# REGULARITY OF FULLY NON-LINEAR ELLIPTIC EQUATIONS ON HERMITIAN MANIFOLDS. III 

RIRONG YUAN

#### Abstract

Under structural conditions which are almost optimal, we derive a quantitative version of boundary estimate then prove existence of solutions to Dirichlet problem for a class of fully nonlinear elliptic equations on Hermitian manifolds.

## 1. Introduction

Let $(M, J, \omega)$ be a compact Hermitian manifold of complex dimension $n \geqslant 2$ with boundary $\partial M, \bar{M}=M \cup \partial M$, and $\omega=\sqrt{-1} g_{i \bar{j}} d z^{i} \wedge d \bar{z}^{j}$ denote the Kähler form being compatible with the complex structure $J$.

Let $\Gamma \subset \mathbb{R}^{n}$ be an open symmetric convex cone containing positive cone

$$
\Gamma_{n}:=\left\{\lambda \in \mathbb{R}^{n}: \text { each component } \lambda_{i}>0\right\} \subseteq \Gamma
$$

with vertex at the origin and with the boundary $\partial \Gamma \neq \emptyset$.
This article is a sequel to [32, 34]. The primary purpose of this paper is to study the following Dirichlet problem for standard equations

$$
\begin{equation*}
f(\lambda(\mathfrak{g}[u]))=\psi \text { in } M, \quad u=\varphi \text { on } \partial M, \tag{1.1}
\end{equation*}
$$

which are determined by smooth symmetric functions $f$, defined in $\Gamma$, of eigenvalues of complex Hessians, where $\mathfrak{g}[u]=\chi+\sqrt{-1} \partial \bar{\partial} u, \chi$ is a smooth real $(1,1)$-form, $\psi$ and $\varphi$ are sufficiently smooth functions.

In a pioneer paper [4, Caffarelli-Nirenberg-Spruck initiated the study of the Dirichlet problem of this type on bounded domains of real Euclidean spaces. Since then the equations of this type have been extensively studied in real and complex variables. In literature the hypotheses on $f$ include

$$
\begin{equation*}
f_{i}(\lambda):=\frac{\partial f}{\partial \lambda_{i}}(\lambda)>0 \text { in } \Gamma, \quad \forall 1 \leqslant i \leqslant n, \tag{1.2}
\end{equation*}
$$

$f$ is concave in $\Gamma$,

$$
\begin{equation*}
\text { For any } \sigma<\sup _{\Gamma} f \text { and } \lambda \in \Gamma \text { we have } \lim _{t \rightarrow+\infty} f(t \lambda)>\sigma, \tag{1.3}
\end{equation*}
$$

and the unbounded condition

$$
\begin{equation*}
\lim _{t \rightarrow+\infty} f\left(\lambda_{1}, \cdots, \lambda_{n-1}, \lambda_{n}+t\right)=\sup _{\Gamma} f, \quad \forall \lambda=\left(\lambda_{1}, \cdots, \lambda_{n}\right) \in \Gamma . \tag{1.5}
\end{equation*}
$$

The author is supported by the National Natural Science Foundation of China (Grant No. 11801587).

Conditions (1.2) and (1.3) coincide respectively the ellipticity and concavity of equation (1.1) for solutions $u$ in the class of $C^{2}$-admissible functions pointwise satisfying $\lambda(\mathfrak{g}[u]) \in \Gamma$. Also the constant

$$
\delta_{\psi, f}:=\inf _{M} \psi-\sup _{\partial \Gamma} f, \text { where } \sup _{\partial \Gamma} f=\sup _{\lambda_{0} \in \partial \Gamma} \limsup _{\lambda \rightarrow \lambda_{0}} f(\lambda)
$$

is used to measure whether or not the equation is degenerate. More explicitly, (1.1) is called non-degenerate if the right-hand side satisfies

$$
\begin{equation*}
\inf _{M} \psi>\sup _{\partial \Gamma} f \tag{1.6}
\end{equation*}
$$

while it is called degenerate if $\inf _{M} \psi=\sup _{\partial г} f$.
The Dirichlet problem was studied by Caffarelli-Kohn-Nirenberg-Spruck [3] for complex Monge-Ampère equation $(\chi \equiv 0)$ on bounded strictly pseudoconvex domains $\Omega \subset \mathbb{C}^{n}$, later extended by Guan [12] to general bounded domains by replacing strictly pseudoconvex restriction to boundary by a subsolution assumption satisfying

$$
\begin{equation*}
f(\lambda(\mathfrak{g}[\underline{u}])) \geqslant \psi, \lambda(\mathfrak{g}[\underline{u}]) \in \Gamma \text { in } \bar{M}, \text { and } \underline{u}=\varphi \text { on } \partial M . \tag{1.7}
\end{equation*}
$$

The subsolution is imposed as a vital tool to deal with second order boundary estimates, as done by [14, 12, 19] for Dirichlet problem of Mong-Ampère type equation on bounded domains; in addition, subsolution has a great advantage in the application to certain geometric problems as it relaxes restrictions to the shape of boundary; see e.g. [5, 16, 17]. Under the subsolution assumption, Li [21] studied Dirichlet problem (1.1) for a class of equations $(\chi \equiv 0)$ on bounded domains, which was extended by the author [33] to Kähler manifolds with nonnegative orthogonal bisectional curvature. On general complex manifolds without imposing such curvature assumption, the Dirichlet problem has only been solved in rather restricted cases, among others include complex Monge-Ampère equation [2, 13], complex inverse $\sigma_{k}$ equations [15], complex $k$-Hessian equations [7, and general equations satisfying (1.5) and $\Gamma=\Gamma_{n}$ [33]. However, little is known for more general fully nonlinear elliptic equations. The primary obstruction is to prove gradient estimate, which is, however, highly open on general complex manifolds. It is pretty hard to prove gradient bound directly, as Błocki [1] and Guan-Li [13] did for complex Monge-Ampère equation. Blow-up argument is an alternative approach to deriving gradient estimate, as shown by Dinew-Kołodziej for complex $k$-Hessian equations on closed Kähler manifolds by combining Liouville type theorem [8, Theorem 0.1] with Hou-Ma-Wu's estimate [20, Theorem 1.1]

$$
\begin{equation*}
\sup _{M} \Delta u \leqslant C\left(1+\sup _{M}|\nabla u|^{2}\right) . \tag{1.8}
\end{equation*}
$$

Recently, Hou-Ma-Wu's estimate and Dinew-Kołodziej's Liouville type theorem have been extended extensively by Székelyhidi [26, Proposition 13, Theorem 20] to very general cases. In an attempt to solve the Dirichlet
problem, one needs to prove a quantitative version of second order boundary estimates

$$
\begin{equation*}
\sup _{\partial M} \Delta u \leqslant C\left(1+\sup _{M}|\nabla u|^{2}\right), \tag{1.9}
\end{equation*}
$$

as shown by Chen [5] and complemented by [2, 23] for complex MongeAmpère equation; while their proof relies heavily on the specific structure of Monge-Ampère operator, thus it does not adapt to general equations.

The author has made some progress in this direction. In [32] the author derived quantitative boundary estimate (1.9) for Dirichlet problem (1.1) for general equations on Hermitian manifolds with holomorphically flat boundary, which was further extended by the author [34 to more general case when the Levi form of $\partial M$, denoted by $L_{\partial M}$, satisfies for any $z \in \partial M$

$$
\begin{equation*}
\left(-\kappa_{1}, \cdots,-\kappa_{n-1}\right) \in \bar{\Gamma}_{\infty}, \tag{1.10}
\end{equation*}
$$

where and hereafter $\kappa_{1}, \cdots, \kappa_{n-1}$ denote the eigenvalues of $L_{\partial M}$ with respect to $\omega^{\prime}=\left.\omega\right|_{T_{\partial M} \cap J T_{\partial M}}$, and $\bar{\Gamma}_{\infty}$ is the closure of $\Gamma_{\infty}$. Hereafter

$$
\Gamma_{\infty}:=\left\{\left(\lambda_{1}, \cdots, \lambda_{n-1}\right):\left(\lambda_{1}, \cdots, \lambda_{n-1}, \lambda_{n}\right) \in \Gamma\right\}
$$

is the projection of $\Gamma$ into $\mathbb{R}^{n-1}$. Such an assumption on shape of boundary is used to compare $\mathfrak{g}_{\alpha \bar{\beta}}$ with $\underline{\mathfrak{g}}_{\alpha \bar{\beta}}$ when restricted to boundary, which enables us to apply Lemmas A. 2 and A. 1 to understand the quantitative version of boundary estimate for double normal derivatives. A follow-up work was presented later in [35], where the author studied equations on Kähler cones from Sasaki geometry; see [17, 25] for more references concerning such equations.

The purpose of this paper is to drop the restriction to boundary. To compare $\mathfrak{g}_{\alpha \bar{\beta}}$ with $\underline{\mathfrak{g}}_{\alpha \bar{\beta}}$ on boundary, we use a method of Caffarelli-NirenbergSpruck [4]. We recall briefly their method of deriving boundary estimate for Dirichlet problem

$$
f\left(\lambda\left(D^{2} u\right)\right)=\psi \text { in } \Omega \subset \mathbb{R}^{n}, \quad u=\varphi \text { on } \partial \Omega .
$$

In order to compare $u_{\alpha \beta}$ with certain data on boundary, they have constructed delicate barrier functions based on a characterization of $\Gamma_{\infty}$ then dealt with boundary estimates for double normal derivatives in the unbounded case; while their estimate is not quantitative and does not figure out how does it rely on the gradient bound. We also refer to [21] for complex equations in $\mathbb{C}^{n}$ and to [30] for the boundary estimate in bounded case.

Combining the method from [4] with the idea of [32, 34], we prove the quantitative boundary estimate without restriction to boundary. This is new even when $M$ is a bounded domain in $\mathbb{C}^{n}$.

Theorem 1.1. Let $(M, J, \omega)$ be a compact Hermitian manifold with smooth boundary, $\psi, \varphi \in C^{\infty}$. Suppose (1.2), (1.3), (1.4), (1.5), (1.6) and (1.7) hold. For any admissible solution $u \in C^{3}(M) \cap C^{2}(\bar{M})$ to the Dirichlet problem (1.1), we have quantitative boundary estimate (1.9).

As a consequence of Theorem 1.1, together with the blow-up argument used in [26, 5], we completely solve the Dirichlet problem for a large class of fully nonlinear elliptic equations on general Hermitian manifolds.

Theorem 1.2. Let $(M, J, \omega)$ and $(f, \Gamma)$ be as in Theorem 1.1. Then for $\varphi \in C^{\infty}(\partial M)$ and $\psi \in C^{\infty}(\bar{M})$ with (1.6), the Dirichlet problem (1.1) has a unique smooth admissible solution.

A basic work in Kähler geometry is Yau's [31] proof of Calabi's conjecture. Recently, Székelyhidi-Tosatti-Weinkove [27] solved Gauduchon's conjecture [11] for dimension $n \geqslant 3$, thereby extending the Calabi-Yau theorem to non-Kähler geometry. The Gauduchon conjecture is reduced to solving a Monge-Ampère equation for ( $n-1$ )-plurisubharmonic ( $n-1$ )-PSH for short) functions

$$
\begin{equation*}
\left(\tilde{\chi}+\frac{1}{n-1}(\Delta u \omega-\sqrt{-1} \partial \bar{\partial} u)+Z\right)^{n}=e^{\phi} \omega^{n} \tag{1.11}
\end{equation*}
$$

on a closed $n$-complex dimensional Hermitian manifold $(M, \omega)$, where

$$
\tilde{\chi}=\frac{1}{(n-1)!} * \omega_{0}^{n-1}, Z=\frac{1}{(n-1)!} * \mathfrak{R e}\left(\sqrt{-1} \partial u \wedge \bar{\partial}\left(\omega^{n-2}\right)\right),
$$

here $\omega_{0}$ is a Gauduchon metric, $*$ is the Hodge star operator with respect to $\omega$; see [24, 29]. Following [18], also [28], we call $u$ is $(n-1)$-PSH if

$$
\begin{equation*}
\tilde{\chi}+\frac{1}{n-1}(\Delta u \omega-\sqrt{-1} \partial \bar{\partial} u)+Z>0 \text { in } M . \tag{1.12}
\end{equation*}
$$

When $n=2$ the equation is a standard complex Monge-Ampère equation that was solved by Cherrier [6]. We refer to [9, 10] for related topics.

