Abstract

The viscous flow of two immiscible fluids in a porous medium on the Darcy scale is governed by a system of nonlinear parabolic equations. If infinite mobility of one phase can be assumed (e.g. in soil layers in contact with the atmosphere) the system can be substituted by the scalar Richards model. Thus, the domain of the porous medium may be partitioned into disjoint subdomains with either the full two-phase or the simplified Richards model dynamics. Extending the one-model approach from \cite{1, 2} we suggest coupling conditions for this hybrid model approach. Based on an Euler implicit discretisation, a linear iterative (\textit{-}-type) domain decomposition scheme is proposed, and proven to be convergent. The theoretical findings are verified by a comparative numerical study that in particular confirms the efficiency of the hybrid ansatz as compared to full two-phase model computations.

Keywords: two-phase flow in porous media, hybrid modelling, domain decomposition, LDD scheme

1. Introduction

Multiphase flow through porous media occurs for a wide variety of natural and technical processes. Examples in soil-related environmental sciences comprise enhanced oil recovery, remediation of contaminated soils, CO\textsubscript{2} storage or evaporation processes in the vadose zone. In the technological realm we mention the design of filters, fuel cells or damping materials. Mathematical modelling and numerical simulation are essential tools for the understanding of multiphase flow processes. However, due to varying material properties or changing flow regimes the governing equations can become strongly heterogeneous leading to severe mathematical and in particular computational problems. To meet these challenges domain decomposition methods are an established approach (see e.g. \cite{3}). The basic idea is to split the domain in subdomains such that each of these subdomains can be equipped with its own model and numerical solver. Following an iterative scheme and by construction of analytically and numerically appropriate coupling conditions an approximate solution on the original mono-domain can then be recovered.

In contrast to existing approaches for homogeneous two-phase flow modelling, the purpose of the present contribution is the development and analysis of a non-overlapping domain decomposition method for \textit{hybrid} two-phase flow modellings. We consider for a porous domain on the Darcy scale the dynamics of two incompressible and viscous fluids, that are assumed to be immiscible. Let the fluids be denoted as the wetting (\textit{w}) and the nonwetting (\textit{nw}) phase, respectively. The domain is decomposed into subdomains with the flow either governed by the full two-phase (TP) model or by the simpler Richards (R) model. The latter applies e.g. for high mobilities of the nonwetting phase. The partition might come along with changes in the relative permeability functions, fluid viscosities and densities, as well as in porosities and intrinsic permeabilities. The major advantage of the hybrid approach is the possible gain of computing time that can be obtained when substituting the full two-phase model system by the approximative scalar Richards equation on parts of the domain.

First, in Section 2, we present coupling conditions for the hybrid TP–R model across the interfaces of subdomains. In fact, the coupling condition for the nonwetting flux in the two-phase model is not at all obvious, given that on the Richards model domain there is no equation for the nonwetting phase. This leads to an unmatched number of unknowns on the different subdomains. We therefore introduce two different coupling conditions depending on the (non)occurrence of gravitational forces. Extending our approach for homogeneous two-phase flow models in \cite{1, 2}, we proceed then in Section 2 with the time-discrete problem and introduce a domain decomposition solver based on simultaneous L-scheme linearisation, see \cite{4, 5}. The resulting scheme is called LDD-TP–R solver. We provide a consistency result that ensures in the case of convergence of the LDD-TP–R solver that the mono-domain solution is recovered (Lemma 2.10). Section 3 contains the core analytical result of the paper, that is the convergence of the LDD-TP–R solver in Theorem 3.3. The idea of the proof is based on bounding the series of iteration errors which implies that the sequence of iteration errors must vanish. A key ingredient to achieve this is to detect matching interface Robin-type terms such that telescopic sums are obtained. In fact, the latter is only possible if the pressure traces that are part of the Robin-type coupling condition on interfaces act as functionals via the \(H_{00}^{1/2}(\Gamma)\)-scalar product and not in the classical way via the dual pairing \(H^{-1/2}(\Gamma) \times H_{00}^{1/2}(\Gamma)\), cf. Remark 2.3 as well as \cite{6}. The convergence is

The work [17] is concerned with two-phase flow with discontinuous capillary pressures. None of these works address the incompressible and viscous fluids, denoted as a wetting one (porous medium which is assumed to be isotropic on each subdomain. We consider the dynamics of two immiscible, boundaries of (\(a \Omega_1 \Omega_2 \subset \mathbb{R}^d\)).

Two-phase flow models and the for a flexible, subdomain-wise combination of the Richards equation and the full two-phase flow model. L-schemes have been suggested in [5, 20], this article adheres to the standard L-scheme, focusing on an drawback of L-schemes is their slower (linear) convergence in comparison to Newton’s scheme. Albeit faster converging iteration are much better conditioned as the ones stemming from e.g. the Newton method, see [5]. Nevertheless, a advantage of its implementation is very easy, it is globally convergent and the linear problems that need to be solved within each applications, e.g. nonlinear poromechanics [18] or fully coupled flow and transport [19]. The L-scheme has the advantage of not involving the computation of derivatives in contrast to the Newton or the modified Picard method. Moreover, its implementation is very easy, it is globally convergent and the linear problems that need to be solved within each iteration are much better conditioned as the ones stemming from e.g. the Newton method, see [5]. Nevertheless, a drawback of L-schemes is their slower (linear) convergence in comparison to Newton’s scheme. Albeit faster converging L-schemes have been suggested in [5, 20], this article adheres to the standard L-scheme, focusing on an LDD scheme for a flexible, subdomain-wise combination of the Richards equation and the full two-phase flow model.

2. Two-phase flow models and the LDD-TP–R solver for the two-domain case

2.1. Coupling the full two-phase flow model with the Richards model: the TP–R model

Let a Lipschitz domain \(\Omega \subset \mathbb{R}^d, d \in \{2, 3\}\), be decomposed into two non-overlapping Lipschitz subdomains \(\Omega_1, \Omega_2 \subset \mathbb{R}^d\) such that \(\Omega = \Omega_1 \cup \Gamma \cup \Omega_2\), with \(\Gamma := (\Omega_1 \cap \Omega_2) \setminus \partial \Omega\) being the interface. The latter is assumed to be a \((d-1)\)-dimensional Lipschitz manifold. By \(n_1, n_2\) we denote the outer normals on the intersection of \(\Gamma\) and the boundaries of \(\Omega_1, \Omega_2\). We refer to Figure 1 for a sketch of the described situation. The entire domain \(\Omega\) is filled by a porous medium which is assumed to be isotropic on each subdomain. We consider the dynamics of two immiscible, incompressible and viscous fluids, denoted as a wetting one \((w)\) and a non-wetting one \((nw)\). Considering a hybrid

\[\Omega \subset \mathbb{R}^d\]

\[\partial \Omega_1\]

\[\Omega_1\]

\[\Omega_2\]

\[\Gamma\]

\[n_1, n_2\]
The fluxes in (4) determine the mass flow coupling between the domains. For subdomain \( l \in \{1, 2\} \), let \( \Omega_{l,T} := \Omega_l \times (0, T) \) and \( \Gamma_T := \Gamma \times (0, T) \). The coupled two-phase–Richards (TP–R) problem consists of finding phase pressures \( p_{w,l}, p_{w,2} \) and \( p_{nw,2} \) solving

\[
\begin{align*}
\Phi_1 \partial_t S_1(p_{w,l}, p_{w,1}) - \nabla \left( \frac{k_{w,1}}{\mu_{w}} k_{w,1}(S_1) \nabla (p_{w,1} + z_w) \right) &= f_{w,1}, \\
\Phi_2 \partial_t S_2(p_{nw,2}, p_{w,2}) - \nabla \left( \frac{k_{w,2}}{\mu_{w}} k_{w,2}(S_2) \nabla (p_{w,2} + z_w) \right) &= f_{w,2}, \\
-\Phi_2 \partial_t S_2(p_{nw,2}, p_{w,2}) - \nabla \left( \frac{k_{w,2}}{\mu_{nw}} k_{nw,2}(1 - S_2) \nabla (p_{nw,2} + z_{nw}) \right) &= f_{nw,2}
\end{align*}
\]

in \( \Omega_{1,T} \) together with

\[
\begin{align*}
p_{w,1} &= p_{w,2}, \\
F_{w,1} \cdot n_1 &= F_{w,2} \cdot n_1, \\
p_{nw,2} &= p_0, \\
F_{nw,2} \cdot n_2 &= F_{nw,1} \cdot n_2
\end{align*}
\]

on \( \Gamma_T \). The problem is closed by suitable initial as well as boundary conditions.

We supplement the notations used in Problem 2.1 including the specification of the fluxes in (4). For subdomain index \( l \in \{1, 2\} \), our primary unknowns are the wetting pressure \( p_{w,l} \) and the nonwetting pressure \( p_{nw,l} \) on \( \Omega_{l,T} \), respectively. The given constant atmospheric pressure is denoted by \( p_0 \) and on \( \Omega_{1,T} \), we have \( p_{nw,1} = p_0 \), by assumption. The functions \( S_l = S_l(p_{nw,l}, p_{w,l}) \in [0, 1] \) denote the wetting saturations and are assumed to be functions of the phase pressures via the capillary pressure saturation relationships \( p_{nw,l}(S_l) = p_{nw,l} - p_{w,l} \), see e.g. [21], i.e., it is assumed that the functions \( p_{nw,l}(S_l) \) are invertible, cf. Assumption 3.1. Since we model two-phase flow, we use the assumption that on all subdomains \( \Omega_l \) only the two phases are present, i.e., the nonwetting saturations \( S_l^{nw} \) can be expressed by the relations

\[
S_l^{nw} = 1 - S_l.
\]

This is already built into the equation (3).

The porosities \( \Phi_l \in (0, 1) \) on each subdomain \( \Omega_l \) are assumed to be constant and furthermore, we denote by \( \rho_0 > 0 \) the density and by \( \mu_{w} > 0 \) the viscosity of phase \( \alpha \in \{w, nw\} \). For simplicity, we assume that the intrinsic permeabilities \( K_l \) are isotropic on every subdomain, i.e., \( K_l = k_{l,l}E_d \). Finally, for \( \alpha \in \{w, nw\} \), \( k_{w,l} \) denotes the given relative permeability, \( f_{\alpha,l} \) a source term and \( z_{\alpha} = \rho_{\alpha}g x z \) is the gravitational force term \((g \text{ being the gravitational acceleration})\). The fluxes in (4) determine the mass flow coupling between the domains. For \( \alpha,l \in \{(w,1), (w,2), (nw,2)\} \) they are given by

\[
F_{\alpha,l} = -\frac{k_{l}}{\mu_{\alpha}} \nabla (k_{\alpha,l}(S_l) (p_{\alpha,l} + z_{\alpha})).
\]

It remains to determine the flux \( F_{nw,1} \). When coupling the Richards model with the two-phase flow equations, it is not clear which conditions should be imposed in (4), because the nonwetting phase is considered to be present, yet remains unmodelled. Since on \( \Omega_1 \) the nonwetting pressure is assumed constant, \( p_{nw,1} = p_0 \), the part of the nonwetting Neumann flux containing the gradient of the pressure (in a two-phase flow model) would have to vanish. However, this is not the case for the gravitational part. Thus, there are two possible ways to account for the gravitational force of the nonwetting phase on \( \Omega_1 \) at the interface. In view of the fact, that the Richards model is the mathematical limit of the two-phase model, cf. [25], one choice is

\[
F_{nw,1} = k_{nw,1} k_{nw,1} (1 - S_2(p_0, p_{w,1})) \nabla z_{nw}.
\]

On the other hand, one could ignore the effect entirely, i.e.

\[
F_{nw,1} = 0.
\]
Remark 2.2 (Extended coupling conditions). The coupling conditions in Problem 2.1 are the generic domain decomposition coupling conditions providing equivalence of the substructured problem to a monodomain formulation. While natural in this sense, they exhibit certain limitations from a modelling perspective. Indeed, since we prescribe the continuity of the phase pressures, the capillary pressures are continuous as well. However, in general, capillary trapping phenomena can occur for heterogeneous soils, where a phase might not enter into another soil layer due to a pressure barrier. This translates to a pressure jump over the interface. Non-matching capillary pressure curves that in addition are extended to multivalued functions for vanishing (wetting or nonwetting) saturations, need to be considered in this case, cf. [26]. This approach reflects pressure discontinuities over the interface by imposing the continuity of the capillary pressures together with the continuity of the wetting pressure in a generalised, multivalued sense. However, the analytical treatment (proof of existence of solutions) of this generalised formulation consists in approximating nonmatching capillary pressure curves by a family of matching curves with continuous phase pressures. From the numerical point of view it is therefore important to investigate the applicability of the LDD solver to the case of continuous pressures not only as a first step, but notably so as an approximation of the more realistic discontinuous case. We refer to [17] for a recent contribution in this direction.

2.2. Function spaces

Before we give the weak formulation for Problem 2.1 we introduce some notions for function spaces on Lipschitz domains and their boundaries, the latter being essential for the analysis of the transmission conditions in the domain decomposition method. In this section, $\Omega \subset \mathbb{R}^d$ denotes a generic Lipschitz domain. In particular, all notations apply to all domains $\Omega, \Omega_1, l = 1, 2$ introduced in the previous sections.

Spaces on $\Omega$. $C_0^\infty(\Omega)$ denotes the space of smooth functions with compact support in $\Omega$. $L^2(\Omega)$ is the space of square-integrable functions equipped with the scalar product $\langle \cdot, \cdot \rangle$. For $s \in \mathbb{R}$, the space $H^s(\mathbb{R}^d)$ denotes the standard Sobolev-Slobodeckij space with norm $\|u\|_{H^s(\Omega)}$. We will need $H^1_d(\Omega) = C_0^\infty(\Omega)^d$, and for vector-valued functions $v : \Omega \rightarrow \mathbb{R}^d$, the space

$$H(\operatorname{div}, \Omega) := \left\{ v \in [L^2(\Omega)]^d \mid \operatorname{div} v \in L^2(\Omega) \right\},$$

together with the norm $\|v\|^2_{H(\operatorname{div}, \Omega)} := \|v\|^2_{L^2} + \|\operatorname{div} v\|^2_{L^2}$, $\operatorname{div} v$ being understood via the integration by parts formula.

