ON THE INFINITARY VAN DER WAERDEN THEOREM

SHAHRAM MOHSENIPOUR

ABSTRACT. We give a purely combinatorial proof for the infinitary van der Waerden theorem.

1. Introduction

In [1], we introduced the following infinitary generalization of van der Waerden’s theorem which has the same relation with van der Waerden’s theorem as the Carlson-Simpson theorem [3] has with the Halse-Jewett theorem [5].

Let \( k \geq 2 \) be a positive integer, then for any finite coloring of \( \mathbb{N} \), there exist positive integers \( d_1, d_2, \ldots, d_n, \ldots \) and a color \( \gamma \) such that for every \( n \in \mathbb{N} \), there exists a positive integer \( a_n \) such that the set

\[
\{a_n + j_1d_1 + \cdots + j_nd_n | 0 \leq j_1, \ldots, j_n \leq k - 1\}
\]

is monochromatic with the color \( \gamma \).

It is possible to deduce the above theorem from the Carlson-Simpson theorem by generalizing the usual proof of deducing van der Waerden’s theorem from the Hales-Jewett theorem. The proof given in [1] uses a more elementary fact on uniformly recurrent infinite words from [6] which has its root in symbolic dynamics. It is worth noting that the above theorem can also be easily deduced from the Furstenberg-Weiss Theorem ([4], Theorem 1.5) by a successive iteration. In this note we present a direct combinatorial proof.

Now we explain some notation and conventions that we will use in our proof presented in the next section. By interval, we mean an interval of positive integers which is a set of the form \( I = \{a, a+1, a+2, \ldots, b\} \) for some positive integers \( a \leq b \). We also denote \( I \) by \([a, b]\), and for \( 1 \leq i \leq b - a + 1 \), by \( I[i] \) we mean the \( i \)th element of the interval \([a, b]\), namely, \( a + i - 1 \). The number of elements of \( I \) is denoted by \(|I|\). If \( b \) is a non-negative integer and \( A \) is a set of integers, then \( \mathbb{T}^bA \) will denote the set \( \{a + b | a \in A\} \). Let \( c \) be a positive integer, by a \( c \)-coloring, we mean a coloring with \( c \) many colors and furthermore the set of colors is \([c] = \{1, \ldots, c\}\). For positive integers \( k \geq 2, c \geq 1 \), \( W(k, c) \) will denote the van der Waerden number.

Key words and phrases. Infinitary van der Waerden’s theorem.
which is the least integer \( n \) such that for any \( c \)-coloring of \([n]\), there exists a monochromatic arithmetic progression of length \( k \).

2. Main Result

Fix positive integers \( k \geq 2, c \geq 1 \). We inductively define sequences of positive integers \( \langle W_n : n \in \mathbb{N} \rangle \) and \( \langle c_n : n \in \mathbb{N} \rangle \) (depending on \( k, c \)) as follows. Put \( W_1 = W(k, c), W_{n+1} = W(k, c_n) \) and \( c_n = c^{W_n \cdots W_1} \). Now let \( I \) be an interval with \( |I| = W_1 \). From \( I \) we inductively define a sequence of intervals \( I_n, n \in \mathbb{N} \) as follows. Let \( I_1 = I \) and

\[
I_{n+1} = I_n \cup T^{W_{n+1}-W_1} I_n \cup T^{2W_{n+1}-W_1} I_n \cup \ldots \cup T^{W_1} I_n.
\]

For instance for \( n = 2 \), we have

\[
I_2 = I_1 \cup T^{W_1} I_1 \cup T^{2W_1} I_1 \cup \ldots \cup T^{W_1} I_1,
\]

which according to \( |I_1| = W_1 \), it is easily seen that \( I_2 \) is an interval with \( |I_2| = W_2 W_1 \). Similarly for each \( n \in \mathbb{N} \), we have that \( I_n \) is an interval with \( |I_n| = W_n \cdots W_1 \). Obviously in the above definition, \( I_n \) depends on \( k, c, n, I \), so we denote it by \( I_n = \mathcal{I}(I, n, k, c) \). If \( k, c \) were fixed and were clear from the context, then we may denote it by \( I_n = \mathcal{I}(I, n) \). We will also use the easy fact that for any positive integer \( b \), the interval \( T^b \mathcal{I}(I, n, k, c) \) can be written in the form of \( \mathcal{I}(J, n, k, c) \) for some interval \( J \) with \( |J| = W_1 \). In fact due to the additive nature of the definition, we have \( T^b \mathcal{I}(I, n, k, c) = \mathcal{I}(T^b I, n, k, c) \).