The Dirichlet problem for equation (1.11) possibly with degenerate righthand side was solved by the author in the second part of [34, in which the boundary is mean pseudoconcave in the sense that

$$
\begin{equation*}
-\left(\kappa_{1}+\cdots+\kappa_{n-1}\right) \geqslant 0 \text { on } \partial M \tag{1.13}
\end{equation*}
$$

In the second part of this paper, we drop such an assumption and completely solve the Dirichlet problem.

Theorem 1.3. Let $(M, J, \omega)$ be a compact Hermitian manifold with smooth boundary. Assume the given data $\varphi, \phi$ are smooth. Suppose there is a $C^{2,1}$-smooth $(n-1)-P S H$ function $\underline{u}$ such that

$$
\begin{equation*}
\left(\tilde{\chi}+\frac{1}{n-1}(\Delta \underline{u} \omega-\sqrt{-1} \partial \bar{\partial} \underline{u})+\underline{Z}\right)^{n} \geqslant e^{\phi} \omega^{n} \text { in } M, \underline{u}=\varphi \text { on } \partial M, \tag{1.14}
\end{equation*}
$$

where $\underline{Z}=\frac{1}{(n-1)!} * \mathfrak{R e}\left(\sqrt{-1} \partial \underline{u} \wedge \bar{\partial}\left(\omega^{n-2}\right)\right)$. Then the Dirichlet problem for equation (1.11) with boundary data

$$
\begin{equation*}
u=\varphi \text { on } \partial M \tag{1.15}
\end{equation*}
$$

is uniquely solvable in class of smooth $(n-1)-P S H$ functions.

The paper is organized as follows. In Section 2 we briefly sketch the proof. In Sections 3 and 4 the quantitative boundary estimates for Dirichlet problem (1.1) and (1.11)-(1.15) are proved respectively. In Appendix A we append two key lemmas which are key ingredients.

## 2. Sketch of proof

For equations (1.1) and (1.11) the following second order estimate

$$
\begin{equation*}
\sup _{M} \Delta u \leqslant C\left(1+\sup _{M}|\nabla u|^{2}+\sup _{\partial M}|\Delta u|\right) \tag{2.1}
\end{equation*}
$$

was proved by Székelyhidi [26, Proposotion 13] and Székelyhidi-TosattiWeinkove [27, Section 3] respectively.

Our goal is to derive the quantitative boundary estimate (1.9), i.e.,

$$
\sup _{\partial M} \Delta u \leqslant C\left(1+\sup _{M}|\nabla u|^{2}\right) .
$$

In [34, the author proved quantitative boundary estimate for tangentialnormal derivatives.

Proposition 2.1 ([34). Let $(M, \omega)$ be a compact Hermitian manifold with $C^{3}$-smooth boundary, $\varphi \in C^{3}(\partial M), \psi \in C^{1}(\bar{M})$. Suppose (1.2), (1.3), (1.6) and (1.7) hold. Then for any admissible solution $u \in C^{3}(M) \cap C^{2}(\bar{M})$ to the Dirichlet problem (1.1), there is a uniform positive constant $C$ depending on $|\varphi|_{C^{3}(\bar{M})},|\underline{u}|_{C^{2}(\bar{M})},|u|_{C^{0}(M)},|\nabla u|_{C^{0}(\partial M)}, \sup _{M}|\nabla \psi|, \partial M$ up to third derivatives and other known data (but neither on $\left(\delta_{\psi, f}\right)^{-1}$ nor on $\sup _{M}|\nabla u|$ ) such that

$$
\begin{equation*}
\left|\nabla^{2} u(X, \nu)\right| \leqslant C\left(1+\sup _{M}|\nabla u|\right) \tag{2.2}
\end{equation*}
$$

for any $X \in T_{\partial M}$ with $|X|=1$, where $\nabla^{2} u$ denotes the real Hessian of $u$, and $\nu$ denotes the unit inner normal vector along the boundary.

Proposition 2.2 ([34). Let $(M, \omega)$ be a compact Hermitian manifold with $C^{3}$ boundary, $\varphi \in C^{3}(\partial M), \psi \in C^{1}(\bar{M})$. Let $u \in C^{3}(M) \cap C^{2}(\bar{M})$ be a $(n-1)$-PSH function to solve the Dirichlet problem (1.11) with boundary value condition (1.15). Suppose (1.14) holds. Then the estimate (2.2) holds for a uniform positive constant $C$ depending on $|\varphi|_{C^{3}(\bar{M})},|\underline{u}|_{C^{2}(\bar{M})},|u|_{C^{0}(M)}$, $|\nabla u|_{C^{0}(\partial M)}, \sup _{M}|\nabla \psi|, \partial M$ up to third derivatives and other known data.

To complete the proof of Theorems 1.1 and [1.3, as in [32, 34], we are guided toward

Proposition 2.3. Let $(M, J, \omega)$ be a compact Hermitian manifold with $C^{3}$ boundary. Let $u \in C^{3}(\bar{M})$ be an admissible solution to Dirichlet problem (1.1) with data $\psi \in C^{0}(\bar{M})$ and $\varphi \in C^{2}(\partial M)$. We denote

$$
T_{\partial M}^{1,0}=T_{\bar{M}}^{1,0} \cap T_{\partial M}^{\mathbb{C}}, \quad \xi_{n}=\frac{1}{\sqrt{2}}(\nu-\sqrt{-1} J \nu) .
$$

Suppose (1.2), (1.3), (1.4), (1.5), (1.6) and (1.7) hold. Then for $\xi_{\alpha}, \xi_{\beta} \in$ $T_{\partial M, x_{0}}^{1,0}, x_{0} \in \partial M, 1 \leqslant \alpha, \beta \leqslant n-1$ satisfying $g\left(\xi_{\alpha}, \bar{\xi}_{\beta}\right)=\delta_{\alpha \beta}$ at $x_{0}$, we have

$$
\begin{equation*}
\mathfrak{g}\left(\xi_{n}, J \bar{\xi}_{n}\right)\left(x_{0}\right) \leqslant C\left(1+\sum_{\alpha=1}^{n-1}\left|\mathfrak{g}\left(\xi_{\alpha}, J \bar{\xi}_{n}\right)\left(x_{0}\right)\right|^{2}\right) \tag{2.3}
\end{equation*}
$$

where $C$ is a uniform positive constant depending only on $\left(\delta_{\psi, f}\right)^{-1},|u|_{C^{0}(M)}$, $|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(\bar{M})}, \partial M$ up to third derivatives and other known data (but not on $\left.\sup _{M}|\nabla u|\right)$.
Proposition 2.4. Let $(M, J, \omega)$ be a compact Hermitian manifold with $C^{3}$ boundary, let $\psi \in C^{0}(\bar{M})$ and $\varphi \in C^{2}(\partial M)$. In addition we assume (1.14) is satisfied. For any $(n-1)-P S H$ function $u \in C^{2}(\bar{M})$ solving Dirichlet problem (1.11) and (1.15), then there is a uniform positive constant $C$ depending only on $\left(\delta_{\psi, f}\right)^{-1},|u|_{C^{0}(M)},|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(\bar{M})}, \partial M$ up to third derivatives and other known data, such that for any $x_{0} \in \partial M$,

$$
\begin{equation*}
\tilde{\mathfrak{g}}\left(\xi_{n}, J \bar{\xi}_{n}\right)\left(x_{0}\right) \leqslant C\left(1+\sum_{\alpha=1}^{n-1}\left|\tilde{\mathfrak{g}}\left(\xi_{\alpha}, J \bar{\xi}_{n}\right)\left(x_{0}\right)\right|^{2}\right) \tag{2.4}
\end{equation*}
$$

Here $\tilde{\mathfrak{g}}$ is denoted by (4.2), and $\xi_{i}$ are as in Proposition 2.3.

## 3. Proof of Proposition 2.3

We always assume $\Gamma$ is of type 1 in the sense of 4], then $\Gamma_{\infty}$ is an open symmetric convex cone in $\mathbb{R}^{n-1}$; otherwise we have done by [34] as $\Gamma_{\infty}=$ $\mathbb{R}^{n-1}$ whenever $\Gamma$ is of type 2 .

In this section we always denote $\mathfrak{g}=\mathfrak{g}[u], \underline{\mathfrak{g}}=\mathfrak{g}[\underline{u}], \mathfrak{g}[v]=\sqrt{-1} \mathfrak{g}[v]_{i \bar{j}} d z_{i} \wedge$ $d \bar{z}_{j}, \chi=\sqrt{-1} \chi_{i \bar{j}} d z_{i} \wedge d \bar{z}_{j}, v_{i}=\frac{\partial v}{\partial z_{i}}, v_{i \bar{j}}=\frac{\partial^{2} v}{\partial z_{i} \partial \bar{z}_{j}}$, etc. And the Greek letters, such as $\alpha, \beta$, range from 1 to $n-1$. We also denote $\sigma(z)$ by the distance function from $z$ to $\partial M$ with respect to $\omega$.
3.1. First ingredient of proof. Given $p_{0} \in \partial M$. We can choose a local holomorphic coordinate systems $\left(z_{1}, \cdots, z_{n}\right), z_{i}=x_{i}+\sqrt{-1} y_{i}$, centered at $p_{0}$, such that $g_{i \bar{j}}(0)=\delta_{i j}, \frac{\partial}{\partial x_{n}}$ is the inner normal vector at the origin, and $T_{p_{0}, \partial M}^{1,0}$ is spanned by $\frac{\partial}{\partial z_{\alpha}}$ for $1 \leqslant \alpha \leqslant n-1$. Let' denote

$$
A(R)=\left(\begin{array}{ccccc}
\mathfrak{g}_{1 \overline{1}} & \mathfrak{g}_{1 \overline{2}} & \cdots & \mathfrak{g}_{1 \overline{(n-1)}} & \mathfrak{g}_{1 \bar{n}} \\
\mathfrak{g}_{2 \overline{1}} & \mathfrak{g}_{2 \overline{2}} & \cdots & \mathfrak{g}_{2 \overline{(n-1)}} & \mathfrak{g}_{2 \bar{n}} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\mathfrak{g}_{(n-1) \overline{1}} & \mathfrak{g}_{(n-1) \overline{2}} & \cdots & \mathfrak{g}_{(n-1) \overline{(n-1)}} & \mathfrak{g}_{(n-1) \bar{n}} \\
\mathfrak{g}_{n \overline{1}} & \mathfrak{g}_{n \overline{2}} & \cdots & \mathfrak{g}_{n \overline{(n-1)}} & R
\end{array}\right)
$$

Denote by $\lambda^{\prime}=\lambda_{\omega^{\prime}}\left(\mathfrak{g}_{\alpha \bar{\beta}}\right), \underline{\lambda}^{\prime}=\lambda_{\omega^{\prime}}\left(\underline{\mathfrak{g}}_{\alpha \bar{\beta}}\right)$. We know

$$
\begin{equation*}
\lambda^{\prime}, \underline{\lambda}^{\prime} \in \Gamma_{\infty} \tag{3.1}
\end{equation*}
$$

By the openness of $\Gamma$ we know there is a uniform positive constant $\varepsilon_{0}$ depending only on $\inf _{z \in \partial M} \underline{\mathfrak{g}}(z) \mid$ such that

$$
\begin{equation*}
\left(\underline{\lambda}_{1}^{\prime}-\varepsilon_{0}, \cdots, \underline{\lambda}_{n-1}^{\prime}-\varepsilon_{0}, R_{0}\right) \in \Gamma . \tag{3.2}
\end{equation*}
$$

The boundary value condition implies

$$
\begin{equation*}
u_{\alpha}(0)=\underline{u}_{\alpha}(0), \quad u_{\alpha \bar{\beta}}(0)=\underline{u}_{\alpha \bar{\beta}}(0)+(u-\underline{u})_{x_{n}}(0) \sigma_{\alpha \bar{\beta}}(0) . \tag{3.3}
\end{equation*}
$$

Let $\eta=(u-\underline{u})_{x_{n}}(0)$, thus at $p_{0}(z=0)$

$$
\begin{equation*}
\mathfrak{g}_{\alpha \bar{\beta}}=\underline{\mathfrak{g}}_{\alpha \bar{\beta}}+\eta \sigma_{\alpha \bar{\beta}} . \tag{3.4}
\end{equation*}
$$

By the maximum principle and boundary value condition, one derives

$$
\begin{equation*}
0 \leqslant \eta \leqslant(\check{u}-\underline{u})_{x_{n}}(0), \quad \underline{u} \leqslant u \leqslant \check{u} \text { in } M, \tag{3.5}
\end{equation*}
$$

where $\check{u}$ is a supersolution solving

$$
\begin{equation*}
\operatorname{tr}_{\omega}(\mathfrak{g}[\check{u}])=0 \text { in } M, \quad \check{u}=\varphi \text { on } \partial M . \tag{3.6}
\end{equation*}
$$

The existence of $\check{u}$ follows from standard theory of elliptic equations of second order.