Spaces on $\Gamma$. The spaces $H^s(\Gamma)$ for $|s| \leq 1$ are defined by understanding that functions on $\partial \Omega$ in local coordinates belong to $H^s(\mathbb{R}^{d-1})$. When the Lipschitz surface $\partial \Omega$ is divided into two surfaces $\Gamma_1$ and $\Gamma_2$, $\partial \Omega = \Gamma_1 \cup \partial \Gamma_1 \cup \Gamma_2$, with $\partial \Gamma_1$ of dimension $d - 2$ in turn being Lipschitz, the spaces $H^s(\Gamma_1)$ for $|s| \leq 1$ can be introduced in the same way. For a function $u \in H^{1/2}(\Gamma_1)$ the extension $\tilde{u}$ by zero on $\partial \Omega \setminus \Gamma_1$ does not imply $u \in H^{1/2}(\partial \Omega)$, see [6, Theorem 3.4.4] and the discussion thereafter. In order to define Neumann traces in a generalised sense via the Green formula on parts of the boundary, we need to define the subspace of those functions in $H^{1/2}(\Gamma)$ for which the extension by zero belongs to $H^{1/2}(\partial \Omega)$, that is

$$H^{1/2}_{00}(\Gamma) := \left\{ u \in H^{1/2}(\Gamma) \mid \tilde{u} \in H^{1/2}(\partial \Omega) \right\}, \quad \|u\|_{H^{1/2}_{00}(\Gamma)} := \|\tilde{u}\|_{H^{1/2}(\partial \Omega)}.$$  

With the scalar product inherited from $H^{1/2}(\partial \Omega)$ the space $H^{1/2}_{00}(\Gamma)$ becomes a Hilbert space. With these definitions, the trace operator $\gamma : H^1(\Omega) \rightarrow H^{1/2}(\Gamma)$ can be defined as extension of the restriction on smooth functions, acting as a bounded, surjective linear operator on these spaces with bounded right inverse $R_\Gamma : H^{1/2}(\Gamma) \rightarrow H^1(\Omega)$, cf. [27, Theorem A.2.3 and p. 132 ff], [6, Theorem 9.2.1, p. 118] or [28, 29]. To ease the notation, we will denote the trace by $u|_{\Gamma}$ instead of $\gamma u$. Moreover, there is a unique linear continuous operator $\gamma^*_{0\partial \Omega} : H(\operatorname{div}, \Omega) \rightarrow H^{-1/2}(\Gamma)$ such that $\gamma^*_{0\partial \Omega} u = \langle u \cdot n \rangle_{\Gamma}$ for $u \in H(\operatorname{div}, \Omega) \cap [C(\overline{\Omega})]^d$. It is in this generalised sense that we will understand Neumann fluxes.

Dual spaces. Denoting the dual spaces $L(H^s, \mathbb{R})$ equipped with the standard norm by $H^s$, functionals $F \in H^s$ can be identified via the Riesz representation theorem as an element of $v_F \in H^s$ itself, i.e. $F(u) = \langle v_F, u \rangle_H$, for $u \in H^s$ and $\langle \cdot, \cdot \rangle_H$ denoting the scalar product. However, extending the form $\langle u, v \rangle_{H^s} := \langle u, v \rangle_{H(\operatorname{div}, \mathbb{R}^d)}$ to $H^{-s}(\mathbb{R}^d) \times H^s(\mathbb{R}^d)$ renders the spaces $H^{-s}(\mathbb{R}^d)$ and $H^s(\mathbb{R}^d)$ mutually dual, providing an alternative representation of functionals on $H^s$, cf. [6, p.9 ff]. A similar duality holds for $H^s$-spaces on $\Omega$ and $\Gamma \subset \partial \Omega$, see [6, Theorem 5.1.12, p. 61]. For the case $s = \frac{1}{2}$ which we need here, we have $H^{1/2}_{00}(\Gamma)' = H^{-1/2}(\Gamma)$ for $\Gamma \subset \partial \Omega$. We will use the symbol $\langle \cdot, \cdot \rangle_{\Gamma}$ for the evaluation $F(\varphi)$ of a functional $F \in H^{-1/2}(\Gamma)$ with a function $\varphi \in H^{1/2}_{00}(\Gamma)$ also referred to as dual pairing.

Remark 2.3. Note that the considerations on duality from above show that each functional $u$ in $H^{1/2}_{00}(\Gamma)'$ has two representations. Namely, there is a function $\tilde{u} \in H^{-1/2}(\Gamma)$ and another function $\overline{u} \in H^{1/2}_{00}(\Gamma)$ such that

$$\langle u, \varphi \rangle_{\Gamma} = \langle \tilde{u}, \varphi \rangle_{H^{1/2}(\Gamma)} \quad \text{and} \quad \langle u, \varphi \rangle_{\Gamma} = \langle \overline{u}, \varphi \rangle_{H^{1/2}_{00}(\Gamma)},$$

hold. The choice of representation will be important in the formulation of the domain decomposition scheme below.
2.3. The LDD-TP–R solver for the TP–R problem

In this section we introduce a time-discrete weak formulation of Problem 2.1 and formulate an LDD solver for this setting. Based on Section 2.2 we define spaces associated to the subdomain partition. For \( l \in \{1, 2\} \), we define

\[
V_l := \left\{ u \in H^1(\Omega_l) \mid u|_{\partial \Omega \cap \partial \Omega_l} \equiv 0 \right\}
\]

and \( \mathcal{V} := \{(u_1, u_2) \in V_1 \times V_2 \mid u_{1|l} \equiv u_{2|l}\} \),

where the norms in the spaces \( V_l \) are the standard \( H^1(\Omega_l) \)-norms, and on \( \mathcal{V} \) the norm \( \|\|_{\mathcal{V}}^2 = \sum_{l=1,2} \|\|_{V_l}^2 \) is used. \( V'_l \) denotes again the dual space of \( V_l \) and is equipped with the usual norm for functionals \( \|\|_{V'_l} = \sup_{\varphi \in V_l} \|F\varphi\|_{V'_l} \).

**Remark 2.4.** Henceforth, we assume that the atmospheric pressure \( p_a \) vanishes. This can be done without loss of generality: let \( \bar{p} \) be a physical pressure and \( \bar{p}_a \) the atmospheric pressure. By introducing \( p := \bar{p} - \bar{p}_a \), the desired normalisation \( p_a = 0 \) is achieved and (1), (2), (3) stay the same, since \( Dp = D\bar{p} \) for all derivatives and \( p_c^{-1}(\bar{p}_w - \bar{p}_a) = S = p_c^{-1}(\bar{p}_w - \bar{p}_a - (\bar{p}_w - \bar{p}_a)) = p_c^{-1}(p_w - p_w) \).

As a consequence the nonwetting pressure unknown in the two-phase model domain \( \Omega_2 \) at a discrete time step will be in \( H^1(\Omega_2) \) and not in the space \( V_2 \).

As the first step towards the LDD solver, we formulate a time discrete version of Problem 2.1. For \( N \in \mathbb{N} \), the introduction of the time step size \( \tau := \frac{T}{N} \) partitions the interval \([0,T]\) into the \( N+1 \) time steps \( t^n := n \tau, n = 0, \ldots, N \).

The functions \( p_{nw,1} : \Omega_1 \to \mathbb{R} \) and \( p_{nw,2}, p_{nw,2} : \Omega_2 \to \mathbb{R} \) denote the unknown time-discrete pressures at time step \( t^n \). In addition, we set \( S^n_l = S_l(p_{nw,1}^n, p_{nw}^n) \) (anticipating \( p_{nw,1}^n = p_a = 0 \)) and abbreviate

\[
E^n_{w,l} := \frac{k_{n,l}}{\mu_{nw}} k_{w,l}(S^n_l), \quad E^n_{nw,l} := \frac{k_{n,l}}{\mu_{nw}} k_{nw,l}(1 - S^n_l).
\]

Consequently the fluxes at \( t^n \) write as

\[
F^n_{w,l} := -k^n_{w,l} \nabla (p^n_{w,l} + z_w), \quad l \in \{1, 2\} \quad \text{and} \quad F^n_{nw,2} := -k^n_{nw,2} \nabla (p^n_{nw,2} + z_w).
\]

Depending on the choices in (6) and (7) the time-discrete flux \( F^n_{w,1} \) is defined in the same way.

With a backward Euler discretisation in time, the time-discrete coupled TP–R problem in weak form then reads as follows.

**Problem 2.5** (Time-discrete TP–R problem). For some \( N \in \mathbb{N} \), let \((p_{w,1}^{0}, p_{w,2}), (p_{nw,2}, p_{nw,2}) \in V \times H^1_0(\Omega_2) \) Then, the time-discrete TP–R problem consists of finding \((p_{w,1}^{n}, p_{w,2}, p_{nw,2}) \in V \times H^1_0(\Omega_2) \), such that \( F^n_{w,l} \cdot n_l \in H^{1/2}(\Gamma') \) holds for \( l = 1, 2 \), \( \alpha \in \{nw\} \) and such that the equations

\[
\langle \Phi_1 S^n_l - \Phi_1 S^{n-1}_l, \varphi_{w,l} \rangle - \tau \langle F^n_{w,l}, \nabla \varphi_{w,l} \rangle + \tau \langle F^n_{w,2} \cdot n_l, \varphi_{w,l} \rangle_{\Gamma} = \tau \langle f^n_{w,1}, \varphi_{w,1} \rangle,
\]

\[
\langle \Phi_2 S^n_{w,1} - \Phi_2 S^{n-1}_w, \varphi_{w,2} \rangle - \tau \langle F^n_{w,2}, \nabla \varphi_{w,2} \rangle + \tau \langle F^n_{w,1} \cdot n_2, \varphi_{w,2} \rangle_{\Gamma} = \tau \langle f^n_{w,2}, \varphi_{w,2} \rangle,
\]

\[
-\langle \Phi_2 S^n_{w,2} - \Phi_2 S^{n-1}_w, \varphi_{w,2} \rangle - \tau \langle F^n_{nw,2}, \nabla \varphi_{w,2} \rangle + \tau \langle F^n_{nw,1} \cdot n_2, \varphi_{w,2} \rangle_{\Gamma} = \tau \langle f^n_{nw,2}, \varphi_{w,2} \rangle
\]

are satisfied for all \( \langle \varphi_{w,1}, \varphi_{w,2} \rangle \in V_1 \times V_2 \) and \( \varphi_{w,2} \in V_2 \).

**Remark 2.6.**

i) In what follows, we will assume, that there is a unique solution \((p_{w,1}^{n}, p_{w,2}, p_{nw,2}) \in V \times H^1_0(\Omega_2) \) for the nonlinear time-discrete Problem 2.5. We are not aware of any results concerning well-posedness but we expect that standard methods for nonlinear parabolic equations can be applied.

ii) Note that traces of functions are implicitly taken in (10)-(12). They are needed for the dual pairings of functionals on \( \Gamma \) or likewise the scalar product of spaces on \( \Gamma \), i.e. \( \langle u, \varphi \rangle_{\Gamma} = \langle u|_{\Gamma}, \varphi|_{\Gamma} \rangle_{\Gamma} \) if \( u, \varphi \in V_1 \).

For each solution \((p_{w,1}^{n}, p_{w,2}, p_{nw,2}) \) of Problem 2.5 the coupling conditions (4) are implicitly fulfilled in a weaker form at each time step \( t^n \). Namely, we have \( p_{w,1}^{n}|_{\Gamma} = p_{w,2}|_{\Gamma} = p_{nw,2}|_{\Gamma} = 0 \) in the sense of traces by the definition of the spaces \( V_l \) and \( H^1_0(\Omega_2) \). The continuity of the fluxes, \( F^n_{\alpha}, n_l \in F^n_{\alpha,3-l} \cdot n_l, \alpha \in \{w, nw\} \), is given as equality of functionals in \( H^{1/2}(\Gamma') \). This is true regardless of the different choices for \( F^n_{nw,2} \).

Next, based on the time-discrete TP–R problem in weak formulation, we define the iterative domain decomposition ansatz with iteration number \( i \in \mathbb{N}_0 \). Extending the notation once more, the functions \( p_{nw,1}^i : \Omega_1 \to \mathbb{R} \) and \( p_{nw,2}^i, p_{nw,2}^i : \Omega_2 \to \mathbb{R} \) denote the unknown ith pressure iterate at time step \( t^n \). We set again \( S^n_1 = S_1(p_{nw,2}^i, p_{nw,2}^i) \) using \( p_{nw,1}^i = p_a = 0 \). With the notations

\[
k^{n,i}_{w,l} := \frac{k_{n,l}}{\mu_{nw}} k_{w,l}(S^n_{l,i}), \quad k^{n,i}_{nw,l} := \frac{k_{n,l}}{\mu_{nw}} k_{nw,l}(1 - S^n_{l,i}),
\]

(13)
the flux iterates at \( t^n \) are given by
\[
F_{\omega,1}^{n,i} := -k_{\omega,1}^{n,i} \nabla (p_{\omega,1}^{n,i} + z_\omega), \quad t \in \{1, 2\}
\]
and
\[
F_{\omega,2}^{n,i} := -k_{\omega,2}^{n,i} \nabla (p_{\omega,2}^{n,i} + z_\omega).
\]
The flux iterate \( F_{\omega,1}^{n,i} \) is defined case by case in the same way.

LDD schemes are designed to deal at the same time with two difficulties of Problem 2.5. Firstly, each equation in Problem 2.5 is doubly nonlinear, nonlinearities being present in the discretised time derivative, as well as in the fluxes. Secondly, the system of equations (10) to (12) is nonlinearly coupled and the coupling conditions contain nonlinearities themselves. The LDD method tackles both of these problems by linearising and decoupling the equations in one single fixed point iteration.

We assume that \( ((p_{\omega,1}^{n-1}, p_{\omega,2}^{n-1}), p_{\text{nc2}}^{n-1}) \in \mathcal{V} \times \mathcal{H}_1^2(\Omega_2) \) is fulfilled for all \( n \), \( l = 1, 2, \) and \( p_{\text{nc2}}^{n,0} := p_{\text{nc2}}^{n-1} \) on \( \Omega_2 \).

Let the numbers \( \lambda_\alpha \in (0, \infty), \alpha \in \{n, nw\} \) be given. They are bound to control the ratio between Dirichlet and flux-type transmission conditions. Following Lions, [3, 30], we introduce the Robin-type interface terms
\[
g_{\alpha,1}^0 := F_{\alpha,1}^{n-1} \cdot n - \lambda_\alpha p_{\alpha,1}^{n-1} \cdot n,
\]
as functionals in \( H_{\infty}^0(\Gamma)^\prime \) for both phases and both subdomains. Since on \( \Omega_1 \) the nonwetting pressure is constant, \( p_{\text{nc1}} = p_\alpha = 0 \), we define either
\[
g_{\text{nc1}}^0 := F_{\text{nc1}}^{n-1} \cdot n_1 = k_{\text{nc1}}^{n-1} \nabla z_{\text{nc1}} \cdot n_1
\]
as gravity effects are included, corresponding to the right hand side of (6), or
\[
g_{\text{nc1}}^0 := F_{\text{nc1}}^{n-1} \cdot n_1 = 0
\]
if gravity effects are excluded, as is expressed through the right hand side of (7).

