FINITE GROUPS WITH FEW CHARACTER VALUES

SESUAI Y. MADANHA

Abstract. A classical theorem on character degrees states that if a finite group has fewer than four character degrees, then the group is solvable. We prove a corresponding result on character values by showing that if a finite group has fewer than eight character values in its character table, then the group is solvable. This confirms a conjecture of T. Sakurai. We also classify non-solvable groups with exactly eight character values.

1. Introduction

Let $G$ be a finite group and $\text{Irr}(G)$ be the set of complex irreducible characters of $G$. Recall the definition of a character degree set:

$$\text{cd}(G) := \{\chi(1) \mid \chi \in \text{Irr}(G)\}.$$ 

The study of the set $\text{cd}(G)$ has received much attention from many authors and has been shown to have strong influence on the structure of $G$. In particular, we have the famous Ito-Michler theorem which states that $G$ has a normal abelian Sylow $p$-subgroup if and only if $p$ does not divide any member of $\text{cd}(G)$. On the other extreme is Thompson’s theorem, which states that if $p$ divides every member of $\text{cd}(G) \setminus \{1\}$, then $G$ has a normal $p$-complement. In this note we shall study a bigger set found in a character table:

$$\text{cv}(G) = \{\chi(g) \mid \chi \in \text{Irr}(G), g \in G\}.$$ 

Little has been done in the study of this set. The first article in this direction is from T. Sakurai [8], who studied groups with very few character values. We shall compare results in [8] with corresponding character degree results. It is well known that $|\text{cd}(G)| = 1$ if and only if $G$ is abelian. Sakurai showed that if $|\text{cv}(G)| \leq 3$, then $G$ is abelian. The converse is not true since $|\text{cv}(C_r)| = r$, where $C_r$ denote the cyclic group of order $r$ for some positive integer $r$.

If $|\text{cd}(G)| = 2$ with $\text{cd}(G) = \{1, n\}$, then either $G$ has an abelian normal subgroup of index $n$, or $n = p^e$ for a prime $p$ and $G$ is direct product of a $p$-group and abelian group. It turns out that a non-abelian group $G$ is such that $|\text{cv}(G)| = 4$ if and only if $G$ is the generalized dihedral group of a non-trivial elementary abelian 3-group ([8 Theorem]). A generalized dihedral group of a non-trivial elementary abelian $p$-group is a group $G_n = [C_p \times C_p \times \cdots \times C_p] \rtimes C_2$, the semidirect product of the direct product of $n$ copies of $C_p$ and $C_2$, where $C_2$ acts on $[C_n \times C_n \times \cdots \times C_n]$ without non-trivial fixed points. For groups with more than four character values, Sakurai remarked on the difficulty to classify these groups. However, a conjecture was proposed which states that if the group has fewer than eight character values, then the group is solvable [8 Remark]. Our aim is to settle this conjecture:

Key words and phrases. character values, character degrees, almost simple groups.
Theorem 1.1. If $|\text{cv}(G)| < 8$, then $G$ is solvable.

Isaacs [5] Theorem 12 proved a result that is now considered classical which states that if $|\text{cd}(G)| < 4$, then $G$ is solvable. Hence Theorem 1.1 is the corresponding result for character values. Our proof uses the classification of finite simple groups.

Malle and Moretó [7] classified non-solvable groups with $|\text{cd}(G)| = 4$ (see Theorem 2.2). We obtain a corresponding result for character values:

**Theorem 1.2.** Let $G$ be a finite non-solvable group. Then $|\text{cv}(G)| = 8$ if and only if $G \cong \text{PSL}_2(5)$ or $\text{PGL}_2(5)$.

2. Preliminary Results

In this section we list some preliminary results that we need to prove our main results. We shall use freely these well known results in the following lemma.

**Lemma 2.1.** Let $G$ be a finite group, $N$ be a normal subgroup of $G$ and $n$ be a positive integer. Then the following hold:

(a) $|\text{cv}(G/N)| \leq |\text{cv}(G)|$,

(b) The character table of $C_n$ has a column with pairwise different values. In particular, $|\text{cv}(C_n)| = n$,

(c) If $G$ is non-abelian, then $0 \in \text{cv}(G)$.

The following is a result of Malle and Moretó [7] in which they classified non-solvable groups with four character degrees.

