} \to Z \subset \mathbb{P}^3$ such that

$$\deg(Z) \cdot \deg(\psi_{2K_Y}) = (2K_Y)^2 = 8$$

In fact there are several possibilities for $\deg(\psi_{2K_Y})$ and $Z = \psi_{2K_Y}(Y)$. One possibility is that

$$\deg(\psi_{2K_Y}) = 4 \text{ and } Z \text{ is a quadric cone.}$$  \hfill (14)

**Remark 4.11.** In case the bicanonical map $\psi_{2K_Y}$ factors through a K3 surface, the surface $Y$ is also called a Todorov surface in the literature (see e.g. (Rit08)). We therefore call surfaces who belong to the case (14) of Proposition 4.10 surfaces of Todorov type.

**Remark 4.12.** (CD89, Thm.2.8, Thm.2.11)

In the case (14) of the above proposition the fundamental group of $Y$ is

$$\pi_1(Y) \cong \mathbb{Z}/2\mathbb{Z}.$$  \hfill (15)

The canonical model of $Y$ is embeddable as complete intersection into $\mathbb{P}(1, 1, 1, 2, 2)/\iota$, where $\iota(x_0 : x_1 : x_2 : y_3 : y_4) := (x_0 : -x_1 : -x_2 : -y_3 : -y_4)$. The minimal models of surfaces of Todorov type are all deformation equivalent and they build a 16-dimensional family.
4.3 Families of Kanev surfaces and surfaces of Todorov type to our polytopes

In this section we want to see which of the canonical Kanev hypersurfaces we constructed are special and we proove that the surfaces with \( p_g(Y) = 1 \), \( q(Y) = 0 \), \( K_Y^2 = 2 \) we constructed are of Todorov type. We show how to describe the universal covering of the latter surfaces by refining the lattice.

**Remark 4.13.** The facet \( \Delta_{\text{can}} \) is common to all polytopes in one class a)-e). Thus for \( Y \) sufficiently nondegenerate, the canonical curve \( K_Y = D_{\text{can}|Y} \) is a nondegenerate curve in \( D_{\text{can}} \). Since \( D_{\text{can}} \) is a normal toric surface, it has singularities in at most the toric fixed points through which \( Y \) does not pass by nondegeneracy. Thus \( K_Y \) defines a smooth curve.

4.4 The two maximal families in a) and b)

**Proposition 4.14.** Consider the maximal polytope \( \Delta \) in the class a) or b), \( f = \sum_{m \in \Delta \cap M} a_m z^m \), \( a_m \in \mathbb{C} \), and the (family of) hypersurfaces \( Z_f \) with closure...
Then the subfamily of hypersurfaces $Z_\Delta$ given by setting
\[ a) : a_{(-1,-1,1)} = a_{(1,0,0)} = a_{(1,1,1)} = 0 \]
\[ b) : a_{(-1,1,0)} = a_{(1,-1,1)} = a_{(1,0,0)} = a_{(1,-1,1)} = 0 \]
has as a general member a special Kanev surfaces.

\textit{Proof.} We prove the proposition for the class $a)$. The condition on the $a_m$ assures that after coarsen the lattice $M$ in the first coordinate by 2 every point $m \in M \cap \Delta$ such that $a_m \neq 0$ stays a lattice point. The canonical facet which had distance 2 to the interior point, then has distance 1 to the origin like all the other facets. Thus we get a reflexive polytope and the hypersurface becomes a K3-surface with R.D.P.. We are left to show that this lattice refinement corresponds to a factorization of $\psi_{2K_Y}$.

We show that the divisor $2D_{can}$ with global sections from $M \cap 2F(\Delta)$ really induces the map $\psi_{2K_Y}$. Then we are done since the lattice points of $2 \cdot F(\Delta)$ have even first coordinate and $D_{can}$ factorizes as in definition (4.8). To show this last point we use the exact sequence
\[ H^0(\mathbb{P}_\Delta, 2D_{can} - Y) \to H^0(\mathbb{P}_\Delta, 2D_{can}) \to H^0(Y, 2K_Y) \to H^1(\mathbb{P}_\Delta, 2D_{can} - Y). \]
Since $2D_{can} - Y = D_{can} + K_{\mathbb{P}_\Delta}$ is the negative of an effective divisor and $D_{can}$ is ample the result follows easily.

\[ \]

\textbf{Example 4.15.} The first Kanev surface was found in ([Kan76]) via the following Fermat polynomial
\[ f(x_0, \ldots, x_3) := x_0^6 + x_1^6 + x_2^6 + x_3^6. \]
Let $X := \{ f = 0 \} \subset \mathbb{P}^3$, $G := \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. Then $G$ acts on $\mathbb{P}^3$ via
\[ g = (-1, \epsilon) : (x_0 : x_1 : x_2 : x_3) \mapsto (x_0 : \epsilon x_1 : \epsilon^2 x_2 : -x_3) \]
where $\epsilon := e^{2\pi i \frac{2}{3}}$, and $G$ leaves $X$ invariant. The quotient $X/G$ is a singular hypersurface in the toric variety $\mathbb{P}^3/G$. Letting $Y_{min}$ denote the minimal resolution of $X/G$, $Y_{min}$ gets a Kanev surface.