**Note 2.7 (Pressure functionals).** For \( p \in \mathcal{V}_t \), we define the pressure functionals \( \langle p, \cdot \rangle_\Gamma \in H_{\infty}^0(\Gamma)^\prime \) on the interface such as the ones appearing in (15) according to
\[
\langle p, \cdot \rangle_\Gamma := \langle p, \cdot \rangle_{1/2}.
\]
In this way, the pressure traces \( p|_\Gamma \) are representing the functionals \( \langle p, \cdot \rangle_\Gamma \in H_{\infty}^0(\Gamma)^\prime \) w.r.t the \( H_{\infty}^0(\Gamma) \)-scalar product, i.e., \( p|_\Gamma = p \), cf. Remark 2.3. This will be important in the proof of Theorem 3.3.

Now, the LDD-TPR scheme approximates the solution to the time-discrete Problem 2.5 at time \( t_n \) by solving subsequently the following problem (LDD-TPR solver), together with the initial iterates given in (14) and (15).

**Problem 2.8 (LDD-TP-R solver).** Let \( L_{\omega,2}, L_{\text{nc2}}, L_{\omega,1} > 0 \) and some previously known iterates \( p_{\alpha,l}^{n,i-1} \in \mathcal{V}_l, \alpha = n, nw \), \( n, l \in \mathbb{N}, n \geq 1 \).

Find \( (p_{\omega,1}^{n,i}, p_{\omega,2}^{n,i}, p_{\text{nc2}}^{n,i}) \in \mathcal{V}_1 \times \mathcal{V}_2 \times \mathcal{V}_2, \) such that
\[
L_{\omega,1} \langle p_{\omega,1}^{n,i}, \varphi_{\omega,1} \rangle - \tau \langle F_{\omega,1}^{n,i}, \nabla \varphi_{\omega,1} \rangle + \tau \langle \lambda_\omega p_{\omega,1}^{n,i} + g_{\omega,1}^{n,i}, \varphi_{\omega,1} \rangle_\Gamma = L_{\omega,1} \langle p_{\omega,1}^{n,i-1}, \varphi_{\omega,1} \rangle - \tau \langle \Phi_1 S_{\omega,1}^{n,i-1} + \Phi_1 S_{\omega,1}^{n,i-1}, \varphi_{\omega,1} \rangle + \tau \langle f_{\omega,1}^{n,i}, \varphi_{\omega,1} \rangle
\]
is fulfilled for \( l \in \{1, 2\} \) with
\[
\langle g_{\omega,1}, \varphi_{\omega,1} \rangle_\Gamma := \langle -2 \lambda_\omega p_{\omega,2}^{n,i-1} - g_{\omega,2}^{n,i-1}, \varphi_{\omega,1} \rangle
\]
as well as
\[
L_{\text{nc2}} \langle p_{\text{nc2}}^{n,i}, \varphi_{\text{nc2}} \rangle - \tau \langle F_{\text{nc2}}^{n,i}, \nabla \varphi_{\text{nc2}} \rangle + \tau \langle \lambda_{\text{nc2}} p_{\text{nc2}}^{n,i} + g_{\text{nc2}}^{n,i}, \varphi_{\text{nc2}} \rangle_\Gamma = L_{\text{nc2}} \langle p_{\text{nc2}}^{n,i-1}, \varphi_{\text{nc2}} \rangle + \langle \Phi_2 S_{\text{nc2}}^{n,i-1} - \Phi_2 S_{\text{nc2}}^{n,i}, \varphi_{\text{nc2}} \rangle + \tau \langle f_{\text{nc2}}^{n,i}, \varphi_{\text{nc2}} \rangle
\]
with
\[
\langle g_{\text{nc1}}^{n,i}, \varphi_{\text{nc1}} \rangle_\Gamma := \langle -2 \lambda_{\text{nc2}} p_{\text{nc2}}^{n,i} - g_{\text{nc2}}^{n,i}, \varphi_{\text{nc1}} \rangle
\]
\[
\langle g_{\text{nc2}}^{n,i}, \varphi_{\text{nc2}} \rangle_\Gamma := \langle -g_{\text{nc2}}^{n,i-1}, \varphi_{\text{nc2}} \rangle_\Gamma
\]
for all \( \varphi_{\omega,1} \in \mathcal{V}_1, \varphi_{\omega,2} \in \mathcal{V}_2 \) and \( \varphi_{\text{nc2}} \in \mathcal{V}_2 \).
Notice that in a two-domain situation the index of the adjacent domain can be denoted by $3 - l$, for any given $l \in \{1, 2\}$, since $3 - l = 2$ for $l = 1$ and $3 - l = 1$ for $l = 2$. This type of notation has been used in Problem 2.8 and will be used henceforth.

**Remark 2.9.** It may look peculiar to introduce an update for the term $g_{i}^{n}$ in (22) and (23) as we do not have any equation for the nonwetting phase on $\Omega_{1}$. However, it is precisely this way of updating the $g_{i}^{n}$ terms, that librates the nonwetting pressure iterates $p_{i}^{n}$ of the requirement to being elements of $H_{0}^{1}(\Omega_{2})$, i.e. to fulfill continuity to the atmospheric pressure in each iteration. Instead, it allows to merely require that $p_{i}^{n}$ is an element of $V_{2}$. This is less restrictive. In the present formulation, the LDD solver enforces $p_{i}^{n} = 0$ in the limit $i \to \infty$ all by itself. Moreover, it enables us to formulate a scheme that treats both model assumptions (6) and (7) in a unified manner.

The assertions of Remark 2.9 will be verified once Problem 2.5 is reformulated such that the reformulation can be recognised as the formal limit system of the solver and the convergence of the LDD-TP-R solver to this reformulation is proven. The reformulation of Problem 2.5 is given in the next section.

### 2.4. Consistency of the LDD-TPR solver with the time-discrete TP-R Problem 2.5

Recall that for a solution $\left((p_{i}^{n}, p_{i}^{n}), p_{i}^{n}\right) \in V \times H_{0}^{1}(\Omega_{2})$ of Problem 2.5 the nonwetting Neumann flux $F_{i}^{n1}$ is defined by the right hand side of either (6) or (7), cf. also (17) and (16). Thus, the functionals

\begin{align*}
g_{w,i} := -\lambda_{w}p_{w,i}^{n} - F_{w,i}^{n} \cdot n_{l} & \quad (l = 1, 2), \tag{24} \\
g_{w,1} := -\lambda_{w}p_{w,1}^{n} + F_{w,1}^{n} \cdot n_{1} & \quad \text{and} \quad g_{w,2} := -\lambda_{w}p_{w,2}^{n} + F_{w,2}^{n} \cdot n_{2}, \tag{25}
\end{align*}

in $H_{0}^{1}(\Gamma')$ fulfill the relations

\begin{align*}
g_{w,1} &= -2\lambda_{w}p_{w,3}^{n} \cdot n_{3} - \lambda_{w}p_{w,1}^{n} \cdot n_{1} - F_{w,3}^{n} \cdot n_{3} - F_{w,1}^{n} \cdot n_{1} - g_{w,3} \quad (l = 1, 2), \\
g_{w,1} &= -2\lambda_{w}p_{w,2}^{n} \cdot n_{2} - g_{w,2} \quad \text{and} \quad g_{w,2} = -g_{w,1}.
\end{align*}

Note that $p_{w,1}^{n} \cdot n_{l} = p_{w,2}^{n} \cdot n_{l} = 0$ and $F_{w,1} = -F_{w,2} \cdot n_{2}$ for $\alpha \in \{w, nw\}$. Problem 2.5 can therefore be written as

\begin{equation}
\langle \Phi_{1}S_{1}^{n} - \Phi_{1}S_{1}^{n-1}, \varphi_{w,1} \rangle - \tau \langle F_{w,1}^{n}, \nabla \varphi_{w,1} \rangle + \tau \langle \lambda_{w}p_{w,1}^{n} + g_{w,1}, \varphi_{w,1} \rangle = \tau \langle f_{w,1}^{n}, \varphi_{w,1} \rangle \tag{19'}
\end{equation}

with

\begin{equation}
\langle g_{w,1}, \varphi_{w,1} \rangle = \langle -2\lambda_{w}p_{w,1}^{n} - g_{w,1}, \varphi_{w,1} \rangle_{\Gamma}, \tag{20'}
\end{equation}

for $l \in \{1, 2\}$ as well as

\begin{equation}
-\langle \Phi_{2}S_{2}^{n} - \Phi_{2}S_{2}^{n-1}, \varphi_{nw,2} \rangle - \tau \langle F_{nw,2}^{n}, \nabla \varphi_{nw,2} \rangle + \tau \langle \lambda_{nw}p_{nw,2}^{n} + g_{nw,2}, \varphi_{nw,2} \rangle_{\Gamma} = \tau \langle f_{nw,2}^{n}, \varphi_{nw,2} \rangle \tag{21'}
\end{equation}

together with

\begin{equation}
\langle g_{nw,1}, \varphi_{nw,2} \rangle_{\Gamma} = \langle -2\lambda_{nw}p_{nw,2}^{n} - g_{nw,2}, \varphi_{nw,2} \rangle_{\Gamma}, \tag{22'}
\end{equation}

\begin{equation}
\langle g_{nw,1}, \varphi_{nw,2} \rangle_{\Gamma} = \langle -g_{nw,1}, \varphi_{nw,2} \rangle_{\Gamma}. \tag{23'}
\end{equation}

We know $p_{nw,2}^{n} \in H_{0}^{1}(\Omega_{2})$ and thus the pressure functionals in (21')–(22') actually disappear. They are written out here to emphasise the structure.

Conversely, any tuple of functions $\left(p_{i}^{n1}, p_{i}^{n2}, p_{i}^{n}\right) \in V_{1} \times V_{2} \times V_{2}$ fulfilling (19')–(23') together with

\begin{equation}
g_{w,1} = F_{w,1}^{n} \cdot n_{1}, \tag{26}
\end{equation}

where $F_{w,1}^{n} \cdot n_{1}$ is defined by the right hand side of either (6) or (7), is a solution of Problem 2.5.

The argument supporting this claim for the wetting phase has been given in the proof of [1, Lemma 2] or [31, Lemma 2.3.12] and it carries over to the situation here.

Regarding the nonwetting phase on $\Omega_{2}$, notice that $p_{nw,2}^{n} \in V_{2}$ follows for all $\varphi_{nw,2} \in V_{2}$ by plugging (23') into (22'). By our definition of the pressure functionals, cf. Note 2.7, as well as by virtue of the surjectivity of the trace operator, this means $(p_{nw,2}^{n} \varphi_{nw,2} \eta \eta_{1/2} = p_{nw,2}^{n} \eta \varphi_{nw,2})_{\Gamma} = 0$ for all $\eta \in H_{0}^{1}(\Gamma')$ and thus $p_{nw,2}^{n} \varphi_{nw,2} = 0$.

Using this and integrating (21') by parts yields $g_{nw,2} = F_{nw,2}^{n} \cdot n_{2}$. Since $g_{nw,2} = -g_{nw,1} = F_{nw,1}^{n} \cdot n_{2}$ by (23') and (26), the continuity of the fluxes follows.

Consequently, we have proven the following
Lemma 2.10 (Limit of the LDD-TP–R solver). Let \( n \in \mathbb{N}, n \geq 1 \), be fixed, the tuple \((p^{n-1}_{w,1}, p^{n-1}_{w,2}, p^{n-1}_{nw,2})\) be given and assume that functions \( (p^n_{w,1}, p^n_{w,2}, p^n_{nw,2}) \in V_1 \times V_2 \times V_2 \) and \( g_{n,l} \in H^{1/2}(\Gamma') \) for \( \alpha \in \{n, nw\} \) and \( l \in \{1, 2\} \), such that \( g_{n,1} \) is given by (26), and such that these functions fulfill the system of equations (19')–(23') for all \( \varphi_{w,1} \in V_1 \) and \( \varphi_{w,2}, \varphi_{nw,2} \in V_2 \).

Then, the interface conditions

\[
p^n_{w,1}|_{\Gamma} = p^n_{w,2}|_{\Gamma} \quad \text{and} \quad p^n_{nw,2}|_{\Gamma} = 0, \tag{27}
\]

\[
F^n_{\alpha,l} : n_l = F^n_{\alpha,3-l} : n_l, \quad \alpha \in \{w, nw\} \quad (l \in \{1, 2\}) \tag{28}
\]

are satisfied in \( H^{1/2}(\Gamma') \) and \((p^n_{w,1}, p^n_{w,2}, p^n_{nw,2})\) solves Problem 2.5. Moreover,

\[
g_{w,l} = -\lambda_w p^n_{w,l}|_{\Gamma} + F^n_{w,l} : n_l \quad (l = 1, 2) \tag{29}
\]

and

\[
g_{nw,2} = -\lambda_{nw} p^n_{nw,2}|_{\Gamma} + F^n_{nw,2} : n_2 \tag{30}
\]

in \( H^{1/2}(\Gamma') \).

Conversely, if \((p^n_{w,1}, p^n_{w,2}, p^n_{nw,2}) \in V \times H^1(\Omega_2)\) is a solution of Problem 2.5 and \( g_{n,1} \) is defined according to (29), \( g_{nw,2} \) according to (30) and \( g_{nw,1} \) given by (26), then \((p^n_{w,1}, p^n_{w,2}, p^n_{nw,2})\) and \( g_{n,l} \) solve the system (19')–(23').

Remark 2.11. Theorem 3.3 below shows that the family \( \{p^n_{w,1}, p^n_{w,2}, p^n_{nw,2}\}_{n \in \mathbb{N}} \) of subsequent solutions to Problem 2.8, together with the iterates \( \{g^n_{n,1}\}_{n \in \mathbb{N}} \) converge to a solution of (19')–(23'). By the just proven lemma, this means solving Problem 2.5. Thus, it is justified to refer to equations (19')–(23') as the limit system to Problem 2.8.

3. Convergence of the LDD-TP–R solver

In this core section we analyse the convergence of the LDD-TP–R solver. Before doing so we state the general assumptions needed (see also the setting in [4, 32]).

Assumption 3.1. Let \( l \in \{1, 2\} \).

a) The intrinsic permeabilities \( k_{w,l} \) belong to \( L^\infty(\Omega, \mathbb{R}_+) \cap C^{0,1}(\Omega, \mathbb{R}_+) \).

b) The relative permeabilities of the wetting phases \( k_{w,l} : [0, 1] \rightarrow [0, 1] \) are strictly monotonically increasing and Lipschitz continuous functions with Lipschitz constants \( L_{k_{w,l}} \). The relative permeabilities of the nonwetting phases \( k_{nw,l} : [0, 1] \rightarrow [0, 1] \) on both domains are strictly monotonically decreasing (as functions of the wetting saturation) and Lipschitz continuous functions with Lipschitz constants \( L_{k_{nw,l}} \).

c) There are numbers \( m_1, m_2 > 0 \) such that we have \( k_{w,l} \geq m_1 \) and

\[
m_2 = \min \left\{ \min_{s \in [0, 1]} \frac{k_{w,2}}{\mu_w} k_{w,2}(s), \min_{s \in [0, 1]} \frac{k_{nw,2}}{\mu_{nw}} k_{nw,2}(s) \right\}, \tag{31}
\]

d) The capillary pressure saturation relationships \( p^c_l(S_l) := p_{nw,l} - p_{w,l} \) are monotonically decreasing functions and therefore the saturations, \( S_l(p^c_l) = S_l(p_{nw,l} - p_{w,l}) \) are also monotonically decreasing as functions of \( p^c_l \). Moreover, they are assumed to be Lipschitz continuous with Lipschitz constants \( L_{S_l} \).