**Theorem 2.2.** [7, Theorem A] Let $G$ be a non-solvable group with $|\text{cd}(G)| = 4$. Then one of the following holds:

(a) $G \cong \text{PSL}_2(2^f) \times A$ for some $f \geq 2$ and some abelian subgroup $A$,

(b) $G$ has a normal subgroup $U$ such that $U \cong \text{PSL}_2(q)$ or $\text{SL}_2(q)$ for some odd $q \geq 5$, and if $C = C_G(U)$, then $C \leq Z(G)$ and $G/C \cong \text{PGL}_2(q)$; or

(c) the group $G$ has a normal subgroup of index 2 that is a direct product of $\text{PSL}_2(9)$ and central subgroup $C$. Furthermore, $G/C \cong M_{10}$, the Mathieu group which the stabilizer of a point in the Mathieu group, $M_{11}$, in its natural permutation representation.

Conversely, if one of (a)-(c) holds, then $|\text{cd}(G)| = 4$.

He and Zhu [4] described non-solvable groups with five and six character degrees:

**Theorem 2.3.** [4, Corollary C] Let $G$ be a non-solvable group and $L$ be the solvable radical of $G$. If $5 \leq |\text{cd}(G)| \leq 6$, then $G'/L$ is isomorphic to $\text{PSL}_2(p^f)$ with $p^f \geq 4$, $\text{PSL}_3(4)$ or $2B_2(2^f)$, where $2^f = 2^{2m+1}$ for some integer $m \geq 1$. Moreover, $G/L$ is an almost simple group.

We classify almost simple groups with five character degrees. We first have some definitions needed in our result: $q = p^f \geq 4$, $\text{Out}(\text{PSL}_2(q)) = \langle \delta \rangle \times \langle \varphi \rangle$, $|\langle \varphi \rangle| = f$, $|\langle \delta \rangle| = \gcd(2, q - 1)$.

**Theorem 2.4.** Let $G$ be a finite almost simple group, that is $S \triangleleft G \leq \text{Aut}(S)$ for some non-abelian simple group $S$. Then $|\text{cd}(G)| = 5$ if and only if one of the following holds:

(a) $G \cong \text{PSL}_2(q)$, $q$ odd, $\text{cd}(G) = \{1, (q + \epsilon)/2, q \pm 1, q\}$,

(b) $G \cong \text{PSL}_2(2^f)\langle \varphi \rangle$, $f > 2$ prime, $\text{cd}(G) = \{1, 2^f - 1, 2^f, (2^f \pm 1)f\}$,

(c) $G \cong \text{PSL}_2(2^f)\langle \varphi^{f/2} \rangle$, $f > 2$ even, $\text{cd}(G) = \{1, 2^f, 2^f + 1, 2(2^f + 1)\}$,
(d) \( G \cong \text{PGL}_2(q) \langle \varphi^{f/2} \rangle, \ f > 2 \text{ even}, q \text{ odd}, \ \text{cd}(G) = \{1, q, q+1, 2(q+1)\}, \)

(e) \( G \cong \text{PGL}_2(3^f) \langle \varphi \rangle, \ f > 2 \text{ even}, \ \text{cd}(G) = \{1, 3^f, 3^f - 1, (3^f \pm 1)f\}, \)

(f) \( G \cong \text{PSL}_2(9) \langle \varphi \rangle \cong S_6, \ f = 2, \ \text{cd}(G) = \{1, 5, 9, 10, 16\}, \)

(g) \( G \cong \text{PSL}_2(5f) \langle \varphi \rangle, \ f > 2 \text{ prime}, \ \text{cd}(G) = \{1, 5f, (5f + 1)/2, 5f - 1, (5f + 1)f\}, \)

(h) \( G \cong \text{PSL}_2(q) \langle \delta \varphi^{f/2} \rangle, \ f > 2 \text{ even}, q \neq 9, p \text{ odd}, \ \text{cd}(G) = \{1, q, q+1, 2(q+1)\}. \)

Proof. First, it is well known that every simple group \( S \) has a non-trivial irreducible character \( \chi \) that can be extended to \( \text{Aut}(S) \). Suppose that \( r \) is a prime that divides the character degree of \( \chi \). If \( r \) divides every character degree of \( G \), then by Thompson’s theorem [5, Corollary 12.2], \( G \) has a normal \( r \)-complement, a contradiction.

We may thus assume that no prime divides every character degree of \( G \). Since \( G \) has five character degrees, there is no prime dividing four character degrees of \( G \). These groups are the groups in [2, Theorem A]. It is sufficient to consider groups in case (c) since the groups in (a)-(b) and (d)-(f) can be ruled out using the character tables in the Atlas [1] and [10].

