ON DETERMINING THE HOMOLOGICAL CONLEY INDEX OF POINCARÉ MAPS IN AUTONOMOUS SYSTEMS

ROMAN SRZEDNICKI

Abstract. A theorem on computation of the homological Conley index of an isolated invariant set of the Poincaré map associated to a section in a rotating local dynamical system $\phi$ is proved. Let $(N, L)$ be an index pair for a discretization $\phi^h$ of $\phi$, where $h > 0$, and let $S$ denote the invariant part of $N \setminus L$; it follows that the section $S_0$ of $S$ is an isolated invariant set of the Poincaré map. The theorem asserts that if the sections $N_0$ of $N$ and $L_0$ of $L$ are ANRs, the homology classes $[u_j]$ of some cycles $u_j$ form a basis of $H(N_0, L_0)$, and for some scalars $a_{ij}$, the cycles $u_j$ and $\sum a_{ij} u_i$ are homologous in the covering pair $(\tilde{N}, \tilde{L})$ of $(N, L)$ and the homology relation is preserved in $(\tilde{N}, \tilde{L})$ under the transformation induced by $\phi^t$ for $t \in [0, h]$ then the homological Conley index of $S_0$ is equal to the Leray reduction of the matrix $[a_{ij}]$. In particular, no information on the values of the Poincaré map or its approximations is required. In a special case of the system generated by a $T$-periodic non-autonomous ordinary differential equation with rational $T/h > 1$, the theorem was proved in the paper M. Mrozek, R. Srzednicki, and F. Weilandt, SIAM J. Appl. Dyn. Syst. 14 (2015), 1348-1386, and it motivated a construction of an algorithm for determining the index.

0. Introduction

Let $v$ be a smooth vector-field on a manifold $X$. Assume that there is a smooth map $\theta$ from $X$ to the circle, represented as $\mathbb{R}/\mathbb{Z}$, such that the derivative of $\theta$ at $v(x)$ is positive for every $x$. It follows that the local dynamical system $\phi$ generated by $v$ is rotating, which roughly means that for every $x \in X$ the angle function $\theta(\phi(x, \cdot))$ is increasing. The transformation which sends a point $x$ of a section $X_0 = \theta^{-1}(a)$ to the point of its return to $X_0$ when the function $\theta(\phi(x, \cdot))$ makes a full rotation around the circle is called a Poincaré map; in the case $a = 0$ we denote it by $\Pi$.

The dynamics of $\Pi$ determines the qualitative properties of $\phi$; in particular, each periodic point of $\Pi$ is an initial point of a periodic trajectory of $\phi$ and chaotic dynamics of $\Pi$ encodes the corresponding chaotic behavior of trajectories of $\phi$.

In the present paper we focus our interest on isolated invariant sets of $\phi$; each such set is also an isolated invariant set for the discretization $\phi^t = \phi(\cdot, t)$ for every $t > 0$ and vice versa: an isolated invariant set $S$ of $\phi^t$ is an isolated invariant set of $\phi$. Moreover, $S_0 = S \cap X_0$ is an isolated invariant set of the map $\Pi$.

Both in the continuous-time setting (like $\phi$ above) and the discrete-time setting (i.e. the iterations of a map), properties of isolated invariant sets are investigated using their index pairs. An index pair $(N, L)$ for an isolated invariant set $S$ is a
pair of compact sets such that $S$ is contained in the interior of $N \setminus L$, the closure of $N \setminus L$ does not contain any larger invariant set then $S$, $L$ is positively invariant in $N$, and $L$ is an exit set of $N$. If $f$ is a discrete-time local dynamical system, the induced self-map $f_{(N,L)}$ of $N/L$ is continuous. The set of non-zero eigenvalues of the linear map $H(f_{(N,L)})$, i.e. the map induced by $f_{(N,L)}$ in homologies with coefficients in a field, does not depend of the choice of an index pair $(N,L)$. If the domain of $f$ is an ANR, the non-zero eigenvalues determine the Lefschetz numbers of $f_{(N,L)}$ and its iterates, and provide the fixed point index and the Lefschetz zeta function of $f$ in a neighborhood of $S$, hence they enable to detect fixed and periodic points of $f$, and, moreover, in the case of the smooth manifold, to estimate the entropy of $S$. Actually, the mentioned invariance of the eigenvalues follows from the invariance of the homological Conley index $CH(S,f)$ defined as the conjugacy class of the Leray reduction $R$ of $H(f_{(N,L)})$. In Section 1 we recall basic notions related to the homological Conley index; for a complementary information we refer to [B M1 M2 M4].

The above remarks indicate that some important facts on the dynamics generated by the vector-field $v$ in a neighborhood of an isolated invariant set $S$ can be detected by the index $CH(S_0,\Pi)$. However, in practice it is difficult to determine the index directly, even though it is stable with respect to small perturbations of the map $\Pi$. An essential obstacle is caused by the exponential growth of errors of numerical methods for trajectories of $\phi$; if the first return time to $X_0$ is large, usually it is impossible to get an approximation of $\phi$ with a required accuracy. There might be other obstacles; for example in systems with a strongly expansive direction the set of points such that the Poincaré map is defined can be too small to be detected since a vast majority of points has the escape time to infinity lesser then the first return time to the section. On the other hand, for a small enough step-size $h$, numerical methods provide satisfactory approximations of the discretization $\phi^h$ and there are computation algorithms which provide index pairs for discrete-time dynamical systems in a rigorous way (see [FT M5 MSW]).

We show that a suitable information on an index pair $(N,L)$ with respect to a discretization $\phi^h$ is sufficient to get the value of $CH(S_0,\Pi)$, without computing $\Pi$ or its approximations. In Theorem 2.1 being the main result of the present paper, a sequence $u_j$, $j = 1, \ldots, n$, of cycles of the pair $(N_0, L_0)$ is considered, where $N_0 = N \cap X_0$ and $L_0 = L \cap X_0$. It is assumed that $N_0$ and $L_0$ are ANRs, the homology classes $[u_j]$ form a basis of the graded vector space $H(N_0, L_0)$, and in the covering pair $(\bar{N}, \bar{L})$ of $(N, L)$ over $[0,1]$, each $u_j$ over $0$ is homologous to a linear combination $\sum a_{ij}u_i$ over 1 and the homology relation is preserved in $(\bar{N}, \bar{L})$ under the transformation induced by $\phi^t$ for $t \in [0,h]$. (A precise formulation of the latter assumption: $(u_j, \sum a_{ij}u_i)$ is an $h$-movable pair of contiguous cycles.) Theorem 2.1 asserts that $CH(S_0, \Pi)$ is equal to the Leray reduction of the matrix $[a_{ij}]$.

As a consequence of the theorem we prove that under the above assumptions on $(N,L)$ and $(N_0,L_0)$, if a homotopy $F: (N_0, L_0) \times [0,1] \to (N,L)$ satisfies $F(x,0) = x$ and $F(x,a) \in X_a$ for all $x \in N_0$ and $a \in [0,1]$, and $\phi^t(F(N_0,a)) \subset N$ and $\phi^t(F(L_0,a)) \subset L$ for all $a \in [0,1]$ and $t \in [0,h]$ then $CH(S_0,\Pi)$ is equal to the conjugacy class of $RH(F(\cdot,1))$; see Corollary 2.1.

In a restricted form, Theorem 2.1 first appeared in [MSW]. A system generated by a $T$-periodic non-autonomous ordinary differential equation was considered there and it was assumed that $T > h$ and $T/h$ is rational. It motivated a construction
of an algorithm for rigorous numerical computing the index. The general version of the theorem given in the present paper provides a theoretical background for extensions of the algorithm to other classes of ordinary differential equations.

This paper is organized as follows. In Section 1 we define all notions and we provide all theorems necessary to formulate and prove the results of the paper. Theorem 2.1 is formulated in Section 2 and its proof is provided in Section 3. The proof consists of several steps; its outline is presented at the beginning of that section. For convenience of the reader, in Appendix A we added proofs of some results from [MSW] in the notation and settings of the present paper.

1. Basic notation and terminology

1.1. Set theory, topology, and algebra. The symbols $\mathbb{R}$, $\mathbb{Z}$, and $\mathbb{N}$ denote, respectively, the sets of real numbers, the set of integers, and the set on non-negative integers. For a map $f$, the inclusion $f \subset X \times Y$ means that $f : D \to Y$ and $D$, the domain of $f$, is a subset of $X$ (the case $D = \emptyset$ is not excluded). If $A \subset X$, then the restriction of $f$ to $A \times Y$ is denoted as $f|_A$. If $A \subset X$, the identity on $X$, and if $n \in \mathbb{N}$, $n \geq 1$, by $f^n$ we denote the $n$-th iterate $f \circ \cdots \circ f$.

A pair $(X,A)$ of topological spaces is called a topological pair if $A \subset X$ and the topology of $A$ is induced from $X$. By a continuous map $f : (X,A) \to (Y,B)$ we mean a continuous $f : X \to Y$ such that $f(A) \subset B$. A topological pair $(X,A)$ is called compact provided both $X$ and $A$ are compact spaces. For a topological pair $(X,A)$ we define its quotient space $X/A$ as

$$X/A := X \setminus A \cup \{\ast\},$$

where $\ast$ is a point outside of $X$, and endow $X/A$ with the strongest topology for which the quotient map $q : X \to X/A$, given by $q(x) = x$ for $x \in X \setminus A$ and $q(A) = \ast$, is continuous. In particular, $X/\emptyset = X \cup \{\ast\}$ has the direct sum topology. We assume that $\ast$ is the same for all constructions of the quotient spaces related to the results of the present paper. It follows, in particular, that $\ast$ is a fixed point of the map $X/A \to Y/B$ generated by a continuous map $(X,A) \to (Y,B)$.

By a graded vector space we mean a direct sum $\bigoplus_{p \in \mathbb{Z}} V_p$ of vector spaces. A graded linear map $\phi : V \to W$ of graded vector spaces $V$ and $W$ is defined as $\bigoplus_p \phi_p$, where $\phi_p : V_p \to W_p$. A graded matrix $A = \bigoplus_p A_p$ is defined as the block-diagonal matrix generated by the matrices $A_p$. If the bases of $V$ and $W$ are fixed, we identify a matrix $A$ with the linear map determined by $A$ in these bases. In the whole text we omit the symbol $\circ$ when composing linear maps.

1.2. The Leray reduction. By an endomorphism we mean a (graded) linear map $\alpha : V_\alpha \to V_\alpha$ of a (graded) vector space $V_\alpha$ into itself. If, moreover, it is an isomorphism, it is called an automorphism. Two automorphisms $\alpha$ and $\beta$ are conjugated, denoted $\alpha \cong \beta$, if there exists an isomorphism $\gamma$ such that $\beta \gamma = \gamma \alpha$. The Leray reduction $R$ is a transformation of $\alpha$ onto an automorphism $R\alpha$ given as follows. Define

$$gker(\alpha) := \bigcup_{n \in \mathbb{N}} \ker(\alpha^n),$$
the generalized kernel of \( \alpha \) and set \( \nabla_\alpha := V_\alpha / \ker(\alpha) \). Let \( \overline{\alpha} \) denote the induced endomorphism of \( \nabla_\alpha \). Define
\[
RV_\alpha := \text{gim}(\overline{\alpha}) := \bigcap_{n \in \mathbb{N}} \text{im}(\overline{\alpha}^n),
\]
the generalized image of \( \overline{\alpha} \), and define \( R\alpha \) as \( \overline{\alpha} \) restricted to \( RV_\alpha \rightarrow RV_\alpha \).