When $\eta=0$, one has $u_{\alpha \bar{\beta}}=\underline{u}_{\alpha \bar{\beta}}$ and the proof is the same as that from [32] where $\partial M$ is Levi flat; see also [34] for the case when $\partial M$ satisfies (1.10).

From now on we assume $\eta>0$. We rewrite $u_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}$ as

$$
\begin{equation*}
u_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}=(1-t)\left(\underline{u}_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}\right)+\left(t\left(\underline{u}_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}\right)+\eta \sigma_{\alpha \bar{\beta}}\right) . \tag{3.7}
\end{equation*}
$$

For simplicity, as in [4] also as in [21], we denote

$$
\begin{equation*}
A_{t}=\sqrt{-1}\left[t\left(\underline{u}_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}\right)+\eta \sigma_{\alpha \bar{\beta}}\right] d z_{\alpha} \wedge d \bar{z}_{\beta} \tag{3.8}
\end{equation*}
$$

Clearly, $\left(A_{1}\right)_{\alpha \bar{\beta}}=u_{\alpha \bar{\beta}}+\chi_{\alpha \bar{\beta}}$ so $\lambda_{\omega^{\prime}}\left(A_{1}\right) \in \Gamma_{\infty}$. On the other hand, $\lambda_{\omega^{\prime}}\left(A_{t}\right) \in$ $\mathbb{R}^{n-1} \backslash \Gamma_{\infty}$ for $t \ll-1$. Let $t_{0}$ be the first $t$ as we decrease $t$ from 1 so that

$$
\begin{equation*}
\lambda_{\omega^{\prime}}\left(A_{t_{0}}\right) \in \partial \Gamma_{\infty} \tag{3.9}
\end{equation*}
$$

Clearly, for a uniform positive constant $T_{0}$ under control,

$$
\begin{equation*}
-T_{0}<t_{0}<1 \tag{3.10}
\end{equation*}
$$

We then have the following identity

$$
A(R)=\left(\begin{array}{cc}
\left(1-t_{0}\right)\left(\mathfrak{g}_{\alpha \bar{\beta}}-\frac{\varepsilon_{0}}{4} \delta_{\alpha \beta}\right) & \mathfrak{g}_{\alpha \bar{n}} \\
\mathfrak{g}_{n \bar{\beta}} & R / 2
\end{array}\right)+\left(\begin{array}{cc}
\left(A_{t_{0}}\right)_{\alpha \bar{\beta}}+\frac{\varepsilon_{0}\left(1-t_{0}\right)}{4} \delta_{\alpha \beta} & 0 \\
0 & R / 2
\end{array}\right),
$$

here $\varepsilon_{0}$ is the constant from (3.2). Let $A^{\prime}(R)=\left(\begin{array}{cc}\left(1-t_{0}\right)\left(\underline{\mathfrak{g}}_{\alpha \bar{\beta}}-\frac{\varepsilon_{0}}{4} \delta_{\alpha \beta}\right) & \mathfrak{g}_{\alpha \bar{n}} \\ \mathfrak{g}_{n \bar{\beta}} & R / 2\end{array}\right)$, and $A^{\prime \prime}(R)=\left(\begin{array}{cc}\left(A_{t_{0}}\right)_{\alpha \bar{\beta}}+\frac{\left(1-t_{0}\right) \varepsilon_{0}}{4} \delta_{\alpha \beta} & 0 \\ 0 & R / 2\end{array}\right)$. Denote

$$
\begin{equation*}
\tilde{\lambda}^{\prime}=\left(\tilde{\lambda}_{1}^{\prime}, \cdots, \tilde{\lambda}_{n-1}^{\prime}\right):=\lambda_{\omega^{\prime}}\left(A_{t_{0}}\right) . \tag{3.11}
\end{equation*}
$$

By (3.10) and (3.5), there is a uniform constant $C_{0}>0$ so that $\left|\tilde{\lambda}^{\prime}\right| \leqslant C_{0}$, that is $\tilde{\lambda}^{\prime}$ is contained a compact subset of $\partial \Gamma_{\infty}$, i.e.

$$
\begin{equation*}
\tilde{\lambda}^{\prime} \in K^{\prime}:=\left\{\lambda^{\prime} \in \partial \Gamma_{\infty}:\left|\lambda^{\prime}\right| \leqslant C_{0}\right\} . \tag{3.12}
\end{equation*}
$$

So there is a uniform positive constant $R^{\prime}$ possibly depending on (( $1-$ $\left.\left.t_{0}\right) \varepsilon_{0}\right)^{-1}$ such that for any $R>R^{\prime}$,

$$
\lambda\left(A^{\prime \prime}(R)\right) \in \Gamma .
$$

By the unbounded condition (1.5) there is a uniform positive constant $R_{1}$ depending on $\left(1-t_{0}\right)^{-1}, \varepsilon_{0}$ and $\underline{\lambda}^{\prime}$ such that

$$
\begin{equation*}
f\left(\left(1-t_{0}\right)\left(\underline{\lambda}_{1}^{\prime}-\frac{\varepsilon_{0}}{2}\right), \cdots,\left(1-t_{0}\right)\left(\underline{\lambda}_{n-1}^{\prime}-\frac{\varepsilon_{0}}{2}\right), R_{1}\right)>f(\lambda(\underline{\mathfrak{g}})) . \tag{3.13}
\end{equation*}
$$

Here is the only place where we use the unbounded condition (1.5). As a contrast, such a unbounded condition can be removed when $t_{0} \leqslant 0$ occurs.

Let's pick $\epsilon=\frac{\left(1-t_{0}\right) \varepsilon_{0}}{4}$ in Lemma A.2, and we set

$$
\begin{aligned}
\frac{R_{c}}{2}= & \frac{4(2 n-3)}{\left(1-t_{0}\right) \varepsilon_{0}} \sum_{\alpha=1}^{n-1}\left|\mathfrak{g}_{\alpha \bar{n}}\right|^{2}+(n-1) \sum_{\alpha=1}^{n-1}|\underline{\mathfrak{g}}|+R_{0}+R_{1}+R^{\prime} \\
& +\frac{(n-1)\left(1-t_{0}\right) \varepsilon_{0}}{4}+\frac{(n-2)\left(1-t_{0}\right) \varepsilon_{0}}{4(2 n-3)},
\end{aligned}
$$

where $\varepsilon_{0}, R_{0}, R_{1}$ and $R^{\prime}$ are fixed constants we have chosen above. It follows from Lemma A. 2 that the eigenvalues $\lambda\left(A^{\prime}\left(R_{c}\right)\right.$ ) of $A^{\prime}\left(R_{c}\right)$ (possibly with an order) shall behavior like

$$
\begin{align*}
& \lambda_{\alpha}\left(A^{\prime}\left(R_{c}\right) \geqslant\left(1-t_{0}\right)\left(\underline{\lambda}_{\alpha}^{\prime}-\frac{\varepsilon_{0}}{2}\right), 1 \leqslant \alpha \leqslant n-1,\right.  \tag{3.14}\\
& \lambda_{n}\left(A^{\prime}\left(R_{c}\right) \geqslant R_{c} / 2-(n-1)\left(1-t_{0}\right) \varepsilon_{0} / 4 .\right.
\end{align*}
$$

In particular, $\lambda\left(A^{\prime}\left(R_{c}\right)\right) \in \Gamma$. So $\lambda\left(A\left(R_{c}\right)\right) \in \Gamma$. Note that (A.3) implies

$$
\begin{equation*}
f\left(\lambda\left(A\left(R_{c}\right)\right)\right) \geqslant f\left(\lambda\left(A^{\prime}\left(R_{c}\right)\right)\right) . \tag{3.15}
\end{equation*}
$$

It follows from (3.13), (3.14), (3.15) that

$$
\begin{equation*}
\mathfrak{g}_{n \bar{n}} \leqslant R_{c} . \tag{3.16}
\end{equation*}
$$

3.2. Second ingredient of proof. To complete the proof of Proposition 2.3. from (3.16), it requires only to prove $\left(1-t_{0}\right)^{-1}$ can be uniformly bounded from above. In other words

$$
\begin{equation*}
\left(1-t_{0}\right)^{-1} \leqslant C . \tag{3.17}
\end{equation*}
$$

In the case when $\partial M$ is holomorphically flat or more generally (1.10), one can check $t_{0} \leqslant 0$ as shown in [32, 34] previously where (1.5) is not necessary. For general case without restriction to boundary, we prove

Lemma 3.1. Let $t_{0}$ be as defined above, then the inequality (3.17) holds for a uniform positive constant $C$ depending on $|u|_{C^{0}(M)},|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(M)}$, $\left(\delta_{\psi, f}\right)^{-1}, \partial M$ up to third derivatives and other known data.

We follow some idea of Caffarelli-Nirenberg-Spruck [4], further extended by Li [21] to equations in $\mathbb{C}^{n}$, and use some notation of [4, 21].

Without loss of generality $t_{0}>\frac{1}{2}$ and $\tilde{\lambda}_{1}^{\prime} \leqslant \cdots \leqslant \tilde{\lambda}_{n-1}^{\prime}$ (as denoted in (3.11)). It was proved in [4, Lemma 6.1] that for $\tilde{\lambda}^{\prime} \in \partial \Gamma_{\infty}$ there is a
supporting plane for $\Gamma_{\infty}$ and one can choose $\mu_{j}$ with $\mu_{1} \geqslant \cdots \geqslant \mu_{n-1} \geqslant 0$ so that

$$
\begin{equation*}
\Gamma_{\infty} \subset\left\{\lambda^{\prime} \in \mathbb{R}^{n-1}: \sum_{\alpha=1}^{n-1} \mu_{\alpha} \lambda_{\alpha}^{\prime}>0\right\}, \quad \sum_{\alpha=1}^{n-1} \mu_{\alpha}=1, \sum_{\alpha=1}^{n-1} \mu_{\alpha} \tilde{\lambda}_{\alpha}^{\prime}=0 . \tag{3.18}
\end{equation*}
$$

By a result of [22] (see also [4, Lemma 6.2]) (assume $\underline{\lambda}_{1}^{\prime} \leqslant \cdots \leqslant \underline{\lambda}_{n-1}^{\prime}$ )

$$
\begin{equation*}
\sum_{\alpha=1}^{n-1} \mu_{\alpha} \underline{\mathfrak{g}}_{\alpha \bar{\alpha}} \geqslant \sum_{\alpha=1}^{n-1} \mu_{\alpha} \underline{\lambda}_{\alpha}^{\prime} \geqslant \inf _{p \in \partial M} \sum_{\alpha=1}^{n-1} \mu_{\alpha} \underline{\lambda}_{\alpha}^{\prime}(p) \geqslant a_{0}>0 . \tag{3.19}
\end{equation*}
$$

Here we use (3.1), (3.12) and (3.18). We shall mention that $a_{0}$ depends on $\operatorname{disc}(\lambda(\underline{\mathfrak{g}}), \partial \Gamma)$. Without loss of generality, we assume $\left(A_{t_{0}}\right)_{\alpha \bar{\beta}}=t_{0} \underline{\mathfrak{g}}_{\alpha \bar{\beta}}+\eta \sigma_{\alpha \bar{\beta}}$ is diagonal at $p_{0}$. From (3.18) one has at the origin

$$
\begin{equation*}
0=t_{0} \sum_{\alpha=1}^{n-1} \mu_{\alpha} \underline{\mathfrak{g}}_{\alpha \bar{\alpha}}+\eta \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}} \geqslant a_{0} t_{0}+\eta \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}} . \tag{3.20}
\end{equation*}
$$