By inspecting [2, Table 1], we have our result. \( \square \)

3. Main Results

**Theorem 3.1.** Let \( G \) be a finite almost simple group, that is \( S < G \leq \text{Aut}(S) \) for some non-abelian simple group \( S \). Then either \( |\text{cv}(G)| \geq 9 \) or \( |\text{cv}(G)| = 8 \) and \( G \in \{\text{PSL}_2(5), \text{PGL}_2(5)\} \). In particular, if \( |\text{cd}(G)| \geq 5 \), then \( |\text{cv}(G)| \geq 9 \).

Proof. Since \( G \) is non-solvable, \( |\text{cd}(G)| \geq 4 \) by [5, Theorem 12.15]. Suppose that \( |\text{cd}(G)| = 4 \). By Theorem [22], it is sufficient to consider the following groups: \( \text{PSL}_2(2^f) \) for some \( f \geq 2 \), \( \text{PGL}_2(q) \) for some odd \( q \geq 5 \) and \( M_{10} \). The character tables of these groups can be found in the Atlas [1], [3] and [9]. In particular, \( |\text{cv}(G)| \geq 9 \) except for \( \text{PSL}_2(5) \) and \( \text{PGL}_2(5) \). In the latter cases \( |\text{cv}(G)| = 8 \) as required.

We may assume that \( |\text{cd}(G)| = 5 \). It is sufficient to consider groups in Theorem [2, 4]. For cases (a) and (f), we have that \( |\text{cv}(G)| \geq 9 \), using character tables in [3] and Atlas [11]. For cases (b), (c) and (g) we have that \( C = G/\text{PGL}_2(q) \) is cyclic of order greater than 2. Then by Lemma [2.1], the character table of \( C \) has a column with pairwise different values. In particular, \( a, b \in \text{cv}(C) \setminus \{-1, 0, 1\} \) with \( a \neq b \). Note that the Steinberg character \( \psi \) of \( \text{PGL}_2(q) \) is extendible to \( G \) and also \( \psi(s) = -1 \) for some \( s \in \text{PSL}_2(q) \) by [3, Theorems 4.7 and 4.9]. Hence \( -1 \in \text{cv}(G) \) and \( |\text{cv}(G)| = |\text{cd}(G)| \cup \{a, b, -1, 0\} \geq 9 \). Suppose that \( C \) is of order 2. Groups with this property are the ones in cases (c), (d) and (h). Consider the characters \( \chi_1, \chi_2 \in \text{Irr}(G) \) such that \( \chi_1(1) = 2(q+1) \) and \( \chi_2(1) = 2(q-1) \). Then since \( \text{PGL}_2(q) \) has no irreducible characters of degrees \( 2(q \pm 1), \chi_i = \theta_{11} + \theta_{12} \) by [5, Theorem 6.2], where \( \theta_{11}, \theta_{12}, \theta_{21}, \theta_{22} \in \text{Irr}(S), \theta_{11}(1) = \theta_{12}(1) = q+1 \) and \( \theta_{21}(1) = \theta_{22}(1) = q-1 \). Using [3, Theorems 4.7 and 4.9], we have that \( \theta_{11}(g) = \theta_{12}(g) = 1 \) and \( \theta_{21}(g) = \theta_{22}(g) = -1 \) for some \( g \in \text{PGL}_2(q) \). Hence \( \chi_1(1) = 2, \chi_1(1) = -2 \) and \( |\text{cd}(G)| \cup \{-2, -1, 0, 2\} \geq 9 \).