**Proposition 1.1.** Let \( \alpha: V_\alpha \rightarrow V_\alpha \) and \( \beta: V_\beta \rightarrow V_\beta \) be linear endomorphisms, let \( \gamma: V_\alpha \rightarrow V_\beta \) and \( \delta: V_\beta \rightarrow V_\alpha \) be linear maps, and let \( r \in \mathbb{N} \) be such that the diagrams
\[
\begin{array}{ccc}
V_\alpha & \overset{\alpha}{\longrightarrow} & V_\alpha \\
\downarrow \gamma & & \downarrow \gamma \\
V_\beta & \overset{\beta}{\longrightarrow} & V_\beta
\end{array}
\quad
\begin{array}{ccc}
V_\alpha & \overset{\alpha^r}{\longrightarrow} & V_\alpha \\
\downarrow \gamma & & \downarrow \gamma \\
V_\beta & \overset{\delta}{\longrightarrow} & V_\beta
\end{array}
\]
commute. Then \( R\alpha \cong R\beta \).

Actually, the same result can be obtained for a general class of functors, called *normal consistent retractors* and a proof of that more general result is contained in [MSW, Appendix A]. Below, in Subsection 1.1 of the appendix we provide a direct proof of Proposition 1.1.

### 1.3. Singular homologies.

In the present paper \( H \) denotes the singular homology functor with coefficients in a field \( \mathbb{F} \). Recall briefly its construction (we refer to [M] for a detailed exposition). Let \( \Delta^d \) denote the standard \( d \)-dimensional simplex, i.e. the convex envelope of the canonical basis of \( \mathbb{R}^{d+1} \). A *singular simplex* on a topological space \( X \) is a continuous map \( \Delta^d \rightarrow X \). By \( S(X) = \bigoplus_d S_d(X) \), the graded vector space of *singular chains*, we mean the set of all formal linear combinations of singular simplexes with coefficients in \( \mathbb{F} \). This is a chain complex and the corresponding boundary operator is denoted \( \partial \). The *support* \(|c|\) of a chain \( c = \sum_i \alpha_i \sigma_i \in S_d(X) \) is defined as
\[
|c| := \bigcup_{i: \alpha_i \neq 0} \sigma_i(\Delta^d).
\]
A continuous map \( f: X \rightarrow Y \) induces a chain map \( S(f): S(X) \rightarrow S(Y) \). Let \( A \subset X \) and let \( i: A \hookrightarrow X \) be the inclusion map. If \( A \subset X, \ c \in S(X), \) and \( |c| \subset A \), we treat \( c \) also as an element of \( S(A) \), hence \( S(i) \) is equal to the inclusion homomorphism \( S(A) \rightarrow S(X) \). For the pair \((X, A)\), the vector spaces of singular *cycles, boundaries*, and *homologies* are denoted, respectively,
\[
Z(X, A) := \{ x \in S(X): \partial x \in S(A) \},
\]
\[
B(X, A) := \partial S(X) + S(A),
\]
\[
H(X, A) := Z(X, A) / B(X, A).
\]
The *homology class* of \( z \in Z(X, A) \) in \( H(X, A) \) is denoted \([z]\). A continuous map \( f: (X, A) \rightarrow (Y, B) \) induces a linear map \( H(f): H(X, A) \rightarrow H(Y, B) \) given by \( H(f)[z] := [S(f)z] \). For \( t \in [0, 1] \), let \((\text{id}, t): (X, A) \rightarrow (X, A) \times [0, 1] \) be defined as \( x \rightarrow (x, t) \). By a *prism operator* \( P: S(X, A) \rightarrow S((X, A) \times [0, 1]) \) we mean a chain homotopy joining the chain maps \( S(\text{id}, 0) \) and \( S(\text{id}, 1) \), i.e.
\[
S(\text{id}, 0) - S(\text{id}, 1) = \partial P + P \partial.
\]
A metrizable space $X$ is called an absolute neighborhood retract (shortly: an ANR) if it is a neighborhood retract in every metrizable space in which it is embedded as a closed subset. If $(X, A)$ is a pair of compact ANRs then its homologies are finite dimensional and the quotient map induces an isomorphism $H(X, A) \to H(X/A,*).

1.4. Local dynamical systems. Let $X$ be a topological space. By a local dynamical system (or, more precisely, a continuous-time local dynamical system) on $X$ we mean a continuous map $\phi: D \to X$, where $D$ is an open subset of $X \times \mathbb{R}$ and the set $D_x := \{t \in \mathbb{R}: (x, t) \in D\}$ is an open interval containing 0 for each $x \in X$, such that if $t \in D_x$ then $s + t \in D_x$ if and only if $s \in D_{\phi(x,t)}$, and

$$\phi(x,0) = x, \quad \phi(\phi(x,t),s) = \phi(x,s+t).$$

If $D = X \times \mathbb{R}$, $\phi$ is called simply a dynamical system. By a semi-dynamical system (or continuous-time semi-dynamical system) on $X$ we mean a continuous map $\phi: X \times [0,\infty) \to X$ satisfying (1). For $A \times J \subset D$ we write $\phi(A,J)$ instead of $\phi(A \times J)$. If $J$ is an interval contained in the domain of $\phi(x,\cdot)$, the set $\phi(x,J)$ is called a segment. Its length is equal to the length of $J$. By $\phi(x)$ and $\phi^+(x)$, the trajectory and, respectively, the positive semi-trajectory of $x$, we mean the segment $\phi(x,J)$ with $J = D_x$ and, respectively, $J = D_x \cap [0,\infty)$, i.e. the set of all $\phi(x,t)$ such that $\phi(x,\cdot)$ is defined at $t$ and, if the positive semi-trajectory is considered, $t \geq 0$. In the case $D_x = \mathbb{R}$, $\phi(x)$ is called a full trajectory.

For a continuous map $f: D \to X$, where $D$ is open in $X$, the sequence $f^n$ of the iterates of $f$ is called a discrete-time local semi-dynamical system (shortly: $f$ is a discrete-time local dynamical system). If, moreover, the domain of $f$ is equal to $X$ (i.e. $f: X \to X$), it is called a discrete-time semi-dynamical system. In this case a positive semi-trajectory of $x$ is defined as the set of all $f^n(x)$, $n \in \mathbb{N}$, and by a full trajectory of $x$ we mean a set $\{x_n: n \in \mathbb{Z}\}$ such that $x_0 = x$, and $f(x_n) = x_{n+1}$ for each $n \in \mathbb{Z}$.

1.5. Isolated invariant sets, index pairs, and the Conley index. In the sequel we assume that $X$ is a locally compact metrizable space $X$. Let $S \subset X$. Both in the continuous-time and discrete-time dynamical systems, $S$ is called invariant if each $x \in S$ has a full trajectory and that trajectory is contained in $S$. An example of invariant set with respect to a continuous-time system $\phi: D \to X$ is the omega-limit set of a point $x \in X$ for which $[0,\infty) \subset D_x$. It is defined as as

$$\omega(x) := \bigcap_{t > 0} \text{cl} \phi(x,[t,\infty)).$$

Let $A \subset X$ and let $\phi$ be an arbitrary local dynamical system. The invariant part of $A$ is the maximal invariant set contained in $A$. It is denoted as $\text{Inv}_\phi A$ or $\text{Inv} A$ if it does not lead to confusions. If $A$ is closed then $\text{Inv} A$ is also closed. A compact set $N \subset X$ is called an isolating neighborhood if $\text{Inv} N \subset \text{int} N$; equivalently: no trajectory contained in $N$ intersects the boundary of $N$. A compact set $S \subset X$ is called isolated invariant if there exists an isolating neighborhood $N$ such that $S = \text{Inv} N$. In this case $N$ is called an isolating neighborhood of $S$.

A pair $(N,L)$ of compact subsets of $X$ is called isolating if

$$\text{Inv} \text{cl}(N \setminus L) \subset \text{int}(N \setminus L).$$
An isolating pair \((N, L)\) is called an \textit{index pair} if \(L\) is \textit{positively invariant in} \(N\) and \(L\) is \textit{an exit set of} \(N\). In the case of a continuous-time local dynamical system \(\phi : D \to X\) this means

\[
\forall x \in L, \ t > 0: \{ \phi(x, [0, t]) \subset N \Rightarrow \phi(x, t) \in L \}\quad (L \text{ is positively invariant in } N),
\]

\[
\forall x \in N, \ t > 0: \{ \phi(x, t) \notin N \Rightarrow \exists t' \in [0, t): \phi(x, [0, t']) \subset N, \ \phi(x, t') \in L \}\quad (L \text{ is an exit set of } N),
\]

while in the case of a discrete-time local dynamical system \(f : D \to X\) it is assumed that the set \(N\) is contained in the domain \(D\) and

\[
f(L) \cap N \subset L \quad (L \text{ is positively invariant in } N),
\]

\[
\text{cl}(f(N) \setminus N) \cap N \subset L \quad (L \text{ is an exit set of } N).
\]

(For a pair satisfying the above conditions the term “weak index pair” was used in [MSW].) If \(S = \text{Inv cl}(N \setminus L)\), the index pair \((N, L)\) is called an \textit{index pair for} \(S\).

**Proposition 1.2.** If \((N, L)\) is an index pair with respect to a continuous-time local dynamical system \(\phi\) then the map

\[
\phi_{(N,L)} : N/L \times [0, \infty) \to N/L,
\]

\[
\phi_{(N,L)}(x, t) := \begin{cases} \phi(x, t), & \text{if } \phi(x, [0, t]) \subset N \setminus L, \\ * & \text{otherwise} \end{cases}
\]

is a semi-dynamical system on \(N/L\).

In the above statement “otherwise” includes the case \((x, t)\) is not contained in the domain of \(\phi\). Similarly through the rest of the paper.

**Proposition 1.3.** If \((N, L)\) is an index pair with respect to a discrete-time local dynamical system \(f\) then the map

\[
f_{(N,L)} : N/L \to N/L,
\]

\[
f_{(N,L)}(x) := \begin{cases} f(x), & \text{if } x, f(x) \in N \setminus L, \\ * & \text{otherwise} \end{cases}
\]

is continuous.

The \textit{homological Conley index} of an invariant set \(S\) in a discrete-time local dynamical system \(f\), denoted \(\text{CH}(S, f)\), is defined as the conjugacy class of the automorphism \(RH(f_{(N,L)})\) for an index pair \((N, L)\), where \(R\) is the Leray reduction. It does not depend on the choice of \((N, L)\).