Together with (3.5), we see at the origin $\{z=0\}$

$$
\begin{equation*}
-\sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}} \geqslant \frac{a_{0} t_{0}}{\sup _{\partial M}|\nabla(\check{u}-\underline{u})|}=: a_{1}>0, \tag{3.21}
\end{equation*}
$$

where $\check{u}$ and $\underline{u}$ are respectively supersolution and subsolution. Let

$$
\Omega_{\delta}=M \cap B_{\delta}(0),
$$

where $B_{\delta}(0)=\{z \in M:|z|<\delta\}$. On $\Omega_{\delta}$, we let

$$
\begin{equation*}
d(z)=\sigma(z)+\tau|z|^{2} \tag{3.22}
\end{equation*}
$$

where $\tau$ is a positive constant to be determined; and let

$$
\begin{equation*}
w(z)=\underline{u}(z)+\left(\eta / t_{0}\right) \sigma(z)+l(z) \sigma(z)+A d(z)^{2}, \tag{3.23}
\end{equation*}
$$

where $l(z)=\sum_{i=1}^{n}\left(l_{i} z_{i}+\bar{l}_{i} \bar{z}_{i}\right), l_{i} \in \mathbb{C}, \bar{l}_{i}=l_{\bar{i}}$, to be chosen as in (3.26), and $A$ is a positive constant to be determined. Furthermore, on $\partial M \cap \bar{\Omega}_{\delta}$, $u(z)-w(z)=-A \tau^{2}|z|^{4}$. On $M \cap \partial B_{\delta}(0)$,

$$
\begin{aligned}
u(z)-w(z) & =u(z)-\underline{u}(z)-\left(\eta / t_{0}\right) \sigma(z)-l(z) \sigma(z)-A d(z)^{2} \\
& \leqslant|u-\underline{u}|_{C^{0}\left(\Omega_{\delta}\right)}-\left(2 A \tau \delta^{2}+\frac{\eta}{t_{0}}-2 n \sup _{i}\left|l_{i}\right| \delta\right) \sigma(z)-A \tau^{2} \delta^{4} \\
& \leqslant-\frac{A \tau^{2} \delta^{4}}{2}
\end{aligned}
$$

provided $A \gg 1$ depending on $|u|_{C^{0}(M)}$.
Let $T_{1}(z), \cdots, T_{n-1}(z)$ be an orthonormal basis for holomorphic tangent space of level hypersurface $\{w: d(w)=d(z)\}$ at $z$, so that at the origin $T_{\alpha}(0)=\frac{\partial}{\partial z_{\alpha}}$ for each $1 \leqslant \alpha \leqslant n-1$.

Such a basis exists: We see at the origin $\partial d(0)=\partial \sigma(0)$. Thus for $1 \leqslant$ $\alpha \leqslant n-1$, we can choose $T_{\alpha}$ such that at the origin $T_{\alpha}(0)=\frac{\partial}{\partial z_{\alpha}}$.

The result of [22] (see also [4, Lemma 6.2]) implies the following lemma.

Lemma 3.2. Let $T_{1}(z), \cdots, T_{n-1}(z)$ be as above, and let $T_{n}=\frac{\partial d}{|\partial d|}$. For a $\operatorname{real}(1,1)$-form $\Theta=\sqrt{-1} \Theta_{i \bar{j}} d z_{i} \wedge d \bar{z}_{j}$, we denote by $\lambda(\Theta)=\left(\lambda_{1}(\Theta), \cdots, \lambda_{n}(\Theta)\right)$ the eigenvalues of $\Theta$ (with respect to $\omega$ ) with order $\lambda_{1}(\Theta) \leqslant \cdots \leqslant \lambda_{n}(\Theta)$. Then for any $\mu_{1} \geqslant \cdots \geqslant \mu_{n}$,

$$
\sum_{i=1}^{n} \mu_{i} \lambda_{i}(\Theta) \leqslant \sum_{i=1}^{n} \mu_{i} \Theta\left(T_{i}, J \bar{T}_{i}\right) .
$$

Let $\mu_{1}, \cdots, \mu_{n-1}$ be as in (3.18), and set $\mu_{n}=0$. Let's denote $T_{\alpha}=$ $\sum_{k=1}^{n} T_{\alpha}^{k} \frac{\partial}{\partial z_{k}}$. For $\Theta=\sqrt{-1} \Theta_{i \bar{j}} d z_{i} \wedge d \bar{z}_{j}$, we define

$$
\Lambda_{\mu}(\Theta):=\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \Theta_{i \bar{j}} .
$$

Lemma 3.3. There are parameters $\tau, A, l_{i}, \delta$ depending only on $|u|_{C^{0}(M)}$, $|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(M)}, \partial M$ up to third derivatives and other known data, such that

$$
\Lambda_{\mu}(\mathfrak{g}[w]) \leqslant 0 \text { in } \Omega_{\delta}, \quad u \leqslant w \text { on } \partial \Omega_{\delta} .
$$

Proof. By direct computation

$$
\begin{aligned}
\Lambda_{\mu}(\mathfrak{g}[w])= & \sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\chi_{i \bar{j}}+\underline{u}_{i \bar{j}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right)+2 A d(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}} \\
& +\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(l(z) \sigma_{i \bar{j}}+l_{i} \sigma_{\bar{j}}+\sigma_{i} l_{\bar{j}}\right) .
\end{aligned}
$$

- At the origin $\{z=0\}, T_{\alpha}^{i}=\delta_{\alpha i}$,

$$
\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\chi_{i \bar{j}}+\underline{u}_{i \bar{j}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right)(0)=\frac{1}{t_{0}} \sum_{\alpha=1}^{n-1} \mu_{\alpha}\left(A_{t_{0}}\right)_{\alpha \bar{\alpha}}=0 .
$$

So there are complex constants $k_{i}$ such that

$$
\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\chi_{i \bar{j}}+\underline{u}_{i \bar{j}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right)(z)=\sum_{i=1}^{n}\left(k_{i} z_{i}+\bar{k}_{i} \bar{z}_{i}\right)+O\left(|z|^{2}\right) .
$$

$$
2 A d(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}} \leqslant-\frac{a_{1} A}{2} d(z)
$$

since

$$
\begin{aligned}
\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}}= & \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(z)+\tau \sum_{\alpha=1}^{n-1} \mu_{\alpha} \\
& +\sum_{\alpha=1}^{n-1} \mu_{\alpha}\left(T_{\alpha}^{i} \bar{T}_{\alpha}^{j}(z)-T_{\alpha}^{i} \bar{T}_{\alpha}^{j}(0)\right) d_{i \bar{j}} \\
= & -a_{1}+\tau+O(|z|) \leqslant-\frac{a_{1}}{4}
\end{aligned}
$$

provided one chooses $0<\delta, \tau \ll 1$. Here we also use (3.21),

$$
\begin{equation*}
\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}(z)=\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}(0)+O(|z|)=\sum_{\alpha=1}^{n-1} \delta_{\alpha i} \delta_{\alpha j}+O(|z|) \tag{3.24}
\end{equation*}
$$

and

$$
\begin{gather*}
\sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(z)=\sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(0)+O(|z|) .  \tag{3.25}\\
l(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \sigma_{i \bar{j}}+\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(l_{i} \sigma_{\bar{j}}+\sigma_{i} l_{\bar{j}}\right) \\
=l(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(0)-\tau \sum_{\alpha=1}^{n-1} \mu_{\alpha}\left(z_{\alpha} l_{\alpha}+\bar{z}_{\alpha} \bar{l}_{\alpha}\right)+O\left(|z|^{2}\right)
\end{gather*}
$$

since by (3.24), $\sum_{i=1}^{n} T_{\alpha}^{i} \sigma_{i}=-\tau \sum_{i=1}^{n} T_{\alpha}^{i} \bar{z}_{i}$ we have

$$
\begin{aligned}
l(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \sigma_{i \bar{j}} & =l(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(0)+O\left(|z|^{2}\right), \\
\sum_{\alpha=1}^{n-1} \mu_{\alpha} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(l_{i} \sigma_{\bar{j}}+\sigma_{i} l_{\bar{j}}\right) & =-\tau \sum_{\alpha=1}^{n-1} \mu_{\alpha}\left(\bar{l}_{\alpha} \bar{z}_{\alpha}+l_{\alpha} z_{\alpha}\right)+O\left(|z|^{2}\right) .
\end{aligned}
$$

Putting these together,

$$
\begin{aligned}
\Lambda_{\mu}(\mathfrak{g}[w]) \leqslant & \sum_{\alpha=1}^{n-1} 2 \mathfrak{R e}\left\{z_{\alpha}\left(k_{\alpha}-\tau \mu_{\alpha} l_{\alpha}+l_{\alpha} \sum_{\beta=1}^{n-1} \mu_{\beta} \sigma_{\beta \bar{\beta}}(0)\right)\right\} \\
& +2 \mathfrak{R e}\left\{z_{n}\left(k_{n}+l_{n} \sum_{\beta=1}^{n-1} \mu_{\beta} \sigma_{\beta \bar{\beta}}(0)\right)\right\}-\frac{A a_{1}}{2} d(z)+O\left(|z|^{2}\right) .
\end{aligned}
$$

Let $l_{n}=-\frac{k_{n}}{\sum_{\beta=1}^{n-1} \mu_{\beta} \sigma_{\beta \bar{\beta}}(0)}$. For $1 \leqslant \alpha \leqslant n-1$, we set

$$
\begin{equation*}
l_{\alpha}=-\frac{k_{\alpha}}{\sum_{\beta=1}^{n-1} \mu_{\beta} \sigma_{\beta \bar{\beta}}(0)-\tau \mu_{\alpha}} . \tag{3.26}
\end{equation*}
$$

From $\mu_{\alpha} \geqslant 0$ and (3.21), we see such $l_{i}$ (or equivalently the $l(z)$ ) are all well defined and are uniformly bounded.

We thus complete the proof if $0<\tau, \delta \ll 1, A \gg 1$.
3.3. Completion of the proof of Lemma 3.1, Let $w$ be as in Lemma
3.3. From the construction above, we know that there is a uniform positive constant $C_{1}^{\prime}$ such that

$$
|\mathfrak{g}[w]|_{C^{0}\left(\Omega_{\sigma}\right)} \leqslant C_{1}^{\prime} .
$$

Let $\lambda[w]=\lambda_{\omega}(\mathfrak{g}[w])$. Assume $\lambda_{1}[w] \leqslant \cdots \leqslant \lambda_{n}[w]$. Lemma 3.3, together with Lemma 3.2, implies

$$
\sum_{\alpha=1}^{n-1} \mu_{\alpha} \lambda_{\alpha}[w] \leqslant 0 \text { in } \Omega_{\delta} .
$$

So $\left(\lambda_{1}[w], \cdots, \lambda_{n-1}[w]\right) \notin \Gamma_{\infty}$ by (3.18). In other words, $\lambda[w] \in X$, where

$$
X=\left\{\lambda \in \mathbb{R}^{n}: \lambda^{\prime} \in \mathbb{R}^{n-1} \backslash \Gamma_{\infty}\right\} \cap\left\{\lambda \in \mathbb{R}^{n}:|\lambda| \leqslant C_{1}^{\prime}\right\} .
$$

Let

$$
\bar{\Gamma}^{\inf _{M} \psi}=\left\{\lambda \in \Gamma: f(\lambda) \geqslant \inf _{M} \psi\right\}
$$

Notice that $\Gamma_{\infty}$ is open so $X$ is a compact subset; furthermore $X \cap \bar{\Gamma}^{\inf _{M} \psi}=$ $\emptyset$. So we can deduce that the distance between $\bar{\Gamma}^{\inf _{M} \psi}$ and $X$ is greater than some positive constant depending on $\delta_{\psi, f}$ and other known data. Therefore, there exists an $\epsilon>0$ such that for any $z \in \Omega_{\delta}$

$$
\epsilon \overrightarrow{\mathbf{1}}+\lambda[w] \notin \bar{\Gamma}^{\overline{\inf }_{M} \psi} .
$$

Since one can choose a positive constant $C^{\prime}$ such that $x_{n} \leqslant C^{\prime}|z|^{2}$ on $\partial M \cap \bar{\Omega}_{\delta}$, there is a positive constant $C_{2}$ depending only on $M$ and $\delta$ so that

$$
x_{n} \leqslant C_{2}|z|^{2} \text { on } \partial \Omega_{\sigma} .
$$

Let $\epsilon$ and $C_{2}$ be as above, we define $h(z)=w(z)+\epsilon\left(|z|^{2}-\frac{x_{n}}{C_{2}}\right)$. Thus

$$
u \leqslant h \text { on } \partial \Omega_{\delta} .
$$

Moreover, $\chi_{i \bar{j}}+h_{i \bar{j}}=\left(\chi_{i \bar{j}}+w_{i \bar{j}}\right)+\epsilon \delta_{i j}$ so $\lambda[h] \notin \bar{\Gamma}^{\inf _{M} \psi}$. By 4, Lemma B], we have

$$
u \leqslant h \text { in } \Omega_{\delta} .
$$

Notice $u(0)=\varphi(0)$ and $h(0)=\varphi(0)$, we have $u_{x_{n}}(0) \leqslant h_{x_{n}}(0)$ then

$$
t_{0} \leqslant \frac{1}{1+\epsilon /\left(\eta C_{2}\right)}, \text { i.e., }\left(1-t_{0}\right)^{-1} \leqslant 1+\frac{\eta C_{2}}{\epsilon} .
$$

Remark 3.4. In fact, (3.5) and (3.3) imply $|u|_{C^{0}(M)}+|\nabla u|_{C^{0}(\partial M)} \leqslant C$.
Remark 3.5. The discussions above work for more general equations of the form

$$
f(\lambda(\chi+\sqrt{-1} \partial \bar{\partial} u+\sqrt{-1} \partial u \wedge \bar{\zeta}+\sqrt{-1} \zeta \wedge \bar{\partial} u))=\psi
$$

where $\zeta=\sum_{i=1}^{n} \zeta_{i} d z^{i}$ is a smooth $(1,0)$-form.