Assumption c) is required to ensure the existence of a solution in each LDD-TP–R solver step, and for the convergence proof of the LDD-TP–R solver as well. It excludes degeneracy and implicitly makes sure that both phases are present on both sides of the interface avoiding trapping effects.

Before stating our main result, we note the following lemma. In view of Assumption 3.1 it is a direct consequence of the Lax–Milgram theorem and guarantees that solving Problem 2.8 is always possible.

Lemma 3.2. Let Assumptions 3.1 hold true. Given \( f^n_{n,l} \in V_l \), Problem 2.8 has a unique solution \( (p^n_{w,1}, p^n_{w,2}, p^n_{nw,2}) \in V_1 \times V_2 \times V_2 \).

Considering a family of subsequent solutions to Problem 2.8, we can now prove the following convergence result for the LDD-TP–R solver.

Theorem 3.3 (Convergence of the LDD-TP–R solver). Let Assumption 3.1 hold true and suppose that there exists a pair \((p^n_{w,1}, p^n_{w,2}, p^n_{nw,2}) \in V \times H^1(\Omega_2)\) that uniquely solves Problem 2.5 satisfying for some \( M > 0 \) the bound

\[
\sup_{l \in \{1, 2\}, \alpha \in \{w, nw\}} \| \nabla (p_{\alpha,l} + z_{\alpha}) \| \leq M. \tag{32}
\]

For \( l \in \{1, 2\}, \alpha \in \{w, nw\} \) let \( \lambda_{\alpha} > 0 \) and \( L_{\alpha,l} > 0 \) be such that we have

\[
\frac{1}{L_{S_1} \Phi_2} - \sum_{\alpha} \frac{1}{2L_{\alpha,2}} > 0 \quad \text{and} \quad \frac{1}{L_{S_1} \Phi_1} - \frac{1}{2L_{w,1}} > 0.
\]
For arbitrary initial pressures \( p_{w,l}^{n,0} := \nu_{w,l} \in \mathcal{V}_l, l = 1, 2 \), and \( p_{nw,2}^{n,0} := \nu_{nw,2} \in H^1_0(\Omega_2) \), let \( \{(p_{w,l}^{n,i}, p_{nw,2}^{n,i})\}_{i=0}^\infty \in (\mathcal{V}_1 \times \mathcal{V}_2 \times \mathcal{V}_2)^\infty \) be a sequence of solutions to Problem 2.8, \( \{g_{\alpha,l}^{i}\}_{i=\infty} \) be defined by (20) and (22)–(23) and \( g_{\alpha,l} \) by (24)–(25) for \( \alpha \in \{w, nw\} \) and \( l \in \{1, 2\} \). Assume, that the time step size \( \tau \) has been chosen to satisfy the conditions

\[
C_2 := \frac{1}{L_{S_2} \Phi_2} - \frac{1}{2L_{w,1}} - \tau \sum_{\alpha} \frac{L_{k_{\alpha,2}}^2 M_{\Phi_2}^2}{2 m_1 \Phi_2^2} > 0, \quad C_1 := \frac{1}{L_{S_1} \Phi_1} - \frac{1}{2L_{w,1}} - \tau \frac{L_{k_{w,1}}^2 M_{\Phi_1}^2}{2 m_1 \Phi_1^2} > 0.
\]

(33)

Then,

\[
p_{w,l}^{n,i} \to p_{w,l} \quad \text{in } \mathcal{V}_l \quad \text{and} \quad g_{\alpha,l} \to g_{\alpha,l} \quad \text{in } \mathcal{V}_l
\]

\[
p_{nw,2}^{n,i} \to p_{nw,2} \quad \text{in } \mathcal{V}_2 \quad \text{and} \quad g_{\alpha,l} \to g_{\alpha,l} \quad \text{in } \mathcal{V}_l
\]

for \( l = 1, 2 \) as \( i \to \infty \). Notably, \( p_{nw,2}^{n,i} \to 0 \) in \( H^{1/2}_0(\Gamma) \) as \( i \to \infty \).

**Remark 3.4 (Explicit time step restriction).** The implicit restrictions (33) on the time step size translate to the explicit form

\[
\tau < \min \left( \left\{ \frac{1}{L_{S_1} \Phi_1} - \frac{1}{2L_{w,1}}, \frac{1}{2m_1 \Phi_1^2} \sum_{\alpha} \frac{L_{k_{\alpha,2}}^2 M_{\Phi_2}^2}{2 m_1 \Phi_2^2} \right\} \right).
\]

(34)

**Proof (of Theorem 3.3):** Note that for the proof, we will actually denote by \( L_{k_{\alpha,l}} \) the Lipschitz constant of the function \( \frac{\|\cdot\|_{\mathcal{V}_l}}{\|\cdot\|_{\mathcal{V}_l}} \) by slight abuse of notation. Define the iteration errors \( e_{p,l}^{n,i} := p_{w,l}^{n,i} - p_{w,l} \) and \( e_{p,l}^{n,i} := p_{nw,2}^{n,i} - p_{nw,2} \) as well as \( e_{g,l}^{n,i} := g_{\alpha,l} - g_{\alpha,l} \) for \( l = 1, 2 \) and \( \alpha \in \{w, nw\} \). Add \( L_{w,1}(p_{w,l}^{n,i} - \varphi_{w,l}) = L_{w,1}(p_{w,l}^{n,i} - \varphi_{w,l}) \) to (19) and respectively \( L_{nw,2}(p_{nw,2}^{n,i} - \varphi_{nw,2}) = L_{nw,2}(p_{nw,2}^{n,i} - \varphi_{nw,2}) \) to (21) and subtract the corresponding equations (19) as well as (21) to get

\[
L_{\alpha,l}(e_{p,l}^{n,i} - e_{p,l}^{n,i-1}, \varphi_{\alpha,l}) \Gamma + \tau \langle \lambda_{\alpha,l} e_{p,l}^{n,i} + e_{g,l}^{n,i}, \varphi_{\alpha,l} \rangle \Gamma
\]

\[
\left( -e_{p,l}^{n,i} - k_{\alpha,l}^{n,i-1} \nabla (p_{p,l}^{n,i} + z_{\alpha}) + k_{\alpha,l}^{n,i} \nabla (p_{p,l}^{n,i} + z_{\alpha}) + e_{p,l}^{n,i} \nabla \varphi_{\alpha,l} \right)
\]

\[
= (-1)^{\beta_{\omega} \omega} \left( \Phi_{S_1}^{n,i} - \Phi_{S_1}^{n,i-1}, \varphi_{\alpha,l} \right) \left( -1 \right)^{\delta_{\omega} \omega} \left( \Phi_{S_1}^{n,i-1} - \Phi_{S_1}^{n,i-1}, \varphi_{\alpha,l} \right)
\]

(35)

where (35) is meaningful for the index combinations \( (\alpha,l) \in \{(w,1),(w,2),(nw,2)\} \). Note the use of the Kronecker delta \( \delta_{\omega} \) to account for the minus sign of the time discretisation for the nonwetting phase.

Inserting for all admissible index combinations \( \varphi_{\alpha,l} := e_{p,l}^{n,i} \) in (35) all the while making use of the identity

\[
L_{\alpha,l}(e_{p,l}^{n,i} - e_{p,l}^{n,i-1}, e_{p,l}^{n,i}) = \frac{L_{\alpha,l}}{2} \left( \|e_{p,l}^{n,i}\|^2 - \|e_{p,l}^{n,i-1}\|^2 + \|e_{p,l}^{n,i} - e_{p,l}^{n,i-1}\|^2 \right),
\]

leads to

\[
\frac{L_{\alpha,l}}{2} \left( \|e_{p,l}^{n,i}\|^2 - \|e_{p,l}^{n,i-1}\|^2 + \|e_{p,l}^{n,i} - e_{p,l}^{n,i-1}\|^2 \right) + \tau \lambda_{\alpha} (e_{p,l}^{n,i} + e_{g,l}^{n,i}, e_{p,l}^{n,i}) \Gamma = \left( \Phi_{S_1}^{n,i} - \Phi_{S_1}^{n,i-1}, (-1)^{\delta_{\omega} \omega} e_{g,l}^{n,i} \right)
\]

\[
- \tau (e_{g,l}^{n,i} e_{p,l}^{n,i}) \Gamma - \tau \left( k_{\alpha,l}^{n,i-1} \nabla (p_{p,l}^{n,i} + z_{\alpha}), e_{p,l}^{n,i} \right) - \tau \left( k_{l}^{n,i-1} \nabla e_{p,l}^{n,i}, e_{p,l}^{n,i} \right).
\]

(36)

Summing over phases \( \alpha = w, nw \) in (36) for \( l = 2 \) and adding the term \( \langle \Phi_{S_2}^{n,i} - \Phi_{S_2}^{n,i-1}, e_{w,2}^{n,i-1} - e_{w,2}^{n,i-1} \rangle \) on both sides of the equation, yields

\[
\sum_{\alpha} \frac{L_{\alpha,l}}{2} \left( \|e_{p,2}^{n,i}\|^2 - \|e_{p,2}^{n,i-1}\|^2 + \|e_{p,2}^{n,i} - e_{p,2}^{n,i-1}\|^2 \right) + \left( \Phi_{S_2}^{n,i} - \Phi_{S_2}^{n,i-1} - e_{w,2}^{n,i-1} - e_{w,2}^{n,i-1} \right)
\]

\[
- \tau \left( k_{\alpha,2}^{n,i} \nabla e_{p,2}^{n,i}, e_{p,2}^{n,i} \right) - \tau \left( k_{l}^{n,i-1} \nabla e_{p,2}^{n,i}, e_{p,2}^{n,i} \right).
\]

(37)
Similarly, adding $\langle \Phi_1 S^0 - \Phi_1 S^{n,i-1} , e_{p,l} \rangle$ to both sides of (36) for $l = 1$, one gets

$$\frac{L_{w,1}}{2} \left( \| e_{p,l} \|^2 + \| e_{w,i} \|^2 \right) + n \left( \Phi_1 S^0 - \Phi_1 S^{n,i-1} , e_{p,l} \right) = \frac{L_{w,1}}{2} \left( \| e_{p,l} \|^2 + \| e_{w,i} \|^2 \right) + \left( \Phi_1 S^0 - \Phi_1 S^{n,i-1} , e_{p,l} \right)$$

$$\sum_{R_4} \tau \left( k_{\alpha,l} - k_{\alpha,l} \right) \nabla (p_0^0 + z) , \nabla e_{p,l} \right) = \tau \left( k_{\alpha,l} - k_{\alpha,l} \right) \nabla \left( p_0^0 + z \right) , \nabla e_{p,l} \right)$$

We proceed to estimate the assigned terms $TP_1 - TP_4$ and $R_1 - R_4$ from (37) and (38).

$TP_1$, $R_1$. Recall that $S_l(p_{w,l}, p_{w,l}) = (p_{w,l})^{-1} (p_{w,l} - p_{w,l})$ for both $l$ and that $p_{w,l} < 0$ so that we actually have the dependence $S_l(p_{w,l}, p_{w,l}) = S_l(p_{w,l}, p_{w,l})$ where $S_l$ as a function of $p_{w,l}$ is monotonically decreasing. Even though $p_{w,l} = 0$ and there is no equation for $p_{w,l}$, we estimate both $TP_1$ and $R_1$ with the same reasoning by setting $p_{w,l} = 0$ and $p_{w,l} = 0$ for all $i \in \mathbb{N}$. Thereby, we have for $l = 1, 2$

$$\left| \Phi_1 S_l(p_{w,l}, p_{w,l}) - \Phi_1 S_l(p_{w,l}, p_{w,l}) \right|^2 \leq L_{\alpha,1} \Phi_l \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right) = \frac{L_{w,2}}{2} \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right) \left( \Phi_2 S^0_l - \Phi_2 S^{n,i-1}_l \right)$$

as a result of the Lipschitz continuity of $S_l$. The monotonicity of $S_l$ allowed dropping the absolute value. Therefore, by integrating (39), we estimate $TP_1$ and $R_1$ by

$$\frac{1}{L_{\alpha,1} \Phi_l} \left( L_{\alpha,1} \Phi_l \right) \left( \Phi_1 S^0_l - \Phi_1 S_l^{n,i-1} \right) \leq \left( \Phi_1 S^0_l - \Phi_1 S_l^{n,i-1} , e_{p,l} \right) \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right) \left( \Phi_2 S^0_l - \Phi_2 S^{n,i-1}_l \right)$$

For $l = 1$, (40) is an estimate for $R_1$ since we had set $e_{w,i} = 0$, and for $l = 2$ it is an estimate for $TP_1$. In this manner, (40) is a condensed notation of both estimates into one.