By [BKS19, Example 6.1] the hypersurface $(X/G) \cap T^3$ has Newton polytope:
\[ \Delta' := \langle (1, 2, 4), (1, 0, 0), (1, 4, 2), (-2, -4, -5) \rangle \]
This polytope is isomorphic to the first maximal polytope $a)$ and $f$ descends to a nondegenerate Laurent polynomial defining $(X/G) \cap T^3$. 

34
4.5 Surfaces of Todorov type

The 3 polytopes $\Delta$ out of the 49 with $l^*(\Delta_{\text{can}}) = 3$ yield 3 families of surfaces $Y = Z_{\Delta} = Z_{\tilde{\Delta}} = Z_{F(\Delta)}$ with $p_g(Y) = 1$, $q(Y) = 0$, $K_Y^2 = 2$.

**Proposition 4.16.** In all 3 cases c), d) and e) the image $\psi_{2K_Y}(Y)$ is a quadric cone and thus $Y$ is a surface of Todorov type. The canonical divisor $K_Y$ defines a hyperelliptic curve of genus 3 respectively.

The universal covering $Y' \to Y$ is induced by the toric morphism given by the lattice refinement

$$\mathbb{Z}e_1 \oplus \frac{1}{2}\mathbb{Z}e_2 \oplus \mathbb{Z}e_3 \subset \mathbb{Z}e_1 \oplus \mathbb{Z}e_2 \oplus \mathbb{Z}e_3.$$ 

The surface $Y'$ has the invariants

$$p_g(Y') = 3, \quad q(Y') = 0, \quad K_{Y'}^2 = 4.$$ (16)

In c) $Y$ has 2 singularities of type $A_3$, in d) $Y$ has 4 singularities of type $A_1$ and in e) $Y$ has 2 singularity of type $A_2$.

**Proof.** According to the pictures c), d) and e) in Construction 2.15 if we let $2 \cdot F(\Delta)_{\text{can}} \cap M = \{y_1, y_2, y_3\}$ chosen as in the pictures, we get in all 3 cases the relation

$$y_2^2 = y_1y_3.$$ 

It is easy to see that $2D_{\text{can}}$ induces the map $\psi_{2K_Y}$. Thus in all 3 cases $\psi_{2K_Y}(Y) \subset \mathbb{P}^3$ is a quadric cone. In order to verify the statement on the universal covering, we have to check that $\pi$ defines a double covering $\pi : Y' \to Y$ with

$$\deg(K_{Y'}) = \deg(\pi^*K_Y),$$

since then the ramification divisor is 0 ([BHPV04, Ch.1.16]). With the formula (5) and the adjunction formula we compute $K_{Y'} = (D'_{\text{can}})|_{Y'}$, where $D'_{\text{can}} = \pi^{-1}(D_{\text{can}})$. Now in all 3 classes we have $l^*(\Delta'_{\text{can}}) = 5$ and thus the equality

$$\deg(K_{Y'}) = 2p_g(K_{Y'}) - 2 = 8 = 2(2p_g(K_Y) - 2) = \deg(\pi^*(K_Y)).$$

The canonical curve $K_Y$ is hyperelliptic since in all cases we have a fibering $D_{\text{can}} \to \mathbb{P}^1$ given by projecting onto the axis $\langle a, c \rangle$ and the hypersurface $Y$.
Figure 10: The polytopes $c)$, $d)$ and $e)$ and their cone $\sigma$ from left to right

c) $\Delta = \langle a = (2, 1, 5), p = (-2, -1, -3), b = (2, 0, 1), d = (2, 2, 1) \rangle$
$F(\Delta) = \langle (0, 0, 0), (1, 1/2, 2), (1, 1/4, 1), (1, 3/4, 1) \rangle$

d) $\Delta = \langle a = (2, -1, 3), b = (2, 0, 1), c = (2, -1, -1), d = (2, -2, 1), p = (-2, 1, -1) \rangle$
$F(\Delta) = \langle (0, 0, 0), (1, -1/2, 1), (1, -1/2, 0), (1, -3/4, 1/2), (1, -1/4, 1/2) \rangle$