1.6. \textbf{Rotating systems and Poincaré maps.} We represent the circle as the quotient group \(\mathbb{R}/\mathbb{Z}\). Assume that \(\theta : X \to \mathbb{R}/\mathbb{Z}\) is a continuous map. For \(a \in \mathbb{R}\) set \(X_a := \theta^{-1}(a + \mathbb{Z})\), hence \(X_a = X_b\) if \(a = b \mod 1\). Define another locally compact metrizable space

\[
\bar{X} := \{(x, a) \in X \times \mathbb{R} : x \in X_a\}.
\]

Let

\[
\zeta : \bar{X} \ni (x, a) \to x \in X, \quad \bar{\theta} : \bar{X} \ni (x, a) \to a \in \mathbb{R}
\]
be the projections. The map $\zeta$ is a covering and the diagram
\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\delta} & \mathbb{R} \\
\bigcup & & \\
X & \xrightarrow{\theta} & \mathbb{R}/\mathbb{Z}
\end{array}
\]
commutes. Let $\phi: D \to X$ be a continuous-time local dynamical system on $X$. It
generates a local dynamical system $\tilde{\phi}$ on $\tilde{X}$ as follows. Let $y \in \tilde{X}$
and let $t \in D_{\zeta(y)}$. Assume $t > 0$, hence $\{\zeta(y)\} \times [0, t] \subset D$. Set $\tilde{\phi}(y, t)$ as the terminal point of the
lift of the path $[0, t] \in s \to \phi(\zeta(y), s) \in X$ starting at $y$. In an analogous way we
deal with the case $t < 0$. Thus $D_y$, the domain of $\tilde{\phi}(y, \cdot)$, is equal to $D_{\zeta(y)}$. In the
sequel we assume that $\phi$ is rotating, which means that for every $y \in Y$ and $t > 0$
such that $t \in D_{\zeta(y)}$,
\[\tilde{\theta}(y) < \tilde{\phi}(y, t).\]

**Proposition 1.4.** For every $y \in \tilde{X}$, the omega-limit set $\omega(y)$ is empty.

For $a \in \mathbb{R}$ define $\tilde{X}_a$ as $\tilde{\theta}^{-1}(a)$, hence $\tilde{X}_a := X_a \times a$. Let $y \in \tilde{X}$ and assume that $\tilde{\phi}(y) \cap \tilde{X}_a \neq \emptyset$. Define the access time of $y$ to $\tilde{X}_a$ as
\[\tau_a(y) := \begin{cases} \sup \{t \in D_y: \tilde{\phi}(y, t) \leq a\} \in [0, \infty), & \text{if } a \geq 0, \\ \inf \{t \in D_y: \tilde{\phi}(y, t) \geq a\} \in (-\infty, 0], & \text{if } a \leq 0. \end{cases}\]
i.e. $\tau_a(y)$ is equal to the time at which the trajectory of $y$ reaches $\tilde{X}_a$. Define a map
\[\tau \subset (\tilde{X} \times \mathbb{R}) \times \mathbb{R}, \quad \tau(y, a) := \tau_a(y).\]

**Proposition 1.5.** The map $\tau$ is continuous, its domain is open, and the map
\[\Phi \subset (\tilde{X} \times \mathbb{R}) \times \tilde{X}, \quad \Phi(y, t) := \tilde{\phi}(y, \tau(y))\]
is a local semi-dynamical system on $\tilde{X}$.

Let $t$ be a real number. If $a = b \mod 1$ then $\tau_{a+t}(x, a) = \tau_{b+t}(x, b)$, hence
\[T_t(x) := \tau_{a+t}(x, a)\]
is independent of the choice of $a \in \theta(x)$. By Proposition 1.5 the formula
\[\Phi(x, t) := \phi(x, T_t(x)).\]
defines another rotating local dynamical system $\Phi$ on $X$. We call it the translation
system associated to $\phi$ and call $\Phi_t := \Phi(\cdot, t)$ a translation map. Even if $\phi$ is a
dynamical system, $\Phi$ can be local, i.e. its domain is an essential subset of $X \times \mathbb{R}$. For $a \in \mathbb{R}$ we treat the translation map as a map
\[\Phi_t \subset X_a \times X_{a+t}.\]
In particular, if $t = 1$ we call $T := T_1$ the return time map and
\[\Phi_1 = \phi(\cdot, T(\cdot)) \subset X_a \times X_a\]
a Poincaré map. In the case $a = 0$, we denote it $\Pi$. Thus, for $n \in \mathbb{N}$,
\[\Pi^n = \Phi_n \subset X_0 \times X_0.\]
For $h \in \mathbb{R}$ we denote by $\phi^h$ the map $\phi(\cdot, h) \subset X \times X$. If $h > 0$, we call it a
discretization of $\phi$. 
Proposition 1.6. Let $S \subset X$. The following conditions are equivalent.

(a) $S$ is an isolated invariant set with respect to $\phi$,
(b) for every (equivalently: for some) $h \neq 0$, $S$ is an isolated invariant set with respect to $\phi^h$,
(c) $S$ is an isolated invariant set with respect to $\Phi$,
(d) for every (equivalently: for some) $t \neq 0$, $S$ is an isolated invariant set with respect to $\Phi_t$,
(e) for every (equivalently: for some) $a \in \mathbb{R}$, $S_a$ is an isolated invariant set with respect to the Poincaré map $\Phi_1 \subset X_a \times X_a$ and $S_{a+t} = \Phi_t(S_a)$ for each $t$.

The equivalence of the conditions (a) and (b) was proved in [MS3] (this result is valid for all local dynamical systems), hence also (c) holds if and only if (d) is satisfied. Since the sets of trajectories of $\phi$ and $\Phi$ are equal each to the other, $S$ has the same isolating neighborhoods in both systems and the equivalence of (a) and (c) is obvious. The equivalence of (c), (d), and (e) is essentially stated as [MSW, Prop. 4.1]. We complete the proof of Proposition 1.6 in Subsection A.2 of the appendix.

Since the map $t \to T_i(x)$ is increasing for each $x \in X$, the following result holds.

Proposition 1.7. A pair $(N, L)$ of compact subsets of $X$ is an index pair with respect to $\phi$ if and only if it is an index pair with respect to the translation system $\Phi$. □

1.7. Contiguous cycles. For $Z \subset X$ and $a \in \mathbb{R}$ define

$$Z_a := Z \cap X_a, \quad \tilde{Z}_a = Z_a \times a.$$ 

Let $J \subset \mathbb{R}$ be an interval. Define

$$\tilde{Z}_J := \{(x, a) \in \tilde{X} : a \in J, \ x \in Z_a\},$$

in particular, $\tilde{X}_J = \tilde{\theta}^{-1}(J)$. In the case $J = \mathbb{R}$ we write $\tilde{Z}$ instead of $\tilde{Z}_R$, hence

$$\tilde{Z}_J = \tilde{Z} \cap \tilde{\theta}^{-1}(J) = \tilde{Z} \cap \tilde{X}_J.$$ 

Let $h > 0$, let $(N, L)$ be an index pair with respect to $\phi^h$, and let $a, b \in \mathbb{R}$, $a \leq b$. Assume that $u \in Z(N_a, L_a)$ and $v \in (N_b, L_b)$. The pair $(u, v)$ is called a pair of contiguous cycles over $[a, b]$ if there exist chains $c \in S(\tilde{N}_{[a, b]})$ and $d \in S(\tilde{L}_{[a, b]})$ such that

$$u \times a - v \times b = \partial c + d,$$

where $u \times a \in Z(\tilde{N}_a, \tilde{L}_a)$ and $v \times b \in Z(\tilde{N}_b, \tilde{L}_b)$ are induced by the maps $x \to (x, a)$ and, respectively, $x \to (x, b)$. A pair of contiguous cycles $(u, v)$ is $h$-movable if for some chains $c$ and $d$ satisfying (2),

$$\tilde{\phi}(|c|, [0, h]) \subset \tilde{N}, \quad \tilde{\phi}(|d|, [0, h]) \subset \tilde{L}.$$ 

We call such chains $c$ and $d$ associated to $(u, v)$.

Proposition 1.8. If $(u, v)$ is an $h$-movable pair of contiguous cycles over $[a, b]$ and $a < b$ then

$$\tilde{\phi}(|u \times a|, [0, h]) \subset \tilde{N}, \quad \tilde{\phi}(|\partial u \times a|, [0, h]) \subset \tilde{L},$$

$$\tilde{\phi}(|v \times b|, [0, h]) \subset \tilde{N}, \quad \tilde{\phi}(|\partial v \times b|, [0, h]) \subset \tilde{L}.$$
Proof. Since
\[ \tilde{\phi}([u \times a - v \times b], [0, h]) = \tilde{\phi}([\partial c - d], [0, h]) \subset \tilde{\phi}([\partial c], [0, h]) \cup \tilde{\phi}([d], [0, h]) \subset \tilde{N} \]
and \(|u \times a| \cap |v \times b| = 0\), two of the required inclusions are satisfied. Since
\[ \tilde{\phi}([\partial u \times a - \partial v \times b], [0, h]) = \tilde{\phi}([d], [0, h]) \subset \tilde{L} \]
and \(|\partial u \times a| \cap |\partial v \times b| = 0\), the other two inclusions also hold. \(\square\)

The following two results are also consequences of the fact that the support of \(\tau\) is a rational number, a proof of Theorem 2.1 is essentially given in Proposition 1.6, that if \(\{u_i\}; j = 1, \ldots, n\) is a basis of \(H(N, 0, L)\) such that \(\{u_j\}; j = 1, \ldots, n\) is a basis of \(H(N, 0, L)\) then \(CH(S_0, \Pi) = \) is equal to the conjugacy class of the Leray reduction RA.

Recall that \(\phi\) is a rotating local dynamical system on \(X\). It follows by Proposition 1.10 that if \(S\) is an isolated invariant set for \(\phi^h\) with some \(h > 0\) then \(S_0\) is an isolated invariant set for the Poincaré map \(\Pi\).

**Theorem 2.1.** Let \(h > 0\) and let \((N, L)\) be an index pair for an isolated invariant set \(S\) with respect to \(\phi^h\). If \(N_0\) and \(L_0\) are ANRs, \(n = \dim H(N_0, L_0)\), \(A = [a_{ij}]\) is a graded \((n \times n)\)-matrix over \(\mathbb{R}\), and \((u_j; \sum_{i=1}^n a_{ij} u_i)\) for \(j = 1, \ldots, n\) is a h-movable pair of contiguous cycles over \([0, 1]\) such that \(\{u_j\}; j = 1, \ldots, n\) is a basis of \(H(N_0, L_0)\) then \(CH(S_0, \Pi) = \) is equal to the conjugacy class of the Leray reduction RA.

Under the assumptions that \(X = X_0 \times \mathbb{R}/\mathbb{Z}\), the return time map \(T\) is constant, \(T > h\), and \(T/h\) is a rational number, a proof of Theorem 2.1 is essentially given in [MSW]. In Section 3 we prove the theorem in full generality.

