INCIDENCE VARIETIES
IN THE PROJECTIVIZED $k$-TH HODGE BUNDLE
OVER CURVES WITH RATIONAL TAILS

IULIA GHEORGHITA AND NICOLA TARASCA

Abstract. Over the moduli space of pointed smooth algebraic curves, the projectivized $k$-th Hodge bundle is the space of $k$-canonical divisors. The incidence loci are defined by requiring the $k$-canonical divisors to have prescribed multiplicities at the marked points. We find a recursive description of the closure of the incidence loci in the projectivized $k$-th Hodge bundle over the moduli space of curves with rational tails, and we use it to compute the classes of such loci in all cases when $k = 1$, and with few exceptions when $k \geq 2$. The classes are expressed as a linear combination of tautological classes indexed by decorated stable graphs, with coefficients enumerating appropriate weightings of decorated stable graphs. As a consequence, we obtain an explicit expression for some relations in tautological rings of moduli of curves with rational tails.

0. Introduction

This study revolves around families of algebraic curves with differentials. For an algebraic curve $C$ which is either smooth or has at-worst-nodal singularities, the stable (holomorphic) abelian differentials are the global sections of the dualizing sheaf $\omega_C$. Similarly, for $k \geq 1$, the stable (holomorphic) $k$-differentials are the global sections of $\omega_C^{\otimes k}$. The $k$-th Hodge bundle $E_{g,n}^k$ is the vector bundle of stable $k$-differentials over the moduli space $\mathcal{M}_{g,n}$ of stable curves of genus $g$ with $n$ marked points. Its projectivization is here

Key words and phrases. Moduli spaces of algebraic curves with differentials, the strata algebra, relations in the tautological ring of moduli spaces of curves.
denoted $\mathbb{P}E_{g,n}^k$. A point of $\mathbb{P}E_{g,n}^k$ consists of a stable $n$-pointed genus $g$ curve together with the class of a nonzero stable $k$-differential modulo scaling by units. In particular, fibers of $\mathbb{P}E_{g,n}^k$ over the locus of smooth curves $M_{g,n}$ consist of $k$-canonical divisors.

The closure of loci of $k$-canonical divisors has been the focus of several recent studies. Pointed curves admitting $k$-canonical divisors with prescribed multiplicities at the marked points define natural loci in $M_{g,n}$. Similar loci can be obtained by requiring the existence of a divisor of zeros and poles of a meromorphic $k$-differential with prescribed multiplicities at the marked points. The closure of such loci has been studied by Farkas and Pandharipande [FP] by means of their moduli space of twisted canonical divisors. This is a proper moduli space inside $\mathcal{M}_{g,n}$ and contains the space of canonical divisors together with some additional components supported on singular curves. A conjecture for the weighted sum of the fundamental classes of all such components in the meromorphic case was proposed by Janda, Pandharipande, Pixton, and Zvonkine [FP, Appendix], together with an algorithm to determine the class of the closure of loci of canonical divisors in $\mathcal{M}_{g,n}$ in both the holomorphic and meromorphic case. Extended to $k \geq 1$ by Schmitt [Sch], this conjecture has now been proved by Bae, Holmes, Pandharipande, Schmitt, and Schwarz [BHP⁺].

It follows that the class of the closure of loci of $k$-canonical divisors in $\overline{M}_{g,n}$ is determined by the algorithm given in [FP, Appendix] and [Sch]. The problem of computing a closed formula for such classes remains open. We make progress in this direction by studying the classes of the closure of loci of $k$-canonical divisors in the moduli space $\mathcal{M}_{g,n}^{rt}$ of curves with rational tails. The space $\mathcal{M}_{g,n}^{rt}$ is a partial compactification of $M_{g,n}$ and consists of stable pointed curves with a component of geometric genus $g$ and possibly additional rational components.

More generally, we study the class of the closure of incidence varieties inside the projectivized $k$-th Hodge bundle over $\mathcal{M}_{g,n}^{rt}$. For this, we use the incidence variety compactification introduced by Bainbridge, Chen, Gendron, Grushevsky, and Möller [BCG⁺1, BCG⁺2].

Specifically, define the incidence locus
\begin{equation}
H^k_{g,n} \subset \mathbb{P}E_{g,n}^k
\end{equation}
as the locus consisting of smooth $n$-pointed genus $g$ curves together with the class of a stable $k$-differential having a zero at each marked point. This locus has codimension $n$ in $\mathbb{P}E_{g,n}^k$. Similarly, we study the incidence loci obtained by imposing the vanishing of the stable $k$-differential at the marked points with prescribed multiplicities. By [BCG⁺1, BCG⁺2], a point of $\mathbb{P}E_{g,n}^k$ is in the closure of such loci if it admits a twisted $k$-differential satisfying certain compatibility conditions (§1.1).

We start by devising a recursive description of the closure of the incidence loci in $\mathbb{P}E_{g,n}^k$ over $\mathcal{M}_{g,n}^{rt}$ (Theorem 2.9). Then we solve the recursion by finding a closed formula (Definition 1) in the Chow ring of $\mathbb{P}E_{g,n}^k$ which
expresses the class of such loci in the restriction of $\mathbb{P}E^k_{g,n}$ over $\mathcal{M}^\text{rt}_{g,n}$ in all cases when $k = 1$ and with few exceptions when $k \geq 2$ (Theorems 2 and 7.1).

Via pull-back, $A^*\left(\mathcal{M}_{g,n}\right)$ injects in the Chow ring of $\mathbb{P}E^k_{g,n}$ and one has

\[
A^*\left(\mathbb{P}E^k_{g,n}\right) \cong A^*\left(\mathcal{M}_{g,n}\right) \left[\eta\right] / \left(\sum_{i=0}^{r} (-\eta)^i c_{r-i} \left(\mathbb{P}E^k_{g,n}\right)\right)
\]

where $r = \text{rank} \left(\mathbb{E}^k_{g,n}\right)$ and $\eta := c_1(\mathcal{O}_{\mathbb{P}E^k_{g,n}}(-1))$.

Our formula (Definitions 1 and 6.1) lies in the tautological ring $R^*\left(\mathbb{P}E^k_{g,n}\right)$ which is the subring of (0.2) generated by the tautological ring $R^*\left(\mathcal{M}_{g,n}\right)$ and $\eta$. The formula is expressed as a linear combination of tautological classes indexed by decorated stable graphs, with coefficients enumerating appropriate weightings of decorated stable graphs, which we describe next.

0.1. Dual graphs of pointed curves with rational tails. For $g \geq 0$, let $G^\text{rt}_{g,n}$ be the set of trees that are dual to strata in the moduli space $\mathcal{M}^\text{rt}_{g,n}$ of $n$-pointed genus $g$ curves with rational tails. Namely, an element in $G^\text{rt}_{g,n}$ is dual to a locally closed stratum in $\mathcal{M}^\text{rt}_{g,n}$ consisting of pointed nodal curves with the same topological type. In particular, an element in $G^\text{rt}_{g,n}$ is a tree consisting of a genus $g$ vertex and possibly additional rational (i.e., genus 0) vertices dual to curve components, edges dual to nodes, and $n$ legs dual to the $n$ marked points.

For a tree $\Gamma$ in $G^\text{rt}_{g,n}$, let $V(\Gamma)$ be the set of vertices, $L(\Gamma)$ be the set of legs, and $E(\Gamma)$ be the set of edges of $\Gamma$. The set $L(\Gamma)$ is often identified with a set of labels, e.g., $L(\Gamma) \cong \{1, \ldots, n\}$.

0.2. Rooted trees. Let $g > 0$ and $\Gamma \in G^\text{rt}_{g,n}$. By identifying the genus $g$ vertex as root, the graph $\Gamma$ is considered as a rooted tree, with all edges oriented away from the root. An edge $e \in E(\Gamma)$ consists of a pair of two half-edges $e = (h^+, h^-)$: we denote by $h^+$ (or head) the half-edge which is further away from the genus $g$ vertex, and by $h^-$ (or tail) the half-edge which is closer to the genus $g$ vertex.

The set $H(\Gamma)$ of half-edges of $\Gamma$ is partitioned as

\[
H(\Gamma) = H^+(\Gamma) \sqcup H^- (\Gamma)
\]

where $H^+(\Gamma)$ (respectively, $H^- (\Gamma)$) is the set of head (resp., tail) half-edges.

0.3. Decorations and weightings. Select $g > 0$ and $\Gamma \in G^\text{rt}_{g,n}$. Let $v_g$ be the genus $g$ vertex in $\Gamma$, and $V_0(\Gamma) := V(\Gamma) \setminus \{v_g\}$ be the set of rational vertices of $\Gamma$. Consider the moduli space

\[
\overline{\mathcal{M}}_\Gamma := \overline{\mathcal{M}}_{g,n(v_g)} \times \prod_{v \in V_0(\Gamma)} \overline{\mathcal{M}}_{0,n(v)}
\]

where $n(v)$ is the valence of a vertex $v$, i.e., the number of legs and half-edges incident to $v$. 
The set of decorations $\Psi(\Gamma)$ of the graph $\Gamma$ is defined here as

$$\Psi(\Gamma) := \left\{ \psi = \prod_{h \in H(\Gamma)} \psi_h^{d_h} : d_h \geq 0 \text{ for all } h \right\} \subset A^*(M_{\Gamma}).$$

For each $h$, the class $\psi_h$ is the first Chern class of the cotangent line bundle at the marked point corresponding to $h$ [GP].