e) $\Delta = \langle a = (2, 0, 1), b = (2, 1, -1), c = (2, 4, -3), d = (2, 1, 1), p = (-2, -2, 1) \rangle$
$F(\Delta) = \langle (0, 0, 0), (1, 3/2, -1), (1, 3/4, 0), (1, 1/2, 0), (1, 3/4, -1/2) \rangle$
intersects a general fibre in 2 points, as could be checked with a Newton polytope type argument. $K_Y$ being of genus 3 follows from $l^*(\Delta_{can}) = 3$ and theorem 4.1. Concerning the invariants in (16): First we have $q(Y') = 0$ since $Y'$ is simply connected. Then we check $l^*(\Delta') = 3$, thus $p_g(Y') = 3$. The intersection number $K^2_{Y'}$, could be calculated with the projection formula ([Laz00, Prop.1.1.28]) as $K^2_{Y'} = 2K^2_Y = 4$. The computation of the singularities follows from figure (10).

Remark 4.17. For the number of lattice points in the polytopes we have

c) : $l(\Delta) = 15$,  
d) : $l(\Delta) = 15$,  
e) : $l(\Delta) = 15$,

that is in c), d) and e) the Laurent polynomial $f$ depends on 15 monomials. In all 3 cases there are 4 points in $\Delta$ with first coordinate odd. If we set the coefficient of these monomials to zero, then we may coarsen the lattice $M$ to

$$\mathbb{Z}e_1 \oplus \mathbb{Z}e_2 \oplus \mathbb{Z}e_3 \supset 2 \cdot \mathbb{Z}e_1 \oplus \mathbb{Z}e_2 \oplus \mathbb{Z}e_3$$

such that in the coarsened lattice $\Delta$ gets reflexive. Just as in the proof of Proposition 4.13 we could argue that we get subfamilies, depending on 11 monomials, such that a general member of it becomes a Todorov surface.

5 Degeneration of the maximal families of Kanev and Todorov type surfaces

We want to show that a Kanev surface can be degenerated into two smooth weak del Pezzo surfaces of degree 2. We use this result to compute the generic Picard number for our families of Kanev surfaces.

5.1 Embedding a canonical Kanev surface

First we embed the canonical Kanev surface $Y$ into $\mathbb{P}(1, 2, 2, 3, 3)$ in order to get a useful total space for the degeneration we will construct (the toric variety changes). We observe that

$$|F(\Delta) \cap M| = 1, \quad |2F(\Delta) \cap M| = 3, \quad |3F(\Delta) \cap M| = 5$$

We have restriction homomorphisms

$$H^0(\mathbb{P}_\Delta, n(Y + K_{\mathbb{P}_\Delta})) \rightarrow H^0(Y, O_Y(nK_Y))$$
where the left hand side has dimension $|n \cdot F(\Delta) \cap M|$ and by remark (4.7)

$$h^0(Y, K_Y) = 1, \quad h^0(Y, 2K_Y) = 3, \quad h^0(Y, 3K_Y) = 5.$$  

Thus if these restriction maps are injective, they are isomorphisms. The kernel is

$$H^0(\mathbb{P}_\Delta, K_{\mathbb{P}_\Delta} + D_{\text{can}}) \quad n = 1, 2, 3$$

and this is certainly 0 for $n = 1, 2$ and for $n = 3$ we get with Serre duality

$$h^0(\mathbb{P}_\Delta, K_{\mathbb{P}_\Delta} + 2D_{\text{can}}) \cong h^3(\mathbb{P}_\Delta, -2D_{\text{can}}) = l^*(2 \cdot F(\Delta)) = 0$$

where the second equality follows from ([CLS11, Ch.9, Thm.9.2.7]). Thus we may embedd $Y$ into $\mathbb{P}(1, 2, 2, 2, 3, 3)$ by using the points of $|n \cdot F(\Delta) \cap M|$ for $n = 1, 2, 3$ as global sections. Under the identification

$$6 \cdot F(\Delta) \cong \Delta$$

these sections are described by the following points:

$$p \equiv x_0 \in F(\Delta), \quad a_2 \equiv y_2 \in 2F(\Delta), \quad c_2 \equiv y_1 \in 2F(\Delta),$$  

$$b_1 \equiv z_3 \in 3F(\Delta), \quad d_1 \equiv 3F(\Delta).$$

as pictured in figure (11). Then the toric varieties $\mathbb{P}_\Delta$ to the maximal polytopes in a) and b) could be described as follows

$$a) : \{ y_1^3 = z_3z_4 \} \subset \mathbb{P}(1, 2, 2, 3, 3), \quad b) : \{ y_1y_2^2 = z_3z_4 \} \subset \mathbb{P}(1, 2, 2, 3, 3)$$