**Corollary 2.1.** Let \(h > 0\), \((N, L)\), and \((N_0, L_0)\) satisfy the assumptions of Theorem 2.1 and let \(F_a; (N_0, L_0) \to (N, L)\) for \(a \in [0, 1]\) be a family of maps such that
\[ F: (N_0, L_0) \times [0, 1] \to (N, L), \quad F(x, a) := F_a(x) \]
is a continuous. If \(F_0 = \text{id}_{N_0}\) and
\[ \phi^t(F_a(N_0)) \subset N, \quad \phi^t(F_a(L_0)) \subset L \]
for all \(a \in [0, 1]\) and \(t \in [0, h]\) then \(CH(S_0, \Pi) = \) is equal to the conjugacy class of \(RH(F_1)\).

**Proof.** Let
\[ \tilde{F}: (\tilde{N}_0, \tilde{L}_0) \times [0, 1] \to (\tilde{N}, \tilde{L}) \]
be the lift of \(F\) and let \(u_i \in Z(N_0, L_0), i = 1, \ldots, n\) be such that \(\{u_i\}; i = 1, \ldots, n\) form a basis of \(H(N_0, L_0)\). Then \((u_i, S(F_i)u_i)\) is an h-movable pair of contiguous cycles over \([0, 1]\), since we can set \(S(F)P(u_i \times 0) \in S(\tilde{N}_0, [0, 1])\) and \(S(F)P\partial(u_i \times 0) \in S(\tilde{L}_0, [0, 1])\), and
\[ P: S(\tilde{N}_0, \tilde{L}_0) \to S((\tilde{N}_0, \tilde{L}_0) \times [0, 1]) \]
is a prism operator. Let $A$ be the matrix of $H(F_1)$ with respect to the basis \{\{u_i\}\}.

Then there exist chains $c \in S(N_1)$ and $b \in S(L_1)$ such that

$$S(F_1)u_i \times 1 - Au_i \times 1 = \partial c + b,$$

hence $(u_i, Au_i)$ is also an $h$-movable pair of contiguous cycles over $[0,1]$ by Proposition 1.1 and the result follows by Theorem 2.1.

3. Proof of Theorem 2.1

3.1. An outline of the proof. Here we sketch the main steps of the proof; sometimes they appear in a different form and in a different order in the rigorous arguments presented in the following subsections.

1st step. We should find an index pair for $\Pi$. For this purpose we construct sets $N', L', N''$, and $L''$ such that

$$(N, L) \supset (N', L) \subset (N', L') \supset (N'', L'')$$

and $(N', L)$ is an index pairs with respect to $\phi^h$, $(N', L')$ is an index pair with respect to both $\phi$ and $\phi^h$, and $(N'', L'')$ is an index pair for the translation map $\Phi^1$. Then $(N_0', L_0')$ is the required index pair. By the construction, $N_0'/L_0' = N_0''/L_0''$, hence $C\{S_0, \Pi\}$ is equal to the conjugacy class of $RH(\Phi^1)$, where $\Phi^1$ is the self-map of $N_0'/L_0'$ induced by $\Phi^1$.

2nd step. In order prove that $RH(\Phi^1) \cong RA$ we apply Proposition 1.1. We should determine an $r \in \mathbb{N}$ and homomorphisms $\gamma$ and $\delta$ between $H(N_0, L_0)$ and $H(N_0'/L_0', *)$ which appear in the corresponding commutative diagrams. We set $r = k + m$, where $k$ and $m$ relate to the maximal sizes of the sequences $x, \phi^h(x), \phi^{2h}(x), \ldots$ contained in $L' \setminus L$ and $N \setminus N'$, respectively. The map $\gamma$ is constructed as follows. Denote by $U$ the linear span of the cycles $u_i$; we treat the matrix $A$ as an endomorphisms of $U$ generated by the map $u_i \to \sum_j a_{ij} u_i$. For $u \in U$ and $\ell \in \mathbb{N}$, the pair of contiguous cycles $(u, A^\ell u)$ over $[0, \ell]$ is $h$-movable. It follows, in particular, that $u \in U$ can be treated as a chain in $N'$ and therefore also as a cycle in $(N_0', L_0)$. Define the class $[u_i]$ as the class of the cycle induced from $u_i$ by the quotient map $N' \to N'/L'$. The classes $[u_i]$ form a basis of $H(N_0, L_0)$, hence the homomorphism $\gamma$ is defined. The map $\delta$ will be determined later.

3rd step. Since we will use $h$-movable contiguous pairs of cycles, one should lift the considered index pairs in the space $X$ to the corresponding pairs in $\tilde{X}$. These pairs are non-compact, hence in order to keep the notation of the theory of isolated invariant sets it is convenient to switch to the quotient space $Y$ of $\tilde{X}$ corresponding to the quotient homomorphism $\mathbb{R} \to \mathbb{R}/p\mathbb{Z}$ for $p > k + m$ large enough. There are derived systems $\psi$ and $\Psi$ in $Y$ corresponding to $\phi$ and $\Phi$, and the index pairs $(Q, P)$, $(Q', P)$, etc., corresponding to the index pairs $(N, L)$, $(N', L)$, etc., respectively. All dynamics related to $\psi$ within the range of $Y$ over the interval $[0, p)$ is the same as the corresponding dynamics of $\tilde{\psi}$. In particular, the notion of the $h$-movability of contiguous cycles over intervals contained in $[0, p)$ has an equivalent formulation in terms of $Y$ and $\psi$.

4th step. For $\ell = 0, \ldots, k + m$ we define homomorphisms $\Gamma_\ell$ from $H(Q_\ell, P_\ell)$ to $H(Q_{\ell+1}, P_{\ell+1})$ as the composition of $\gamma$: $H(N_0, L_0) \to H(N_0'/L_0', *)$ with the isomorphisms induced by the map $x \to (x, \gamma)$ and its inverse, and for $\ell < k + m$ we denote also by $A$ a homomorphisms $H(Q_\ell, P_\ell) \to H(Q_{\ell+1}, P_{\ell+1})$ corresponding to the endomorphism of $H(N_0, L_0)$ induced by the matrix $A$. In order to get the equation
$H(\Psi'_i)\gamma = \gamma A$ we should prove that $H(\Psi'_i)\Gamma_0 = \Gamma_1 A$. To this purpose we denote by $C$ and $B$ the sets of points $y$ such that $\psi(y, [0, h]) \subset Q$ and $\psi(y, [0, h]) \subset P$, respectively, and we define a map $F$ from $(C_{[0,1]}, B_{[0,1]})$ to $(Q'_i/P'_i, *)$ which collapses $C_{[0,1]}$ along the trajectories of the semi-dynamical system $\psi(Q', P')$. Then the homomorphism $S(F)$ applied to chains associated to each pair $(u_i, Au_i)$ of contiguous cycles over $[0,1]$ provides the required equality.

**5th step.** In order to define the map $\delta$ required in the 2nd step, at first we construct a continuous map $G$ from $(C_{[0,1]}, B_{[0,1]})$ to $(Q'_i/P'_i, *)$. If $\tau_k$ is defined at $y \in C_{[0,1]}$, there are $\overline{y} \in [0, h]$ and $\overline{T} \in \mathbb{N}$ such that $\tau_k(y) = \overline{y} + \overline{T} k$. We set $G(y)$ as the image of $\psi(\overline{y}, \overline{T} k)$ under the $\overline{T}$-iterate the map $\psi(Q', P')$. The number $k$ and the set $P'$ are chosen in the way that $G_{|C_0}$ factors through $C_0/P' = Q'_0/P'_0$. The induced continuous map $Q'_0/P'_0 \to Q'_k/P'_k$ is denoted $r$. We prove directly that $r$ composed with the quotient map $j': Q'_k/P_k \to Q'/P'_k$ is equal to $\Psi'_k$. For $u \in U$, we denote by $\overline{u}$ the chain induced from $u \times k$ by the quotient map $Q'_k \to Q'_k/P_k$.

We prove that the classes $[\overline{u}]$ are linearly independent in $H(Q'_k/P_k, \ast)$. In an analogous way as $S(F)$ in the 4th step, the homomorphism $S(G)$ applied to chains associated to the pair of contiguous cycles $(u_i, A^k u_i)$ over $[0, 1]$ provides the equation $H(r)\Gamma_0[u_i \times 0] = [\overline{u}]$ in $H(Q'_k/P_k, \ast)$, where $u_i = A^k u_i$.

**6th step.** We take an arbitrary homology class $[z]$ in $H(Q'_k/P_k, \ast)$. Its image under the homomorphism induced by the inclusion map $Q'_k/P_k \to Q_k/P_k$ is equal to the image of $[\overline{u}]$ for exactly one $u \in U$. We define the map $\Delta: H(Q'_0/P'_0, \ast) \to H(Q_{k+m}/P_{k+m})$ as the composition of $H(r)$, the map $[z] \to [u \times k]$, and $A^m$. Consequently, we get the equation $\Delta \Gamma_0 = A^{k+m}$ by the 5th step. By the choice of $m$ we are able to construct a continuous map $d: Q_k/P_k \to Q'_k[P_{k+m}]/P_{k+m}$ such that $S(d)[z]$ is homologous to $S(d)[\overline{u}]$. Furthermore, there is a continuous map $J$ which collapses $Q'_k[P_{k+m}]/P_{k+m}$ to $Q'/P'_{k+m}$ along the trajectories of the semi-dynamical system $\psi(Q', P')$. We apply $S(J)$ to the above homologous cycles and as a result we conclude that $H(\Psi'_k)\Gamma_0[u \times k] = H(\psi_k)H(J)[z]$. Since $J \circ r = \Psi'_k$, we should prove that $H(\Psi'_k)\Gamma_k = \Gamma_{k+m}A^m$ by the 4th step, the equation $\Gamma_{k+m}(\ast) = H(\psi_k)A^m$ holds. Thus, we may define $\Delta$ composed with the isomorphisms induced by the maps $x \to (x, 0)$ and $(x, k + m) \to x$, satisfies $\delta = A^{k+m}$ and $\gamma = H(\Psi'_k)A^{k+m}$, hence the theorem follows.

### 3.2. Auxiliary index pairs.

Define

$$K := \bigcup \{ \sigma \subset N : \sigma \text{ is a segment starting at a point in } L \},$$

$$M := \bigcup \{ \sigma \subset N : \sigma \text{ is a segment of length } h \},$$

$$N' := K \cup M.$$

**Proposition 3.1.**

(a) $(N', L)$ is an index pair for $S$ with respect to $\phi^h$,

(b) $\phi^h(N') \cap N \subset N'$,

(c) $(N', K)$ is an index pair for $S$ with respect to $\phi$.

This result was proved in [MSW Sec. 5.2]. We provide its proof within the settings of the present paper in Subsection [A.3] of the appendix.