Select $\psi = \prod_{h \in H(\Gamma)} \psi_h^{d_h}$ in $\Psi(\Gamma)$, and define the following set of pairs:

$$H(\Gamma, \psi) := \left\{ (h, e) \mid h \in H^+(\Gamma), 0 \leq e \leq d_h \right\} \sqcup \left\{ (h, e) \mid h \in H^-(\Gamma), 1 \leq e \leq d_h \right\}. \tag{0.4}$$

One has $|H(\Gamma, \psi)| = |E(\Gamma)| + \deg \psi$.

For a half-edge $h$ of $\Gamma$, let $\iota(h)$ be the half-edge such that $(h, \iota(h)) \in E(\Gamma)$. Define the capacity of a head half-edge $h^+$ in $H^+(\Gamma)$ as

$$\ell_{h^+} := \left\{ \begin{array}{l}
\text{number of legs of } \Gamma \text{ in the maximal} \\
\text{connected subtree containing } h^+, \text{ but not } \iota(h^+).
\end{array} \right. \tag{0.5}$$

One has $\ell_{h^+} \geq 2$ for all $h^+$.

A weighting of the decorated stable graph $(\Gamma, \psi)$ is a function

$$w : H(\Gamma, \psi) \rightarrow \mathbb{N}$$

satisfying the following conditions:

$$\begin{cases}
\ell_{h^+} - 1 \geq w(h^+, 0) \geq w(h^+, 1) \geq \cdots \geq w(h^+, d_{h^+}) \\
1 \leq w(h^-, 1) < \cdots < w(h^-, d_{h^-}) < w(\iota(h^-), 0)
\end{cases} \tag{0.6}$$

for all heads $h^+$, and for all tails $h^-$. The set of weightings of the decorated stable graph $(\Gamma, \psi)$

$$(0.7) \quad W_{\Gamma, \psi} := \{ \text{weightings of } (\Gamma, \psi) \}$$

is a finite set. For a weighting $w$ of $(\Gamma, \psi)$, define the corresponding weight of $(\Gamma, \psi)$ as

$$w(\Gamma, \psi) := \prod_{(h, e) \in H(\Gamma, \psi)} w(h, e). \tag{0.8}$$

Define the coefficients $c_{\Gamma, \psi}$ as

$$c_{\Gamma, \psi} := \sum_{w \in W_{\Gamma, \psi}} w(\Gamma, \psi). \tag{0.9}$$
For instance, one has
\[
(\Gamma, \psi) = \begin{array}{c}
\text{g} \\
\text{ψ}
\end{array} \quad \Rightarrow \quad c_{\Gamma, \psi} = 7,
\]
\[
(\Gamma, \psi) = \begin{array}{c}
\text{g} \\
\text{ψ}
\end{array} \quad \Rightarrow \quad c_{\Gamma, \psi} = 6,
\]
\[
(\Gamma, \psi) = \begin{array}{c}
\text{g} \\
\text{ψ}
\end{array} \quad \Rightarrow \quad c_{\Gamma, \psi} = 42.
\]

Here and throughout, rational vertices are contracted into points for convenience, and \(\psi\)-classes decorate their corresponding half-edges (later in the paper, \(\psi\)-classes will decorate legs too).

0.4. The graph formula. For \(g > 0\), a graph \(\Gamma \in G_{g,n}^r\) defines the moduli space \(\overline{M}_\Gamma\) from (0.3) together with a gluing map of degree one \(\overline{M}_\Gamma \to \overline{M}_{g,n}\).

Similarly, define \(\mathbb{P}E^k_\Gamma\) as the fiber product
\[
(0.10)
\]
\[
\begin{array}{c}
\xi_\Gamma \\
\downarrow
\end{array} \quad \begin{array}{c}
\mathbb{P}E^k_\Gamma \\
\downarrow
\end{array} \quad \begin{array}{c}
\mathbb{P}E^k_{g,n} \\
\downarrow
\end{array} \quad \begin{array}{c}
\overline{M}_\Gamma \\
\downarrow
\end{array} \quad \begin{array}{c}
\overline{M}_{g,n}.
\end{array}
\]

The image of \(\xi_\Gamma\) has codimension equal to \(|E(\Gamma)|\) in \(\mathbb{P}E^k_{g,n}\). We set \(\eta := \xi^*_\Gamma(\eta)\) in \(A^*(\mathbb{P}E^k_\Gamma)\), so that for any cycle \(\alpha\), one has \(\xi_{\Gamma,*}(\alpha \cdot \eta) = \xi_{\Gamma,*}(\alpha) \cdot \eta\) by the projection formula. We need few more classes, introduced below.

Let \(\rho_\ell: \overline{M}_{g,n} \to \overline{M}_{g,1}\) be the map obtained by forgetting all but the \(\ell\)-th marked point, and \(\omega_\ell := \rho_\ell^*(\psi)\) in \(R^*(\overline{M}_{g,1})\), where \(\psi\) is the \(\psi\)-class in \(R^*(\overline{M}_{g,1})\). Define \(\omega_\ell := \xi^*_\Gamma(\omega_\ell)\) in \(A^*(\overline{M}_\Gamma)\), for \(\ell = 1, \ldots, n\).

For \(h \in H(\Gamma)\), define \(\omega_h := \xi^*_\Gamma(\omega_h)\) in \(A^*(\overline{M}_\Gamma)\) for a leg \(\ell\) which is further away from the root than \(h\). This definition is independent of the choice of such a leg \(\ell\) (see also [CT1, §1.2]).

Finally, for \(\psi = \prod_{h \in H(\Gamma)} \psi_h^{d_h}\) in \(\Psi(\Gamma)\), let
\[
\beta_{\Gamma, \psi} := \prod_{h \in H^+(\Gamma)} (k \omega_h - \eta)^{1+d_h} \prod_{h \in H^-(\Gamma)} (k \omega_h - \eta)^{d_h} \in A^*(\mathbb{P}E^k_\Gamma).
\]

One has \(\deg \beta_{\Gamma, \psi} = |E(\Gamma)| + \deg \psi\). We are now ready for the graph formula:

**Definition 1.** Define \(F^k_{g,n} \in R^n(\mathbb{P}E^k_{g,n})\) as
\[
F^k_{g,n} := \sum_{\Gamma \in G_{g,n}^r} (-1)^{|E(\Gamma)|} \xi_{\Gamma,*} \left[ \prod_{\ell \in L(\Gamma)} (k \omega_\ell - \eta) \sum_{\psi \in \Psi(\Gamma)} c_{\Gamma, \psi} \psi \beta_{\Gamma, \psi}^{-1} \right].
\]

To verify that \(F^k_{g,n}\) has degree \(n\), observe that the product of the divisor classes \(k \omega_\ell - \eta\) for \(\ell = 1, \ldots, n\) has degree \(n\), and for each \((\Gamma, \psi)\), the factor
\[ \beta_{\Gamma, \psi}^{1} \] cancels out some of the factors \( k \omega - \eta \) to offset the codimension of the image of \( \xi_{\Gamma} \) and the degree of \( \psi \).

For example, when \( n \in \{1, 2\} \), one has

\[ F_{g,1}^{k} = k \omega_{1} - \eta \in R^{1}\left(\mathbb{P}E_{g,1}^{k}\right), \]

\[ F_{g,2}^{k} = k \omega_{1} - \eta - \omega_{2} - \eta \in R^{2}\left(\mathbb{P}E_{g,2}^{k}\right). \]

Already for \( n = 3 \), the expansion of the cycle \( F_{g,3}^{k} \) is lengthy. We include this and more examples in §8. Our first result about abelian differentials is:

**Theorem 1.** For \( k = 1 \) and \( g \geq 2 \), one has

\[ \left[ H_{1}^{1, g,n} \right] = F_{g,1}^{1} \in A^{n}\left(\mathbb{P}E_{g,1}^{1}|_{M_{g,n}^{1}}\right). \]

The statement holds for all \( n \). Since abelian differentials of genus \( g \) curves have degree \( 2g - 2 \), the loci \( H_{1}^{1, g,n} \) are empty for \( n > 2g - 2 \). In this case, Theorem 1 gives relations in the tautological ring, as discussed in the next Corollary 1. More generally, for \( k \geq 1 \), we prove the following statement:

**Theorem 2.** For \( g \geq 2 \), one has

\[ \left[ H_{k}^{1, g,n} \right] = F_{g,n}^{k} \]

in:

(i) \( A^{n}\left(\mathbb{P}E_{g,n}^{k}|_{M_{g,n}^{1}}\right) \) when

\[ \begin{cases} k = 1; \text{ or} \\ k \geq 2 \text{ and } n \leq k(2g - 2) - 1; \end{cases} \]

(ii) \( A^{n}\left(\mathbb{P}E_{g,n}^{k}\right) \) when \( n \leq k \).