### 5.2 Degenerations of Kanev surfaces

We may subdivide the maximal polytope $\Delta$ in the classes a) and b) at a plane of symmetry to obtain

$$\Delta_1 = \langle p, a, b, c \rangle, \quad \Delta_2 = \langle p, a, c, d \rangle$$

This subdivision corresponds to a degeneration of toric varieties: In the first polytope $\Delta_1$ every monomial containing a $z_4$ part gets killed and in $\Delta_2$ every monomial containing a $z_3$ part gets killed. Thus the degenerations are described by

$$a) : \{ ty_1^3 = z_3z_4 \} \subset B \times \mathbb{P}(1, 2, 2, 3, 3), \quad b) : \{ ty_1y_2^2 = z_3z_4 \} \subset B \times \mathbb{P}(1, 2, 2, 3, 3)$$
for some open neighborhood $B \subset \mathbb{C}$ of 0 with coordinate $t$. We get
\[ \mathbb{P}_{\Delta_1} = \{ z_3 = 0 \} \cong \mathbb{P}(1, 2, 2, 3), \quad \mathbb{P}_{\Delta_2} = \{ z_4 = 0 \} \cong \mathbb{P}(1, 2, 2, 3) \]
Note that $\Delta_1 \cap \Delta_2$ defines a reflexive polytope. We get a degeneration of hypersurfaces into two components $Y_1 \subset \mathbb{P}_{\Delta_1}$ and $Y_2 \subset \mathbb{P}_{\Delta_2}$ with Newton polytopes $\Delta_1$ and $\Delta_2$ if we ask the coefficients $a_m, m \in \Delta_1 \cap \Delta_2$ to be equal in both Laurent polynomials.
Let $X_t$ be the fibre over $t \in B$. We use that for del Pezzo surfaces $Y$ with R.D.P. the situation is opposite as for canonical models of surfaces of general type: $-K_Y$ is ample and a minimal resolution of singularities is crepant and adds, just as for surfaces of general type, some $(-2)$-curves.

**Definition 5.1.** [Dol12, Def.8.1.4]
A nonsingular surface $S$ with $-K_S$ big and nef is called a weak del Pezzo surface. The integer $K_S^2$ is called the degree of $S$.

The minimal resolution of a del Pezzo surface with R.D.P. is a weak del Pezzo surface. A weak del Pezzo surface of degree $r$ can be realized as the blow up of $\mathbb{P}^2$ in $9 - r$ points ([Dol12, Cor.8.1.17]).

**Proposition 5.2.** A sufficiently nondegenerate canonical Kanev surface $Y := X_t, t \neq 0$, in the maximal families a) or b) can be degenerated into two weak del-Pezzo surfaces $\tilde{Y}_1, \tilde{Y}_2$ of degree 2 that meet transversally in an elliptic curve.

![Figure 11: The global sections $x_0, y_1, y_2, z_3, z_4$ that become coordinates on $\mathbb{P}(1, 2, 2, 3, 3)$](image)
Figure 12: The maximal polytope $\Delta$ in $a$ on the left and the decomposition into two polytopes $\Delta_1$ and $\Delta_2$ on the right.

**Remark 5.3.** By sufficiently nondegenerate we mean that the Laurent polynomial defining the hypersurface is not only nondegenerate with respect to its Newton polytope $\Delta$ but also with respect to the two polytopes $\Delta_1$ and $\Delta_2$.

**Proof.** For a generic choice of the coefficients $a_m$ the fibre $X_0$ has two components that intersect transversally in an elliptic curve, since the polytope $\Delta_1 \cap \Delta_2$ is reflexive. We have the following relations between the torus invariant divisors on $\mathbb{P}_{\Delta_1} \cong \mathbb{P}(1, 2, 2, 3)$:

$$D_{abp} \equiv_{lin} D_{bcp} \equiv_{lin} 2D_{abc}, \quad D_{acp} \equiv_{lin} 3D_{abc}.$$  

For the hypersurface $Y_1$ and the canonical divisor $K_{\mathbb{P}_{\Delta_1}}$ this means:

$$Y_1 \sim_{lin} 6D_{abc}, \quad K_{\mathbb{P}_{\Delta_1}} \sim_{lin} -8D_{abc}$$

since we may choose $p$ as the origin and then every facet of $\Delta_1$ passes through the origin except from $\Delta_{abc}$ which has distance 6 to $p$. By the adjunction formula we get $K_{Y_1} = (\mathbb{P}_{\Delta_1} \cong \mathbb{P}(1, 2, 2, 3)$:

$$K^{2}_{Y_1} = 6D_{abc}.(-2D_{abc}).(-2D_{abc}) = 24D_{abc}^3 = 24 \cdot \frac{1}{2} \cdot 2 \cdot 3 = 2.$$  

Thus $Y_1$, and analogously $Y_2$, get (singular) del-Pezzo surfaces of degree 2.