**Lemma 3.1** ([Sa], Lemma 5.3). There exists a continuous function $\alpha: N' \to [0, 1]$ such that
The time map $T$ is defined on the set $\alpha^{-1}(1)$. Let $W$ be a compact neighborhood of $\alpha^{-1}(1)$ contained in the domain of $T$. Set

$$
\lambda := \max\{h, \max\{T(x) : x \in W\}\}.
$$

Choose a number $c < 1$ such that if $\alpha(x) \geq c$ then $x \in W$ and $\phi(x, [0, \lambda]) \subset N' \setminus K$. Set

$$
L' := \alpha^{-1}([0, c]), \quad N'' := \alpha^{-1}([c, 1]), \quad (3)
$$

hence $T$ is defined on $\text{cl}(N' \setminus L')$ and

$$
\phi(\text{cl}(N' \setminus L'), [0, \lambda]) \subset N' \setminus K.
$$

Proposition 3.2. ($N', L'$) is an index pair for $S$ with respect to both $\phi$ and $\phi^h$.

Again, essentially the same result was given in [MSW, Sec. 5.2]. We provide a proof of Proposition 3.2 in Subsection A.4.3

As a direct consequence of the definition of $N''$ and $L''$, and Proposition 3.2 one can verify that $(N'', L'')$ is an index pair for $S$ with respect to $\Phi_1$ (actually, also with respect to $\phi$, $\phi^h$, and $\Phi$). In particular, the requirement that $N''$ is contained in the domain of $\Phi_1$ is satisfied by (3). Consequently, an index pair for the Poincaré map $\Pi$ is given in the following result.

Proposition 3.3. $(N_0'', L_0'')$ is an index pair for $S_0$ with respect to $\Pi$. 

Propositions 3.2 and 3.3 imply that $(N', L')$ is an index pair for $\Phi$. Set

$$
\Phi' := \Phi(N', L'),
$$

hence for $a, t \in \mathbb{R}$ the map $\Phi'_t = \Phi'(-, t) : N'_a/L'_a \to N'_a+t/L'_a+t$ is given as

$$
\Phi'_t(x) = \begin{cases} 
\phi(N', L')(x, T_t(x)), & \text{if } x \in N'_a \setminus L'_a \text{ and } T_t \text{ is defined at } x, \\
\ast, & \text{otherwise}
\end{cases}
$$

Since $N''/L'' = N'/L'$,

$$
\Pi(N_0'', L_0'') = \Phi'_1 : N'_0/L'_0 \to N'_0/L'_0.
$$

Therefore, by Proposition 3.3 in order to prove Theorem 2.1 it suffices to show that

$$
(4) \quad RH(\Phi'_1) \cong RA.
$$

3.3. Reformulations of Theorem 2.1

Set $f := \phi^h$.

Lemma 3.2. There exist $\kappa$ and $\mu$ in $\mathbb{N}$ such that

$$
\{x \in L' \setminus L : f(x), \ldots, f^\kappa(x) \in N' \setminus L\} = \emptyset,
$$

$$
\{x \in N \setminus N' : f(x), \ldots, f^\mu(x) \in N \setminus N'\} = \emptyset.
$$

Proof: If for every $n$ there is a $x_n \in L' \setminus L$ such that $f(x_n), \ldots, f^n(x_n) \in N' \setminus L$, hence, by the positive invariance of $L'$ in $N$, also $f(x_n), \ldots, f^n(x_n) \in L' \setminus L$, then $\omega(x) \subset \text{cl}(L' \setminus L)$ for each accumulation point $x$ of $\{x_n\}$, contrary to the fact that both $(N', L)$ and $(N', L')$ are isolating pairs for $S$, hence the first equation holds.

Since $S \cap \text{cl}(N \setminus N') = \emptyset$, the second statement follows by a similar argument. 

We claim that the return time map $T$ satisfies

\[ \inf\{ T(x) : x \in N \} > 0. \]

Indeed, assume $x_n \in N$ and $T(x_n) \to \inf\{ T(x) : x \in N \}$. Let $x_0 \in N$ be the limit of $x_n$. If $T$ is defined at $x_0$ then there is nothing to prove. Assume the opposite. Since $\phi(\cdot, h)$ is defined at $x_0$ (as it is required for an index pair with respect to $f$), there is a neighborhood $W$ of $(x_0, 0)$ in $\bar{X}$ such that

\[ \bar{\phi}(W, [0, h]) \cap \bar{X}_1 = \emptyset, \]

hence $T(x_n) > h$ for $n$ large enough and the inequality follows.

We fix $\kappa$ and $\mu$ satisfying Lemma 3.3. Thanks to (5), there is an $\nu \in \mathbb{N}$ such that

\[ h < \nu \inf\{ T(x) : x \in N \}. \]

Define

\[ k := \nu \kappa, \quad m := \nu \mu. \]

Since $H(\Phi_i^\ell) = H(\Phi_i')$ for every positive integer $\ell$, Proposition 1.4 implies that the equation (1) is proved if we show that the following result holds true.

**Proposition 3.4.** There are homomorphisms

\[ \gamma : H(N_0, L_0) \to H(N_0'/L_0', *), \quad \delta : H(N_0'/L_0', *) \to H(N_0, L_0) \]

such that the diagrams

\[ 
\begin{align*}
H(N_0, L_0) & \xrightarrow{A} H(N_0, L_0) \\
& \gamma \downarrow \\
H(N_0'/L_0', *) & \xrightarrow{H(\Phi_i')} H(N_0'/L_0', *) \\
& \delta \downarrow \\
H(N_0'/L_0', *) & \xrightarrow{H(\Phi_i')} H(N_0'/L_0', *) \\
& \gamma \\
& \delta \\
& \gamma
\end{align*}
\]

 commute.

Let us fix an integer $p \geq k + m + \nu$. We identify the space $\mathbb{R}/p\mathbb{Z}$ with the interval $[0, p)$ endowed with the corresponding topology and we construct a quotient space $Y$ of $\bar{X}$ by identifying $(x, a)$ with $(x, b)$ if $a = b \mod p$, i.e.

\[ Y = \{(x, a) \in X \times [0, p) : x \in X_a \} \subset X \times \mathbb{R}/p\mathbb{Z}. \]

The maps $a \to a + p\mathbb{Z} \to a + \mathbb{Z}$ generate coverings $\zeta_p : \tilde{X} \to Y$ and $\zeta_p : Y \to X$. Let $\psi$ be the local dynamical dynamical system on $Y$ defined by lifting $\phi$ with respect to $\zeta_p$ in an analogous way as $\tilde{\phi}$ was constructed. This is a rotating system. Let $\Psi$ denote the translation system associated to $\psi$; actually, $\Psi$ is induced on $Y$ from the system $\tilde{\Phi}$ given in Proposition 1.4.

Let $a \in [0, p)$. Similarly as in the case of $\tilde{X}$, we set $Y_a := X_a \times a$ and, more generally, for $Z \subset Y$ and a closed interval $I \subset [0, a)$,

\[ Z_I := \{(x, a) \in Y : a \in I\}. \]

The map $\tilde{\zeta}_p$ identifies the set $\tilde{X}_I$ with $Y_I$ as topological spaces and therefore we do not distinguish between the dynamics of $\tilde{\phi}$ and $\psi$ (as well as $\tilde{\Phi}$ and $\Psi$) restricted to these sets. In particular, Proposition 1.4 has the following reformulation.

**Lemma 3.3.** If $I$ is a closed interval in $[0, p)$ then the system $\psi$ has no omega-limit sets contained in $Y_I$. \quad \square
We are adopt from $\widetilde{\phi}$ the notion of an $h$-movable pair of contiguous cycles over any interval contained in $[0, k + m]$ and therefore all results stated below for $\psi$ are valid also for $\widetilde{\phi}$. Define $g := \psi h$ and
\[
S^* := \{(x, a) \in Y : x \in S_a \},
Q := \{(x, a) \in Y : x \in N_a \}, \quad P := \{(x, a) \in Y : x \in L_a \},
\]
\[
Q' := \{(x, a) \in Y : x \in N'_a \}, \quad P' := \{(x, a) \in Y : x \in L'_a \}.
\]
The set $S^*$ is isolated invariant in $Y$ and $(Q, P)$, $(Q', P')$ are index pairs for $S^*$ with respect to $g$ by Propositions 3.1(a) and 3.2 and $(Q', P')$ is an index pair for $S^*$ with respect to $\psi$ and $\Psi$ by Propositions 1.7 and 3.2. Moreover, by Proposition 3.1(b),
\[
g(Q') \cap Q \subset Q'
\]
and by (3) and the choice of $\kappa$ and $\mu$,
\[
(7) \quad \psi(cl(Q' \setminus P'), [0, h]) \subset Q' \setminus P,
\]
\[
(8) \quad \{y \in P' \setminus P : g(y), \ldots, g^\kappa(y) \in Q' \setminus P\} = \emptyset,
\]
\[
(9) \quad \{y \in Q \setminus Q' : g(y), \ldots, g^\mu(y) \in Q \setminus Q'\} = \emptyset.
\]
The system $g$ and the map $g$ generate the semi-dynamical systems $g(Q, P)$, $g(Q', P')$, $\psi(Q', P')$, and $\Psi := \Psi(Q', P')$. For $a, a + t \in [0, p)$ set
\[
\Psi_t := \Psi_t(y, t) : Q_a / P_a \rightarrow Q_{a+t} / P_{a+t},
\]
and we reformulate Proposition 3.4 to the following equivalent statement.

**Proposition 3.5.** For $\ell = 0, \ldots, k + m$ there is a homomorphism $\Gamma_\ell : H(Q_\ell, P_\ell) \rightarrow H(Q_{\ell+1}, P_{\ell+1})$ such that
\[
(\text{a}) \text{ the diagram}
\]
\[
\begin{array}{ccccc}
H(Q_0, P_0) & \xrightarrow{A} & H(Q_1, P_1) \\
\downarrow \Gamma_0 & & \downarrow \Gamma_1 \\
H(Q'_0 / P'_0, *) & \xrightarrow{H(\Psi_1)} & H(Q'_1 / P'_1, *)
\end{array}
\]
commutes,
\[
(\text{b}) \text{ there is a homomorphism } \Delta \text{ such that the diagram}
\]
\[
\begin{array}{ccc}
H(Q_0, P_0) & \xrightarrow{A^{k+m}} & H(Q_{k+m}, P_{k+m}) \\
\downarrow \Gamma_0 & & \downarrow \Gamma_{k+m} \\
H(Q'_0 / P'_0, *) & \xrightarrow{H(\Psi_{k+m})} & H(Q'_{k+m} / P'_{k+m}, *)
\end{array}
\]
commutes.
A proof of Proposition 3.5 (hence, as a consequence, also of Theorem 2.1) is presented in the subsequent subsections.