The statement implies that the classes of the loci \( H_{k}^{1, g,n} \) are tautological in the appropriate ring determined by \( k \), \( g \), and \( n \). This extends the result of Sauvaget [Sau1] showing that for \( k = 1 \), incidence loci in \( \mathbb{P}E_{g,n}^{1} \) are tautological by means of a recursive description independent from ours. Sauvaget informed us that the techniques of [Sau2] could also be used to conclude that incidence loci are tautological over \( M_{g,n}^{1} \).

In the case \( k \geq 2 \) and \( n = k(2g - 2) \) left out by the statement, the cycle \( F_{g,n}^{k} \) decomposes as the sum of the classes of \( H_{k}^{1, g,n} \) and an additional locus. We discuss this case in Remarks 2.10 and 7.3.

Our most general result is described in §7 and concerns the study of incidence loci with prescribed multiplicities. Namely, for an \( n \)-tuple \( m = (m_{1}, \ldots, m_{n}) \) of positive integers, let \( H_{g,n}^{k, m} \subset \mathbb{P}E_{g,n}^{k} \) be the incidence locus consisting of stable \( n \)-pointed genus \( g \) curves together with the class of a
stable $k$-differential having a zero of order at least $m_\ell$ at the $\ell$-th marked point for each $\ell = 1, \ldots, n$. Theorem 7.1 shows that the class of $\mathbb{P}^k_{g,m}$ in the appropriate Chow ring determined by the values of $k$, $g$, and $m$ is given by the cycle $F^k_{g,m}$ from Definition 6.1 with few exceptions. Theorem 2 is the specialization of Theorem 7.1 at $m = (1, \ldots, 1)$.

0.5. Tautological relations. For $k = 1$ and $n > 2g - 2$, Theorem 2 gives the following vanishing statement:

**Corollary 1.** For $g \geq 2$ and $n > 2g - 2$, one has

$$F^1_{g,n} = 0 \quad \text{in } R^n \left( \mathbb{P}^1_{g,n} | \mathcal{M}^\tau_{g,n} \right).$$

This statement provides explicit expressions for relations in the tautological ring $R^n \left( \mathbb{P}^1_{g,n} | \mathcal{M}^\tau_{g,n} \right)$. By construction, these are restrictions of relations in $R^n \left( \mathbb{P}^1_{g,n} \right)$. Moreover, Corollary 1 induces relations in the tautological ring $R^* \left( \mathcal{M}^\tau_{g,n} \right)$. For instance, in §8.2 we check that for $g = 2$ and $n = 3$, Corollary 1 induces the restriction to $R^2 \left( \mathcal{M}^\tau_{2,3} \right)$ of the relation from [BP].

Determining whether there exist more relations in $R^* \left( \mathcal{M}_{g,n} \right)$ than the ones that are currently known is an open problem [Fab, Pix, PPZ, Jan, Pan]. It is unclear whether all the relations from Corollary 1 are in the space of known relations, and in fact we wonder whether Corollary 1 would contribute any new relations.

0.6. Structure of the proof. We start by computing the class of the closure of the incidence locus (0.1) for $n = 2$ over the whole moduli space of stable pointed curves in §1. Already in this case, one finds that the class over the locus of curves with rational tails extends over the moduli space of stable pointed curves in the range $k \geq 2$, i.e., $n \leq k$ here.

We proceed in §2 by determining a recursive identity (Theorem 2.9) satisfied by the classes of the closure of the loci (0.1) in $\mathbb{P}^k_{g,n}$ over $\mathcal{M}^\tau_{g,n}$. The identity extends over $\overline{\mathcal{M}}_{g,n}$ when $n \leq k$. The incidence variety compactification from [BCG+1, BCG+2] plays a key role in the arguments in §1–2.

Finally, we show how the cycle $F^k_{g,n}$ from Definition 1 solves the recursion. For this, we first analyze certain cycles on moduli spaces of pointed rational curves related to $F^k_{g,n}$ in §3–5, and show how they satisfy a recursive identity (Theorem 5.4). This will be used to conclude that the cycles $F^k_{g,n}$ satisfy the same recursion as the classes of the closure of the loci (0.1) in $\mathbb{P}^k_{g,n}$ over $\mathcal{M}^\tau_{g,n}$ (Theorem 7.2). The proof of Theorem 2 is given in §7 together with the proof of the more general statement about the incidence loci $\overline{\mathcal{M}}^k_{g,m}$ with prescribed multiplicities. We conclude with some examples and checks in §8.

Acknowledgements. Conversations with Dawei Chen and Renzo Cavalieri and their collaborations on related projects [CT3, CT2, CT1] provided the inspiration and the groundwork that made our results possible. We would
I. GHEORGHITA AND N. TARASCA

like to thank Rahul Pandharipande, Georg Oberdieck, and Adrien Sauvaget for comments and questions on a preliminary version of this work.

1. The incidence locus for \( n = 2 \)

The class of the incidence locus for \( n = 1 \) is given by:

**Lemma 1.1** ([Sau1, §1.6], [KSZ, §4]). For \( k \geq 1 \) and \( g \geq 2 \), one has

\[
\mathbb{H}^{k}_{g,1} \equiv k \omega - \eta \in \text{Pic} \left( \mathbb{P} \mathcal{E}^{k}_{g,1} \right).
\]

In this section, we study the case \( n = 2 \) and compute the class of the locus \( \mathbb{H}^{k}_{g,2} \) in \( \mathbb{P} \mathcal{E}^{k}_{g,2} \). First we set some notation. Let

\[
\begin{array}{c}
\circ \quad 1 \\
\circ \quad 2 \\
g
\end{array}
\]

be the push-forward of \( \mathbb{H}^{k}_{g,1} \subseteq \mathbb{P} \mathcal{E}^{k}_{g,1} \) via the map \( \mathbb{P} \mathcal{E}^{k}_{g,1} \to \mathbb{P} \mathcal{E}^{k}_{g,2} \) obtained by attaching at the marked point of an element in \( \mathbb{P} \mathcal{E}^{k}_{g,1} \) a rational tail containing the two marked points, and extending stable \( k \)-differentials by zero on the attached rational tail. The class of (1.1) is denoted below as

\[
\begin{array}{c}
\circ \quad 1 \\
\circ \quad 2 \\
g
\end{array}
\]

and is the push-forward of the class of \( \mathbb{H}^{k}_{g,1} \) given by Lemma 1.1.

Moreover, let

\[
\begin{array}{c}
\circ \quad 1 \\
\circ \quad 2 \\
g^{-1}
\end{array}
\]

be the locus consisting of curves with an elliptic tail containing both marked points together with a class of a stable \( k \)-differential \( \mu \) whose restriction \( \mu_{1} \) to the elliptic component is identically zero. Such a stable \( k \)-differential \( \mu \) has a pole of order at most \( k - 1 \) at the preimage of the node in the genus \( g - 1 \) component. This locus has codimension \( k + 1 \) in \( \mathbb{P} \mathcal{E}^{k}_{g,2} \).

**Theorem 1.2.** Let \( g \geq 2 \). For \( k = 1 \), one has

\[
(1.2) \quad \mathbb{H}^{1}_{g,2} \equiv (\omega_{1} - \eta)(\omega_{2} - \eta) - \begin{array}{c}
\circ \quad 1 \\
\circ \quad 2 \\
g
\end{array} - \sum_{i=1}^{\lfloor g/2 \rfloor} \begin{array}{c}
\circ \quad 1 \\
\circ \quad 2 \\
g^{-i}
\end{array} \in A^{2} \left( \mathbb{P} \mathcal{E}^{1}_{g,2} \right)
\]
and for $k \geq 2$, one has

$$\mathbb{P}^k_{g,2} \equiv (k \omega_1 - \eta) (k \omega_2 - \eta) - \frac{k \omega - \eta}{g} \in A^2(\mathbb{P}^k_{g,2}).$$

Theorem 1.2 follows by combining the next Proposition 1.4 and Lemma 1.1.

1.1. Preliminaries. To study the closure of $\mathbb{P}^k_{g,2}$ in $\mathbb{P}^k_{g,2}$, we use the incidence variety compactification from [BCG+1, BCG+2]. We review here some basic facts about stable $k$-differentials and the incidence variety compactification which will be used in this and the next section, and refer the reader to [BCG+1, BCG+2] for further details.

Let $C$ be a nodal curve, and $\tilde{C} \to C$ its normalization. Let $Q_1, \ldots, Q_s$ be the nodes in $C$, and for each $Q_i$, let $Q_i^+$ and $Q_i^-$ be its two preimages in $\tilde{C}$. The space of stable $k$-differentials on $C$ is identified via pull-back with the space of $k$-differentials on $\tilde{C}$ admitting poles of order at most $k$ at the preimages of the nodes and satisfying the $k$-residue condition at $Q_i^+$ and $Q_i^-$ for each $i$. To express the $k$-residue condition, one proceeds as follows. For a differential $\mu$ with a pole of order at most $k$ at a point $P$, the $k$-residue $\text{Res}_P^k(\mu)$ is the coefficient of $t^{-k}(dt)^k$ in the Laurent series expansion of $\mu$ at $P$, for a formal coordinate $t$ at $P$. This definition is independent of $t$ since $\mu$ has a pole of order at most $k$ at $P$. The $k$-residue condition at $Q_i^+$ and $Q_i^-$ is

$$\text{Res}_{Q_i^+}^k(\mu) = (-1)^k \text{Res}_{Q_i^-}^k(\mu).$$

A twisted $k$-differential $\tau$ on a nodal curve $C$ is a collection $\tau = \{\tau_i\}_i$ of (possibly meromorphic) $k$-differentials, one for each irreducible component of $C$. Following the terminology of limit linear series, we will refer to the elements $\tau_i$ of $\tau$ as the aspects of $\tau$ on the irreducible components of $C$.