To the class $a$): The only singular cone $\sigma$ is spanned by $n_{abc}$ and $n_{acp}$ and comes from the edge $\langle a, c \rangle$. We have

$$n_{abc} - n_{acp} = (-1, 0, 0) - (1, -2, 0) = 2 \cdot (-1, 1, 0),$$

$$a - c = (2, 1, -2) - (2, 1, 1) = 3 \cdot (0, 0, -1).$$

40
Thus the hypersurfaces $Y_0$ and $Y_1$ both intersect the closed orbit $V(\sigma)$ of singularities in 3 points which are $A_1$ singularities. Note that since the coefficients to the monomials on the edge $\langle a, c \rangle$ coincide on the two components, the three singular points on $Y_1$ and $Y_2$ coincide.

We refine the normal fan of $P(1, 2, 2, 3)$ by adding the ray $\tau := (0, -1, 0)$. Then the proper transform $\tilde{Y}_i$ of $Y_i$ meets the exceptional divisor $E$ in three $(-2)$-curves $E_{i,1}$, $E_{i,2}$, $E_{i,3}$, compare construction (3.21).

We write $\tilde{C} := \tilde{Y}_1 \cap \tilde{Y}_2$. The edge $\langle a, c \rangle$ defines the curve $\{x_0 = z_3 = z_4 = 0\}$ on $P_{\Delta_i} \cong P(1, 2, 2, 3)$. But on $P_\Delta$ we get just one or two torus fixed points $\{x_0 = y_1^3 = z_3 = z_4 = 0\}$ in $a$ and $\{x_0 = y_1 y_2^2 = z_3 = z_4 = 0\}$ in $b$. The hypersurface does not pass through these fixed points, thus the other fibres $X_t$, $t \in B \setminus \{0\}$ remain the same.

We have $K_{Y_i} = \pi^*(K_{Y_1})$, thus we still have $K_{Y_i}^2 = 2$ but $-K_{Y_i}$ is no longer ample but only big and nef. Thus $\tilde{Y}_1$ and $\tilde{Y}_2$ get so called weak del Pezzo surfaces of degree 2.

Remark 5.4. With the description in figure (11) it could be checked that the two (families of) degenerate hypersurfaces actually coincide.

It is easy to derive a degeneration of a minimal Kanev surface $Y_{\min}$ in the maximal families in $a$ or $b$): Remember that in $a$ ($b$) $Y$ has 3 singularities of type $A_2$ (type $A_1$) coming from the edge $\langle a, p \rangle$, which lies on the plane of symmetry. By further refining the normal fan of $V$, we get two (one) global exceptional divisors $E'$, $E''$ ($E'$) whose restrictions $E'_t := E'_{|X_t}$ and $E''_t := E''_{|X_t}$ consist of three $(-2)$-curves.

**Proposition 5.5.** ([Pers77, Prop.2.4.1])

Let $D$ and $D'$ be two global divisors with restrictions $D_t := D_{|X_t}$, $D'_t := D'_{|X_t}$.

Then we have

$$D_t \cdot D'_t = (D_0)_1 \cdot (D'_0)_1 + (D_0)_2 \cdot (D'_0)_2$$
where \((D_0)_i\) and \((D'_0)_i\) denote the divisors \(D_0 \subset Y_i\) and \(D'_0 \subset Y_i\).

By this formula and the adjunction formula it is easy to see that every such \((-2)\)-curve splits in the degenerate fibre into two \((-1)\)-curves, one on every component of the degenerate fibre, that meet in a common point.

5.3 Degeneration of surfaces of Todorov type

For our examples of surfaces of Todorov type the canonical model is embeddable as a weighted complete intersection into \(\mathbb{P}(1,1,1,2,2)/\iota\), with one equation defining the toric variety. Here \(\iota(x_0 : y_1 : y_2 : y_3 : y_4) := (x_0 : -x_1 : -x_2 : -y_3 : -y_4)\). Every of the 3 polytopes has a plane of symmetry at which we may subdivide the polytope to get \(\Delta_1 := \langle a, b, c, p \rangle\) and \(\Delta_2 := \langle a, c, d, p \rangle\) with \(\mathbb{P}_{\Delta_1} \cong \mathbb{P}(1,1,1,2)/\iota\) and \(\Delta_1 \cap \Delta_2\) reflexive. By the adjunction formula the canonical divisor \(K_{Y_1}\) (and analogously \(K_{Y_2}\)) is given by

\[
K_{Y_1} \sim_{\text{lin}} -D_{abc|Y_1}.
\]