$TP_2$, $R_2$. Young’s inequality $|xy| \leq \varepsilon |x|^2 + \frac{1}{4\varepsilon} |y|^2$ with $\varepsilon > 0$ applied to the term $TP_2$, gives

$$\left| TP_2 \right| = \left| (\Phi_2 S_{p,l} - \Phi_2 S_{p,l}^{n,i-1} , e_{p,l} - (e_{w,i} - e_{p,l})) \right| \leq \frac{L_{w,2}}{2} \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right) + \frac{1}{2 L_{w,2}} \left( \Phi_2 S^0_l - \Phi_2 S^{n,i-1}_l \right) \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right)$$

where we chose $\varepsilon^2_{\alpha} = \frac{L_{w,2}}{2}$ for $\alpha = w, mw$. The analogous choice of $\varepsilon^2_{w} = \frac{L_{w,2}}{2}$ for $l = 1$ yields

$$\left| R_2 \right| = \left| (\Phi_1 S^0_l - \Phi_1 S_l^{n,i-1} , e_{p,l} - (e_{w,i} - e_{p,l})) \right| \leq \frac{L_{w,2}}{2} \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right) + \frac{1}{2 L_{w,2}} \left( \Phi_1 S^0_l - \Phi_1 S_l^{n,i-1} \right) \left( \| e_{w,i} \|^2 + \| e_{p,l} \|^2 \right)$$

$TP_3$, $R_3$. $TP_3$ and $R_3$ can be estimated together as well. We have

$$\left| \left( k_{\alpha,l} - k_{\alpha,l} \right) \nabla \left( p_0 + z \right) , \nabla e_{p,l} \right| \leq \left( k_{\alpha,l} - k_{\alpha,l} \right) \nabla \left( p_0 + z \right) , \nabla e_{p,l} \right| \| \nabla e_{p,l} \|^2$$

for $(\alpha, l) \in \{(w,1), (w,2), (mw,2)\}$. To derive (41), the Lipschitz-continuity of $k_{\alpha,l}$ and the assumption $\| \nabla \left( p_0 + z \right) \| < M$ was used. $e_{\alpha,l}$ will be chosen later. Equation (41) is the estimate for $R_3$ for $l = 1, \alpha = w$ and the estimate for $TP_3$ is obtained by summing over the phase index $\alpha$.

$$\left| TP_3 \right| \leq \tau \sum_{\alpha} L_{k_{\alpha,2}} M e_{\alpha,2} \left( \| \Phi_2 S^0 \|^2 - \Phi_2 S^{n,i-1}_l \right) \left( \| \nabla e_{p,2} \|^2 \right) + \tau \sum_{\alpha} L_{k_{\alpha,2}} M e_{\alpha,2} \left( \| \nabla e_{p,2} \|^2 \right). \quad (42)$$
TP₁, R₄. Finally, by Assumption 3.1c), we estimate R₄ by

\[ R₄ = \tau \left( \frac{L_{w,1}}{2} \| \epsilon^{w,i}_{p,1} \|^2 - \| \epsilon^{w,i}_{p,1} \|^2 \right) + \frac{1}{L_{S₂} \phi₂} \| \Phi₂S₁^₂ - \Phi₂Sⁿ_{i=1}^1 \|^2 \]

Analogously on the two-phase domain for TP₁, we have the estimate

\[ TP₁ = \tau \sum_{α} \left( \frac{L_{α,2}}{2} \| \epsilon^{α,i}_{p,2} \|^2 - \| \epsilon^{α,i}_{p,2} \|^2 \right) + \frac{1}{L_{S₁} \phi₁} \| \Phi₁S₁^{n+1} - \Phi₁Sⁿ_{i=1}^{n+1} \|^2 \]

Combining the just derived estimates in (40)–(43) and (44) with equations (37) and (38), one arrives at

\[ \sum_{α} \frac{L_{α,2}}{2} \left( \| \epsilon^{α,i}_{p,2} \|^2 - \| \epsilon^{α,i}_{p,2} \|^2 \right) + \frac{1}{L_{S₂} \phi₂} \| \Phi₂S₁^₂ - \Phi₂Sⁿ_{i=1}^1 \|^2 \]

\[ + \tau \sum_{α} \left( \frac{L_{k,α,2}}{4\epsilon₂Φ₂} \| \nabla \epsilon^{α,i}_{p,2} \|^2 \right) \leq \sum_{α} \frac{1}{2L_{α,2}} \| \Phi₂S₁^₂ - \Phi₂Sⁿ_{i=1}^1 \|^2 \]

on \( Ω₂ \), and on \( Ω₁ \), at

\[ \sum_{α} \frac{L_{w,1}}{2} \left( \| \epsilon^{w,i}_{p,1} \|^2 - \| \epsilon^{w,i}_{p,1} \|^2 \right) + \frac{1}{L_{S₁} \phi₁} \| \Phi₁S₁^{n+1} - \Phi₁Sⁿ_{i=1}^{n+1} \|^2 \]

\[ + \tau \sum_{α} \left( \frac{L_{k,α,2}}{4\epsilon₂Φ₂} \| \nabla \epsilon^{w,i}_{p,1} \|^2 \right) \leq \sum_{α} \frac{1}{2L_{w,1}} \| \Phi₁S₁^{n+1} - \Phi₁Sⁿ_{i=1}^{n+1} \|^2 \] (46)

In order to handle the interface terms \( I_R \) in (38) and \( I_{TP} \) in (37), recall that we defined the pressure functionals according to Note 2.7. This allows us to treat the interface terms in the following way: Subtracting (20) from (20′) for \( α = w \) and (22), (23) from (22) and (23) respectively for \( α = nw \), all the while using the representations \( ϵ^{g,i}_{g,i} ∈ H₀₀(Γ) \) of the functionals \( ϵ^{g,i}_{g,i} ∈ H₀₀(Γ) \) (cf. Remark 2.3), we obtain

\[ \bar{ϵ}^{g,i}_{g,i} = -2\lambdaα\bar{ϵ}^{g,i}_{g,i} - \bar{ϵ}^{g,i}_{g,i} \]

for \( (α, l) \in \{(w, 1), (w, 2), (nw, 1)\} \) as well as

\[ \bar{ϵ}^{nw,i}_{g,i} = -\bar{ϵ}^{nw,i}_{g,i} \]

This leads to the relations

\[ \| \epsilon^{w,i}_{p,1} \|^₂ \| _{1/2} = \frac{1}{4\lambda₂w} \left( \| \epsilon^{w,i}_{p,1} \|^₂ \| _{1/2} - 4\lambda₂\epsilon^{w,i}_{g,i} \epsilon^{w,i}_{p,1} \right) \] (47)

\[ \| \epsilon^{w,i}_{p,1} \|^₂ \| _{1/2} = \frac{1}{4\lambda₂w} \left( \| \epsilon^{w,i}_{p,1} \|^₂ \| _{1/2} - 4\lambda₂w\epsilon^{p,i}_{g,2} \epsilon^{w,i}_{p,1} \right) \] (48)

\[ 0 = \frac{1}{4\lambda₂w} \left( \| \epsilon^{w,i}_{p,1} \|^₂ \| _{1/2} - \| \epsilon^{w,i}_{p,1} \|^₂ \right) \] (49)

Inserting for \( l = 1 \) equation (47) into (46) and for \( l = 2 \) (47) as well as (48) in (45), yields

\[ \left( \frac{1}{L_{S₂} \phi₂} - \sum_{α} \left( \frac{L_{k,α,2}}{4\epsilon₂Φ₂} \right) \right) \| \Phi₂S₁^₂ - \Phi₂Sⁿ_{i=1}^1 \|^² + \tau \sum_{α} \left( \bar{m}₂ - \frac{L_{k,α,2}M}{4\epsilon₂Φ₂} \right) \| \nabla \epsilon^{α,i}_{p,2} \|^² \]

\[ \leq \sum_{α} \frac{L_{α,2}}{2} \left( \| \epsilon^{α,i}_{p,2} \|^² - \| \epsilon^{α,i}_{p,2} \|^² \right) + \tau \sum_{α} \left( \| \epsilon^{α,i}_{p,2} \|^² \right) \] (50)

for \( Ω₂ \) and

\[ \left( \frac{1}{L_{S₁} \phi₁} - \frac{1}{2L_{w,1}} - \tau \frac{L_{k,α,2}}{4\epsilon₂Φ₂} \right) \| \Phi₁S₁^{n+1} - \Phi₁Sⁿ_{i=1}^{n+1} \|^² + \tau \sum_{α} \left( \bar{m}₁ - \frac{L_{k,α,2}M}{4\epsilon₂Φ₂} \right) \| \nabla \epsilon^{w,i}_{p,1} \|^² \]

\[ \leq \frac{L_{w,1}}{2} \left( \| \epsilon^{w,i}_{p,1} \|^² - \| \epsilon^{w,i}_{p,1} \|^² \right) + \frac{1}{4\lambda₂w} \left( \| \epsilon^{w,i}_{p,1} \|^² - \| \epsilon^{w,i}_{p,1} \|^² \right) \] (51)

for \( Ω₁ \), where we dropped denoting the representing element by \( ́ \).
Now choose $\epsilon_{\alpha,l} = L_{k_{\alpha,l}}M/(2m_{\Phi_1})$ such that $m_l - L_{k_{\alpha,l}}M/(4\epsilon_{\alpha,l} m_{\Phi_1}) = \frac{m_l}{2} > 0$. Recall that by assumption the numbers $L_{k_{\alpha,l}}$ have been chosen large enough that $\frac{1}{2L_{k_{\alpha,l}}} + \frac{1}{3} \sum_{\alpha} \frac{1}{L_{k_{\alpha,l}}} > 0$ as well as $\frac{1}{L_{k_{\alpha,l}}} - \frac{1}{2L_{w_{l}}} > 0$, and in addition the time step restriction (33) is satisfied for a sufficiently small $\tau$. Summing up the equations (50) and (51), then adding zero in the form of (49) to the result and thereafter summing with respect to iterations $i = 1, \ldots, r$ leads to

$$
\sum_{i=1}^{r} \sum_{l=1}^{r} C_l \| \Phi_l S^n_i - \Phi_l S^{n,i-1}_i \|^2 + \tau \sum_{i=1}^{r} \left( \frac{m_1}{2} \| \nabla \epsilon_{p,1} \|^2 + \frac{m_2}{2} \sum_{\alpha} \| \nabla \epsilon_{p,2,\alpha} \|^2 \right) 
\leq \sum_{\alpha} \frac{L_{\alpha,2}}{2} \left( \| \epsilon_{p,2,\alpha} \|^2 - \| \epsilon_{p,2,\alpha} \|^2 \right) + \frac{L_{w_{1,1}}}{2} \left( \| \epsilon_{p,1,\alpha} \|^2 - \| \epsilon_{p,1,\alpha} \|^2 \right) + \tau \sum_{l=1}^{r} \sum_{\alpha} \frac{1}{4\alpha} \left( \| \epsilon_{g,l,1/2} \|^2 - \| \epsilon_{g,l,1/2} \|^2 \right),
$$

(52)

where $C_l$ is defined in (33) and the telescopic nature of the sums on the right hand side have been exploited. Equation (52) implies the estimates

$$
\sum_{i=1}^{r} \sum_{l=1}^{r} C_l \| \Phi_l S^n_i - \Phi_l S^{n,i-1}_i \|^2 \leq C,
$$

(53)

$$
\tau \sum_{i=1}^{r} \left( \frac{m_1}{2} \| \nabla \epsilon_{p,1} \|^2 + \frac{m_2}{2} \sum_{\alpha} \| \nabla \epsilon_{p,2,\alpha} \|^2 \right) \leq C,
$$

(54)

$$
\sum_{\alpha} \frac{L_{\alpha,2}}{2} \| \epsilon_{p,2,\alpha} \|^2 + \frac{L_{w_{1,1}}}{2} \| \epsilon_{p,1,\alpha} \|^2 + \tau \sum_{l=1}^{r} \sum_{\alpha} \frac{1}{4\alpha} \| \epsilon_{g,l,1/2} \|^2 \leq C,
$$

(55)

with

$$
C := \sum_{\alpha} \frac{L_{\alpha,2}}{2} \| \epsilon_{p,2,\alpha} \|^2 + \frac{L_{w_{1,1}}}{2} \| \epsilon_{p,1,\alpha} \|^2 + \tau \sum_{l=1}^{r} \sum_{\alpha} \frac{1}{4\alpha} \| \epsilon_{g,l,1/2} \|^2.
$$

Since $C$ is independent of $r$, we thereby conclude that

$$
\| \Phi_l S^n_i - \Phi_l S^{n,i-1} \|; \| \nabla \epsilon_{p,1} \| \longrightarrow 0 \quad \text{as} \ i \rightarrow \infty,
$$

(56)

for all appearing combinations of $l \in \{1, 2\}$ and $\alpha \in \{w, nw\}$. Due to the partial homogeneous Dirichlet boundary, the Poincaré inequality is applicable cf. [27, Theorem A.2.5, p. 252] for functions in $V_l$. Thus, equation (56) further implies $\| \epsilon_{p,1} \| \rightarrow 0$ as $i \rightarrow \infty$ for all admissible index combinations.

In order to show that $\epsilon_{p,1,\alpha} \rightarrow 0$ in $V_l$ for all appearing indices, we subtract (19) from (19') for $\alpha = w, l = 1, 2$, and (21) from (21') for $\alpha = nw, l = 2$ and consider only test functions in $\varphi_{\alpha,l} \in C_{0}^\infty(\Omega_l)$, i.e.

$$
-\tau \langle \Phi_{\alpha,l}^m - F_{\alpha,l}^n, \nabla \varphi_{\alpha,l} \rangle = L_{\alpha,1} \langle \epsilon_{p,1} - \epsilon_{p,1,\alpha}, \varphi_{\alpha,l} \rangle + \langle -1 \delta_{w\alpha} \Phi_l S^n_i - \Phi_l S^{n,i-1}_i, \varphi_{\alpha,l} \rangle.
$$

(57)

Thus, $\nabla \langle \Phi_{\alpha,l}^m - F_{\alpha,l}^n, \varphi_{\alpha,l} \rangle$ exists in $L^2(\Omega_l)$ and

$$
-\tau \nabla \langle \Phi_{\alpha,l}^m - F_{\alpha,l}^n, \varphi_{\alpha,l} \rangle = L_{\alpha,1} \langle \epsilon_{p,1} - \epsilon_{p,1,\alpha}, \varphi_{\alpha,l} \rangle + \langle -1 \delta_{w\alpha} \Phi_l S^n_i - \Phi_l S^{n,i-1}_i \rangle
$$

(58)

almost everywhere, from which we deduce for $\varphi_{\alpha,l}$ now taken to be in $V_l$

$$
\left| \langle \nabla \langle \Phi_{\alpha,l}^m - F_{\alpha,l}^n, \varphi_{\alpha,l} \rangle, \varphi_{\alpha,l} \rangle \right| \leq \frac{L_{\alpha,1}}{\tau} \| \epsilon_{p,1} - \epsilon_{p,1,\alpha} \| \| \varphi_{\alpha,l} \| + \frac{1}{\tau} \| \Phi_l S^n_i - \Phi_l S^{n,i-1} \| \| \varphi_{\alpha,l} \|.
$$

Introducing the abbreviation $\| \Psi_{\alpha,l}^{n,i}(\varphi_{\alpha,l}) \|$ for the left hand side of (59), the limit

$$
\sup_{\varphi_{\alpha,l} \in V_l} \left\| \Psi_{\alpha,l}^{n,i}(\varphi_{\alpha,l}) \right\|_{V_l} \leq \frac{L_{\alpha,1}}{\tau} \| \epsilon_{p,1} - \epsilon_{p,1,\alpha} \| + \frac{1}{\tau} \| \Phi_l S^n_i - \Phi_l S^{n,i-1} \| \longrightarrow 0
$$

as $i \rightarrow \infty$ follows as a consequence of (53) and (54). In other words $\| \Psi_{\alpha,l}^{n,i} \|_{V_l} \rightarrow 0$ as $i \rightarrow \infty$. On the other hand, starting again from (35) (without the added zero term), this time however inserting $\varphi_{\alpha,l} \in V_l$ and integrating by parts, keeping in mind (58), one deduces that

$$
\langle \epsilon_{g,l,\alpha} \varphi_{\alpha,l} \rangle = -\lambda_{\alpha} \langle \epsilon_{p,1,\alpha}, \varphi_{\alpha,l} \rangle + \langle (F_{\alpha,l}^n - F_{\alpha,l}^n) \cdot n_1, \varphi_{\alpha,l} \rangle.
$$