**Proposition 2.1.** Let \( k \geq 2, c \geq 1, n \geq 1 \) be positive integers and let \( I \) be an interval with \( |I| = W_1 \). Then for any \( c \)-coloring of \( \mathcal{I}(I, n) \), there exist \( a, d_1, \ldots, d_n \) such that \( d_k \leq W_k \) for \( k = 1, \ldots, n \) and the following set

\[
\{ a + j_1 d_1 + \cdots + j_n d_n | 0 \leq j_1, \ldots, j_n \leq k - 1 \}
\]

is included in \( \mathcal{I}(I, n) \) and is monochromatic.

**Proof.** The proof is by induction on \( n \). The case \( n = 1 \) is just van der Waerden’s theorem and \( d_1 \leq W_1 \) is obvious. Now assume that the assertion is true for \( n \), we prove it for \( n + 1 \). Let \( \chi : \mathcal{I}(I, n+1) \rightarrow [c] \) is a \( c \)-coloring. By definition we have

\[
\mathcal{I}(I, n + 1) = \bigcup_{i=0}^{W_{n+1}-1} T^{iW_n \cdots W_1} \mathcal{I}(I, n).
\]

For simplicity we denote the interval \( T^{iW_n \cdots W_1} \mathcal{I}(I, n) \) by \( J_i \) (Recall that \( |J_i| = W_n \cdots W_1 \)). Now we define a coloring \( \chi^* \) on the set \( \{ 0, 1, \ldots, W_{n+1} - 1 \} \) as follows. For \( 0 \leq i < j < W_{n+1} \) we put \( \chi^*(i) = \chi^*(j) \) if for every \( 1 \leq t \leq W_n \cdots W_1 \) we have \( \chi(J_i[t]) = \chi(J_j[t]) \). Since \( \chi \) is a \( c \)-coloring, the number of colors for \( \chi^* \) is \( c^{W_n \cdots W_1} = c_n \). Thus from \( W_{n+1} = W(k, c_n) \) it follows that there exist \( 0 \leq b_1 < b_2 < \cdots < b_k \leq W_{n+1} - 1 \) with

\[
b_2 - b_1 = b_3 - b_2 = \cdots = b_k - b_{k-1} = d^* \leq W_{n+1}
\]
such that $\chi^*(b_1) = \chi^*(b_2) = \cdots = \chi^*(b_k)$. Having

$$J_{b_1} = T^{b_1 W_n \cdots W_l} I(I, n) = I(T^{b_1 W_n \cdots W_l} I, n),$$

we can use the induction hypothesis for the interval $T^{b_1 W_n \cdots W_l} I$ and the restriction of the $c$-coloring $\chi$ to this interval and thus obtain positive integers $a, d_1, \ldots, d_n$ and a color $\gamma \in [c]$ such that the set

$$\{a + jd_1 + \cdots + jd_n d_n | 0 \leq j \leq d_1, \ldots, j_n \leq k - 1\}$$

is included in $J_{b_1}$ and is monochromatic with the color $\gamma$. Moreover we have $d_1 \leq W_1, \ldots, d_n \leq W_n$. Now according to what we have obtained it is easily seen that for $j = 0, \ldots, k - 1$ we have $T^{jd_1} J_{b_1} = J_{b_1 + j}$. So for $1 \leq i \leq W_n \cdots W_1$ and $j = 0, \ldots, k - 1$ we get the relation $J_{b_1 + j} [i] = J_{b_1} [i] + jd^*$. Now let $a^* \in J_{b_1}$, then there is $1 \leq i^* \leq W_n \cdots W_1$ such that $a^* = J_{b_1} [i^*]$. Therefore for $j = 0, \ldots, k - 1$, we have

$$\chi(a^*) = \chi(J_{b_1} [i^*]) = \chi(J_{b_1 + j} [i^*]) = \chi(J_{b_1} [i^*] + jd^*) = \chi(a^* + jd^*).$$

Putting this together with the induction hypothesis, we infer that the set

$$\{a + jd_1 + \cdots + jd_n d_n + j_n d^*_n | 0 \leq j_1, \ldots, j_n, j_n + 1 \leq k - 1\}$$

is monochromatic with the color $\gamma$ too. Now set $d_{n+1} = d^*$. Also recall that $d^* \leq W_{n+1}$ and observe that the above set is included in $J_{b_1} \cup \cdots \cup J_{b_k}$ which is included in $I (I, n + 1)$. So the assertion is proved for $n + 1$ and the proof is complete.