The closure of strata of smooth pointed curves and $k$-differentials with all zeros and poles marked with prescribed multiplicities is described for $k = 1$ in [BCG+1, Thm 1.3] and for $k \geq 2$ in [BCG+2, Thm 1.5]. An element $(C, P_1, \ldots, P_n, \mu)$, where $(C, P_1, \ldots, P_n)$ is a stable pointed curve and $\mu$ is a (possibly meromorphic) stable $k$-differential, is in the closure of such strata if and only if it admits a twisted $k$-differential compatible with a certain full order on the dual graph of $C$. The maxima in the full order are required to correspond to the irreducible components where $\mu$ is not identically zero. The twisted $k$-differential is required to: coincide with $\mu$ on the maxima; have zeros and poles at the marked points with prescribed multiplicities; satisfy the matching zero and pole order property at vertical nodes; satisfy the $k$-residue condition at horizontal nodes; and satisfy the global $k$-residue condition. We refer the reader to [BCG+1, BCG+2] for the description of these compatibility conditions.
1.2. A set-theoretic statement. The following statement is a preliminary step toward the proof of Theorem 1.2. For $i \in \{1, 2\}$, let $\pi_i : \mathbb{P}E_{g,2}^k \to \mathbb{P}E_{g,1}^k$ be the map obtained by forgetting the $i$-th marked point (and relabeling the remaining marked point as $P_1$).

**Proposition 1.3.** The intersection

$$\pi_1^{-1}(\mathbb{H}_{g,1}^k) \cap \pi_2^{-1}(\mathbb{H}_{g,1}^k) \subset \mathbb{P}E_{g,2}^k$$

consists of the following components for $k = 1$:

$$\mathbb{H}_{g,2}^k, \quad \mathbb{H}_{g,1}^k, \quad g-1\bigg|_{\mu_1=0}, \quad 1 \bigg|_{\mu_2=2}, \quad for \ 1 \leq i \leq \lfloor g/2 \rfloor,$$

and for $k \geq 2$:

$$\mathbb{H}_{g,2}^k \quad and \quad \mathbb{H}_{g,1}^k.$$

**Proof.** By definition, $\mathbb{H}_{g,2}^k$ is the only component of the intersection (1.3) which intersect the locus of smooth curves for all $k \geq 1$. To study the additional components over the locus of nodal curves, we consider the incidence variety compactification of

$$\mathbb{H}_{g,k(2g-2)}^k \subset \mathbb{P}E_{g,k(2g-2)}^k$$

from [BCG+1, BCG+2] and regard $\mathbb{H}_{g,1}^k$ in $\mathbb{P}E_{g,1}^k$ and $\mathbb{H}_{g,2}^k$ in $\mathbb{P}E_{g,2}^k$ as the images of $\mathbb{H}_{g,k(2g-2)}^k$ under the maps

$$\mathbb{P}E_{g,k(2g-2)}^k \to \mathbb{P}E_{g,1}^k \quad and \quad \mathbb{P}E_{g,k(2g-2)}^k \to \mathbb{P}E_{g,2}^k$$

obtained by forgetting all but the first one or two marked points, respectively. This provides the description of the boundaries of $\mathbb{H}_{g,1}^k$ and $\mathbb{H}_{g,2}^k$ in terms of twisted $k$-differentials that we use below.

The intersection (1.3) consists of $(C, P_1, P_2, \mu)$, where $(C, P_1, P_2)$ is a stable two-pointed curve and $\mu$ is the class of a stable $k$-differential, such that each marked point $P_i$ is a zero of some twisted $k$-differential of type $\mu$.

The locus $\mathbb{H}_{g,2}^k$ consists of $(C, P_1, P_2, \mu)$ where both marked points are zeros of the same twisted $k$-differential of type $\mu$ for all $k \geq 1$.

For a general $(C, P_1, P_2, \mu)$ in the second locus listed in (1.4) or (1.5), $\mu$ has a simple zero at the preimage of the node on the genus $g$ component. Then each marked point is a simple zero of a twisted $k$-differential of type $\mu$ whose aspect on the rational tail has a pole of order $2k + 1$ at the node.

When $k = 1$, consider the third locus listed in (1.4) and select a general element in it, with elliptic tail denoted $E$. Since we can always find a twisted
abelian differential whose aspect on $E$ has a pole of order 2 at the node and a zero at one of the marked points, the image of the third locus under $\pi_i$ is in $\mathbb{H}_{g,1}^i$, for $i \in \{1, 2\}$. The aspect of such a twisted abelian differential on $E$ does not vanish generically at both marked points, hence such a locus is not in $\mathbb{H}_{g,2}^i$. However, when $k \geq 2$, such a locus has codimension $k + 1$ and is contained in $\mathbb{H}_{g,2}^k$. Indeed, one can always find a twisted $k$-differential whose aspects on $E$ has a pole of order at least $k + 1$ at the node and vanishes at both marked points.

For the remaining types of loci in (1.4), consider their general element. The restriction of a general abelian differential $\mu$ to the two components of positive genus is holomorphic and non-zero at the nodes. The global residue condition [BCG+1, Def. 1.2(4)] is satisfied by a twisted abelian differential of type $\mu$ whose aspect on the rational component has simple zeros at one of the marked points and at a smooth point generically away from the other marked point, and poles of order 2 at both nodes. This implies that the last types of loci in (1.4) are in (1.3) when $k = 1$. However, when $k \geq 2$, the restriction of a general stable $k$-differential $\mu$ to the two components of positive genus has a pole of order $k$ at each node, hence the aspect on the rational component of a twisted $k$-differential of type $\mu$ cannot have any zeros. It follows that the last loci in (1.4) do not lie in the intersection (1.3) for $k \geq 2$.

Next, we show that the loci in (1.4) and (1.5) are the only ones in (1.3) for $k = 1$ and $k \geq 2$, respectively. To detect components of (1.3) over the locus of nodal curves, we analyze a general element $(C, P_1, P_2, \mu)$ in the inverse image of the locus of nodal curves from $\overline{M}_{g,2}$ and in (1.3). It suffices to consider the following cases: (a) the curve $C$ has exactly one node; or (b) the curve $C$ has two nodes.

For the one-nodal case, we show that $(C, P_1, P_2, \mu)$ is in one of the first three loci in (1.4) when $k = 1$, or in one of the loci in (1.5) when $k \geq 2$.

If $C$ is one-nodal with a non-disconnecting node, then both marked points need to be in the support of $\mu$. Hence $(C, P_1, P_2, \mu)$ is in fact in $\mathbb{H}_{g,2}^k$. If $C$ is one-nodal with a rational tail containing both marked points, then necessarily $\mu$ vanishes at the preimage of the node in the genus $g$ component. Hence $(C, P_1, P_2, \mu)$ is in the second locus listed in (1.4) or in (1.5).

In the remaining cases of one-nodal $C$ with a disconnecting node, assume first that each marked point is in a component of $C$ where $\mu$ is not identically zero. Then $\mu$ vanishes at both marked points, hence $(C, P_1, P_2, \mu)$ is in $\mathbb{H}_{g,2}^k$. We are left with the case when $C$ is one-nodal, and one or both marked points are on a component of $C$ of positive genus where $\mu$ is identically zero. If $k = 1$ and $\mu$ is identically zero on an elliptic component containing both marked points, then $(C, P_1, P_2, \mu)$ is in the third locus listed in (1.4). Otherwise, $(C, P_1, P_2, \mu)$ is the general element of a locus of codimension higher than two inside $\mathbb{H}_{g,2}^k$. Indeed, there exists a twisted $k$-differential of
type \( \mu \) whose aspect on the component of \( C \) where \( \mu \) is identically zero has a zero at the one or two marked points in there and has a pole of order at least \( k + 1 \) at the node; in case one marked point is on the component where \( \mu \) is not identically zero, then such point must be a zero of \( \mu \).

Finally, we analyze the two-nodal case, and show that necessarily \( k = 1 \) and \( (C, P_1, P_2, \mu) \) is in the loci of the fourth type listed in (1.4).

If \( C \) has only disconnecting nodes and nonrational components, then both marked points are generically away from the zeros of \( \mu \), hence such an element is not in (1.3). Likewise, a general element of a locus of two-nodal curves with a twice marked rational tail is not in (1.3), since the support of \( \mu \) does not generically contain the preimage of the node in the nonrational component adjacent to the rational tail. If \( C \) contains a rational bridge with one marked point, then the other marked point is generically away from the support of \( \mu \). If instead \( C \) has a twice marked rational bridge, then \( (C, P_1, P_2, \mu) \) is in one of the loci of the fourth type listed in (1.4), and as discussed at the beginning of the proof, such loci are in (1.3) but not in \( \mathbb{P}^k g,2 \) only for \( k = 1 \).