## 4. Proof of Proposition 2.4

The equation (1.11) can be reduced to

$$
\begin{equation*}
\log P_{n-1}(\lambda(\tilde{\mathfrak{g}}[u]))=\psi \text { in } M \tag{4.1}
\end{equation*}
$$

for $\psi=(n-1) \phi+n \log (n-1)$, where

$$
\begin{equation*}
\tilde{\mathfrak{g}}_{i \bar{j}}=u_{i \bar{j}}+\tilde{\chi}_{i \bar{j}}+W_{i \bar{j}}, \tag{4.2}
\end{equation*}
$$

here $\check{\chi}_{i \bar{j}}=\left(\operatorname{tr}_{\omega} \tilde{\chi}\right) g_{i \bar{j}}-(n-1) \tilde{\chi}_{i \bar{j}}, W_{i \bar{j}}=\left(\operatorname{tr}_{\omega} Z\right) g_{i \bar{j}}-(n-1) Z_{i \bar{j}}$. Locally,

$$
\begin{equation*}
Z_{i \bar{j}}=\frac{g^{p \bar{q}} \bar{T}_{q l}^{l} g_{i \bar{j}} u_{p}+g^{p \bar{q}} T_{p k}^{k} g_{i \bar{j}} u_{\bar{q}}-g^{k \bar{l}} g_{i \bar{q}} \bar{T}_{l j}^{q} u_{k}-g^{k \bar{l}} g_{q \bar{j}} T_{k i}^{q} u_{\bar{l}}-\bar{T}_{j l}^{l} u_{i}-T_{i k}^{k} u_{\bar{j}}}{2(n-1)}, \tag{4.3}
\end{equation*}
$$

where $T_{i j}^{k}$ are the torsions, see also [27]. Here

$$
f(\lambda)=\log P_{n-1}(\lambda)=\sum_{i=1}^{n} \log \mu_{i}, \quad \mu_{i}=\sum_{j \neq i} \lambda_{j}
$$

with corresponding cone

$$
\begin{equation*}
\mathcal{P}_{n-1}=\left\{\lambda \in \mathbb{R}^{n}: \mu_{i}>0, \forall 1 \leqslant i \leqslant n\right\} . \tag{4.4}
\end{equation*}
$$

One can verify that condition (1.12) is equivalent to $\lambda(\tilde{\mathfrak{g}}[u]) \in \mathcal{P}_{n-1}$ in $\bar{M}$, which allows one to seek the solutions of (4.1) or equivalently (1.11) within the framework of elliptic equations, since $f(\lambda)=\log P_{n-1}(\lambda)$ satisfies (1.2), (1.3) and (1.4) in $\mathcal{P}_{n-1}$.
4.1. Preliminaries. Throughout this section we denote

$$
\tilde{\mathfrak{g}}=\tilde{\mathfrak{g}}[u], \quad Z=Z[u], W=W[u], \underline{\tilde{\mathfrak{g}}}=\tilde{\mathfrak{g}}[\underline{u}], \underline{Z}=Z[\underline{u}], \underline{W}=W[\underline{u}]
$$

for solution $u$ and subsolution $\underline{u}$.
Fix $x_{0} \in \partial M$. Around $x_{0}$ we set local holomorphic coordinates $\left(z_{1}, \cdots, z_{n}\right)$, $z_{i}=x_{i}+\sqrt{-1} y_{i}$, centered at $x_{0}$, such that $g_{i \bar{j}}(0)=\delta_{i j}$ and $\frac{\partial}{\partial x_{n}}$ is the inner normal vector at the origin, and $T_{x_{0}}{ }_{\partial M}^{1,0}$ is spanned by $\frac{\partial}{\partial z_{\alpha}}$ for $1 \leqslant \alpha \leqslant n-1$.

By (4.3), (3.3) and $W[v]_{i \bar{j}}=\left(\operatorname{tr}_{\omega} Z[v]\right) g_{i \bar{j}}-(n-1) Z[v]_{i \bar{j}}$, one can verify that at the origin $(\{z=0\})$

$$
\begin{gather*}
\sum_{\alpha=1}^{n-1} W[v]_{\alpha \bar{\alpha}}=(n-1) Z[v]_{n \bar{n}},  \tag{4.5}\\
\sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}[v]_{\alpha \bar{\alpha}}=\sum_{\alpha=1}^{n-1}\left(v_{\alpha \bar{\alpha}}+\check{\chi} \alpha \bar{\alpha}\right)+\sum_{\alpha=1}^{n-1} W[v]_{\alpha \bar{\alpha}},  \tag{4.6}\\
2(n-1) Z[v]_{n \bar{n}}=\sum_{\alpha, \beta=1}^{n-1}\left(\bar{T}_{\alpha \beta}^{\beta} v_{\alpha}+T_{\alpha \beta}^{\beta} v_{\bar{\alpha}}\right),  \tag{4.7}\\
\sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}=\sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}+(u-\underline{u})_{x_{n}} \sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}} . \tag{4.8}
\end{gather*}
$$

We rewrite $W[v]_{i \bar{j}}$ as follows

$$
W[v]_{i \bar{j}}=W_{i \bar{j}}^{k} v_{k}+W_{i \bar{j}}^{\bar{k}} v_{\bar{k}} .
$$

One can see

$$
\begin{equation*}
\sum_{\alpha=1}^{n-1} W_{\alpha \bar{\alpha}}^{n}=\sum_{\alpha=1}^{n-1} W_{\alpha \bar{\alpha}}^{\bar{n}}=0 \tag{4.9}
\end{equation*}
$$

at the origin.
4.2. A key ingredient and its proof. As in Section 3, we set $\eta=(u-$ $\underline{u})_{x_{n}}(0)$. We know that $\eta \geqslant 0$. Let

$$
\begin{equation*}
t_{0}=-\eta \sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(0) / \sum_{\alpha=1}^{n-1} \underline{\underline{\mathfrak{g}}}_{\alpha \bar{\alpha}}(0) \tag{4.10}
\end{equation*}
$$

We assume throughout $\eta>0$. (Otherwise $t_{0}=0$ and the proof is almost parallel to that given in [34] $)$. From $\lambda(\underline{\tilde{\mathfrak{g}}}) \in \mathcal{P}_{n-1}$ we know $\sum_{\alpha=1}^{n-1} \underline{\mathfrak{g}}_{\alpha \bar{\alpha}}(0)>0$. Clearly $t_{0}<1$ since $\sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}(0)>0\left(\lambda(\tilde{\mathfrak{g}}) \in \mathcal{P}_{n-1}\right)$.

Lemma 4.1. There is a uniform positive constant $C$ depending on $\left(\delta_{\psi, f}\right)^{-1}$, $|u|_{C^{0}(\bar{M})},|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(\bar{M})}, \partial M$ up to third derivatives and other known data such that

$$
\left(1-t_{0}\right)^{-1} \leqslant C
$$

In what follows we assume $t_{0}>\frac{1}{2}$. Since $\eta$ has a uniform upper bound, thus at origin

$$
\begin{equation*}
-\sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(0) \geqslant t_{0} \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}(0) / \eta \geqslant \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}(0) / 2 \eta \geqslant a_{2} \tag{4.11}
\end{equation*}
$$

where

$$
a_{2}=\inf _{z \in \partial M} \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}(z) / 2 \sup _{\partial M}|\nabla(u-\underline{u})|
$$

As in Section 3 we set on $\Omega_{\delta}$

$$
d(z)=\sigma(z)+\tau|z|^{2}
$$

where $\tau$ is a positive constant to be determined; and let

$$
w(z)=\underline{u}(z)+\left(\eta / t_{0}\right) \sigma(z)+l(z) \sigma(z)+A d(z)^{2}
$$

where $A$ is a positive constant to be determined, and $l(z)=\sum_{i=1}^{n}\left(l_{i} z_{i}+\bar{l}_{i} \bar{z}_{i}\right)$ where $l_{i} \in \mathbb{C}, \bar{l}_{i}=l_{\bar{i}}$ to be chosen as in (4.12).

As in Section 3, let $T_{\alpha}=\sum_{k=1}^{n} T_{\alpha}^{k} \frac{\partial}{\partial z_{k}}$ be an orthonormal basis of holomorphic tangent space of level hypersurface $\{w: d(w)=d(z)\}$ at $z, 1 \leqslant$ $\alpha \leqslant n-1$, such that at origin $T_{\alpha}(0)=\frac{\partial}{\partial z_{\alpha}}$. Let's define a local operator $\Lambda$ : For a real $(1,1)$-form $\Theta=\sqrt{-1} \Theta_{i \bar{j}} d z_{i} \wedge d \bar{z}_{j}$,

$$
\Lambda(\Theta)=\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \Theta_{i \bar{j}}
$$

Lemma 4.2. There are parameters $\tau, \delta, A$ and $l(z)$ depending on $|u|_{C^{0}(M)}$, $|\nabla u|_{C^{0}(\partial M)},|\underline{u}|_{C^{2}(M)}, \partial M$ up to third derivatives and other known data such that

$$
\Lambda(\tilde{\mathfrak{g}}[w]) \leqslant 0 \text { in } \Omega_{\delta}, \quad u \leqslant w \text { on } \partial \Omega_{\delta} .
$$

Proof. Direct computations give

$$
\begin{gathered}
w_{i}=\underline{u}_{i}+\frac{\eta}{t_{0}} \sigma_{i}+l_{i} \sigma+l(z) \sigma_{i}+2 A d d_{i} \\
w_{i \bar{j}}=\underline{u}_{i \bar{j}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}+l(z) \sigma_{i \bar{j}}+\left(l_{i} \sigma_{\bar{j}}+\sigma_{i} l_{\bar{j}}\right)+2 A d d_{i \bar{j}}+2 A d_{i} d_{\bar{j}}
\end{gathered}
$$

Then

$$
\begin{aligned}
\Lambda(\tilde{\mathfrak{g}}[w])= & \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\left(\check{\chi}_{i \bar{j}}+\underline{w}_{i \bar{j}}+W_{i \bar{j}}^{p} w_{p}+W_{i \bar{j}}^{\bar{q}} w_{\bar{q}}\right)\right. \\
= & \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\check{\chi}_{i \bar{j}}+\underline{u}_{i \bar{j}}+W_{i \bar{j}}^{p} \underline{u}_{p}+W_{i \bar{j}}^{\bar{q}} u_{\bar{q}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right) \\
& +l(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \sigma_{i \bar{j}}+\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\sigma_{i} l_{\bar{j}}+l_{i} \sigma_{\bar{j}}\right) \\
& +2 A d(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}}+\frac{\eta}{t_{0}} \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} \sigma_{p}+W_{i \bar{j}}^{\bar{q}} \sigma_{\bar{q}}\right) \\
& +l(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} \sigma_{p}+W_{i \bar{j}}^{\bar{q}} \sigma_{\bar{q}}\right)+\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} l_{p}+W_{i \bar{j}}^{\bar{q}} l_{\bar{q}}\right) \sigma \\
& +2 A d(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} d_{p}+W_{i \bar{j}}^{\bar{q}} d_{\bar{q}}\right) .
\end{aligned}
$$