We have a morphism \(\pi : \mathbb{P}(1,1,1,2) \to \mathbb{P}(1,1,1,2)/\iota\) of degree 2 and thus may compute

\[
(K_{Y_1})^2 = (-D_{abc|Y_1})^2 = 4 \cdot D_{abc}^3 = 2 \cdot \pi^*(D_{abc})^3 = 2 \cdot \frac{1}{1 \cdot 1 \cdot 1 \cdot 2} = 1.
\]

The singularities of \(Y_1\) and \(Y_2\) come from the edge \(\langle a, c \rangle\), yielding 4 singularities of type \(A_1\) respectively. We get
Theorem 5.6. A sufficiently nondegenerate canonical surface of Todorov type from the examples c), d) or e) could be degenerated into 2 weak del Pezzo surfaces of degree 1 meeting transversally in an elliptic curve.

5.4 The generic Picard rank for the maximal family in the classes a) and b)

For canonical Kanev surfaces $Y$ the Picard group is torsion free, since every torsion would come from torsion in $H^1(Y, \mathbb{Z})$, but Kanev surfaces are simply connected. It should be possible to compute the generic Picard number of Kanev surfaces in toric 3-folds by Hodge theoretic methods similar to ([BrGr10]), but another approach via degenerations seems to be more elegant to the author.

Of course we have the following bounds for the Picard number $\rho(Y)$:

$$1 \leq \rho(Y) \leq h^{1,1}(Y) = 19$$

and it is known, that the surfaces with Picard number 19 are dense in the moduli space of all Kanev surfaces ([Bean13 Prop.9]), just as for K3-surfaces. We follow arguments of ([GH85]) and ([Lop91]) who found the Picard groups of several surfaces by degenerating these surfaces.

Construction 5.7. First note that the Picard group of a component $\tilde{Y}_i$ is isomorphic to $\mathbb{Z}^8$: $\tilde{Y}_i$ can be gotten by blowing up $\mathbb{P}^2$ in $9 - K_{\tilde{Y}_i}^2 = 7$ points. Thus the Picard group of $\tilde{Y}_i$ is given by the pullback of an hyperplane class and seven $(-1)$-curves $G_{i,1}, ..., G_{i,7}$. Writing $\tilde{X}_0 := \tilde{Y}_1 \cup \tilde{Y}_2$, we have

$$\text{Pic}(\tilde{X}_0) \cong \text{Pic}(\tilde{Y}_1) \times_{\text{Pic}(\tilde{C})} \text{Pic}(\tilde{Y}_2)$$

(17)

and we may write the divisors on $\tilde{X}_0$ as pairs $(D, D')$ where $D \in \text{Pic}(\tilde{Y}_1)$ and $D' \in \text{Pic}(\tilde{Y}_2)$. Since

$$\tilde{Y}_1 + \tilde{Y}_2 = \tilde{X}_0 \sim_{\text{lin}} 0$$

we get by restriction

$$N_{\tilde{C}/\tilde{Y}_1} \otimes N_{\tilde{C}/\tilde{Y}_2} \sim_{\text{lin}} 0,$$

where $N_{\tilde{C}/\tilde{Y}_i} = (O_{\tilde{Y}_i}(6) - E_{i,1} - E_{i,2} - E_{i,3})_{\tilde{C}}$ ([Pers77 Prop.2.4.3]). The line bundles $(O_{\tilde{Y}_1}(1), O_{\tilde{Y}_2}(-1))$ and $(E_{1,j}, -E_{2,j})$ define Picard classes on $\tilde{X}_0$. We now look for Picard classes on $\tilde{X}_0$ that continue to nontrivial Picard classes on $X_t$ for $t$ generic. There are 4 possible types of Picard classes on $\tilde{X}_0$:
• \((\mathcal{O}(1), \mathcal{O}(-1))\) which certainly continues to \(X_t\).

• The (two) exceptional divisor(s) \(E'\) (and \(E''\)) in \(b\) and \(a\) yield \((-1)\)-curves on \(X_0\). On \(X_t\) they yield six \((-2)\)-curves in \(a\) and three \((-2)\)-curves in \(b\).

• The divisors \((E_{1,j}, -E_{2,j})\) coming from the \((-2)\)-curves \(E_{i,1}, E_{i,2}, E_{i,3}\).

• A linear combination of the \((-1)\)-curves \(G_{i,j}\).