Similar arguments cover the case when \( C \) is irreducible with two non-disconnecting nodes, as well as the case when \( C \) has both a non-disconnecting node and a disconnecting node. We are left with the case when \( C \) has two components meeting in two points. If both components of \( C \) are nonrational, the restriction of \( \mu \) to each component has generically poles of order \( k \) at both nodes, and the marked points are generically not in the support of \( \mu \). If \( C \) has a (marked) rational component, the restriction of \( \mu \) to the genus \( g - 1 \) component has generically poles of order \( k \) at the two nodes, forcing there to be no zeros of \( \mu \) on the rational component.

\[ \square \]

1.3. Computation of multiplicities. We conclude here the proof of Theorem 1.2. The intersection (1.3) is generically transverse over \( \mathcal{M}_{g,2} \), hence the component \( \mathbb{P}^k g,2 \) has multiplicity one in the intersection for all \( k \geq 1 \). Then Proposition 1.3 implies that there exist \( a, b, c_i \in \mathbb{Q} \), with \( i = 1, \ldots, \lfloor g/2 \rfloor \), such that for \( k = 1 \), one has

\[
\pi_1^* \left[ \mathbb{P}^1 g,1 \right] \cdot \pi_2^* \left[ \mathbb{P}^1 g,1 \right] = \left[ \mathbb{P}^1 g,2 \right] + a \begin{array}{c} \omega - \eta \\ 2 \end{array} + b \begin{array}{c} g-1 \\ 2 \end{array} + \mu=0^{1} + \sum_{i=1}^{\lfloor g/2 \rfloor} c_i \begin{array}{c} g-i \\ 2 \end{array} \in A^2 \left( \mathbb{P}^1 g,2 \right),
\]

and for \( k \geq 2 \), one has

\[
\pi_1^* \left[ \mathbb{P}^k g,1 \right] \cdot \pi_2^* \left[ \mathbb{P}^k g,1 \right] = \left[ \mathbb{P}^k g,2 \right] + a \begin{array}{c} k \omega - \eta \\ 2 \end{array} + b \begin{array}{c} g-1 \\ 2 \end{array}^{1} \in A^2 \left( \mathbb{P}^k g,2 \right).
\]
Proposition 1.4. One has

\[ a = 1 \quad \text{for} \quad k \geq 1, \]

\[ b = c_i = 1 \quad \text{for all} \quad i \quad \text{and} \quad k = 1. \]

Proof. To find the coefficient \( a \), let \( \pi : \mathbb{P}^k_{g,2} \to \mathbb{P}^k_g \) be the forgetful map and consider \( \pi_* \) of (1.6) and (1.7). One has

\[
\pi_* \left( \pi^* \left[ \mathbb{H}^k_{g,1} \right] \cdot \pi^* \left[ \mathbb{H}^k_{g,1} \right] \right) = k^2 (2g - 2)^2 \left[ \mathbb{P}^k \right],
\]

\[
\pi_* \left( \mathbb{H}^k_{g,2} \right) = k(2g - 2)(k(2g - 2) - 1) \left[ \mathbb{P}^k \right],
\]

\[
\pi_* \left( \frac{g \omega - \eta}{g} \right)^{1} = k(2g - 2) \left[ \mathbb{P}^k \right],
\]

for all \( k \geq 1 \), and the push-forward of the other classes in (1.6) vanishes. Hence \( a = 1 \). This concludes the proof of the statement for \( k \geq 2 \).

For \( k = 1 \), to find the coefficient \( b \), we restrict to a test surface \( S \) in \( \mathbb{P}^1_{g,2} \) defined as follows: consider a pencil of plane cubics of degree 12 along with a section of the Hodge bundle over \( \overline{\mathcal{M}}_{1,1} \), identify one of its basepoints with a general point on a fixed general genus \( g - 1 \) curve with a general abelian differential, vary the first marked point along the genus \( g - 1 \) component, and let the second marked point be one of the other basepoints of the pencil of plane cubics. We compute the following intersections below:

\[
(1.8) \quad S \cdot \pi^* \left[ \mathbb{H}^1_{g,1} \right] \cdot \pi^* \left[ \mathbb{H}^1_{g,1} \right] = 2(g - 1) - 1,
\]

\[
(1.9) \quad S \cdot \mathbb{H}^1_{g,2} = 2(g - 1) - 2,
\]

\[
(1.10) \quad S \cdot \left( \frac{g - 1}{\mu_1 = 0} \right)^{1} = 1.
\]

Moreover, \( S \) has empty intersection with the remaining classes in (1.6). These intersections imply that \( b = 1 \).

Since \( \lambda_1 = 1 \) on the elliptic pencil, where \( \lambda_1 \) is the first Chern class of the Hodge bundle, the section of the Hodge bundle over \( \overline{\mathcal{M}}_{1,1} \) assigns the zero abelian differential to precisely one elliptic curve in the elliptic pencil.

The intersection in (1.10) is contributed by the element of \( S \) where the elliptic tail has the zero abelian differential, and the marked point in the genus \( g - 1 \) component collides with the node, creating a rational bridge.

The remaining intersections can be computed using the description of the boundaries of these loci provided by the incidence variety compactification.

The intersection in (1.9) is contributed by the elements of \( S \) where the elliptic tail has the zero abelian differential, and the marked point in the genus \( g - 1 \) component coincides with one of the zeros of the differential (such zeros are generically away from the node). For each such element of
there exists a twisted abelian differential whose aspect on the elliptic tail
has a zero at the marked point and a pole of order 2 at the node. The
intersection is transverse along all such contributions.

The intersection in (1.8) consists of the sum of the contributions to (1.9)
and (1.10). Indeed, the contribution to (1.10) is clearly in \( \pi_1^{-1}(\overline{\mathcal{H}}_{g,1}) \), because
the second marked point is in the elliptic tail with a zero differential, so that a
suitable twisted differential can be found as above, and it is also seen to be in
\( \pi_2^{-1}(\overline{\mathcal{H}}_{g,1}) \) by taking a twisted differential whose aspect on the rational bridge
has poles of order 2 at both nodes and simple zeros at the first marked point
and at some other smooth point. Such a twisted differential satisfies the
global residue condition of the incidence variety compactification [BCG+1,
Def. 1.2(4)]. The intersection is transverse along all such contributions.

We remark that the contribution to (1.10) is not in \( \mathcal{H}^1_{g,2} \); a twisted differ-
ential vanishing at the second marked point has order \(-2\) at the preimage
of the node in the elliptic component, and generically order 0 at the preimage
of the node in the genus \( g - 1 \) component. It follows that the aspect on the
rational bridge has orders 0 and \(-2\) at the nodes, hence does not vanishes
at the first marked point.

To find the coefficient \( c_i \), for \( 1 \leq i \leq \lfloor g/2 \rfloor \), consider the test surface \( S_i \) in
\( \mathbb{P}\mathcal{E}^1_{g,2} \) obtained as follows: select a general element of the boundary divisor
\( \Delta_i \cdot (1) \) in \( \mathbb{P}\mathcal{E}^1_{g,2} \) consisting of curves with a genus \( i \) component containing
precisely the first marked point, and vary the two marked points in their
corresponding components. In particular, elements of \( S_i \) have a fixed general
stable differential \( \mu \). When a marked point collides with the node, it gives
rise to a rational bridge, and \( \mu \) is extended by zero on such rational bridges.

We show the following intersections below:

\[
\begin{align*}
(1.11) \quad S_i \cdot \pi_1^* \left[ \overline{\mathcal{H}}^1_{g,1} \right] \cdot \pi_2^* \left[ \overline{\mathcal{H}}_{g,1}^1 \right] &= (2i - 1)(2(g - i) - 1), \\
(1.12) \quad S_i \cdot \overline{\mathcal{H}}_{g,2}^1 &= (2i - 1)(2(g - i) - 1) - 1, \\
(1.13) \quad S_i \cdot \begin{array}{c} i \\ g-i \\ 1 \\ 2 \end{array} &= 1.
\end{align*}
\]

Moreover, \( S_i \) has empty intersection with the remaining classes in (1.6). It
follows that \( c_i = 1 \), for all \( 1 \leq i \leq \lfloor g/2 \rfloor \).

The intersection (1.13) is contributed by the element of \( S_i \) where both
marked points collide with the node, creating two rational bridges.

The intersection (1.12) is contributed by those elements of \( S_i \) where ei-
ther both marked points coincide with zeros of the differential, or where ex-
actly one of the marked points collides with the node and the other marked
point is a zero of the differential. In the cases when exactly one of the
marked points collides with the node, creating a rational bridge, there ex-
ists a twisted differential of type \( \mu \) whose aspect on the rational bridge has
zeros at the marked point and at some other smooth point, poles of order 2 at the nodes, and satisfies the global residue condition \[ \text{BCG}^1, \text{Def. 1.2(4)}. \]

The intersection is transverse along all such contributions.