(60)
We already know, that \( \|e_{i,j}^{n}\|_{V_j} \rightarrow 0 \) as \( i \rightarrow 0 \) and we will use the continuity of the trace operator to deal with the term \( \langle e_p^{n,i}, \varphi_{\alpha,l} \rangle \). For the last summand in (60) we have by the integration by parts formula

\[
\left\langle \left( F_{\alpha,l}^n - F_{\alpha,l}^n \right) \cdot n_l, \varphi_{\alpha,l} \right\rangle = \Psi_{\alpha,l} \varphi_{\alpha,l} + \left\langle F_{\alpha,l}^n - F_{\alpha,l}^n, \nabla \varphi_{\alpha,l} \right\rangle,
\]

and the second term can be estimated by

\[
\left| \left\langle k_{\alpha,l} \nabla \left( p_{\alpha,l} + z_{\alpha} \right) - k_{\alpha,l} \nabla \left( p_{\alpha,l} \right), \nabla \varphi_{\alpha,l} \right\rangle \right|
\leq \left| \left\langle k_{\alpha,l} \nabla \left( p_{\alpha,l} + z_{\alpha} \right) - k_{\alpha,l} \nabla e_p^{n,i}, \nabla \varphi_{\alpha,l} \right\rangle \right|
\leq \frac{L_{k_{\alpha,l}} M}{\Phi_l} \left\| \nabla e_p^{n,i} \right\|_{V_l} \leq \left\| \nabla \varphi_{\alpha,l} \right\|_{V_l},
\]

where we used the same reasoning as in (41) and \( \max |k_{\alpha,l}| \leq M_{k_{\alpha,l}}. \) With this, we get

\[
\left\| \left( F_{\alpha,l}^n - F_{\alpha,l}^n \right) \cdot n_l, \varphi_{\alpha,l} \right\|_{V_l} \leq \left\| \left( \nabla \varphi_{\alpha,l} \right) \right\|_{V_l} + \frac{L_{k_{\alpha,l}} M}{\Phi_l} \left\| \nabla e_p^{n,i} \right\|_{V_l} \rightarrow 0,
\]

as \( i \rightarrow \infty \) from (61). Finally, we deduce from (60) and the continuity of the trace operator (with constant \( C \)) on Lipschitz domains

\[
\sup_{\varphi_{\alpha,l} \in V_l} \left\| \frac{\left\langle e_{\alpha,l}^{n,i}, \varphi_{\alpha,l} \right\rangle}{\| \varphi_{\alpha,l} \|_{V_l}} \right\|_{V_l} \leq \lambda_\alpha C \left\| e_{p,l}^{n,i} \right\|_{V_l} + \left\| \Psi_{\alpha,l} \varphi_{\alpha,l} \right\|_{V_l} + \frac{L_{k_{\alpha,l}} M}{\Phi_l} \left\| \nabla \varphi_{\alpha,l} \right\|_{V_l} \rightarrow 0,
\]

as \( i \rightarrow \infty. \) This shows \( e_{g,l}^{n,i} \rightarrow 0 \) in \( V_l \) for all valid index combinations and concludes the proof. \( \square \)

4. The LDD-TPR solver for the multi-domain case

In this section we provide a generalisation of Problem 2.5 to a multi-domain setting. An in-depth presentation with a multi-domain convergence result can be found in [31, Section 4.4].

We start with a generalisation of our geometric notations. The domain \( \Omega \subset \mathbb{R}^d \) is partitioned into a finite number of non-overlapping Lipschitz subdomains \( \Omega_i \subset \Omega \) such that \( \Omega = \bigcup_{i=1}^m \Omega_i \). The interior of intersections of the boundary of neighbouring domains, \( \Gamma_{kl} := \Gamma_k \cap \Gamma_l \setminus \partial (\Omega_k \cap \Omega_l) \) that in addition have non-zero \( (d-1) \)-dimensional Hausdorff measure are called interfaces and are submanifolds of dimension \( d-1 \). As a consequence, the outer normal \( n_{kl} \in \mathbb{S}^{d-1} \) pointing from \( \Omega_k \) to \( \Omega_l \) is defined almost everywhere on \( \Gamma_{kl} \). Let \( I \subset \mathbb{N} \) be a multi-index set. Furthermore, let \( I_l := \text{int} (\partial \Omega_l \setminus \Gamma_l) \) denote that particular part of the boundary of \( \Omega_l \) intersecting with \( \partial \Omega_l \) for all \( l \in I \) for which \( I_l \) is \( (d-1) \)-dimensional. Then \( \partial \Omega_l = \bigcup_{l \in I} \Gamma_l \) and \( \partial \Omega = \bigcup_{l \in I} \Gamma_l \).

Let \( \mathcal{J}^R, \mathcal{J}^T \subset I \) with \( I = \mathcal{J}^R \cup \mathcal{J}^T \) be the (possibly empty) sets of indices denoting the subdomains \( \Omega_i \) on which the Richards equation (4) or the full two-phase system (2) is imposed. If neither \( \mathcal{J}^R \neq \emptyset \) nor \( \mathcal{J}^T \neq \emptyset \), denote by \( \mathcal{J}^{RT} \subset \mathcal{T} \) the indices of domain patches, that model the full two-phase flow but have at least one neighbouring subdomain that assumes the Richards model sharing an interface of dimension \( (d-1) \). Similarly, define the subset \( \mathcal{J}^{RT} \subset \mathcal{T} \) of Richards subdomains with a two-phase neighbour. Given a subdomain \( \Omega_k \) with \( k \in \mathcal{J}^R \), let \( \mathcal{J}^{k,T} \subset \mathcal{J} \) be the set of indices of neighbouring Richards subdomains. Analogously, for \( \Omega_k \) with \( k \in \mathcal{J}^T \), let \( \mathcal{J}^{k,T} \subset \mathcal{J} \) be the set of indices of neighbouring two-phase subdomains.

Turning to function spaces, we decompose \( H^1_0(\Omega) \) into spaces

\[
\mathcal{V}_l := \left\{ u \in H^1(\Omega_l) \mid u|_{\partial \Omega_l \cap \partial \Omega} = 0 \right\}
\]

and set

\[
\hat{\mathcal{V}} := \bigoplus_{j=1}^m \mathcal{V}_j, \quad \mathcal{V} := \left\{ (u_1, \ldots, u_m) \in \hat{\mathcal{V}} \mid u_l|_{\Gamma_{lk}} = u_k|_{\Gamma_{lk}}, l \in I, k \in I_l \right\},
\]

the latter being \( H^1_0(\Omega) \). In case \( \Omega_k \) is an internal subdomain, i.e. \( \partial \Omega_k \cap \partial \Omega = \emptyset \), we have \( \mathcal{V}_k = H^1(\Omega_k) \). If a purely Richards or purely two-phase domain decomposition is considered, i.e. no TP–R coupling occurs, the space
\( \mathcal{V}_w \) can be used for the wetting phases, (Richards) and also the nonwetting phases (two-phase). If both models are present, however, we refine the notion of \( \mathcal{V}_w \), the space for the nonwetting phase. For all \( k \in J^R \) define \( \mathcal{V}_n^w := \mathcal{V}_1 \), \( \mathcal{V}_n^{nw} := \{0\} \) for \( k \in J^R \) and set the general space for the nonwetting phase

\[
\mathcal{V}_n^{nw} := \bigoplus_{j=1}^W \mathcal{V}_j \quad \text{and} \quad \mathcal{V}_n^{nw} := \{ (u_1, \ldots, u_W) \in \mathcal{V}_n^{nw} \mid u_l|_{\Gamma_{lk}} = u_k|_{\Gamma_{lk}}, l \in J^R \}.
\]

Note, that since for \( k \in J^R \) we set \( \mathcal{V}_n^{nw} = \{0\} \), \( u_l|_{\Gamma_{lk}} = u_k|_{\Gamma_{lk}} \) for \( k \in J^R \) actually means \( u_l|_{\Gamma_{lk}} = 0 \). Lastly, in order to define Neumann traces, we need those subspaces of the spaces \( \mathcal{V}_n^x \) and \( \mathcal{V}_n^{nw} \) for which traces on each interface to neighbours can be extended by zero. We set

\[
\mathcal{V}_n^{k,00} := \{ u \in \mathcal{V}_n^k \mid u|_{\Gamma_{ki}} \in H_{00}^{1/2}(\Gamma_{ki}), l \in J_k \} \quad \text{and} \quad \mathcal{V}_n^{00} := \bigoplus_{j=1}^W \mathcal{V}_j^{0,00}
\]

for \( \alpha \in \{w, nw\} \).

With the above notations a multi-domain semi-discrete formulation of Problem 2.5 reads as

**Problem 4.1** (Semi-discrete TP-R problem, multi-domain). Given functions \((p_{w}^{n-1}, p_{nw}^{n-1}) \in \mathcal{V}_w \times \mathcal{V}^{nw} \), find \((p_{w}^{n}, p_{nw}^{n}) \in \mathcal{V}_w \times \mathcal{V}^{nw} \), such that all fluxes fulfill \( F_{n,l}^{\alpha} \cdot \mathbf{n}_{lk} \in H_{00}^{1/2}(\Gamma_{lk}) \) for \( l \in J, k \in J_l, \alpha \in \{w, nw\} \), and the equations

\[
\langle \Phi_l S_l^{\alpha} - \Phi_1 S_l^{\alpha-1}, \varphi_{w,l} \rangle = -\tau \langle F_{w,l}^{\alpha} \cdot \nabla \varphi_{w,l} \rangle + \tau \sum_{k \in J_l} \langle F_{w,k}^{\alpha} \cdot \mathbf{n}_{lk}, \varphi_{w,l} \rangle_{\Gamma_{lk}} = \tau \langle j_{w,l}^{\alpha}, \varphi_{w,l} \rangle,
\]

as well as

\[
-\langle \Phi_n S_n^{\alpha} - \Phi_1 S_n^{\alpha-1}, \varphi_{nw,l} \rangle = \tau \langle F_{nw,l}^{\alpha} \cdot \nabla \varphi_{nw,l} \rangle + \tau \sum_{k \in J_l} \langle F_{nw,k}^{\alpha} \cdot \mathbf{n}_{lk}, \varphi_{nw,l} \rangle_{\Gamma_{lk}} = \tau \langle j_{nw,l}^{\alpha}, \varphi_{nw,l} \rangle
\]

are satisfied for \( l \in J^R, j \in J^R \) and for all \((\varphi_{w,1}, \varphi_{w,2}, \ldots, \varphi_{w,W}) \in \mathcal{V}_n^{00} \).

As we have seen in the previous section, cf. Lemma 2.10, introducing a Robin type formulation allows to drop the pressure continuity that is implicitly contained in the definition of our spaces \( \mathcal{V}_w \) and \( \mathcal{V}^{nw} \). Instead, the pressure continuity becomes part of the equations to solve and is thereby more accessible to implementation. Setting analogously to equations (24)–(25) for \( \lambda_{\alpha,k}^{l,k} = \lambda_{\alpha,k}^{l,k} > 0 \)

\[
g_{\alpha,lk} := -\lambda_{\alpha,nw}^{l,k} \cdot \mathbf{n}_{lk} + F_{\alpha,l}^{\alpha} \cdot \mathbf{n}_{lk}, \quad (l \in J), (k \in J_l) \quad \text{and} \quad \alpha \in \{n, nw\},
\]

in \( H_{00}^{1/2}(\Gamma_{lk}) \), where as in the previous sections \( g_{nw,lk} = F_{nw,l}^{\alpha} \cdot \mathbf{n}_{lk} \) on Richards subdomains \( l \in J^R \) are only nonzero if the neighbour \( \Omega_k \) assumes the two-phase model, i.e., \( k \in J^R \), and gravity is included, Problem 4.1 can be equivalently reformulated into

**Problem 4.2** (Semi-discrete TP-R problem, limit formulation, multi-domain). Let functions \((p_{w}^{n-1}, p_{nw}^{n-1}) \in \mathcal{V}_w \times \mathcal{V}^{nw} \) as well as real numbers \( \lambda_{\alpha,k}^{l,k} > 0 \) be given for all interfaces \( \Gamma_{lk}, l \in J, k \in J_l \), and appearing phases \( \alpha \).