3.4. **Beginning of the proof of Proposition 3.5.** The identities and the inclusion map $e: Q' \to Q$ induce the following continuous maps in the quotient spaces:

$$j: Q'/P \to Q/P, \quad q: Q \to Q/P,$$

$$j': Q'/P' \to Q'/P', \quad q': Q' \to Q'/P'.$$

It follows that $q'$ is a restriction of $q$ and $j' \circ q'$ is equal to the quotient map $Q' \to Q'/P'$. (Actually, $j$ is an inclusion map since $Q'/P \subset Q/P$ and the quotient topology on $Q'/P$ coincides with the topology induced from $Q/P$, but we will not take advantage of this fact later.) In order to simplify notation, by the same letters $e$, $j$, $j'$, $q$, and $q'$ we denote also their restrictions, for example for $a \in \{0, p\}$ we have $e: Q'_a \hookrightarrow Q_a$, $j: Q'_a/P_a \hookrightarrow Q_a/P_a$, $q: Q_a \to Q_a/P_a$, etc. In the sequel we will use also the sets

$$C := \{y \in Q: \psi(y, [0,h]) \subset Q\}, \quad B := \{y \in Q: \psi(y, [0,h]) \subset P\}.$$ Clearly, $(C,B) \subset (Q',P)$.

Set $U := \{u = \sum_i \alpha_i u_i : \alpha_i \in \mathbb{F}\}$. This is the linear subspace of $S(N_0)$ spanned on the cycles $u_i$, $i = 1, \ldots, n$, and $A$ is an endomorphism $U \to U$. By assumption, the pair $(u_i, Au_i)$ is $h$-movable for each $u_i$, hence for every $u \in U$ and all $\ell < \ell' \in \mathbb{N}$, $(u, A^{\ell'-\ell}u)$ is an $h$-movable pair of contiguous cycles over $[\ell, \ell']$ as a consequence of Propositions 1.9 and 1.10. In particular, by Proposition 1.8 for each $u \in U$ and $\ell = 0, \ldots, k + m$,

$$u \times \ell \in Z(C_\ell, B_\ell).$$

A comment on the notation we use: in the sequel the chain $u \times \ell$ will appear as a cycle in $Z(C_\ell, B_\ell)$ or $Z(Q_\ell, P_\ell)$, or $Z(Q'_\ell, P_\ell)$. It will be clear from the context in which of the homologies $H(C_\ell, B_\ell)$, $H(Q_\ell, P_\ell)$, and $H(Q'_\ell, P_\ell)$ the class $[u \times \ell]$ is treated.

Since the map $x \to (x, \ell)$ is a homeomorphism $(N_0, L_0) \to (Q_\ell, P_\ell)$, the classes $[u_i \times \ell]$ form a basis of $H(Q_\ell, P_\ell)$. Moreover, since $(N_0, L_0)$ is a pair of compact ANRs, for $\ell = 0, \ldots, k + m$ the map

$$H(q): H(Q_\ell, P_\ell) \to H(Q'_\ell/P_\ell, *)$$

is an isomorphism. Set

$$\overline{\nu}' := S(q')(u \times \ell) \in Z(Q'_\ell/P_\ell, *),$$

$$V_\ell := \{[\overline{\nu}']: u \in U\} \subset H(Q'_\ell/P_\ell, *).$$

Since the bottom arrow in the commutative diagram

$$\begin{array}{ccc}
H(Q'_\ell, P_\ell) & \xrightarrow{H(q)} & H(Q'_\ell/P_\ell, *) \\
H(e) \downarrow & & \downarrow H(j) \\
H(Q_\ell, P_\ell) & \xrightarrow{H(q)} & H(Q_\ell/P_\ell, *)
\end{array}$$

is an isomorphism, $[\overline{\nu}']$ is a basis of $V_\ell$ and

$$H(j)[V_\ell]: V_\ell \to H(Q_\ell/P_\ell, *)$$
is an isomorphism. Let $I_\ell$ denote the inclusion homomorphism $V_\ell \to H(Q'_\ell/P_\ell, *)$. Define
\[ \Gamma_\ell := H(j')I_\ell H(j)|_{V_\ell}^{-1} H(q) : H(Q_\ell,P_\ell) \to H(Q'_\ell/P'_\ell, *). \]

For $u \in U$,
\[ (10) \quad I_\ell H(j)|_{V_\ell}^{-1} H(q)[u \times \ell] = [\pi'] = [S(q')(u \times \ell)], \]
hence
\[ (11) \quad \Gamma_\ell[u \times \ell] = [S(j' \circ q')(u \times \ell)]. \]

3.5. Proof of Proposition 3.5 (a). Define
\[ F : (C_{[0,1]}, B_{[0,1]}) \to (Q'_1/P'_1), \]
\[ F(y) := \begin{cases} \psi(Q', P')(j'(q'(y)), \tau_1(y)), & \text{if } \tau_1 \text{ is defined at } y, \\ \ast, & \text{otherwise}, \end{cases} \]
hence $F(y) = j'(q'(y))$ for $y \in C_1$. The map is continuous. Indeed, it is continuous on the set of points in which $\tau_1$ defined and that set contains $\text{cl}(Q' \setminus P')[0,1]$ by the definition of $P'$. On the other hand, if $y \in P'[0,1]$, then $F(y) = \ast$ independently of whether $\tau_1$ is defined or not defined at $y$, hence the continuity of $F$ follows.

Now we are able to prove the required equation
\[ (12) \quad H(\Psi'_1)\Gamma_0 = \Gamma_1 A. \]

Let $u \in U$. It follows by (11),
\[ H(\Psi'_1)\Gamma_0[u \times 0] = [S(\psi(Q', P')(\cdot, \tau_1(\cdot)) \circ j' \circ q')(u \times 0)] = [S(F)(u \times 0)], \]
and
\[ \Gamma_1 A[u \times 0] = [S(j' \circ q')(Au \times 1)] = [S(F)(Au \times 1)]. \]

Since
\[ S(F)(Au \times 1) - S(F)(u \times 0) = \partial S(F)c + S(F)b \in B(Q'_1/P'_1, *), \]
where the chains $c$ and $b$ are associated to the contiguous pair of cycles $(u, Au)$, the equation (12) holds.

3.6. Auxiliary maps. At first we establish two facts concerning the access time maps.

Lemma 3.4.
\[ \begin{align*} 
& (a) \text{ If } y \in Q_0 \text{ and } \tau_k \text{ is defined at } y \text{ then } \kappa h < \tau_k(y). \\
& (b) \text{ If } y \in Q_k \text{ and } \tau_{k+m} \text{ is defined at } y \text{ then } \mu h < \tau_{k+m}(y). 
\end{align*} \]

Proof. This is an immediate consequence of the choice of $k$ and $m$. \hfill \square

Lemma 3.5. If for $y \in C_{[0,k]}$ the map $\tau_k$ is not defined at $y$ then there exist $t > h$, $\epsilon > 0$, and a neighborhood $W'$ of $y$ such that
\[ (13) \quad \psi(W', [0, t + h + \epsilon]) \cap Y_k = \emptyset, \]
\[ (14) \quad \psi(W', [t, t + h + \epsilon]) \cap Q = \emptyset. \]
Proof. Since $Q$ and $Y_k$ are closed, it is enough to prove the equations hold if $W$ is replaced by the point $y$. Set
\[ t_y = \sup \{ t > 0 : \psi(y, t) \in Q \}, \]
hence $t_y \geq h$. Moreover, $t_y < \infty$, since otherwise the omega-limit set $\omega(y)$ has a nonempty intersection with the compact set $Q_{[0, k]}$ contradictory to Lemma 3.3. Since $\psi(y, t_y) \in Q$, the interval $[t_y + \epsilon, t_y + h + 2\epsilon]$ is contained in the domain of $\psi(y, \cdot)$ for a sufficiently small $\epsilon > 0$ and the result is proved for $t := t_y + \epsilon$. \[
\square
\]
For $y \in Y_{[0, k]}$ such that $\tau_k$ is defined at $y$ associate the numbers $\tau_y \in [0, h)$ and $\ell_y \in \mathbb{N}$ such that $\tau_k(y) = \tau_y + \ell_y h$. Define a map
\[ G : (C_{[0, k]}, B_{[0, k]}) \to (Q'_k/P_k, *), \]
\[ G(y) := \begin{cases} \tau_y, & \text{if } \tau_k \text{ is defined at } y, \\ * & \text{otherwise}, \end{cases} \]
thus $G(y) = q'(y)$ for $y \in C_k$. The map $G$ is continuous, which can be proved as follows. If $\tau_k$ is defined at $y$, it is also defined in a neighborhood of $y$. Clearly, $G$ is continuous at $y$ if $\tau_y > 0$. Assume $\tau_y = 0$, hence $g(y) \in Q'$. Let $y_n \to y$. If $\ell_{y_n} = \ell_y$ then $G(y_n) \to G(y)$. Let $\tau_y \to 1$. Since $\tau_k(y_n)$ is close to $\tau_k(y)$, $\ell_{y_n} = \ell_y - 1$ which implies
\[ G(y_n) = g^{-1}_{(Q', P)}(q'(\psi(y_n, \tau_y))), \]
\[ g^{-1}_{(Q', P)}(q'(\psi(y_n, \tau_y))) = G(y), \]
Assume that $\tau_k$ is not defined at $y$, hence $G(y) = *$. Let $t, \epsilon$, and $W$ be associated to $y$ by Lemma 3.3. Let $y' \in W$ and $y' \neq y$. If $\tau_k$ is not defined at $y'$ then $G(y') = *$. Finally, assume that $\tau_k$ is defined at $y'$. By (13),
\[ t + h + \epsilon < \tau_k(y'), \]
hence $\tau_{y'} \geq 2$ and, as a consequence of (14), there is an $\ell < \tau_{y'}$ such that at least one of the points $g^\ell(\psi(y', \tau_{y'}))$ and $g^{\ell+1}(\psi(y', \tau_{y'}))$ does not belong to $Q$, hence $G(y') = *$ and the proof of the continuity of $G$ is finished.

Define
\[ R : Q'_0 \to Q'_k/P_k, \quad R(y) := \begin{cases} G(y), & \text{if } y \in C_0, \\ * & \text{otherwise}. \end{cases} \]
The definition is correct. Indeed, since $cl(Q'_0 \setminus C_0) \subset P'_0$ by (7), it suffices to prove that $G(y) = *$ for every $y \in P'_0 \cap C_0$. This holds true if $\tau_k$ is not defined at $y$. Assume therefore that $\tau_k$ is defined at $y$, thus $\tau_y \geq \kappa$ by Lemma 3.3(a). Since $\psi(y, \tau_y) \in P'$, the equation (5) implies that $g^{n_{P', \tau}}(q'(\psi(y, \tau_y))) = *$, hence again $G(y) = *$. Since $G$ is a continuous map, $R$ is also continuous. Since $R$ is equal to * on $P'_0$, there is a continuous map $r : Q'_0/P'_0 \to Q'_k/P_k$ such that
\[ r \circ j' \circ q' = R. \]
It follows, in particular,
\[ S(r \circ j' \circ q')(u \times 0) = S(G)(u \times 0) \]
for every $u \in U$. We assert that
\[ j' \circ r = \Psi_k' : Q'_0/P'_0 \to Q'_k/P'_k. \]
Indeed, let \( y \in Q'_0 \setminus P'_0 \). Assume that \( j'(r(y)) \in Q'_k \setminus P'_k \), hence
\[
\overline{g'}(\psi(y, \bar{\tau}_y)) \in Q' \setminus P', \\
g'(\psi(y, \bar{\tau}_y)) \in Q' \setminus P
\]
for all \( 0 \leq \ell < \ell_y \). This is possible only if \( g'(\psi(y, \bar{\tau}_y)) \in Q' \setminus P' \) for all \( 0 \leq \ell \leq \ell_y \) and the latter is equivalent to \( \psi(y, [0, \tau_k(y)]) \subset Q' \setminus P' \) by the inclusion (17) and the positive invariance of \( P' \) in \( Q' \) with respect to \( \psi \), hence \( \Psi_k(y) \in Q'_k \setminus P'_k \). Since the inverse implication is trivial, the equation (10) is proved.