However, the contribution to (1.13) is not in (1.12), since there exist no twisted differential of type \( \mu \) vanishing at both marked points. For this, assume there exists a twisted differential \( \tau \) of type \( \mu \) whose aspects \( \tau_1 \) and \( \tau_2 \) on the two rational bridges have zeros at the two marked points. Since \( \mu \) is holomorphic and non-zero at the preimages of the nodes in the components of genus \( i \) and \( g-i \), it follows that \( \tau_1 \) and \( \tau_2 \) have a pole of order 2 at the nodes \( Q_1 \) and \( Q_2 \) where the rational bridges meet the genus \( i \) and \( g-i \) components, respectively. Then, since \( \tau_1 \) and \( \tau_2 \) vanish at the marked points, for degree reasons one has that \( \tau_1 \) and \( \tau_2 \) must each have a pole of order at least 1 at the node \( Q_0 \) where the two rational bridges meet. As the sum of the order of the poles at \( Q_0 \) has to be equal to 2, one has that \( \tau_1 \) and \( \tau_2 \) must each have a simple pole at \( Q_0 \). The global residue condition \[ \text{BCG}^1, \text{Def. 1.2(4)} \]

requires that \( \text{Res}_{Q_1}(\tau_1) = \text{Res}_{Q_2}(\tau_2) = 0 \). By the residue theorem, this forces the residues at \( Q_0 \) to be zero, a contradiction. \( \square \)

Theorem 1.2 immediately follows from (1.6), (1.7), and Proposition 1.4 after replacing the class of \( \mathbb{P}^k_{g,1} \) as in Lemma 1.1.

2. A recursive identity for incidence loci

We present here a recursive identity for the class of the incidence locus \( \mathbb{H}_{g,n}^k \) over curves with rational tails, extending the results of the previous section to \( n \geq 2 \). We start by proving Theorem 2.1, and we conclude the section with the more general Theorem 2.9.

First we define the extra loci \( E_I \) generalizing (1.1) to \( n \geq 2 \). For \( m \leq n-1 \), consider the locus

\[
\mathbb{H}_{g,m}^k \subset \mathbb{P}E_{g,n-m}^k \quad \text{where} \quad m = (m, 1^{n-m-1})
\]

consisting of smooth genus \( g \) curves with \( n-m \) marked points together with the class of a stable \( k \)-differential having a zero of order at least \( m \) at the first marked point and zeros at the other marked points. This locus has codimension \( n-1 \) in \( \mathbb{P}E_{g,n-m}^k \).

For a non-empty \( I \subseteq \{1, \ldots, n-1\} \) of size \( |I| = m \), let

\[
\gamma : \mathbb{P}E_{g,n-m}^k \times \overline{\mathcal{M}}_{0, I \cup \{n,h_n\}} \longrightarrow \mathbb{P}E_{g,n}^k
\]

be the gluing map of degree one obtained by identifying the first marked point on elements of \( \mathbb{P}E_{g,n-m}^k \) with the marked point \( h_n \) of elements in \( \overline{\mathcal{M}}_{0, I \cup \{n,h_n\}} \) (and relabeling the other marked points of elements in \( \mathbb{P}E_{g,n-m}^k \) by elements of \( \{1, \ldots, n-1\} \setminus I \) in case \( n-m > 1 \), i.e., \( |I| < n-1 \)) and extending stable \( k \)-differentials by zero on the attached rational tail.
The *extra locus* $E_I$ is defined as

$$E_I := \gamma_* \mathbb{H}^k_{g,m} \subset \mathbb{P}^k_{g,n}.$$  

A general element of $E_I$ consists of a stable pointed curve with a rational tail containing the marked points with labels in $I \cup \{n\}$ and a genus $g$ component containing the remaining marked points, together with a stable $k$-differential vanishing with order $m$ at the preimage of the node in the genus $g$ component and vanishing at all marked points in the genus $g$ component. For $n = 2$, the locus $E_I$ with $I = \{1\}$ recovers (1.1).

Let $\pi_n : \mathbb{P}^k_{g,n} \to \mathbb{P}^k_{g,n-1}$ be the map obtained by forgetting the last marked point, and let $\rho_n : \mathbb{P}^k_{g,n} \to \mathbb{P}^k_{g,1}$ be the map obtained by forgetting all but the last marked point (and relabeling it as $P_1$).

**Theorem 2.1.** For $g \geq 2$ and $n \geq 2$, the identity

$$\pi_n^* \left[ \mathbb{H}^k_{g,n-1} \right] \cdot \rho_n^* \left[ \mathbb{H}^k_{g,1} \right] = \mathbb{H}^k_{g,n} + \sum \left| I \right| \left[ E_I \right]$$

where the sum is over all non-empty $I \subseteq \{1, \ldots, n-1\}$, holds in:

(i) $A^n \left( \mathbb{P}^k_{g,n} \right|$ $| \mathcal{M}^n_g)$ when

$$k = 1; \text{ or}$$

$$k = 2 \text{ and } n \leq 2(2g - 2) - 2; \text{ or}$$

$$k \geq 3 \text{ and } n \leq k(2g - 2) - 1;$$

(ii) $A^n \left( \mathbb{P}^k_{g,n} \right)$ when $n \leq k$.

When (2.4) holds, the loci $\mathbb{H}^k_{g,m} \subset \mathbb{P}^k_{g,n-m}$ from (2.1) with $m \leq n - 1$ are of pure codimension $n - 1$ and are obtained from $\mathbb{H}^k_{g,n-1} \subset \mathbb{P}^k_{g,n-1}$ by colliding the first $m$ marked points. Hence, from the class of $\mathbb{H}^k_{g,n-1}$, one computes the classes of the loci from (2.1) by colliding points, and the classes of the extra loci $E_I$ from (2.3) by push-forward via the corresponding map $\gamma$. It follows that Theorem 2.1 expresses the class of the incidence locus $\mathbb{H}^k_{g,n}$ recursively in $n$.

We start with the following Lemma, which explains how we use the hypothesis (2.4):

**Lemma 2.2.** Let $k \geq 2$, let $g$ and $n$ be such that (2.4) holds, and $m \leq n - 1$. The locus of $k$-differentials that are $k$-th powers of abelian differentials has positive codimension inside the closure of $\mathbb{H}^k_{g,m} \subset \mathbb{P}^k_{g,n-m}$ from (2.1).

Here are some examples showing how the lemma fails when (2.4) fails. When $k = 2$ and $n = 4g - 5$, consider the locus

$$\mathbb{H}^2_{g,m} \subset \mathbb{P}^2_{g,1} \quad \text{where} \quad m = (4g - 6).$$

This locus has two components: a component parametrizing quadratic differentials which have generically a zero of order $4g - 6$ at the marked point and
simply zeros at two distinct unmarked points; and a component parametrizing quadratic differentials that are squares of abelian differentials and have generically a zero of order $4g - 6$ at the marked point and a double zero at an unmarked point. These two components have equal dimension by [BCG$^+$2, Theorem 1.1] or [Sch].

Similarly, when $k \geq 3$ and $n = k(2g - 2)$, consider the locus

$$\mathbb{H}^{k}_{g,m} \subset \mathbb{P}E^{k}_{g,1}, \quad \text{where} \quad m = (k(2g - 2) - 1).$$

This locus has two components of the same dimension: a component parametrizing $k$-differentials which have a zero of order $k(2g - 2) - 1$ at the marked point and a simple zero at an unmarked point; and a component parametrizing $k$-th powers of abelian differentials vanishing with order $k(2g - 2)$ at the marked point.

Proof of Lemma 2.2. For $k \geq 2$ and $m \leq n - 1$, consider a locus $\mathbb{H}^{k}_{g,m}$ in $\mathbb{P}E^{k}_{g,n-m}$ as in (2.1), and write $\mathbb{H}^{k}_{g,m} = A \cup B$, where $A$ (respectively, $B$) is the closure of the locus of differentials in $\mathbb{H}^{k}_{g,m}$ that are not $k$-th powers of abelian differentials, (resp., are $k$-th powers of abelian differentials).

Differentials in $A$ have generically a zero of order $m$ and $k(2g - 2) - m$ simple zeros. Differentials in $B$ have generically a zero of order $k \left\lceil \frac{m}{k} \right\rceil$ (i.e., the smallest multiple of $k$ which is greater than or equal to $m$) and $(2g - 2) - \left\lceil \frac{m}{k} \right\rceil$ zeros of order $k$. From [BCG$^+$2, Theorem 1.1], one has

$$\dim A = 2(k + 1)(g - 1) - m, \quad \dim B = 4(g - 1) - \left\lceil \frac{m}{k} \right\rceil + 1.$$

It follows that for values of $m$ small enough, $B$ has positive codimension in $\mathbb{H}^{k}_{g,m}$, and moreover, the loci $A$ and $B$ have equal dimension for values of $m$ such that

$$(k - 1)2(g - 1) = m - \left\lceil \frac{m}{k} \right\rceil + 1.$$ \hspace{1cm} (2.7)

A case study shows that this equality fails when (2.4) holds. Indeed, if $k \mid m$, then (2.7) only holds for $k = 2$ and $m = 4g - 6$. This implies $n \geq 4g - 5$, e.g., the case given by (2.5). Otherwise, if $k \nmid m$, then $m \equiv k - 1 \mod k$, hence $m = k(2g - 2) - 1$. This is the case given by (2.6). The statement follows. \hfill $\square$

To prepare for the proof of Theorem 2.1, we study the components of the intersection

$$\pi^{-1}_{n}(\mathbb{H}^{k}_{g,n-1}) \cap \rho^{-1}_{n}(\mathbb{H}^{k}_{g,1}) \subset \mathbb{P}E^{k}_{g,n}.$$ \hspace{1cm} (2.8)

By definition, $\mathbb{H}^{k}_{g,n}$ is the only component of (2.8) over $\mathcal{M}_{g,n}$.