Find \((p_{w}^{n}, p_{nw}^{n}) \in \mathcal{V}_w \times \mathcal{V}^{nw} \) and \( g_{\alpha,lk} \in H_{00}^{1/2}(\Gamma_{lk}) \), \( l \in J, k \in J_l, \alpha \in \{n, nw\} \) such that on Richards domains, i.e., \( l \in J^R \), the terms \( g_{\alpha,lk} \) are given by

\[
g_{nw,lk} = F_{nw,l}^{\alpha} \cdot \mathbf{n}_{lk}, \quad \text{for} \quad l \in J^R, \quad \text{and} \quad k \in J^R_{\alpha,k},
\]

\[
g_{nw,lk} = 0, \quad \text{for} \quad l \in J^R \quad \text{and} \quad k \in J_l \setminus J^R_{\alpha,k},
\]

\[
g_{nw,lk} = 0, \quad \text{for} \quad l \in J \setminus J^R \quad \text{and} \quad k \in J_l,
\]

where \( F_{nw,l}^{\alpha} \cdot \mathbf{n}_{lk} \in H_{00}^{1/2}(\Gamma_{lk}) \) are defined by the right hand side of each (6) or (7), and these functions \((p_{w}^{n}, p_{nw}^{n})\) and \( g_{\alpha,lk} \) fulfill the equations

\[
\langle \Phi_l S_l^{\alpha} - \Phi_1 S_l^{\alpha-1}, \varphi_{w,l} \rangle = -\tau \langle F_{w,l}^{\alpha} \cdot \nabla \varphi_{w,l} \rangle + \tau \sum_{k \in J_l} \langle \lambda_{\alpha,k}^{l,k} + g_{w,lk}, \varphi_{w,l} \rangle_{\Gamma_{lk}} = \tau \langle j_{w,l}^{\alpha}, \varphi_{w,l} \rangle,
\]
for $l \in \mathcal{I}^R$ with
\[
\langle g_{w,l,k}, \varphi_{w,l} \rangle_{\Gamma_{lk}} = \langle -2 \lambda_{n,w}^k p_{w,l,k} - g_{w,k,l}, \varphi_{w,l} \rangle_{\Gamma_{lk}} \quad (k \in \mathcal{I}_l),
\]
\[
\langle g_{nw,l,k}, \varphi_{nw,k} \rangle_{\Gamma_{lk}} = \langle -2 \lambda_{nw}^k p_{nw,l,k} - g_{nw,k,1}, \varphi_{nw,k} \rangle_{\Gamma_{lk}} \quad (k \in \mathcal{I}_l^R),
\]
and for $j \in \mathcal{T}^P$ the equations
\[
\langle \Phi_j S_{\alpha}^n - \Phi_j S_{\alpha}^{n-1}, \varphi_{w,j} \rangle - \tau \langle F^n_{w,j \cdot}, \nabla \varphi_{w,j} \rangle + \tau \sum_{k \in \mathcal{I}_j} \langle \lambda_{w}^k p_{w,l,k} + g_{w,j,k}, \varphi_{w,j} \rangle_{\Gamma_{jk}} = \tau \langle f^n_{w,j}, \varphi_{w,j} \rangle,
\]
\[
\langle \Phi_j S_{\alpha}^n - \Phi_j S_{\alpha}^{n-1}, \varphi_{nw,j} \rangle - \tau \langle F^n_{nw,j \cdot}, \nabla \varphi_{nw,j} \rangle + \tau \sum_{k \in \mathcal{I}_j} \langle \lambda_{nw}^k p_{nw,l,k} + g_{nw,j,k}, \varphi_{nw,j} \rangle_{\Gamma_{jk}} = \tau \langle f^n_{nw,j}, \varphi_{nw,j} \rangle,
\]

together with
\[
\langle g_{w,j,k}, \varphi_{w,j} \rangle_{\Gamma_{jk}} = \langle -2 \lambda_{w}^k p_{w,l,k} - g_{w,j,k}, \varphi_{w,j} \rangle_{\Gamma_{jk}} \quad (k \in \mathcal{I}_j),
\]
\[
\langle g_{nw,j,k}, \varphi_{nw,j} \rangle_{\Gamma_{jk}} = \langle -2 \lambda_{nw}^k p_{nw,l,k} - g_{nw,j,k}, \varphi_{nw,j} \rangle_{\Gamma_{jk}} \quad (k \in \mathcal{I}_j \cap \mathcal{T}^P),
\]
\[
\langle g_{nw,j,k}, \varphi_{nw,j} \rangle_{\Gamma_{jk}} = \langle -g_{nw,j,k}, \varphi_{nw,j} \rangle_{\Gamma_{jk}} \quad (k \in \mathcal{T}^P_{\text{TR}}),
\]
for all $(\varphi_{\alpha,1}, \varphi_{\alpha,2}, \ldots, \varphi_{\alpha,w}) \in \tilde{V}_0^\alpha.$

Remark 4.3 (Necessity of $\tilde{V}_0^\alpha$ as test function space). In order to define Neumann traces on parts of a boundary $\Gamma \subset \partial \Omega$ of a Lipschitz domain $\Omega$, test functions $\varphi \in H^{1/2}(\Gamma)$ need to be extendable by zero and these are precisely the functions in $H^{1/2}(\Gamma)$. If we tested the above problems with functions $\varphi_{\alpha,l} \in \tilde{V}_0^\alpha$, the traces $\varphi|_{\Gamma_{lk}}$ for $k \in \mathcal{I}_l$ a priori would only lie in $H^{1/2}(\Gamma_{lk})$. For the Neumann traces appearing in Problem 4.1 and Problem 4.2 to be well-defined, we need $\varphi|_{\Gamma_{lk}} \in H^{1/2}_{\text{tr}}(\Gamma_{lk})$ for $k \in \mathcal{I}_l$, however. Testing with $\varphi_{\alpha,l} \in \tilde{V}_0^\alpha$ precisely alleviates that problem.

As before, Problem 4.2 shows how to design the multi-domain LDD-TP–R solver step.

Problem 4.4 (LDD-TP–R solver step, multi-domain, version 1). Given $(p_{w}^{n-1}, p_{nw}^{n-1}) \in \mathcal{V}_w \times \mathcal{V}_{nw}$, set on all subdomains $\Omega_l$, $l \in \mathcal{I}$, for some $L_{\alpha,l} > 0$ as initial iterates
\[
p_{w}^{n,0} := p_{w}^{n-1},
\]
where $\alpha \in \{w\}$ for $l \in \mathcal{I}^R$ and $\alpha \in \{w, nw\}$ for $l \in \mathcal{T}^P$ as well as
\[
g_{\alpha,l,k} := F_{\alpha,l,k}^{n-1} \cdot n_{lk} - \lambda_{\alpha}^k p_{\alpha,l,k}^{n-1} \rangle_{\Gamma_{lk}}
\]
in $H^{1/2}_{\text{tr}}(\Gamma_{lk})$ for $k \in \mathcal{I}_l$ and $\lambda_{\alpha}^k = \frac{\lambda_{\alpha}^l}{L_{\alpha,l}} > 0$. As before, for Richards domains, $\Omega_l$ with $l \in \mathcal{I}^R$, and on interfaces $\Gamma_{lk}$ to a two-phase domain, i.e. $k \in \mathcal{T}^P_{\text{TR}}$, equation (72) becomes
\[
g_{\alpha,l,k} := F_{\alpha,l,k}^{n-1} \cdot n_{lk}
\]
and the fluxes $F_{\alpha,l,k}^{n-1} \cdot n_{lk}$ are defined by the right hand side of either (6) or (7). On interfaces $\Gamma_{lk}$ between Richards domains, we take
\[
g_{nw,l,k} = 0.
\]
Given the iterates $(p_{w}^{n,i}, p_{nw}^{n,i}) \in \tilde{V}_w \times \tilde{V}_{nw}$, as well as $g_{\alpha,l,k}^{n,i} \in H^{1/2}_{\text{tr}}(\Gamma_{lk})$, $(N \in i \geq 1)$, one step of the LDD-TP–R solver consists of finding $(p_{w}^{n,i}, p_{nw}^{n,i}) \in \tilde{V}_w \times \tilde{V}_{nw}$ such that on Richards subdomains, i.e. $l \in \mathcal{I}^R$, the equations
\[
L_{w,l}(p_{w}^{n,i}, \varphi_{w,l}) - \tau \langle F_{w,l \cdot}^{n,i}, \nabla \varphi_{w,l} \rangle + \tau \sum_{k \in \mathcal{I}_l} \langle \lambda_{w}^k p_{w,l,k}^{n,i} + g_{w,l,k}, \varphi_{w,l} \rangle_{\Gamma_{lk}} = \tau \langle f_{w,l}, \varphi_{w,l} \rangle,
\]
\[
= L_{w,l}(p_{w}^{n,i-1}, \varphi_{w,l}) - \langle \Phi_{l} S_{\alpha}^{n,i-1} - \Phi_{l} S_{\alpha}^{n-1}, \varphi_{w,l} \rangle + \tau \langle f_{w,l}, \varphi_{w,l} \rangle,
\]
with
\[
\langle g_{w,l,k}, \varphi_{w,l} \rangle_{\Gamma_{lk}} := \langle -2 \lambda_{w}^k p_{w,l,k} - g_{w,l,k}, \varphi_{w,l} \rangle_{\Gamma_{lk}} \quad (k \in \mathcal{I}_l),
\]
\[
\langle g_{nw,l,k}, \varphi_{nw,k} \rangle_{\Gamma_{lk}} := \langle -2 \lambda_{nw}^k p_{nw,l,k} - g_{nw,l,k}, \varphi_{nw,k} \rangle_{\Gamma_{lk}} \quad (k \in \mathcal{I}_l^R).
\]
are satisfied, and on two-phase domains, \( (j \in \mathcal{T}_{TP}) \), the equations

\[
L_{\alpha,j}(p_{\alpha,j}^{n,i}, \varphi_{\alpha,j}) - \tau \langle F_{\alpha,j}^{n,i}, \nabla \varphi_{\alpha,j} \rangle + \tau \sum_{k \in I_j} \langle \lambda_{\alpha}^k p_{\alpha,j}^{n,i} + g_{\alpha,jk}^{n,i}, \varphi_{\alpha,j} \rangle_{\Gamma_{jk}} = \langle L_{\alpha,j}^{n,i-1}, \varphi_{\alpha,j} \rangle + \tau \langle f_{\alpha,j}^{n,i}, \varphi_{\alpha,j} \rangle,
\]

for \( \alpha \in \{n, nw\} \) along with

\[
\begin{align*}
\langle g_{w,jk}^{i}, \varphi_{w,j} \rangle_{\Gamma_{jk}} &:= \langle -2\lambda_{w} p_{w,jk}^{n,i-1} - g_{w,jk}^{n,i}, \varphi_{w,j} \rangle_{\Gamma_{jk}} \quad (k \in I_j), \\
\langle g_{w,jk}^{i}, \varphi_{w,j} \rangle_{\Gamma_{jk}} &:= \langle -2\lambda_{w} p_{w,jk}^{n,i-1} - g_{w,jk}^{n,i}, \varphi_{w,j} \rangle_{\Gamma_{jk}} \quad (k \in I_j \cap \mathcal{T}_{TP}), \\
\langle g_{w,jk}^{i}, \varphi_{w,j} \rangle_{\Gamma_{jk}} &:= \langle -g_{w,jk}^{n,i-1}, \varphi_{w,j} \rangle_{\Gamma_{jk}} \quad (k \in \mathcal{T}_{TP})
\end{align*}
\]

are fulfilled for all test functions \((\varphi_{w}, \varphi_{nw}) \in \widehat{\mathcal{V}}_{00} \times \widehat{\mathcal{V}}_{00}^m\).

**Remark 4.5.** We note that the iterates \((p_{\alpha,j}^{n,i}, p_{\alpha,j}^{n,i-1})\) are only required to be in \(\widehat{\mathcal{V}}_{\alpha} \times \widehat{\mathcal{V}}_{nw}^m\) and need not to be in \(\mathcal{V}_{\alpha} \times \mathcal{V}_{nw}^m\) (the latter meaning continuity over interfaces). If the family of subsequent solutions to the \(\alpha\) in \(H_{\alpha}
Remark 4.7. Note that the key difference between Problem 4.4 and Problem 4.6 is the test function space and consequently the space on which the functionals \(g_{\alpha,l}^{n,i}\) act.

5. Numerical validation of the LDD-TP–R solver

In this section, we turn to the numerical validation of the LDD-TP–R solver for the case \(d = 2\). We provide examples for two different substructurings. For a two-domain case, we compare the performance of the LDD-TP–R solver to the full two-phase flow model. In addition, we discuss the choice of solver parameters. For a multi-domain example involving an inner subdomain, we illustrate the performance as well. Both domain partitions are displayed in Figure 2.
DATA | $\Omega_1$ | $\Omega_2$
---|---|---
$k_{w,l}(s)$ | $s^2$ | $s^3$
$k_{rw,l}(s)$ | $(1-s)^2$ | $(1-s)^3$
$S_l(p_c)$ | \[
\begin{cases}
1 & p_c \geq 0 \\
0 & p_c < 0
\end{cases}
\] | \[
\begin{cases}
1 & p_c \geq 0 \\
0 & p_c < 0
\end{cases}
\]
$p_w(x,y,t)$ | $-7 - (1 + t^2)(1 + x^2 + y^2)$ | $-7 - (1 + t^2)(1 + x^2 + y^2)$
$p_{mc,x,y}(x,y,t)$ | $-2 - t(1.1 + y + x^2)$ | $-2 - t(1.1 + y + x^2)$

Table 1: TP-R coupling on two domains: coefficient functions and exact solutions.

All experiments were implemented using PYTHON and FENICS' main library DOLFIN, cf. [33, 34]. The code for all examples along with its documentation can be found at [35]. For a detailed description of the design principles we refer to [31]. Here we restrict ourselves to a listed summary regarding the grid and the ansatz functions.

**Substructuring and meshes.** All subdomains $\Omega_l \subset \Omega \subset \mathbb{R}^2$ and triangular meshes are constructed by the FENICS mesh tool MSH. To ensure that the meshes are matching, submeshes $\mathcal{T}_l$ on each subdomain $\Omega_l$ are always extracted from a global conforming mesh $\mathcal{T}$ on $\Omega$. This means, mesh vertices and faces always lie on the polygons defining the interfaces, and no facets intersect interfaces. In this way, neighbouring subdomains share vertices and facets over interfaces. DOLFIN was instructed to use PARMETIS as mesh partitioner. An example of such a mesh can be seen in Figure 7b). If $d_\Delta$ is the diameter (two times the circumradius) of a mesh cell (triangle) $\Delta \in \mathcal{T}$, the mesh size $h_l$ on each domain is defined as $h_l = \max\{d_\Delta : \Delta \in \mathcal{T}_l\}$. On each subdomain mesh, FENICS’ first-order Lagrange finite elements, $P_1 A^0$, were used as ansatz spaces $V_{h,l} \subset V_l$.

**Interfaces terms and communication.** The calculation of the Robin-interface terms across interfaces and the data exchange across interfaces requires manual assembly of the fluxes involving gradients of $P_1 A^0$ functions. The calculation of interface terms is done dof-wise and their communication over interfaces needs to take into account the different mesh and dof numberings on each subdomain adjacent to a given interface. The calculation of the approximations $g_{\alpha,lk}^{h,i}$ of the $g_{\alpha,lk}$-terms uses discontinuous Galerkin elements of degree 1, $P_1 A^2$. The reason is twofold. On the one hand, the calculation of $g_{\alpha,lk}^{h,0}$ necessitates the assembly of fluxes (since we use the initial iterates of Problem 4.4), involving thereby the gradient of a $P_1$ function, hence the need for discontinuous ansatz functions, and on the other hand it seemed desirable to have the same number of degrees of freedom as the pressures that need to be added to these terms.