- At origin $z=0, T_{\alpha}^{i}=\delta_{\alpha i}$, so

$$
\begin{aligned}
& \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\check{\chi}_{i \bar{j}}+\underline{u}_{i \bar{j}}+W_{i \bar{j}}^{p} \underline{u}_{p}+W_{i \overline{\bar{j}}}^{\bar{q}} \underline{u}_{\bar{q}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right)(0) \\
= & \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}(0)+\frac{\eta}{t_{0}} \sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(0)=0 .
\end{aligned}
$$

Thus there are complex constants $k_{i}$ such that on $\Omega_{\sigma}$,

$$
\begin{aligned}
& \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\check{\chi}_{i \bar{j}}+\underline{u}_{i \bar{j}}+W_{i \bar{j}}^{p} \underline{u}_{p}+W_{i \bar{j}}^{\bar{q}} u_{\bar{q}}+\frac{\eta}{t_{0}} \sigma_{i \bar{j}}\right) \\
= & \sum_{i=1}^{n}\left(k_{i} z_{i}+\bar{k}_{i} \bar{z}_{i}\right)+O\left(|z|^{2}\right) .
\end{aligned}
$$

- Next, we see

$$
2 A d(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}} \leqslant-\frac{A a_{2} d(z)}{2},
$$

provided $0<\delta, \tau \ll 1$, since

$$
\begin{aligned}
\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} d_{i \bar{j}} & =\left(\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}-\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}(0)\right) d_{i \bar{j}}+\sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(z)+(n-1) \tau \\
& =(n-1) \tau-a_{2}+O(|z|) \leqslant-\frac{a_{2}}{4}
\end{aligned}
$$

by (3.24) and $\sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(z)=\sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(0)+O(|z|)$.

$$
\begin{aligned}
& l(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \sigma_{i \bar{j}}+\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\sigma_{i} l_{\bar{j}}+l_{i} \sigma_{\bar{j}}\right) \\
= & l(z) \sum_{\alpha=1}^{n-1} \sigma_{\alpha \bar{\alpha}}(0)+\tau \sum_{\alpha=1}^{n-1}\left(z_{\alpha} l_{\alpha}+\bar{z}_{\alpha} \bar{l}_{\alpha}\right)+O\left(|z|^{2}\right)
\end{aligned}
$$

since by (3.24) and $\sum_{i=1}^{n} T_{\alpha}^{i} \sigma_{i}=-\tau \sum_{i=1}^{n} T_{\alpha}^{i} \bar{z}_{i}$ one has

$$
\begin{gathered}
l(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j} \sigma_{i \bar{j}}=l(z) \sum_{\alpha=1}^{n-1} \mu_{\alpha} \sigma_{\alpha \bar{\alpha}}(0)+O\left(|z|^{2}\right) \\
\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(\sigma_{i} l_{\bar{j}}+l_{i} \sigma_{\bar{j}}\right)=-\tau \sum_{\alpha=1}^{n-1}\left(z_{\alpha} l_{\alpha}+\bar{z}_{\alpha} \bar{l}_{\alpha}\right)+O\left(|z|^{2}\right) .
\end{gathered}
$$

- At the origin,

$$
\begin{aligned}
& \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} \sigma_{p}+W_{i \bar{j}}^{\bar{q}} \sigma_{\bar{q}}\right)(0) \\
= & \sum_{\alpha, \beta=1}^{n-1}\left(W_{\alpha \bar{\alpha}}^{\beta} \sigma_{\beta}+W_{\alpha \bar{\alpha}}^{\bar{\beta}} \sigma_{\bar{\beta}}\right)(0)+\sum_{\alpha=1}^{n-1}\left(W_{\alpha \bar{\alpha}}^{n} \sigma_{n}+W_{\alpha \bar{\alpha}}^{\bar{n}} \sigma_{\bar{n}}\right)(0)=0,
\end{aligned}
$$

since $\sigma_{\beta}(0)=0$, and by (4.9)

$$
\sum_{\alpha=1}^{n-1} W_{\alpha \bar{\alpha}}^{n}(0)=0, \quad \sum_{\alpha=1}^{n-1} W_{\alpha \bar{\alpha}}^{\bar{n}}(0)=0
$$

Thus on $\Omega_{\sigma}$,

$$
l(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} \sigma_{p}+W_{i \bar{\jmath}}^{\bar{q}} \sigma_{\bar{q}}\right)(z)=O\left(|z|^{2}\right)
$$

and there are complex constants $m_{i}$ such that
$\frac{\eta}{t_{0}} \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} \sigma_{p}+W_{i \bar{j}}^{\bar{q}} \sigma_{\bar{q}}\right)(z)=\sum_{i=1}^{n}\left(m_{i} z_{i}+\bar{m}_{i} \bar{z}_{i}\right)+O\left(|z|^{2}\right)$.

- Similarly $\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} d_{p}+W_{i \bar{j}}^{\bar{q}} d_{\bar{q}}\right)(0)=0$, thus on $\Omega_{\delta}$,

$$
\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} d_{p}+W_{i \bar{j}}^{\bar{q}} d_{\bar{q}}\right)(z)=O(|z|)
$$

and so

$$
2 A d(z) \sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} d_{p}+W_{i \bar{j}}^{\bar{q}} d_{\bar{q}}\right)(z)=\operatorname{Ad}(z) O(|z|) .
$$

- Finally

$$
\sum_{\alpha=1}^{n-1} T_{\alpha}^{i} \bar{T}_{\alpha}^{j}\left(W_{i \bar{j}}^{p} l_{p}+W_{i \bar{j}}^{\bar{q}} l_{\bar{q}}\right) \sigma(z) \leqslant C_{1} \sigma(z) .
$$

Therefore, we get

$$
\begin{aligned}
\Lambda(\tilde{\mathfrak{g}}[w]) \leqslant & 2 \mathfrak{R e} \sum_{\alpha=1}^{n-1}\left[z_{\alpha}\left(k_{\alpha}+m_{\alpha}+l_{\alpha}\left(\sum_{\beta=1}^{n-1} \sigma_{\beta \bar{\beta}}(0)-\tau\right)\right)\right] \\
& \left.+2 \mathfrak{R e}\left[z_{n}\left(k_{n}+m_{n}+l_{n} \sum_{\beta=1}^{n-1} \sigma_{\beta \bar{\beta}}(0)\right)\right)\right] \\
& -\frac{a_{2} A d(z)}{2}+A d(z) O(|z|)+C_{1} \sigma(z)+O\left(|z|^{2}\right) .
\end{aligned}
$$

We complete the proof if $0<\tau, \delta \ll 1, A \gg 1$, and we set

$$
\begin{equation*}
l_{\alpha}=-\frac{k_{\alpha}+m_{\alpha}}{\sum_{\beta=1}^{n-1} \sigma_{\beta \bar{\beta}}(0)-\tau} \text { for } 1 \leqslant \alpha \leqslant n-1, l_{n}=-\frac{k_{n}+m_{n}}{\sum_{\beta=1}^{n-1} \sigma_{\beta \bar{\beta}}(0)} . \tag{4.12}
\end{equation*}
$$

We can see each $\left|l_{i}\right|$ is uniformly bounded, since $\sum_{\beta=1}^{n-1} \sigma_{\beta \bar{\beta}}(0) \leqslant-a_{2}<0$.
4.3. Proof of Lemma 4.1, Let $\lambda(\tilde{\mathfrak{g}}[w])=\left(\lambda_{1}[w], \cdots, \lambda_{n}[w]\right)$, let $\mu_{i}[w]=$ $\sum_{j \neq i} \lambda_{j}[w]$ and we assume $\lambda_{1}[w] \leqslant \cdots \leqslant \lambda_{n}[w]$. Denote by

$$
\mathcal{P}_{n-1}^{\inf _{M} \psi}=\left\{\lambda \in \mathcal{P}_{n-1}: \sum_{i=1}^{n} \log \mu_{i} \geqslant \inf _{M} \psi\right\} .
$$

As in section 3 we set $h(z)=w(z)+\epsilon\left(|z|^{2}-\frac{x_{n}}{C_{2}}\right)$ where $C_{2}$ be chosen so that $x_{n} \leqslant C_{2}|z|^{2}$ on $\partial \Omega_{\delta}$. Thus

$$
u \leqslant h \text { on } \partial \Omega_{\delta} .
$$

Lemmas 4.2 and 3.2 give

$$
\sum_{\alpha=1}^{n-1} \lambda_{\alpha}[w] \leqslant 0 \text { in } \Omega_{\delta} .
$$

That is, in $\Omega_{\delta}$,

$$
\lambda[w] \notin \mathcal{P}_{n-1} \text {, i.e. } \mu[w] \notin \Gamma_{n} .
$$

Then there is $0<\epsilon \ll 1$ depending on $\delta_{\psi, f}, \lambda[w]$, torsion tensor and other known data such that

$$
\lambda[h] \notin \mathcal{P}_{n-1}^{\inf _{M} \psi} .
$$

By [4, Lemma B] again, we have

$$
u \leqslant h \text { in } \Omega_{\delta} .
$$

Notice $u(0)=\varphi(0)$ and $h(0)=\varphi(0)$, we have $(u-h)_{x_{n}}(0) \leqslant 0$ then

$$
\left(1-t_{0}\right)^{-1} \leqslant 1+\frac{\eta C_{2}}{\epsilon} .
$$

4.4. Completion of proof of Proposition [2.4. Around $x_{0}$ we use the local holomorphic coordinates we have chosen above; furthermore, we assume that $\left(\tilde{\mathfrak{g}}_{\alpha \bar{\beta}}\right)$ is diagonal at the origin $\left(x_{0}=\{z=0\}\right)$. In the proof the discussion is done at the origin, and the Greek letters, such as $\alpha, \beta$, range from 1 to $n-1$. Let $\mu_{i}=\sum_{j \neq i} \lambda_{j}$, and

$$
\tilde{f}(\mu)=f(\lambda)=\sum_{i=1}^{n} \log \mu_{i} .
$$

Let's denote

$$
\tilde{A}(R)=\left(\begin{array}{cccc}
R-\tilde{\mathfrak{g}}_{1 \overline{1}} & & & -\tilde{\mathfrak{g}}_{1 \bar{n}} \\
& \ddots & & \vdots \\
& & R-\tilde{\mathfrak{g}}_{(n-1) \overline{(n-1)}} & -\tilde{\mathfrak{g}}_{(n-1) \bar{n}} \\
-\tilde{\mathfrak{g}}_{n \overline{1}} & \cdots & -\tilde{\mathfrak{g}}_{n(n-1)}^{n-1} & \sum_{\alpha=1}^{n=1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}
\end{array}\right) .
$$

In particular, when $R=\operatorname{tr}_{\omega}(\tilde{\mathfrak{g}}), \tilde{A}(R)=\operatorname{tr}_{\omega}(\tilde{\mathfrak{g}}) \omega-\tilde{\mathfrak{g}}$. By (4.8) and (4.10), $\tilde{A}(R)$ can be rewritten as

$$
\underline{\tilde{\tilde{A}}}(R)=\left(\begin{array}{cccc}
R-\tilde{\mathfrak{g}}_{1 \overline{1}} & & & -\tilde{\mathfrak{g}}_{1 \bar{n}} \\
& \ddots & & \vdots \\
& & R-\tilde{\mathfrak{g}}_{(n-1) \overline{(n-1)}} & -\tilde{\mathfrak{g}}_{n-1) \bar{n}} \\
-\tilde{\mathfrak{g}}_{n \overline{1}} & \cdots & -\tilde{\mathfrak{g}}_{n(n-1)} & \left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}
\end{array}\right) .
$$

That is $\underline{\tilde{A}}(R)=\tilde{A}(R)$. Similar as before, there is a uniform positive constant $R_{0}$ depending on $\left(1-t_{0}\right)^{-1}$ and $\left(\inf _{\partial M} \operatorname{dist}\left(\lambda(\tilde{\mathfrak{g}}), \partial \Gamma_{n}\right)\right)^{-1}$ (but not on $\left.\left(\delta_{\psi, f}\right)^{-1}\right)$ such that

$$
\tilde{f}\left(R_{0}, \cdots, R_{0},\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}\right)>\psi .
$$

Therefore, there is a positive constant $\varepsilon_{0}$, depending on $\inf _{\partial M} \operatorname{dist}\left(\lambda(\tilde{\mathfrak{g}}), \partial \Gamma_{n}\right)$, such that $\left(R_{0}-\varepsilon_{0}, \cdots, R_{0}-\varepsilon_{0},\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \underline{\tilde{\mathfrak{g}}}_{\alpha \bar{\alpha}}-\varepsilon_{0}\right) \in \Gamma_{n}$,

$$
\begin{equation*}
\tilde{f}\left(R_{0}-\varepsilon_{0}, \cdots, R_{0}-\varepsilon_{0},\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}-\varepsilon_{0}\right) \geqslant \psi . \tag{4.13}
\end{equation*}
$$