Lemma 2.3. Let $k$, $g$, and $n$ be such that (2.4) holds. The loci $E_{I} \subset \mathbb{P}E^{k}_{g,n}$ for all non-empty $I \subseteq \{1, \ldots, n - 1\}$ are contained in the intersection (2.8), but not in $\mathbb{H}^{k}_{g,n}$.
Proof. The argument is similar to the one used for Proposition 1.3. For a non-empty $I \subseteq \{1, \ldots, n-1\}$, consider a general element $(C, P_1, \ldots, P_n, \mu)$ in $E_I$. By definition, the curve $C$ has a rational tail containing the marked points with labels in $I \sqcup \{n\}$, and the stable $k$-differential $\mu$ has a zero of order $|I|$ at the preimage of the node in the genus $g$ component of $C$ and zeros at the marked points in the genus $g$ component.

To see that $E_I$ is in $\pi_{n-1}^{-1}\left(\mathbb{H}^k_{g,n-1}\right)$, we need to construct a twisted $k$-differential of type $\mu$ satisfying the conditions of the incidence variety compactification and vanishing at the first $n-1$ marked points. For this, consider the twisted $k$-differential whose aspect on the genus $g$ component will be the restriction of $\mu$ on that component, while the aspect on the rational component will have a pole of order $2k + |I|$ at the node and zeros at the marked points with labels in $I$. When $k = 1$, the global residue condition [BCG+1, Def. 1.2(4)] is satisfied since the residue of the twisted abelian differential at the preimage of the node in the rational component is zero. When $k \geq 2$, using Lemma 2.2, the hypothesis (2.4) implies that the restriction of $\mu$ to the genus $g$ component is generically not the $k$-th power of an abelian differential. It follows that the global $k$-residue condition is automatically satisfied [BCG+2, Def. 1.4(4)(ii)].

In order for $E_I$ to be in $\rho_{n-1}^{-1}\left(\mathbb{H}^k_{g,1}\right)$, we need to construct a twisted $k$-differential of type $\mu$ satisfying the conditions of the incidence variety compactification and vanishing at the last marked point. This is as in the previous paragraph, just simpler, and is made possible by the fact that $\mu$ vanishes with order $|I| \geq 1$ at the preimage of the node in the genus $g$ component. There is no single twisted $k$-differential of type $\mu$ vanishing at all marked points, hence $E_I$ is not in $\mathbb{H}^k_{g,n}$. The statement follows.

Next, we prove the converse of Lemma 2.3 over the locus of curves with rational tails. We use an inductive argument by means of the following maps: For $1 \leq i \leq n-1$, the map $\pi_i : \mathbb{PE}^k_{g,n} \to \mathbb{PE}^k_{g,n-1}$ is obtained by forgetting the marked point $P_i$, and relabeling the marked points $P_j$ for $j > i$ as $P_{j-1}$.

**Proposition 2.4.** Let $k$, $g$, and $n$ be such that (2.4) holds. The locus $\mathbb{H}^k_{g,n}$ and the extra loci $E_I \subset \mathbb{PE}^k_{g,n}$ for all non-empty $I \subseteq \{1, \ldots, n-1\}$ are the only components of (2.8) over $\mathcal{M}^n_{g,n}$.

**Proof.** We proceed by induction on $n$. The base case $n = 2$ is treated by Proposition 1.3. For $n \geq 3$, let $B$ be an irreducible component of (2.8) over $\mathcal{M}^n_{g,n}$. For $1 \leq i \leq n-1$, the image of (2.8) under $\pi_i$ is

$$\pi_i\left(\pi_{n-1}^{-1}\left(\mathbb{H}^k_{g,n-1}\right) \cap \rho_{n-1}^{-1}\left(\mathbb{H}^k_{g,1}\right)\right) = \pi_i\left(\pi_{n-1}^{-1}\left(\mathbb{H}^k_{g,n-1}\right)\right) \cap \rho_{n-1}^{-1}\left(\mathbb{H}^k_{g,1}\right) = \pi_{n-1}^{-1}\left(\mathbb{H}^k_{g,n-2}\right) \cap \rho_{n-1}^{-1}\left(\mathbb{H}^k_{g,1}\right).$$

(2.9)
By the induction hypothesis, it follows that \( \pi_i(B) \) is either in \( \mathbb{P}^k_{g,n-1} \) or in one of the loci

\[
E_\mathcal{T} \subset \mathbb{P}^k_{g,n-1} \quad \text{for } \varnothing \neq \mathcal{T} \subseteq \{1, \ldots, n-2\}.
\]

The rational tail in a general element of one of such \( E_\mathcal{T} \) contains the marked points with labels in \( \mathcal{T} \cup \{n-1\} \).

Consider a general element \((C, P_1, \ldots, P_n, \mu)\) in \( B \), and assume \( B \not\subseteq \mathbb{P}^k_{g,n} \). This implies that there is no twisted \( k \)-differential of type \( \mu \) vanishing at all marked points. We show below that \( B \subseteq E_\mathcal{I} \) for some \( \mathcal{I} \).

If \( \pi_i(B) \subseteq \mathbb{P}^k_{g,n-1} \), then \( C \) has a twisted \( k \)-differential of type \( \mu \) vanishing at all points \( P_j \) with \( j \neq i \). This implies that \( \mu \) vanishes at those marked points and preimages of nodes that are in the genus \( g \) component of \( C \); and moreover, for each preimage of a node in the genus \( g \) component, the order of vanishing is at least equal to the number of marked points \( P_j \) with \( j \neq i \) contained in the maximal rational subcurve of \( C \) intersecting the genus \( g \) component at that node.

For \( B \) to be in \( (2.8) \) while \( B \not\subseteq \mathbb{P}^k_{g,n} \), the point \( P_i \) needs to replace \( P_n \) as a zero of the twisted \( k \)-differential in the following sense. Assume that \( P_n \) is in the genus \( g \) component of \( \pi_i(C) \). Then the only possibility for \( P_i \) in \( C \) is to be in a rational tail containing only the marked points \( P_i \) and \( P_n \). In this case, \( B \subseteq E_\mathcal{I} \) with \( \mathcal{I} = \{i\} \). Otherwise, assume that \( P_n \) is in a rational component of \( \pi_i(C) \), and let \( R \) be the maximal rational subcurve of \( C \) containing \( P_n \). Then \( P_i \) is necessarily in \( R \). In this case, \( B \subseteq E_\mathcal{I} \) with \( \mathcal{I} \cup \{n\} \) equal to the set of markings in \( R \).

Next, assume \( \pi_i(B) \subseteq E_\mathcal{T} \) for some \( \mathcal{T} \) as in \( (2.10) \). Then, the point \( P_i \) is in a rational component of \( C \). Let \( R \) be the maximal rational subcurve of \( C \) containing \( P_n \). In particular, \( \mathcal{T} \cup \{n-1\} \) is the set of markings in \( \pi_i(R) \).

We argue that the point \( P_i \) is not in \( R \). Let \( Q \) be the node of \( C \) where the genus \( g \) component intersects \( R \). Since \( \pi_i(B) \not\subseteq E_\mathcal{T} \) while \( B \not\subseteq \mathbb{P}^k_{g,n} \), the stable \( k \)-differential \( \mu \) vanishes at the preimage of \( Q \) in the genus \( g \) component with order precisely equal to \( |\mathcal{T}| \). It follows that if \( P_i \) is in \( R \), then there is no twisted \( k \)-differential of type \( \mu \) vanishing at all the first \( n-1 \) marked points, a contradiction to \( (2.8) \).

Hence the point \( P_i \) is in the complement of \( R \) in \( C \). We deduce that \( B \subseteq E_\mathcal{I} \) where \( \mathcal{I} \) is obtained from \( \mathcal{T} \) after increasing by one all \( j \in \mathcal{T} \) such that \( j \geq i \) (this shift is due to the relabeling of points given by the map \( \pi_i \)).

The statement follows. \( \square \)

Next, we show that when \( n \leq k \), Proposition 2.4 extends over \( \overline{\mathcal{M}}_{g,n} \):

**Proposition 2.5.** When \( n \leq k \), the intersection \( (2.8) \) is contained only over the locus of curves with rational tails.

**Proof.** We again proceed by induction on \( n \). The base case \( n = 2 \) is treated by Proposition 1.3. For \( n \geq 3 \), let \( B \) be an irreducible component of \( (2.8) \)
which does not lie over $\mathcal{M}^r_{g,n}$. We will show that each such $B$ has positive codimension in either $\mathbb{H}^k_{g,n}$ or one of the extra loci $E_I \subset \mathbb{P}^k_{g,n}$.

Let $1 \leq i \leq n - 1$. Using (2.9) as in the proof of Proposition 2.4, the induction hypothesis implies that $\pi_i(B)$ is in either $\mathbb{H}^k_{g,n-1}$ or one of the loci $E_T \subset \mathbb{P}^k_{g,n-1}$ for some $T$ as in (2.10). Additionally, since $B$ does not lie over $\mathcal{M}^r_{g,n}$, one has that $B$ has strictly contained in either $H^k_{g,n} - 1$ or one of the $E_I$. Let $(C, P_1, \ldots, P_n, \mu)$ be a general element in $B$.