By (6) and (9), the following map is correctly defined:
\[
D : Q \to Q'/P, \quad D(y) := \begin{cases} 
q'(g''(y)), & \text{if } g(y), \ldots, g'''(y) \in Q, \\
\ast, & \text{otherwise.}
\end{cases}
\]
This map is continuous. Indeed, let \( y \in Q \). If \( g''(y) \notin Q \) for some \( 1 \leq \ell \leq \mu \) then also \( g''(y) \notin Q \) for every \( y' \) in a neighborhood of \( y \), hence \( D(y') = \ast \). Assume that \( g(\bar{y}), \ldots, g''(y) \in Q \) and let \( y_n \to y \). If \( g(y_n), \ldots, g'''(y_n) \in Q \) then \( D(y_n) \to D(y) \).

Finally, define
\[
d : Q_k/P_k \to Q'_{k,k+m}/P'_{k,k+m},
\]
i.e. \( d(y) = D(y) \) if \( y \in Q'_k \setminus P_k \). Moreover, again by (17),
\[
d \circ j = g''(Q', P') : Q_k/P_k \to Q'_{k,k+m}/P'_{k,k+m}.
\]

Finally, define
\[
J : Q'_{k,k+m}/P'_{k,k+m} \to Q'_{k+m}/P'_{k+m},
\]
\[
J(y) := \begin{cases} 
\psi(Q', P')(y, \tau_{k+m}(y)), & \text{if } y \in Q' \setminus P' \text{ and } \tau_{k+m} \text{ is defined at } y, \\
\ast, & \text{otherwise.}
\end{cases}
\]
The map \( J \) is continuous. Indeed, it suffices to check only the case where \( \tau_{k+m} \) is not defined at \( y \in Q' \setminus P' \). \( y_n \to y \), and \( \tau_{k+m} \) is defined at \( y_n \). Let
\[
t_y := \inf \{ t > 0 : \psi(y, t) \notin \text{cl}(Q' \setminus P') \}.
\]
There exists a \( \epsilon > 0 \) such that for almost all \( n \), \( t_y + \epsilon < \tau_{k+m}(y_n) \) and \( \psi(y_n, t_y + \epsilon) \notin \text{cl}(Q' \setminus P') \), hence \( J(y_n) = \ast \) and the continuity of \( J \) is proved. By definition,
\[
J|_{Q'_k/P'_k} = \Psi'_m.
\]
Moreover, if \( y \in Q'_{k,k+m} \setminus P'_{k,k+m} \) and \( \tau_{k+m} \) is defined at \( y \) then for \( t \leq \tau_{k+m}(y) \),
\[
J(y) = J(\psi(Q', P')(y, t)),
\]
hence, by Lemma 3.4(b),
\[
J|_{Q'_k/P_k} = J \circ g''(Q', P')|_{Q'_k/P_k}.
\]
3.7. **Proof of Proposition 3.5 (b).** We will prove that

\[ \Delta := A^m H(q)^{-1} H(j) R : H(Q_0/P_0, \ast) \rightarrow H(Q_{k+m}, P_{k+m}) \]

is the required map, i.e.

\[ \Delta \Gamma_0 = A^{k+m}, \]

\[ \Gamma_{k+m} \Delta = H(\Psi_{k+m}). \]

In order to prove (20), we will show that the diagram

\[ \begin{array}{ccc}
H(Q_0, P_0) & \xrightarrow{A^k} & H(Q_k, P_k) \\
\downarrow{\Gamma_0} & & \downarrow{I_k H(j) H(q)} \\
H(Q_0/P_0, \ast) & \xrightarrow{H(r)} & H(Q_k/P_k, \ast)
\end{array} \]

commutes. To this purpose we should prove that

\[ H(r) \Gamma_0 = \Lambda, \]

where \( \Lambda \) denotes the composition of the upper and the right arrows, i.e.

\[ \Lambda := I_k H(j) H(q) A^k : H(Q_0, P_0) \rightarrow H(Q_k/P_k, \ast). \]

Let \( u \in U \). By (11) and (15),

\[ H(r) \Gamma_0 [u \times 0] = [S(r \circ j' \circ q')(u \times 0)] = [S(G)(u \times 0)]. \]

On the other hand, by (10),

\[ \Lambda [u \times 0] = [S(q')(A^k u \times k)] = [S(G)(A^k u \times k)]. \]

Since

\[ S(G)(A^k u \times k) - S(G)(u \times 0) = S(G)c + S(G)b \in B(Q_k/P_k, \ast) \]

for chains \( c \) and \( b \) associated to the contiguous pair of cycles \((u, A^k u)\), the left and the right hand sides of (23) coincide and thus the diagram (22) commutes.

The commutativity of (22) immediately implies the required equation (20). Indeed,

\[ \Delta \Gamma_0 = A^m H(q)^{-1} H(j) I_k H(j) H(q) A^k = A^{k+m}. \]

It remains to prove the equation (21). To this end let us take an arbitrary homology class \([z] \in H(Q_k/P_k, \ast)\), where \( z \) is cycle in \( Z(Q_k/P_k, \ast) \). Since

\[ H(q) : H(Q_k, P_k) \rightarrow (Q_k/P_k, \ast) \]

is an isomorphism, there exists a \( u \in U \) such that

\[ H(j)[z] = H(q)[u \times k], \]

hence \( H(j)[z] = H(j)[\overline{m}^k] \) and therefore there exist chains \( \eta \in S(Q_k/P_k) \) and \( \xi \in S(\ast) \) satisfying

\[ S(j)z - S(j)[\overline{m}^k] = \partial \eta + \xi. \]

Since the diagram

\[ \begin{array}{ccc}
Q'/P & \xrightarrow{g(Q', P')} & Q'/P' \\
\downarrow{j'} & & \downarrow{j'} \\
Q'/P' & \xrightarrow{g(Q', P')} & Q'/P'
\end{array} \]
commutes (because $P'$ is positively invariant in $Q'$) and the equation (17) holds, applying $S(j' \circ d)$ to the equation (25) one gets
\[ S(g''_{(Q',P')})S(j')z - S(g''_{(Q',P')})S(j')\overline{\pi} = \partial S(j' \circ d)\eta + \xi, \]
hence, by (19),
\[ S(J)S(j')z - S(J)S(j')\overline{\pi} = \partial S(J \circ j' \circ d)\eta + \xi \]
and therefore the equation (18) implies
\[ (26) \]
\[ H(\Psi'_m)H(j')[z] = H(\Psi'_m)H(j')[\overline{\pi}]. \]
By definition,
\[ H(j')[\overline{\pi}] = \Gamma[u \times k], \]
and by an iterated application of (14),
\[ H(\Psi'_m)\Gamma[k[u \times k] = \Gamma[k+m]A^m[u \times k], \]
therefore the equations (24) and (26) imply
\[ H(\Psi'_m)H(j')[z] = \Gamma[k+m]A^m H(q)^{-1} H(j)[z]. \]
The latter equation together with the equation (16) provide the commutativity of the diagram
\[
\begin{array}{ccc}
H(Q_k,P_k) & \xrightarrow{A^m} & H(Q_{k+m},P_{k+m}) \\
\text{H(q)^{-1} H(j)} & & \text{H(k+m)} \\
H(\Psi'_m) & & H(Q'_k,P'_k) \\
\text{H(\Psi'_m)} \downarrow & & \text{H(\Psi'_m)} \\
H(Q'_0,P'_0) & \xrightarrow{\Gamma} & H(Q'_{k+m},P'_{k+m}) \\
\end{array}
\]
Thus
\[ \Gamma[k+m] \Delta = H(\Psi'_m)H(\Psi'_m) \]
and therefore the equation (21) holds. This concludes the proof of Proposition 3.5 as well as the proof of Theorem 2.1.

\[ \square \]

\section*{Appendix A.}

\subsection*{A.1. Proof of Proposition 1.1.}
Since $\text{gker}(\alpha) = \text{gker}(\alpha')$, $\overline{\alpha'} = \overline{\alpha'}$ and since $\text{gim}(\overline{\pi}) = \text{gim}(\overline{\pi'})$,
\[ R(\alpha') = (R\alpha')', \quad \text{RV}_{\alpha'} = \text{RV}_{\alpha} \]
and the same equations hold with $\alpha$ replaced by $\beta$. Moreover, the maps
\[ \Gamma: \text{RV}_{\alpha} \to \text{RV}_{\beta}, \quad \Gamma(v + \text{gker}(\alpha)) := \gamma(v) + \text{gker}(\beta), \]
\[ \Delta: \text{RV}_{\beta} \to \text{RV}_{\alpha}, \quad \Delta(v + \text{gker}(\beta)) := \delta(v) + \text{gker}(\alpha) \]
are well defined and the diagrams
\[
\begin{array}{ccc}
\text{RV}_{\alpha} & \xrightarrow{R_{\alpha}} & \text{RV}_{\alpha} \\
\Gamma & & \Gamma \\
\text{RV}_{\beta} & \xrightarrow{R_{\beta}} & \text{RV}_{\beta} \\
\end{array}
\quad
\begin{array}{ccc}
\text{RV}_{\alpha} & \xrightarrow{(R\alpha)'_{\alpha}} & \text{RV}_{\alpha} \\
\Gamma & & \Gamma \\
\text{RV}_{\beta} & \xrightarrow{(R\beta)'_{\beta}} & \text{RV}_{\beta} \\
\end{array}
\]
commute. Since \((R\alpha)^r = \Delta\Gamma\) is an automorphism, \(\Gamma\) is a monomorphism, and since \((R\beta)^r = \Gamma\Delta\) is an automorphism, \(\Gamma\) is an epimorphism. Therefore \(\Gamma\) is an isomorphism and the result follows. \(\square\)

A2. Proof of Proposition 1.6. As it was already mentioned, the equivalence of (c) and (d) is a general result, valid for any local dynamical system \(\Phi\) on a locally compact space \(X\). Here is a proof:

\((c) \Rightarrow (d)\). We can assume \(t > 0\). Since \(S\) is invariant with respect to \(\Phi\), it is also invariant with respect to \(\Phi_t := \Phi(-t)\). If \(N\) is an isolating neighborhood of \(S\) in the system \(\Phi\) then there is a compact neighborhood \(W\) of \(S\) such that \(\Phi(W, [-t, t]) \subset N\), hence \(W\) is an isolating neighborhood of \(S\) in \(\Phi_t\).