Note that

$$
\tilde{A}(R)=\underline{\tilde{A}}(R)=R I_{n}-\left(\begin{array}{cccc}
\tilde{\mathfrak{g}}_{1 \overline{1}} & & & \tilde{\mathfrak{g}}_{1 \bar{n}} \\
& \ddots & & \vdots \\
& & \tilde{\mathfrak{g}}_{(n-1) \overline{(n-1)}} & \tilde{\mathfrak{g}}_{(n-1) \bar{n}} \\
\tilde{\mathfrak{g}}_{n \overline{1}} & \cdots & \overline{\tilde{g}_{n \overline{(n-1)}}} & R-\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}
\end{array}\right) .
$$

here $I_{n}=\left(\delta_{i j}\right)$. Let's pick $\epsilon=\frac{\varepsilon_{0}\left(1-t_{0}\right)}{2(n-1)}$ in Lemma A. 2 and set

$$
R_{s}=\frac{2(n-1)(2 n-3)}{\varepsilon_{0}\left(1-t_{0}\right)} \sum_{\alpha=1}^{n-1}\left|\tilde{\mathfrak{g}}_{\alpha \bar{n}}\right|^{2}+(n-1) \sum_{\alpha=1}^{n-1}\left|\tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}\right|+\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1}\left|\underline{\mathfrak{g}}_{\alpha \bar{\alpha}}\right|+R_{0},
$$

where $\varepsilon_{0}$ and $R_{0}$ are fixed constants so that (4.13) holds. Let $\lambda\left(\underline{\tilde{A}}\left(R_{s}\right)\right)=$ $\left(\lambda_{1}\left(R_{s}\right), \cdots, \lambda_{n}\left(R_{s}\right)\right)$ be the eigenvalues of $\underline{\tilde{A}}\left(R_{s}\right)$. It follows from Lemma A. 2 that

$$
\begin{aligned}
& \lambda_{\alpha}\left(R_{s}\right) \geqslant R_{s}-\tilde{\mathfrak{g}}_{1 \overline{1}}-\frac{\varepsilon_{0}}{2(n-1)}, \forall 1 \leqslant \alpha<n, \\
& \lambda_{n}\left(R_{s}\right) \geqslant\left(1-t_{0}\right) \sum_{\alpha=1}^{n-1} \tilde{\mathfrak{g}}_{\alpha \bar{\alpha}}-\frac{\varepsilon_{0}}{2} .
\end{aligned}
$$

Therefore

$$
\tilde{f}\left(\lambda\left(\tilde{A}\left(R_{s}\right)\right)\right) \geqslant \psi .
$$

We get

$$
\operatorname{tr}_{\omega}(\tilde{\mathfrak{g}}) \leqslant R_{s} .
$$

Consequently, together with Lemma 4.1 and Proposition [2.2, we derive Proposition 2.4 and so the following quantitative boundary estimate.

Theorem 4.3. Under the assumptions of Theorem 1.3. for any $(n-1)$ PSH function $u \in C^{3}(M) \cap C^{2}(\bar{M})$ solving the Dirichlet problem (1.11) and (1.15), we have

$$
\sup _{\partial M} \Delta u \leqslant C\left(1+|\nabla u|^{2}\right) .
$$

4.5. Further discussion. The results above are valid for more general equations

$$
\begin{equation*}
f(\lambda(* \Phi[u]))=\psi \text { in } M, u=\varphi \text { on } \partial M \tag{4.14}
\end{equation*}
$$

on compact Hermitian manifolds with smooth boundary, where

$$
* \Phi[u]=\chi+\Delta u \omega-\sqrt{-1} \partial \bar{\partial} u+\varrho Z[u],
$$

and $\varrho$ is a smooth function, i.e.

$$
\Phi[u]=* \chi+\frac{1}{(n-2)!} \sqrt{-1} \partial \bar{\partial} u \wedge \omega^{n-2}+\frac{\varrho}{(n-1)!} \mathfrak{R e}\left(\sqrt{-1} \partial u \wedge \bar{\partial} \omega^{n-2}\right) .
$$

In addition to (1.2), (1.3), (1.4), we further assume

$$
\begin{equation*}
\lim _{t \rightarrow+\infty} f\left(\lambda_{1}+t, \cdots, \lambda_{n-1}+t, \lambda_{n}\right)=\sup _{\Gamma} f, \quad \forall \lambda \in \Gamma . \tag{4.15}
\end{equation*}
$$

The case $\Gamma \neq \Gamma_{n}$ is completely solved in [34], since $\Gamma_{\mathbb{R}^{1}}^{\infty}=\mathbb{R}$ for $\Gamma \neq \Gamma_{n}$, where

$$
\Gamma_{\mathbb{R}^{1}}^{\infty}=\{c \in \mathbb{R}:(c, R, \cdots, R) \in \Gamma \text { for some } R>0\} .
$$

Thus it requires only to consider the case $\Gamma=\Gamma_{n}$.
Theorem 4.4. Let $(M, J, \omega)$ be a compact Hermitian manifold with smooth boundary, we assume $\varphi, \psi$ are all smooth and satisfies (1.6). Suppose $f$ satisfies (1.2), (1.3), (1.4) and (4.15). Suppose there is a $C^{2,1}$ subsolution with

$$
\begin{equation*}
f(\lambda(* \Phi[\underline{u}])) \geqslant \psi, \quad * \Phi[\underline{u}]>0 \text { in } \bar{M}, \underline{u}=\varphi \text { on } \partial M . \tag{4.16}
\end{equation*}
$$

Then Dirichlet problem (4.14) admits a unique smooth solution with $* \Phi[u]>$ 0 in $\bar{M}$.

## Appendix A. Key lemmas

The following two lemmas proposed in earlier works [32, 34] are key ingredients in proof of Propositions 2.3 and 2.4 .

## A.1. A characterization of concave function satisfying (1.4).

Lemma A. 1 ([34). If $f$ satisfies (1.2) and (1.3), then the following three statements are equivalent each other.
(a) $f$ satisfies (1.4).
(b) $\sum_{i=1}^{n} f_{i}(\lambda) \mu_{i}>0$ for any $\lambda, \mu \in \Gamma$.

Proof. The concavity of $f$ means

$$
\begin{equation*}
\sum_{i=1}^{n} f_{i}(\lambda)\left(\mu_{i}-\lambda_{i}\right) \geqslant f(\mu)-f(\lambda) \text { for } \lambda, \mu \in \Gamma \tag{A.1}
\end{equation*}
$$

(b) $\Rightarrow(\mathbf{a})$ For any $\lambda, \mu \in \Gamma, t \lambda-\mu \in \Gamma$ for some $t \gg 1$. Thus $f(t \lambda)>f(\mu)$ for such $t$.
(a) $\Rightarrow$ (b) Fix $\lambda \in \Gamma$. The condition (1.4) implies that for any $\mu \in \Gamma$, there is $T \geqslant 1$ (may depend on $\mu$ ) such that for each $t>T, f(t \mu)>f(\lambda)$. Together with (A.1), one gets $\sum_{i=1}^{n} f_{i}(\lambda)\left(t \mu_{i}-\lambda_{i}\right)>0$. Thus, $\sum_{i=1}^{n} f_{i}(\lambda) \lambda_{i}>0$ (if one takes $\mu=\lambda)$ then $\sum_{i=1}^{n} f_{i}(\lambda) \mu_{i}>0$.

Lemma A. 1 implies that for any $n \times n$ Hessian matrices $A=\left(A_{i \bar{j}}\right), B=$ $\left(B_{i \bar{j}}\right)$ with $\lambda(A) \in \Gamma$ and $\lambda(B) \in \Gamma$,

$$
\begin{equation*}
\frac{\partial F}{\partial A_{i \bar{j}}}(A) B_{i \bar{j}}>0 \tag{A.2}
\end{equation*}
$$

where we denote $F(A)=f(\lambda(A))$. Consequently, (A.2) and (A.1) imply

$$
\begin{equation*}
F(A+B)>F(A) \tag{A.3}
\end{equation*}
$$

for any $A, B$ satisfying $\lambda(A), \lambda(B) \in \Gamma$.

## A.2. A quantitative lemma.

Lemma A. 2 ([32]). Let $A$ be an $n \times n$ Hermitian matrix

$$
\left(\begin{array}{ccccc}
d_{1} & & & & a_{1}  \tag{A.4}\\
& d_{2} & & & a_{2} \\
& & \ddots & & \vdots \\
& & & d_{n-1} & a_{n-1} \\
\bar{a}_{1} & \bar{a}_{2} & \cdots & \bar{a}_{n-1} & \mathbf{a}
\end{array}\right)
$$

with $d_{1}, \cdots, d_{n-1}, a_{1}, \cdots, a_{n-1}$ fixed, and with a variable. Denote $\lambda=$ $\left(\lambda_{1}, \cdots, \lambda_{n}\right)$ by the eigenvalues of $A$. Let $\epsilon>0$ be a fixed constant. Suppose that the parameter a in A satisfies the quadratic growth condition

$$
\begin{equation*}
\mathbf{a} \geqslant \frac{2 n-3}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}+(n-1) \sum_{i=1}^{n-1}\left|d_{i}\right|+\frac{(n-2) \epsilon}{2 n-3}, \tag{A.5}
\end{equation*}
$$

where $\epsilon$ is a positive constant. Then the eigenvalues (possibly with an order) behavior like

$$
\begin{aligned}
& \left|d_{\alpha}-\lambda_{\alpha}\right|<\epsilon, \forall 1 \leqslant \alpha \leqslant n-1, \\
& 0 \leqslant \lambda_{n}-\mathbf{a}<(n-1) \epsilon .
\end{aligned}
$$

For convenience we will give the proof of Lemma A.2. We start with the case of $n=2$. In this case, we prove that if $\mathbf{a} \geqslant \frac{\left|a_{1}\right|^{2}}{\epsilon}+d_{1}$ then

$$
0 \leqslant d_{1}-\lambda_{1}=\lambda_{2}-\mathbf{a}<\epsilon .
$$

Let's briefly present the discussion as follows: For $n=2$, the eigenvalues of A are $\lambda_{1}=\frac{\mathbf{a}+d_{1}-\sqrt{\left(\mathbf{a}-d_{1}\right)^{2}+4\left|a_{1}\right|^{2}}}{2}$ and $\lambda_{2}=\frac{\mathbf{a}+d_{1}+\sqrt{\left(\mathbf{a}-d_{1}\right)^{2}+4\left|a_{1}\right|^{2}}}{2}$. We can assume $a_{1} \neq 0$; otherwise we are done. If $\mathbf{a} \geqslant \frac{\left|a_{1}\right|^{2}}{\epsilon}+d_{1}$ then one has

$$
0 \leqslant d_{1}-\lambda_{1}=\lambda_{2}-\mathbf{a}=\frac{2\left|a_{1}\right|^{2}}{\sqrt{\left(\mathbf{a}-d_{1}\right)^{2}+4\left|a_{1}\right|^{2}}+\left(\mathbf{a}-d_{1}\right)}<\frac{\left|a_{1}\right|^{2}}{\mathbf{a}-d_{1}} \leqslant \epsilon .
$$

Here we use $a_{1} \neq 0$ to verify that the strictly inequality in the above formula holds. We hence obtain Lemma A. 2 for $n=2$.

The following lemma enables us to count the eigenvalues near the diagonal elements via a deformation argument. It is an essential ingredient in the proof of Lemma A. 2 for general $n$.