The implementation of the $g_{\alpha,lk}^{h,i}$ terms is done in the following way. The LDD solver, upon entering time step $n$, first assembles $g_{\alpha,lk}^{h,0}$. On each domain $\Omega_l$, $l \in \mathcal{T}$, the approximation $F_{\alpha,l}^{h,n-1}$ of the flux $F_{\alpha,l}^{n-1}$ is assembled in $P_1 A^2 \times P_1 A^2$ and $F_{\alpha,l}^{h,n-1} \cdot n_{lk} \in P_1 A^2$ is added dof-wise to $p_{\alpha,l}^{h,n-1} |_{\Gamma_{lk}}$ for dofs that lie on facets belonging to the interface $\Gamma_{lk}$, $k \in \mathcal{T}_l$. The resulting dofs of the $g_{\alpha,lk}^{h,0}$-term are then saved to interface dictionaries for communication. During the $i$th iteration of the LDD solver on $\Omega_l$, the $g_{\alpha,lk}^{h,i-1}$ and $p_{\alpha,lk}^{h,i-1}$ dofs of the neighbour $k$ are read from these interface dictionaries and are added – again dof-wise – along $\Gamma_{lk}$ to get $g_{\alpha,lk}^{h,i} \in P_1 A^2$. Since the form assembly of Problem 4.6 is done in $P_1 A^0$, the $g_{\alpha,lk}^{h,i}$ terms enter the form as projections $\Pi g_{\alpha,lk}^{h,i} \in P_1 A^0$, where $\Pi : P_1 A^2 \to P_1 A^0$ is the projection onto $P_1 A^0$. All appearing linear systems were solved using the Generalised Minimal Residual Method (GMRES) in conjunction with Incomplete LU preconditioning (ILU) as realised in the FENICS library. We will use the following

**Notation 5.1.** By $p_{\alpha,l}^{e,n}$ we denote manufactured solutions, and $p_{\alpha,l}^{e,n} := p_{\alpha,l}^{e,n}(\cdot,\cdot, t_n)$ are their evaluation at time step $t_n$. We have $p_{\alpha,l}^{r,n} = p_{\alpha,l}^{e,n}$ since manufactured solutions solve the semi-discrete TP-R problem. Numerical approximations are denoted with an additional $h$, i.e., $p_{\alpha,l}^{h,n}$ is the numerical approximation of $p_{\alpha,l}^{e,n} / p_{\alpha,l}^{h,n}$ and the symbols $p_{\alpha,l}^{h,i}$ denote the numerical approximation of the iterates $p_{\alpha,l}^{h,i}$ of the LDD-TP–R solver. Note, that the index $n$ is dropped in this case. This means that $p_{\alpha,l}^{h,i}$ always denotes the iterates in the calculation of the $n$-th time step.

### 5.1. Two-domain computations

We start the numerical validation of the LDD-TP–R solver for the two-domain case shown in Figure 2(a).

**Homogeneous intrinsic permeability and porosity.** We assume the permeability and porosity in both domains to be the same and demonstrate the convergence of the scheme using a manufactured solution. Modelling the flow of water and air, all soil parameters are listed in Table 2(a). For the relative permeabilities, $S$-$p_e$ relationships as well as the manufactured solution expressions we refer to Table 1.
Five domains with inner subdomain.

\[ \Omega \] with a simulation of the same setting, assuming constant nonwetting pressure, soil parameters running a test case with varying intrinsic permeabilities and porosities. The values used are listed in Table 2: TP–R coupling on two domains: soil parameters for same (a) and varying (b) intrinsic permeabilities and porosities.

The nomenclature of the interfaces follows the conventions introduced in section 4.

\[ \text{Parameter} \quad \Omega_1 \quad \Omega_2 \quad \text{PARAMETER} \quad \Omega_1 \quad \Omega_2 \]

(a) TP–R coupling on two domains: soil parameters for the case with the same intrinsic permeabilities and porosities. (b) TP–R coupling on two domains: case with varying intrinsic permeabilities and porosities.

Figure 3 shows the results for a simulation over 1500 time steps of size \( \tau = 0.001 \) on the time interval \( [0, T] = [0, 1.5] \) using a mesh size \( h \approx 0.071 \). The algorithm was set to terminate after the stopping criterion

\[ \| p_{\alpha, l}^{h,i} - p_{\alpha, l}^{h,i-1} \|_2 \leq \epsilon_s := 2 \cdot 10^{-6} \]

had been reached for all appearing \( l \) and \( \alpha \). Parameters of the TP–R solver were chosen as \( L_{\text{w},1} = 0.007 \) and \( L_{\text{w},2} = 0.005 \) for all phases \( \alpha \in \{ w, nw \} \) and \( \lambda_1^2 = \lambda_2^2 = 0.75 \). Figure 3(a) shows the relative error norms with respect to the exact solution over time, demonstrating that the accuracy remains invariant over time. The relative error of the nonwetting phase remains steadily around 0.009, that of the wetting phases below 0.01%. The nonwetting phase shows a greater approximation error, which is not unexpected, since no nonwetting phase equation is assumed in \( \Omega_1 \). Figure 3(b) displays the errors of the solver for the time step 1500 at time \( T = 1.5 \).

To determine how the use of the TP–R coupling in this situation affects both accuracy and performance, we compare with a simulation of the same setting, assuming constant nonwetting pressure, \( p_{\text{nw},1} \equiv 0 \) on \( \Omega_1 \) and use the LDD solver for two-phase flow equations in \( \Omega_1 \) and \( \Omega_2 \) (LDD-TP–TP solver, see [2] for details). As Figure 3(c) shows, the same precision is achieved in both cases, using either the LDD-TP–R or the LDD-TP–TP solver. The worst relative error can be observed for the nonwetting phase on \( \Omega_2 \), similarly to the case of the TP–R coupling shown in Figure 3(a). This suggests that the error is not dominated by the use of the TP–R coupling in place of the complete TP–TP coupling.

Naturally, the LDD-TP–TP solver is slower, having to solve an additional system. The subsequent errors at a fixed time step, Figure 3(d), show in addition, that the LDD-TP–TP solver needs 199 iterations in the 1500th time step to achieve the same stopping criterion. 29 iterations were needed in the first time step.

These results show that in situations in which the assumptions for the validity of the Richards equation hold, the hybrid LDD-TP–R solver excels over the LDD-TP–TP solver as there is a noticeable performance gain at virtually no loss of approximation accuracy.

**Heterogeneous intrinsic permeabilities and porosities.** We investigate numerically the influence of heterogeneous soil parameters running a test case with varying intrinsic permeabilities and porosities. The values used are listed in Table 2: TP–R coupling on two domains: soil parameters for same (a) and varying (b) intrinsic permeabilities and porosities.
Figure 3: TP–R coupling on two domains: Relative error norms (a) and subsequent errors at a fixed time step (b) for a simulation over 1500 time steps with same intrinsic permeabilities and porosities, and parameters $h \approx 0.071$, $\tau = 1 \times 10^{-3}$, $L_{w,1} = 0.007$ and $L_{w,2} = 0.005$, $\alpha \in \{w, nw\}$ and $\lambda_{w}^{12} = \lambda_{nw}^{12} = 0.75$. Relative error norms (c) and subsequent errors at a fixed time step (d) for a simulation of the same situation using the same parameters, but assuming a TP–TP coupling and assumed zero nonwetting phase.
2(b). Relative permeabilities, $p$–$S$ relationships and the exact solutions are the same as before, cf. Table 1. Grid parameters remain the same, namely $h \approx 0.071$, and $\tau = 0.001$ for the time step. Figure 4 shows results for a simulation comprising 1500 time steps using LDD-TP–R parameters $\lambda^w_{12} = 0.5$, $L_{w,1} = 0.007$ and $L_{\alpha,2} = 0.0005$, for $\alpha \in \{w, nw\}$. The stopping criterion was set to $\epsilon_s = 2 \cdot 10^{-6}$. As can be seen from Figure 4(a) the final approximation precision is unaffected by the more challenging soil parameters compared to the case with same intrinsic permeabilities. Mind the adjusted LDD-TP–R parameters $L_{\alpha,i}$ and $\lambda^w_{\alpha,i}$, however. In contrast to the previously shown case more iterations are needed to achieve the stopping criterion precision as is visible in Figure 4(b). Required iterations ranged from 63 iterations in the first time step to 348 iterations in time step 1500 shown in Figure 4(b).

Comparison to coarser time step size. Figure 5(a) and Figure 5(b) show the same situation but simulated with a coarser time step $\tau = 1 \cdot 10^{-2}$ reaching $T = 15$ after 1500 iterations. Interestingly, the error norms of all phases are in the same range as for the simulation with the finer time step, cf. Figure 5(a), albeit the errors of the wetting phases behaving noticeably worse. The increase of error that starts taking place around $T = 10$ is due to solver maxing out the maximal iterations number, 1000. After $t = 10$ the solver always iterates 1000 times but fails to reach the stopping criterion. The effect is shown in Figure 5b(c) depicting the 1000 iterations in time step $t_{1500}$ that the solver uses without reducing the subsequent errors sufficiently. Notably, convergence is very slow.

To compare the behaviour of the solver at a similar time than is depicted in Figure 4(b), Figure 5(b) shows the behaviour of the solver at $t = 1.67$. used to achieve the error tolerance $\epsilon_s = 1 \cdot 10^{-9}$. This means that up to this point in time, the LDD-TP–R solver needs less iterations in each time step of the simulation using $\tau = 0.01$ than in the example using $\tau = 0.001$, all the while achieving the same level of approximation error!

Influence of LDD-TP–R parameters. The LDD solver is sensitive to the numerical parameters. To illustrate this dependence, we revisit the previous example with varying permeabilities and porosities keeping the grid parameters the same, but varying the LDD-TP–R parameters: Figure 6 shows results of a simulation of 800 time steps using $\lambda^w_{12} = 4$, $L_{w,1} = 0.025$ and $L_{w,2} = 0.05$, $L_{nw,2} = 0.025$ as well as $\epsilon_s = 3 \cdot 10^{-6}$ as the stopping criterion. While the wetting phase error on $\Omega_1$ at around 0.01% compares to the one in Figure 4(a), Figure 6(a) shows that the errors of both phases on $\Omega_2$ are an order of magnitude worse than what has been shown in Figure 4(a). Accordingly, Figure 6(b) indicates by the high number of required iterations as well as the tilts observable in the subsequent error plots of the phases on $\Omega_2$, that the solver is struggling to find the solution. The required iterations to achieve the stopping criterion in this case ranged from 40 in the first time step to 577 in the 800th time step depicted in Figure 6(b).

5.2. Multi-domain computations

We advance from the two-domain examples to a multi-domain example featuring an inner subdomain, see Figure 2(b). We assume the Richards equation on subdomains 1, 5 and the full two-phase flow model on subdomains...
Figure 5: TP–R coupling on two domains: Relative error norms (a) and subsequent errors at a fixed time step (b) and (c) for the same situation as in Figure 4 but simulated using a coarser time step $\tau = 1 \cdot 10^{-2}$. 
During the calculation for the first time step, consequently, it was necessary to adjust the solver. The behaviour of the solver when gravity is taken into account is shown in Figure 9(b). To stabilise the nonwetting phase of the inner subdomain shows a degradation in accuracy whereas the other phase errors are in line with the two-domain examples. Figure 8(a) shows the relative error norms over time for a simulation of 1000 time steps of size $\tau = 1 \cdot 10^{-3}$. The LDD-TP–R parameters were set to $L_{w,l} = 0.01$, $L_{nw,l} = 0.004$ and $\lambda_{w}^{k} = 1$ as well as $\lambda_{nw}^{k} = 0.25$ for all $l \in J$ and $k \in J_k$. The error of the nonwetting phase of the inner subdomain $\Omega_3$, which is the worst of all phases and subdomains stays consistently below $5 \cdot 10^{-3}$. The nonwetting phases of $\Omega_2$ and $\Omega_4$ don’t surpass $1 \cdot 10^{-3}$ and all wetting phases stay below $2 \cdot 10^{-4}$. The nonwetting phase on the inner subdomain shows a degradation in accuracy whereas the other phase errors are in line with the two-domain examples.

Figure 8(b) shows the subsequent errors for the time step $t_{1000}$. The stopping criterion was $\epsilon_s = 1 \cdot 10^{-6}$ and was reached after 202 iterations. The first time step required 106 iterations.

**Including gravity.** The behaviour of the solver when gravity is taken into account is shown in Figure 9(b). To stabilise the solver, it was necessary to adjust the LDD-TP–R parameters to $L_{w,l} = 0.5$ and $\lambda_{w}^{l} = 4$ for all phases $\alpha = w, nw$, $l \in J$ and $k \in J_k$. A tilting behaviour in the subsequent error curves can be seen. This leads to plateaus in the curves and consequently, 370 iterations were required for time step $t_{1000} = 1.0$ to achieve the stopping criterion with $\epsilon_s = 5 \cdot 10^{-6}$. During the calculation for the first time step, 193 iterations were required. Albeit the solver exhibiting more struggle,
Figure 7: TP–R coupling on a five domain substructuring. Highlighted are the areas where different models are being used (a). The dotted areas features Richards equations and the striped areas the two-phase flow model. Unstructured triangular mesh (b) for mesh_resolution = 32.

6. Conclusions

In this work we proposed a new domain decomposition approach for hybrid two-phase flow systems. For new coupling conditions between domains with different two-phase flow models we developped an approach combining an $L$-type linearisation of the nonlinearities with a generalised nonoverlapping alternating Schwarz method, the LDD-TP–R solver. This formulation unifies the work of both, [1] and [2] on homogeneous two-phase models and allows for the treatment of complex modelling situations involving very heterogeneous soil parameters. The LDD-TP–R solver has been analysed rigorously on the time-discrete level. Numerical experiments for two- and multi-domain settings confirm the theoretical findings. In particular, they show the possible gain of computing time when using the hybrid model instead of employing an expensive full two-phase model on the entire domain.

As the LDD-TP–R solver linearises and decouples the substructured problem, it can either be used as a pure domain decomposition method, as a basis for effective parallel computation, or in a model-adaptive domain decomposition setting, in which an envisioned model change (two-phase/Richards) dictate the substructuring. Future work will be directed to design such an algorithm that might also include an adaptive choice of models based on our error analysis.

the overall approximation quality, despite oscillating a bit seems unaffected as Figure 9(a) shows. The error of the nonwetting phase of the inner subdomain remains under $5 \cdot 10^{-3}$ for all times, and all other errors are lower. The tilting behaviour and occurence of plateaus was observed for all examples featuring the inclusion of gravity and is most probably due to the inherent instability of standard finite element methods for advection-dominated regimes.
(a) Relative error norms $\|p^{c,n}_{\alpha,l} - p^{h,n}_{\alpha,l}\|_2/\|p^{c,n}_{\alpha,l}\|_2$ over time $t$ for all occurring $(\alpha,l)$.

(b) Subsequent errors $\|p^{h,i}_{\alpha,l} - p^{h,i-1}_{\alpha,l}\|_2$ over iteration $i$ at time step $n = 1000$, $t_n = 1.0$.

Figure 8: TP–R coupling on five-domain substructuring with inner subdomain: Relative error norms (a) and subsequent errors at a fixed time step (b) for a simulation over 1000 time steps with same intrinsic permeabilities and porosities, excluding gravity and parameters $h \approx 0.070 - 0.071$, $\tau = 1 \cdot 10^{-3}$, $L_{w,l} = 0.01$, $L_{rw,l} = 0.004$ and $\lambda^{lk}_{w} = 1$, $\lambda^{lk}_{rw} = 0.25$, $l \in \mathcal{I}$, $k \in \mathcal{J}$. We envisage that our approach is not only effective for the basic two-phase flow models encountered here but can be also extended to more complex model hierarchies for multi-phase flow and/or multi-component transport.