**Theorem 2.2.** Let $k \geq 2, c \geq 1$ be positive integers, then for any $c$-coloring of $\mathbb{N}$, there exist positive integers $d_1, d_2, \ldots, d_n, \ldots$ and the color $\gamma \in [c]$ such that for every $n \in \mathbb{N}$, there exists a positive integer $a_n$ such that the set

$$\{a_n + jd_1 + \cdots + jd_n d_n | 0 \leq j_1, \ldots, j_n \leq k - 1\}$$

is monochromatic with the color $\gamma$.

**Proof.** We fix $k \geq 2, c \geq 1$ and a coloring $\chi : \mathbb{N} \to [c]$. We inductively define sequences of intervals $\langle J_m; m \in \mathbb{N} \rangle$ and $\langle J^*_m; m \in \mathbb{N} \rangle$ as follows. Let $J_1 = [1, W_1]$ and put $J^*_m = [1 + \max J_m, W_1 + \max J_m]$; $J_{m+1} = I(J^*_m, m)$. According to Proposition 2.1 for every $m \in \mathbb{N}$, there exist positive integers $e_m, l_m, \ldots, l_{mm}$ such that the set

$$A_m := \{e_m + jd_1 l_m + \cdots + jd_n l_{mm} | 0 \leq j_1, \ldots, j_m \leq k - 1\} \subset J_m$$

is monochromatic. Moreover for every $m \in \mathbb{N}$ we have

$$l_m \leq W_1, \ldots, l_{mm} \leq W_m.$$

Since the set of colors is finite, there exist $\gamma \in [c]$ and an infinite subset $S_0 \subset \mathbb{N}$ such that for each $m \in S_0$, the set $A_m$ is monochromatic with the color $\gamma$. Let $S_0 = \{m_i | i \in \mathbb{N}\}$ with $m_i < m_{i+1}$, then from the pigeonhole principle and

$$l_{m_1}, l_{m_2}, l_{m_3}, \ldots \leq W_1$$
it follows that there exists an infinite subset \( S_1 \subset S_0 \) such that for every \( t_1, t_2 \in S_1 \), we have \( l_{t_1} = l_{t_2} \). Similarly, by iterative use of the pigeonhole principle we obtain an infinite sequence of subsets

\[
S_0 \supset S_1 \supset \cdots \supset S_n \supset \cdots
\]

such that each \( S_n \) is infinite and we have that if \( t_1, t_2 \in S_n \), then \( l_{t_1} = l_{t_2} \).

For \( n \in \mathbb{N} \), let \( s_n = \min S_n \) and set \( a_n = e_{s_n}, d_n = l_{s_n} \). Now we verify that the set

\[
\{a_n + j_1d_1 + \cdots + j_nd_n | 0 \leq j_1, \ldots, j_n \leq k-1\}
\]

is monochromatic with the color \( \gamma \). To see this, first observe that

\[
a_n + j_1d_1 + \cdots + j_nd_n = e_{s_n} + j_1l_{s_1} + \cdots + j_nl_{s_n}.
\]

As \( s_n \in S_0 \), we have \( e_{s_n} + j_1l_{s_1} + \cdots + j_nl_{s_n} \in A_{s_n} \) and therefore

\[
\chi(e_{s_n} + j_1l_{s_1} + \cdots + j_nl_{s_n}) = \gamma.
\]

Also from \( s_n \in S_1, \ldots, s_n \in S_{n-1} \), we get

\[
l_{s_1} = l_{s_1}, \ldots, l_{s_n} = l_{s_{n-1}}(n-1),
\]

which implies that

\[
\chi(a_n + j_1d_1 + \cdots + j_nd_n) = \chi(e_{s_n} + j_1l_{s_1} + \cdots + j_nl_{s_n})
\]

\[
= \chi(e_{s_n} + j_1l_{s_1} + \cdots + j_nl_{s_n}) = \gamma.
\]

This finishes the proof. \( \square \)

By an easy modification of the arguments, we actually can prove a stronger theorem which is correspondent to Carlson’s generalization \([2]\) of the Carlson-Simpson theorem. See also Theorem 3 of \([1]\).

**Theorem 2.3.** Let \( c \geq 1 \) be a positive integer. Let \( 1 \leq k_1 \leq k_2 \leq \cdots \leq k_n \leq \cdots \) be a sequence of positive integers \( \geq 2 \), then for any \( c \) coloring of \( \mathbb{N} \), there exist positive integers \( d_1, d_2, \ldots, d_n, \ldots \) and the color \( \gamma \in [c] \) such that for every \( n \in \mathbb{N} \), there exists a positive integer \( a_n \) such that the set

\[
\{a_n + j_1d_1 + \cdots + j_nd_n | 0 \leq j_1 \leq k_1 - 1, \ldots, 0 \leq j_n \leq k_n - 1\}
\]

is monochromatic with the color \( \gamma \).