Lemma A. 3 ([32]). Let A be an $n \times n$ Hermitian matrix

$$
\left(\begin{array}{ccccc}
d_{1} & & & & a_{1} \\
& d_{2} & & & a_{2} \\
& & \ddots & & \vdots \\
& & & d_{n-1} & a_{n-1} \\
\bar{a}_{1} & \bar{a}_{2} & \cdots & \bar{a}_{n-1} & \mathbf{a}
\end{array}\right)
$$

with $d_{1}, \cdots, d_{n-1}, a_{1}, \cdots, a_{n-1}$ fixed, and with $\mathbf{a}$ variable. Denote $\lambda_{1}, \cdots, \lambda_{n}$ by the eigenvalues of A with the order $\lambda_{1} \leqslant \lambda_{2} \leqslant \cdots \leqslant \lambda_{n}$. Fix a positive
constant $\epsilon$. Suppose that the parameter a in the matrix A satisfies the following quadratic growth condition

$$
\begin{equation*}
\mathbf{a} \geqslant \frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}+\sum_{i=1}^{n-1}\left[d_{i}+(n-2)\left|d_{i}\right|\right]+(n-2) \epsilon . \tag{A.6}
\end{equation*}
$$

Then for any $\lambda_{\alpha}(1 \leqslant \alpha \leqslant n-1)$ there exists an $d_{i_{\alpha}}$ with lower index $1 \leqslant i_{\alpha} \leqslant n-1$ such that

$$
\begin{gather*}
\left|\lambda_{\alpha}-d_{i_{\alpha}}\right|<\epsilon,  \tag{A.7}\\
0 \leqslant \lambda_{n}-\mathbf{a}<(n-1) \epsilon+\left|\sum_{\alpha=1}^{n-1}\left(d_{\alpha}-d_{i_{\alpha}}\right)\right| .
\end{gather*}
$$

Proof. Without loss of generality, we assume $\sum_{i=1}^{n-1}\left|a_{i}\right|^{2}>0$ and $n \geqslant 3$ (otherwise we are done, since A is diagonal or $n=2$ ). Note that in the assumption of the lemma the eigenvalues have the order $\lambda_{1} \leqslant \lambda_{2} \leqslant \cdots \leqslant \lambda_{n}$. It is well known that, for a Hermitian matrix, any diagonal element is less than or equals to the largest eigenvalue. In particular,

$$
\begin{equation*}
\lambda_{n} \geqslant \mathbf{a} . \tag{A.9}
\end{equation*}
$$

We only need to prove (A.7), since (A.8) is a consequence of (A.7), (A.9) and

$$
\begin{equation*}
\sum_{i=1}^{n} \lambda_{i}=\operatorname{tr}(\mathrm{A})=\sum_{\alpha=1}^{n-1} d_{\alpha}+\mathbf{a} . \tag{A.10}
\end{equation*}
$$

Let's denote $I=\{1,2, \cdots, n-1\}$. We divide the index set $I$ into two subsets by

$$
\mathbf{B}=\left\{\alpha \in I:\left|\lambda_{\alpha}-d_{i}\right| \geqslant \epsilon, \forall i \in I\right\}
$$

and $\mathbf{G}=I \backslash \mathbf{B}=\left\{\alpha \in I\right.$ : There exists an $i \in I$ such that $\left.\left|\lambda_{\alpha}-d_{i}\right|<\epsilon\right\}$.
To complete the proof we need to prove $\mathbf{G}=I$ or equivalently $\mathbf{B}=\emptyset$. It is easy to see that for any $\alpha \in \mathbf{G}$, one has

$$
\begin{equation*}
\left|\lambda_{\alpha}\right|<\sum_{i=1}^{n-1}\left|d_{i}\right|+\epsilon . \tag{A.11}
\end{equation*}
$$

Fix $\alpha \in \mathbf{B}$, we are going to give the estimate for $\lambda_{\alpha}$. The eigenvalue $\lambda_{\alpha}$ satisfies

$$
\begin{equation*}
\left(\lambda_{\alpha}-\mathbf{a}\right) \prod_{i=1}^{n-1}\left(\lambda_{\alpha}-d_{i}\right)=\sum_{i=1}^{n-1}\left(\left|a_{i}\right|^{2} \prod_{j \neq i}\left(\lambda_{\alpha}-d_{j}\right)\right) . \tag{A.12}
\end{equation*}
$$

By the definition of $\mathbf{B}$, for $\alpha \in \mathbf{B}$, one then has $\left|\lambda_{\alpha}-d_{i}\right| \geqslant \epsilon$ for any $i \in I$. We therefore derive

$$
\begin{equation*}
\left|\lambda_{\alpha}-\mathbf{a}\right|=\left|\sum_{i=1}^{n-1} \frac{\left|a_{i}\right|^{2}}{\lambda_{\alpha}-d_{i}}\right| \leqslant \sum_{i=1}^{n-1} \frac{\left|a_{i}\right|^{2}}{\left|\lambda_{\alpha}-d_{i}\right|} \leqslant \frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}, \text { if } \alpha \in \mathbf{B} . \tag{A.13}
\end{equation*}
$$

Hence, for $\alpha \in \mathbf{B}$, we obtain

$$
\begin{equation*}
\lambda_{\alpha} \geqslant \mathbf{a}-\frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2} . \tag{A.14}
\end{equation*}
$$

For a set $\mathbf{S}$, we denote $|\mathbf{S}|$ the cardinality of $\mathbf{S}$. We shall use proof by contradiction to prove $\mathbf{B}=\emptyset$. Assume $\mathbf{B} \neq \emptyset$. Then $|\mathbf{B}| \geqslant 1$, and so $|\mathbf{G}|=n-1-|\mathbf{B}| \leqslant n-2$.

In the case of $\mathbf{G} \neq \emptyset$, we compute the trace of the matrix $A$ as follows:

$$
\begin{align*}
\operatorname{tr}(\mathrm{A}) & =\lambda_{n}+\sum_{\alpha \in \mathbf{B}} \lambda_{\alpha}+\sum_{\alpha \in \mathbf{G}} \lambda_{\alpha} \\
& >\lambda_{n}+|\mathbf{B}|\left(\mathbf{a}-\frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}\right)-|\mathbf{G}|\left(\sum_{i=1}^{n-1}\left|d_{i}\right|+\epsilon\right) \\
& \geqslant 2 \mathbf{a}-\frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}-(n-2)\left(\sum_{i=1}^{n-1}\left|d_{i}\right|+\epsilon\right)  \tag{A.15}\\
& \geqslant \sum_{i=1}^{n-1} d_{i}+\mathbf{a}=\operatorname{tr}(\mathrm{A}),
\end{align*}
$$

where we use (A.6), (A.9), (A.11) and (A.14). This is a contradiction.
In the case of $\mathbf{G}=\emptyset$, one knows that

$$
\begin{equation*}
\operatorname{tr}(\mathrm{A}) \geqslant \mathbf{a}+(n-1)\left(\mathbf{a}-\frac{1}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}\right)>\sum_{i=1}^{n-1} d_{i}+\mathbf{a}=\operatorname{tr}(\mathrm{A}) . \tag{A.16}
\end{equation*}
$$

Again, it is a contradiction.
We now prove $\mathbf{B}=\emptyset$. Therefore, $\mathbf{G}=I$ and the proof is complete.
We apply Lemma A. 3 to prove Lemma A. 2 via a deformation argument.
Proof of Lemma A.2. Without loss of generality, we assume $n \geqslant 3$ and $\sum_{i=1}^{n-1}\left|a_{i}\right|^{2}>0$ (otherwise $n=2$ or the matrix A is diagonal, and then we are done). Fix $a_{1}, \cdots, a_{n-1}, d_{1}, \cdots, d_{n-1}$. Denote $\lambda_{1}(\mathbf{a}), \cdots, \lambda_{n}(\mathbf{a})$ by the eigenvalues of A with the order $\lambda_{1}(\mathbf{a}) \leqslant \cdots \leqslant \lambda_{n}(\mathbf{a})$. Clearly, the eigenvalues $\lambda_{i}(\mathbf{a})$ are all continuous functions in a. For simplicity, we write $\lambda_{i}=\lambda_{i}(\mathbf{a})$.

Fix $\epsilon>0$. Let $I_{\alpha}^{\prime}=\left(d_{\alpha}-\frac{\epsilon}{2 n-3}, d_{\alpha}+\frac{\epsilon}{2 n-3}\right)$ and

$$
P_{0}^{\prime}=\frac{2 n-3}{\epsilon} \sum_{i=1}^{n-1}\left|a_{i}\right|^{2}+(n-1) \sum_{i=1}^{n-1}\left|d_{i}\right|+\frac{(n-2) \epsilon}{2 n-3} .
$$

In what follows we assume $\mathbf{a} \geqslant P_{0}^{\prime}$ (i.e. (A.5) holds). The connected components of $\bigcup_{\alpha=1}^{n-1} I_{\alpha}^{\prime}$ are as in the following:

$$
J_{1}=\bigcup_{\alpha=1}^{j_{1}} I_{\alpha}^{\prime}, J_{2}=\bigcup_{\alpha=j_{1}+1}^{j_{2}} I_{\alpha}^{\prime} \cdots, J_{i}=\bigcup_{\alpha=j_{i-1}+1}^{j_{i}} I_{\alpha}^{\prime}, \cdots, J_{m}=\bigcup_{\alpha=j_{m-1}+1}^{n-1} I_{\alpha}^{\prime} .
$$

(Here we denote $j_{0}=0$ and $j_{m}=n-1$ ). Moreover

$$
J_{i} \bigcap J_{k}=\emptyset, \text { for } 1 \leqslant i<k \leqslant m .
$$

Let

$$
\widetilde{\operatorname{Card}}_{k}:\left[P_{0}^{\prime},+\infty\right) \rightarrow \mathbb{N}
$$

be the function that counts the eigenvalues which lie in $J_{k}$. (Note that when the eigenvalues are not distinct, the function $\widetilde{\text { Card }}_{k}$ denotes the summation of all the multiplicities of distinct eigenvalues which lie in $J_{k}$ ). This function measures the number of the eigenvalues which lie in $J_{k}$.

The crucial ingredient is that Lemma A.3yields the continuity of $\widetilde{\operatorname{Card}}_{i}(\mathbf{a})$ for $\mathbf{a} \geqslant P_{0}^{\prime}$. More explicitly, by using Lemma A. 3 and

$$
\lambda_{n} \geqslant \mathbf{a} \geqslant P_{0}^{\prime}>\sum_{i=1}^{n-1}\left|d_{i}\right|+\frac{\epsilon}{2 n-3}
$$

we conclude that if a satisfies the quadratic growth condition (A.5) then

$$
\begin{align*}
& \lambda_{n} \in \mathbb{R} \backslash\left(\bigcup_{k=1}^{n-1} \overline{I_{k}^{\prime}}\right)=\mathbb{R} \backslash\left(\bigcup_{i=1}^{m} \overline{J_{i}}\right),  \tag{A.17}\\
& \lambda_{\alpha} \in \bigcup_{i=1}^{n-1} I_{i}^{\prime}=\bigcup_{i=1}^{m} J_{i} \text { for } 1 \leqslant \alpha \leqslant n-1 .
\end{align*}
$$

Hence, $\widetilde{\operatorname{Card}}_{i}(\mathbf{a})$ is a continuous function in the variable $\mathbf{a}$. So it is a constant. Together with the line of the proof of [4, Lemma 1.2] we see that $\widetilde{\operatorname{Card}}_{i}(\mathbf{a})=j_{i}-j_{i-1}$ for sufficiently large a. The constant of $\widetilde{\operatorname{Card}}_{i}$ therefore follows that

$$
\widetilde{\operatorname{Card}}_{i}(\mathbf{a})=j_{i}-j_{i-1} .
$$

We thus know that the $\left(j_{i}-j_{i-1}\right)$ eigenvalues

$$
\lambda_{j_{i-1}+1}, \lambda_{j_{i-1}+2}, \cdots, \lambda_{j_{i}}
$$

lie in the connected component $J_{i}$. Thus, for any $j_{i-1}+1 \leqslant \gamma \leqslant j_{i}$, we have $I_{\gamma}^{\prime} \subset J_{i}$ and $\lambda_{\gamma}$ lies in the connected component $J_{i}$. Therefore,

$$
\left|\lambda_{\gamma}-d_{\gamma}\right|<\frac{\left(2\left(j_{i}-j_{i-1}\right)-1\right) \epsilon}{2 n-3} \leqslant \epsilon .
$$

Here we also use the fact that $d_{\gamma}$ is midpoint of $I_{\gamma}^{\prime}$ and every $J_{i} \subset \mathbb{R}$ is an open subset.

To be brief, if for fixed index $1 \leqslant i \leqslant n-1$ the eigenvalue $\lambda_{i}\left(P_{0}^{\prime}\right)$ lies in $J_{\alpha}$ for some $\alpha$, then Lemma A. 3 implies that, for any $\mathbf{a}>P_{0}^{\prime}$, the corresponding eigenvalue $\lambda_{i}(\mathbf{a})$ lies in the same interval $J_{\alpha}$. Adapting the line of the proof [4. Lemma 1.2] to our context, we get the asymptotic behavior as a goes to infinity.