The divisors \(E_{i,j}\) come from a resolution of singularities and we already observed in the proof of proposition [1.3] that these divisors do not continue to nontrivial divisors on \(X_t\). Concerning the \((-1)\)-curves \(G_{i,j}\) first note that by a result of Kodaira ([Kod63]) these intersect the curve \(\tilde{C}\). It follows easily from this that none of the 7 point in \(\mathbb{P}^2\) we blow up are infinitely near.

**Theorem 5.8.** For a general minimal Kanev surface \(Y\) in the maximal family \(a\) or \(b\) we have for \(\rho(Y) := \text{rk Pic}(Y)\)

\[
a: \rho(Y) = 7, \quad b: \rho(Y) = 4\]

**Proof.** Certainly we have \(\rho(X_t) \geq 7\) in \(a\) and \(\rho(X_t) \geq 4\) in \(b\). Now given a nontrivial effective Picard class \(F_t\) in \(X_t\) for \(t\) generic, after a base change \(t \mapsto t^4\) (which is harmless) we may find a global divisor \(F\) restricting to \(F_t\) on \(X_t\) ([Pers77, Prop.2.6.1]). Then up to adding multiples of \(\mathcal{O}(1), E', E''\) we may assume that the restriction \(F_0 := F|_{X_0}\) is given by

\[
F_0 = \left(\sum_{j=1}^{7} r_j G_{1,j}, \sum_{j=1}^{7} s_j G_{2,j}\right), \quad r_j, s_j \in \mathbb{Z}
\]

Let \(\phi_i : \tilde{Y}_i \to \mathbb{P}^2\) be the blowing-up morphism. We get

\[
\mathcal{O}_{\tilde{Y}_i}(\tilde{C}) = \phi_i^* \mathcal{O}_{\mathbb{P}^2}(3) - \sum_{j=1}^{7} G_{i,j}
\]

Thus \(\mathcal{O}_{\tilde{Y}_1}(\tilde{C}).(\sum_{j=1}^{7} r_j G_{1,j}) = \sum_{j=1}^{7} r_j \) and \(\mathcal{O}_{\tilde{Y}_2}(\tilde{C}).(\sum_{j=1}^{7} s_j G_{2,j}) = \sum_{j=1}^{7} s_j \) and

\[
\sum_{j=1}^{7} r_j = \sum_{j=1}^{7} s_j.
\]
The divisor $\mathcal{O}(-2) + E$ splits into $(K_{\tilde{Y}_1}, -K_{\tilde{Y}_2})$ and we get

$$K_{\tilde{Y}_1} \cdot \sum_{j=1}^{7} r_j G_{1,j} - K_{\tilde{Y}_2} \sum_{j=1}^{7} s_j G_{2,j} = -2 \sum_{j=1}^{7} r_j + 2 \sum_{j=1}^{7} s_j = 0$$

since we may compute the canonical divisor $K_{\tilde{Y}_i}$ from the blow up model.

On the other hand $\mathcal{O}_{\tilde{Y}_1}(-2) = (-2D_{abc})_{\tilde{Y}_1}$, $\mathcal{O}_{\tilde{Y}_2}(2) = (2D_{acd})_{\tilde{Y}_2}$ and the divisor $(K_{\tilde{Y}_1}, -K_{\tilde{Y}_2})$ comes from the global divisor

$$-2D + E,$$

where $D := \{x_0 = t^i y_1^3 - z_3 z_4 = 0\}$.

On the hypersurface $X_t \subset \{t^i y_1^3 - z_3 z_4 = 0\}$, $E$ is trivial, whereas $D$ restricts to $D_{abcd} | X_t = K_{X_t}$. From proposition (5.5) we get

$$K_{X_t}.F_t = (D_{abcd})_{\mid X_t}.F_t = -\frac{1}{2} (K_{\tilde{Y}_1}.F_0 - K_{\tilde{Y}_2}.F_0) = 0.$$

Thus $F_t$ consists of a linear combination of $(-2)$-curves and does not yield new Picard classes. The result follows since we have some variant of upper semicontinuity for the Picard number, i.e. for $t \in B \setminus \{0\}$ outside of countably many points the Picard number of $X_t$ is not larger than that of $X_0$.

We also want to consider the case of a generic Kanev surface, which does not necessarily lie as hypersurface in a toric variety, and use the following two facts (compare [Cat78]):

- A canonical Kanev surface $Y$ may be embedded as a weighted complete intersection of type $(6,6)$ into $\mathbb{P}(1,2,2,3,3)$ and the canonical divisor $K_Y$ comes from the divisor $\{x_0 = 0\}$.
- All minimal Kanev surfaces are deformation equivalent.