\((d) \Rightarrow (c)\). Let \(t \neq 0\), let \(S\) be an isolated invariant set with respect to \(\Phi_t\), and let \(N\) be its isolating neighborhood. There is an \(\epsilon > 0\) such that \(\Phi(S, [-\epsilon, \epsilon]) \subset N\). Since \(\Phi_t(S)\) is invariant with respect to \(\Phi_t\), \(\Phi_t(S) \subset S\), hence \(\Phi(S, [-\epsilon, 2\epsilon]) \subset N\), etc. Consequently, \(\Phi(S, \mathbb{R}) = S\), i.e. \(S\) is invariant for \(\Phi\). Since each invariant set with respect to \(\Phi\) contained in \(N\) is also invariant for \(\Phi_t\), \(N\) is also an isolating neighborhood of \(S\) with respect to \(\Phi\).

Now we assume that \(\Phi\) is the translation system associated to \(\phi\). In order to finish the proof it suffices to prove that (d) is equivalent to (e). We follow the notation from Subsection 1.0.

\((d) \Rightarrow (e)\). Let \(N\) be an isolating neighborhood of \(S\) with respect to \(\Phi_1\). Then \(N_a\) is an isolating neighborhood of \(S_a\) for \(\Phi_1\) restricted to \(X_a \times X_a\). Let \(t \in [0, 1]\), hence \(\Phi_t(S_a) \subset S_{a+t}\) and \(\Phi_{-t}(S_{a+t}) \subset S_a\) by the the invariance of \(S\) with respect to \(\Phi\) stated in the implication (d) \(\Rightarrow (c)\). Thus \(\Phi_t(S_a) = S_{a+t}\).

\((e) \Rightarrow (d)\). Let \(a, t \in \mathbb{R}\). Since the maps \(\Phi_t\) and \(\Phi_{-t}\) are mutually inverse homeomorphisms in neighborhoods of \(S_a\) and \(S_{a+t}\), respectively, \(S_a\) is isolated invariant if and only \(S_{a+t}\) is isolated invariant in \(\Phi_1\). For \(t \in [0, 1]\) let \(N_t\) be an isolating neighborhood of \(S_a\). There exists an \(\epsilon_t > 0\) such that \(\zeta(N_t \times (t - \epsilon_t, t + \epsilon_t))\) is an isolating neighborhood of \(S_t\) if \(|t' - t| < \epsilon_t\). Let \(t_1, \ldots, t_k \in (0, 1)\) be such that

\[
[0, 1] \subset (-\epsilon_0, \epsilon_0) \cup (1 - \epsilon_0, 1 + \epsilon_0) + \bigcup_{i = 1, \ldots, k} (t_i - \epsilon_i, t_i + \epsilon_i).
\]

Set \(t_0 := 0\). Then the union of the sets \(\zeta(N_{t_i} \times (t_i - \epsilon_i, t_i + \epsilon_i))\) for \(i = 0, \ldots, k\) is an isolating neighborhood of \(S\) with respect to \(\Phi_1\), hence (d) is satisfied for \(t = 1\). Thus (d) is satisfied for an arbitrary \(t\) by the equivalence of (c) and (d). \(\square\)

A3. Proof of Proposition 3.1. At first we prove that the sets \(K\), \(M\), and \(N'\) are compact. We begin with a proof of the compactness of \(K\). Since \(L\) is positively invariant in \(N\) with respect to \(\phi^h\),

\[
K = \bigcup \{\sigma \subset N: \sigma\ is a segment with length in [0, h] starting at a point in L\}.
\]

Let \(x_n \in K, n \in \mathbb{N}\). There are \(y_n \in L\) and \(t_n \in [0, h]\) such that \(x_n = \phi(y_n, t_n)\) and \(\phi(y_n, [0, t_n]) \subset N\). We can assume \(y_n \to y \in L\) and \(t_n \to t \in [0, h]\) as \(n \to \infty\); it follows \(\phi(y, [0, t]) \subset N\). Therefore \(x_n \to \phi(y, t) \in K\) as \(n \to \infty\) and the compactness of \(K\) follows. Clearly, an analogous argument implies that the set \(M\) is compact, hence \(N'\) is a compact set as well.

Lemma A.1. If \(x \in M\), \(\phi^h(x) \in N\), and \(\phi(x, [0, h]) \not\subset N\) then \(\phi^h(x) \in K\).
Proof. By assumption there is a number \( s \) such that
\[
\text{(27)} \quad s \in (0, h], \quad \phi(x, [s, h]) \subset N, \quad \exists \epsilon_n \in (0, s), \quad \epsilon_n \to 0: \phi(x, s - \epsilon_n) \notin N
\]
Moreover, there are \( y \in N \) and \( t \in (0, h] \) such that \( \phi(y, [0, h]) \subset N \) and \( x = \phi(y, t) \), hence \( \phi(x, [0, h - t]) \subset N \). Then
\[
h < s + t - \epsilon_n < s + t \leq 2h
\]
for every \( n \), since otherwise
\[
\phi(x, [0, h - t]) \cup \phi(x, [s - \epsilon_n, h]) = \phi(x, [0, h]) \subset N;
\]
a contradiction. It follows
\[
z_n := \phi(y, s + t - h - \epsilon_n) \in N, \quad z_n \to z := \phi(y, s + t - h),
\]
and, by (27),
\[
\phi^h(z_n) = \phi(x, s - \epsilon_n) \notin N, \quad \phi^h(z) = \phi(x, s) \in N.
\]
Since \( L \) is an exit set of \( N \), \( \phi(x, s) \in L \) and therefore \( \phi^h(x) \in K \).

Lemma A.2. If \( x \in K \) and \( \phi^h(x) \in N \) then \( \phi^h(x) \in K \).

Proof. Let \( y \in L, x = \phi(y, t), \) and \( \phi(y, [0, t]) \subset N \). Since \( L \) is positively invariant in \( N \), we can assume \( t \in (0, h) \). If \( \phi(x, [0, h]) \subset N \) then also \( \phi(y, [0, h + t]) \subset N \), hence \( \phi^h(x) = \phi(y, t + h) \in K \). Assume that \( \phi(x, [0, h]) \notin N \). Let \( s \) satisfy (27). If \( h < s + t \) then also \( h < s + t - \epsilon_n \) for sufficiently large \( n \), hence
\[
\phi(y, s + t - h - \epsilon_n) \in \phi(y, (0, t)) \subset N
\]
and, by the argument in the proof of Lemma A.1, we conclude that \( \phi^h(x) \in K \).
Finally, assume that \( s + t \leq h \). Then
\[
\phi^h(y) = \phi(x, h - t) \in \phi(x, [s, h]) \subset N,
\]
hence \( \phi^h(y) \in L \) because \( L \) is positively invariant in \( N \). Therefore
\[
\phi^h(x) \in \phi(\phi^h(y), [0, t]) \subset K.
\]

Proof of (b). Let \( x \in N' \). Assume first that \( x \in M \). If \( \phi(x, [0, h]) \subset N \) then
\[
\phi^h(x) \in M \subset N'.
\]
If, on the other hand, \( \phi(x, [0, h]) \notin N \) then \( \phi^h(x) \in K \subset N' \) by Lemma A.1. Now let \( x \in K \). Then \( \phi^h(x) \in K \subset N' \) by Lemma A.2.

Proof of (a). Let \( W \) be a neighborhood of \( S \) such that \( \phi(W, [0, h]) \subset \text{int}(N \setminus L) \). It follows \( S \subset \text{int} N' \), hence also \( S \subset \text{int}(N' \setminus L) \) and therefore
\[
S \subset \text{Inv cl}(N' \setminus L) \subset \text{Inv cl}(N \setminus L) = S
\]
which means the pair \((N', L)\) is isolating. Since \( N' \subset N \), \( L \) is positively invariant in \( N' \). Finally, let \( x_n \in N' \) be such that \( \phi^h(x_n) \notin N' \). Assume that \( x_n \to x \) and \( \phi^h(x) \in N' \). Since \( \phi^h(x_n) \notin N \) by the conclusion (b) and \( L \) is an exit set of \( N \), \( \phi^h(x) \in L \) and therefore \( L \) is an exit set of \( N' \) as well.

Proof of (c). By Proposition 1.3 S is an isolated invariant set with respect to \( \phi \). Since \( S \cap K = \emptyset, K \) is closed, and the conclusion (a) holds,
\[
S \subset \text{int}(N' \setminus L) \cap (X \setminus K) = \text{int}(N' \setminus K)
\]
and therefore
\[
\text{Inv}_\phi \text{cl}(N' \setminus K) \subset \text{Inv}_\phi \text{cl}(N' \setminus L) = S \subset \text{int}(N' \setminus K),
\]
i.e. the pair \((N', K)\) is isolating. It follows directly by definition that \(K\) is positively invariant in \(N'\) and it remains to prove that \(K\) is an exit set of \(N'\). To this reason assume that \(t \geq 0\) and
\[
\phi(x, [0, t]) \subset N', \quad \phi(x, t + \epsilon_n) \notin N'
\]
for a sequence \(\epsilon_n\) such that \(\epsilon_n > 0, \epsilon_n \to 0\). If \(x \in K\) then obviously \(\phi(x, t) \in K\).
In the other case \(x \in M\), hence \(x = \phi(y, h-t)\) for some \(y \in N\) and \(\phi(y, [0, h]) \subset N\).
Set \(y_n := \phi(y, \epsilon_n)\). Clearly, \(y_n \in N'\) for \(n\) large enough and \(\phi^n(y_n) \notin N'\), hence \(\phi^h(y_n) \notin N\) by the conclusion (b). Since \(L\) is an exit set of \(N\) with respect to \(\phi^h\), \(\phi(x, t) = \phi^h(y) \in L\) and the required property of the pair \((N, L)\) is proved. 

A.4. Proof of Proposition 3.2

As one can check directly, \((N', L')\) is an index pair for \(S\) with respect to \(\phi\) (see also [Sa, Rem. 5.4]). By Proposition 3.1 (a), for the system \(\phi^h\) the set \(S\) equal to the invariant part of \(\text{cl}(N' \setminus L')\) and \(L'\) is an exit set of \(N'\), hence in order to prove that \((N', L')\) is an index pair for \(S\) with respect to \(\phi^h\) it remains to prove that \(L'\) is positively invariant in \(N'\). Let \(x \in L'\) and assume that \(\phi^h(x) \in N'\). If \(\phi(x, [0, h]) \subset N'\) then clearly \(\phi^h(x) \in L'\). If, in the other hand, \(\phi(x, [0, h]) \notin N'\) then Lemmas A.1 and A.2 guarantee that \(\phi^h(x) \in K \subset L'\) and the result follows.