Going forward we may assume that \( |\text{cd}(G)| \geq 6 \). Suppose that \( |\text{cd}(G)| \geq 6 \) and \( S \cong \text{PSL}_2(q) \). We may assume that \( G \) is not isomorphic to \( \text{PSL}_2(2^f) \) with \( f \geq 2 \), \( \text{PSL}_2(p^f) \) with \( p \) odd or \( \text{PGL}_2(p^f) \) with \( p \) odd. Let \( H \in \{\text{PSL}_2(2^f), f \geq 2 \} \cup \{\text{PSL}_2(q), q \text{ odd} \} \cup \{\text{PGL}_2(q), q \text{ odd} \} \). If \( G \cong \text{HC}_r \), where \( r \ | \ f, r > 2 \). Then arguing as above, we have that \( a, b \in \text{cv}(C) \setminus \{-1, 1\} \) and \( |\text{cv}(G)| = |\text{cd}(G)| \cup \{-1, 0, a, b\} \geq 10 \). If \( G \cong \text{HC}_2, 2 \ | \ f \). Then either \( 2(q-1) \) or \( 2(q+1) \) is a character degree of \( G \). Arguing as above, we have that either \( -2 \in \text{cv}(C) \) or \( 2 \in \text{cv}(C) \). Since \( -1, 0 \in \text{cv}(G) \) and \( |\text{cd}(G)| \geq 6 \) we have that \( |\text{cv}(G)| \geq 9 \).
If $S \cong \text{PSL}_3(4)$, then the result follows using the character table in the Atlas [1]. Suppose that $S \cong \mathbb{B}_2(2^j)$, where $2^j = 2^{2m+1}$ for some integer $m \geq 1$. If $G \cong \mathbb{B}_2(2^j)$, it follows that $|\text{cv}(G)| \geq 9$ by the character table in [10, Theorem 13]. We may assume that $S < G < \text{Aut}(S)$. Then $C = G/S$ is cyclic of odd order. Using the argument as in the case of $\text{PSL}_2(q)$ above, we have that $a, b \in \text{cv}(C) \setminus \{-1, 1\}$. Hence $|\text{cv}(G)| \geq |\text{cd}(G) \cup \{a, b, 0\}| = 9$.

If $|\text{cd}(G)| \geq 7$, then by column orthogonality, there is a character value which is a negative number and so $|\text{cv}(G)| \geq 9$. This concludes our proof. □

**Proof of Theorem 1.1** We prove our result using induction on $|G|$. Since $|\text{cv}(G)| < 8$, every homomorphic image of $G$ has the same property. Let $N$ be a minimal normal subgroup of $G$. If another such minimal normal subgroup, say $M$, exists then $G$ is the subdirect product of solvable groups $G/N$ and $G/M$, and so is solvable. This implies that $N$ is unique and non-abelian. Hence $G$ is almost simple group. The result follows by Theorem 3.1.

Before we prove Theorem 1.2, we recall a definition. If $N \triangleleft G$, then $\text{Irr}(G|N) = \{\chi \in \text{Irr}(G) \mid N \nsubseteq \ker \chi\}$ and $|\text{cd}(G|N)| = \{\chi(1) \mid \chi \in \text{Irr}(G|N)\}$.

**Proof of Theorem 1.2** Since $G$ is non-solvable, $|\text{cd}(G)| \geq 4$. If $5 \leq |\text{cd}(G)| \leq 6$, then by Theorem 2.3, $G/L$ is isomorphic to $\text{PSL}_2(p^j)$, $p^j \geq 4$, $\text{PSL}_3(4)$ or $\mathbb{B}_2(2^j)$, where $2^j = 2^{2m+1}$ for some integer $m \geq 1$, where $L$ is the solvable radical of $G$. Specifically, $G/L$ is an almost simple group. Using Theorem 3.1, $|\text{cd}(G)| \geq |\text{cd}(G/L)| \geq 9$.

If $|\text{cd}(G)| = 4$, then using Theorem 2.2 and Theorem 3.1, it is sufficient to consider $G \cong \text{PSL}_2(5) \times A$ for some abelian subgroup $A$ or $G/C \cong \text{PGL}_2(5)$, where $C = C_G(U)$, $U = \text{PSL}_2(5)$ or $\text{SL}_2(5)$ with $C \leq Z(G)$ and $U$ is a normal subgroup of $G$. Suppose that $G \cong \text{PSL}_2(5) \times A$ with non-trivial $A$. Consider $\theta \in \text{Irr}(\text{PSL}_2(5))$ such that $\theta(1) = 5$ and $\phi \in \text{Irr}(A)$ such that $\phi(g) = k < 0$. Then $\chi(1 \times g) = \theta(1) \times \phi(g) = 5k < 0$ and $|\text{cv}(G)| \geq 9$. Suppose that $G$ is a group in the latter case. We want to show that $C = 1$. Suppose that $C \neq 1$. Let $Z(G)U = N$ and note that $\text{cd}(G|N) \geq 3$ by [6, Theorem B]. Then there is a $\chi \in \text{Irr}(G)$ such that $\chi(1) = m \in \text{cd}(G|N) \setminus \{1, 2\}$. For $1 \neq z \in Z(G)$, we have that $\chi(z) = -m$. This means that $|\text{cv}(G)| \geq |\text{PGL}_2(5) \cup \{-m\}| = 9$. Therefore $G = \text{PGL}_2(5)$ and that concludes our argument. □