Thus in general we have to replace our toric equation by a weighted sextic. The arguments of construction (5.7) still remain valid, in particular the $(-1)$-curves $G_{i,j}$ do not continue to nontrivial Picard classes on $Y$, and for generic $Y$ there are no $(-2)$-curves on $Y$. We may deduce the following

**Theorem 5.9.** The generic Picard number of a Kanev surface $Y$ is $\rho(Y) = 1$.

**Proof.** The only divisor classes that continue are multiples of $\mathcal{O}(1)$.
Remark 5.10. Given a non-maximal polytope $\Delta$ in the classes $a$) or $b$), we consider the canonical model $Z_{F(\Delta)}$. Then we subdivide the maximal polytope $\Delta_{max}$ containing $\Delta$ at the plane of symmetry into two polytopes $\Delta_1, \Delta_2$ and get two components $Y_1$ and $Y_2$. We still have

$$Y_i \sim_{\text{lin}} \sum_{\nu \in \Sigma_{\Delta_i}} \text{ord}_{\Delta}(\nu)D_{\nu} = 6D_{abc}, \quad K_{Y_i} \sim_{\text{lin}} -2D_{abc\mid Y_i}.$$ 

$D_{abc} \subset \mathbb{P}_{F(\Delta)}$ is ample and thus $Y_i$ gets a singular del-Pezzo surface of degree 2. Further every polytope contains the edge of singularities $\langle a, c \rangle$ and thus for a sufficiently generic hypersurface the $(-2)$-curves do not continue to divisors on $Z_{F(\Delta)}$. Finally the torus fixed point $(1 : 0 : 0)$ to $p$ is a nonsingular point on $\mathbb{P}_{\Delta} \cong \mathbb{P}(1, 2, 2, 3)$. Thus the only increasement of the Picard number comes from the singularities of $Z_{F(\Delta)}$. We listed the generic Picard number for the subfamilies in $a$) and $b$) in the tables (1) and (2). The generic Kanev surface has Picard number 1 and the coarse moduli space $\mathcal{M}$ of Kanev surfaces exists and is 18 dimensional. For every $\alpha \in \text{Pic}(X)$ the set $\{ t \in B \mid \alpha \in H^{1,1}(X_t) \}$ is either empty, of codimension 1 or all of $B$. $X_t$ has Picard number 19 if and only if $H^{2,0}(X_t) \oplus H^{0,2}(X_t)$ is defined over $\mathbb{Q}$, thus there are only countably many Kanev surfaces with Picard number 19 and similar as for K3-surfaces in (Huy16, Ch.17, 1.3) every Picard number between 1 and 19 gets accepted by some Kanev surface.

Example 5.11. The Fermat sextic in $\mathbb{P}^3$ defines an hypersurface with maximal Picard number, and since there is a dominant rational map $X \rightarrow Y_{\text{min}}$, $Y_{\text{min}}$ has also maximal Picard number 19 ([Beau13, Prop.2, Cor.1]).

5.5 The generic Picard number for surfaces of Todorov type

Quite analogously we get the generic Picard number of surfaces of Todorov type. But here by (15) the Picard group has torsion $\mathbb{Z}/2\mathbb{Z}$.

Theorem 5.12. A minimal surface of Todorov type in the examples $c)$, $d)$ and $e)$ has generic Picard number

$$c) : \rho(Y) = 7, \quad d) : \rho(Y) = 5, \quad e) : \rho(Y) = 5. \quad \square$$

Theorem 5.13. The generic Picard number of a minimal Todorov surface $Y$ is $\rho(Y) = 1$. \quad \square
Table 1: polytopes such that $\Delta_{\text{can}}$ has 3 vertices sorted as in figure (2) from the top to the bottom and from left to right. The arrows indicate that the polytopes are not canonically closed and the ID of the canonical closure is the polytope above the arrows (e.g. ID5389063 has canonical closure ID546219)

$$F(\Delta) = \langle (0, 0, 0), (1, 1/3, 0), (1, 2/3, 0), (1, 1/2, -1/2) \rangle$$
$$p := (-4, -2, 1), a_2 := (-2, -1, 0), c_2 := (-2, -1, 1), b_1 := (-1, -1, 1),$$
$$d_1 := (-1, 0, 1), a_1 := (0, 0, -1), 0 := (0, 0, 0), c_1 := (0, 0, 1),$$
$$ab := (1, 0, 0), bc := (1, 0, 1), ad := (1, 1, 0), cd := (1, 1, 1),$$
$$b := (2, 0, 1), a := (2, 1, -2), ac_1 := (2, 1, -1), ac_2 := (2, 1, 0),$$
$$c := (2, 1, 1), d := (2, 2, 1)$$