Consider the case when $\pi_i(B) \subset H^k_{g,n}$. We can assume that $C$ has no rational tails, otherwise we can replace $B$ with the higher-dimensional locus whose general element is obtained by smoothing all rational tails in $C$.

First, suppose that $C$ is a curve with (at least) one disconnecting node, a genus $a$ subcurve, and a genus $g - a$ subcurve, where $1 \leq a \leq g - 1$. If $\mu$ is generically nonzero on each component and vanishes at the $n$ marked points, then $B$ has codimension at least $n + 1$ and is contained in $H^k_{g,n}$. Consider instead the case where $\mu$ is identically zero on the genus $a$ subcurve, and vanishes at all marked points on the genus $g - a$ subcurve. The codimension of this locus is at least

$$N := h^0(C_a, \omega_{C_a}^{\otimes k}(kQ)) + 1 = k(2a - 1) - a + 2,$$

where $C_a$ is the genus $a$ subcurve of $C$, and $Q$ is the node connecting $C_a$ to the rest of $C$. The assumption $n \leq k$ implies

$$n < n(2i - 1) - i + 2 \leq N.$$  

Thus, $B$ has codimension higher than $n$. Furthermore, since $\pi_i(B) \subset \mathbb{H}^k_{g,n-1}$, there exists a twisted $k$-differential of type $\mu$ vanishing at $P_j$ with $j \neq i$. If $P_i$ is on the genus $g - a$ subcurve, it must also be a zero of $\mu$ since $B \subset \pi^{-1}_n(\mathbb{H}^k_{g,n-1})$. If $P_i$ is on the genus $a$ subcurve, then since $n < N$, we may find a potentially different twisted $k$-differential of type $\mu$ vanishing at all marked points on $C_a$ including $P_i$. In all cases, one concludes that $B$ is in $\mathbb{H}^k_{g,n}$. The case where $C$ has (at least) one non-disconnecting node and $\mu$ is generically nonzero and vanishes at all marked points is similar.

Now suppose that $C$ has a rational bridge, and $\mu$ is nonzero on the nonrational components. In order for this locus to be in (2.8), $\mu$ must be identically zero on the rational bridge, and we must have poles of order at most $k - 1$ at the nodes on the nonrational components meeting the bridge. These conditions allow the marked points on the rational bridge to be zeros of a twisted $k$-differential of type $\mu$. Moreover, a pole of order $k$ on a nonrational component implies that the vertices corresponding to that nonrational component and to the rational bridge are on the same level in the ordered dual graph of $C$, a contradiction to the assumption that $\mu$ is nonzero on nonrational components. In this case, $B$ has codimension at least $n + 1$ and is contained
in $\mathbb{P}^k_{g,n}$. The case where $C$ has a rational component meeting the rest of the curve in two non-disconnecting nodes is similar.

Finally, assume that $\pi_i(B) \subset E_T = \pi_i(E_I)$ for some $I$. This requires that $C$ have a rational tail containing $P_n$. Let $m + 1$ be the number of marked points on the maximal rational subcurve $R$ of $C$ containing $P_n$. In order for $B$ to be in (2.8), $\mu$ needs to vanish with order at least $m$ at the nodal point in $C \setminus R$ meeting $R$. This implies that $B$ is contained in $E_I$. \hfill \Box

Theorem 2.1 will follow from Propositions 2.4 and 2.5 after determining the multiplicity of each component in the intersection (2.8). For this, we start with some preliminary computations. Let

\begin{equation}
L_n := \pi_n^* \left[ \mathbb{P}^k_{g,n-1} \right] \cdot \rho_n^* \left[ \mathbb{P}^k_{g,1} \right] \in A^n \left( \mathbb{P}^k_{g,n} \right).
\end{equation}

**Lemma 2.6.** Let $k$, $g$, and $n$ be such that (2.4) holds. For $1 \leq i \leq n - 1$, one has

\begin{align}
(\pi_i)_* \left[ \mathbb{P}^k_{g,n} \right] &= (k(2g - 2) - (n - 1)) \left[ \mathbb{P}^k_{g,n-1} \right], \\
(\pi_i)_* [L_n] &= (k(2g - 2) - (n - 2)) L_{n-1}, \\
(\pi_i)_* [E_I] &= \begin{cases} (k(2g - 2) - (n - 2)) E_T & \text{if } i \notin I, \\
[\mathbb{P}^k_{g,n-1}] & \text{if } I = \{i\}, \\
0 & \text{if } i \in I \text{ and } |I| > 1 \end{cases}
\end{align}

in $A^{n-1}(\mathbb{P}^k_{g,n-1})$. In (2.14), when $i \notin I$, the set $\mathcal{T}$ is obtained from $I$ after decreasing by one all $j \in I$ with $j > i$.

**Proof.** For (2.12), the restriction of $\pi_i$ to $\mathbb{P}^k_{g,n}$ has degree $k(2g - 2) - (n - 1)$ over $\mathbb{P}^k_{g,n-1}$, equal to the number of unmarked zeros of the $k$-differential $\mu$ for a general $(C, P_1, \ldots, P_{n-1}, \mu)$ in $\mathbb{P}^k_{g,n-1}$.

For (2.13), since one may forget the marked points in any order, one has $\rho_n = \rho_{n-1} \circ \pi_i$. Using the projection formula, one computes

\begin{align}
(\pi_i)_* [L_n] &= (\pi_i)_* \left( \pi_n^* \left[ \mathbb{P}^k_{g,n-1} \right] \cdot \rho_n^* \left[ \mathbb{P}^k_{g,1} \right] \right) \\
&= (\pi_i)_* \left( \pi_n^* \left[ \mathbb{P}^k_{g,n-1} \right] \right) \cdot \rho_n^* \left[ \mathbb{P}^k_{g,1} \right] \\
&= c \pi_{n-1}^* \left[ \mathbb{P}^k_{g,n-2} \right] \cdot \rho_{n-1}^* \left[ \mathbb{P}^k_{g,1} \right] \\
&= c L_{n-1}
\end{align}

where $c := k(2g - 2) - (n - 2)$. The third equality follows from $(\pi_i)_*, \pi_n^* = \pi_{n-1}^* (\pi_i)_*$ and the first part of the statement.

Finally, for (2.14), when $i \notin I$, the restriction of $\pi_i$ to $E_I$ has generically degree $k(2g - 2) - (n - 2)$ over $E_T$, equal to the number of zeros at unmarked smooth points of the $k$-differential in a general element of $E_T$. Indeed, from Lemma 2.2, a $k$-differential in a general element of $E_T$ is not the $k$-th power...
of an abelian differential when \( k \geq 2 \), hence has a zero of order \( |T| \) at the preimage of the node in the genus \( g \) component of \( C \), simple zeros at the \( n - 2 - |T| \) marked points in the genus \( g \) component of \( C \), and simple zeros elsewhere for all \( k \geq 1 \).

When \( I = \{ i \} \), the restriction of \( \pi_i \) to \( E_I \) has generically degree one over \( \mathbb{P}_{g,n-1}^k \). In the remaining case when \( i \in I \) and \( |I| > 1 \), the restriction of \( \pi_i \) to \( E_I \) has generically one-dimensional fibers. The statement follows. \( \square \)

Also, we will use intersections with the following test space. For \( n \geq 3 \), let \( C \) be a general smooth genus \( g \) curve, and identify a general point \( Q \) in \( C \) with a general point in a rational curve \( R \) containing the marked points \( P_1, \ldots, P_{n-1} \). Consider the \( n \)-dimensional test space \( T \subset \mathbb{P}^k_{g,n} \) consisting of elements \((C \cup_Q R, P_1, \ldots, P_n, \mu)\) obtained by varying the \( k \)-differential \( \mu \) in a general \( \mathbb{P}^{n-1} \subset \mathbb{P}^kH^0(C, \omega_C^k) \), and the point \( P_n \) along \( C \). One has \( T \cong \mathbb{P}^{n-1} \times C \).

**Lemma 2.7.** Let \( k \), \( g \), and \( n \) be such that (2.4) holds. One has

\[
T \cdot \left[ \mathbb{P}^k_{g,n} \right] = k(2g - 2) - (n - 1),
\]

\[
T \cdot L_n = k(2g - 2),
\]

\[
T \cdot [E_I] = \begin{cases} 1 \quad &\text{if } I = \{1, \ldots, n-1\}, \\ 0 \quad &\text{otherwise}. \end{cases}
\]

**Proof.** The intersection (2.15) is contributed by those elements \((\mu, P_n)\) of \( T \cong \mathbb{P}^{n-1} \times C \) for which there exists a twisted \( k \)-differential of type \( \mu \) vanishing at all marked points. The only possibility is that \( \mu \) is the \( k \)-differential \( \mu_0 \) which vanishes with order \( n-1 \) at \( Q \) (such \( \mu_0 \) is generically unique, and after Lemma 2.2, \( \mu_0 \) is generically not the \( k \)-th power of an abelian differential when \( k \geq 2 \)), and \( P_n \) coincides with one of the remaining \( k(2g - 2) - (n - 1) \) zeros of \( \mu_0 \) in \( C \). The intersection is transverse along all such elements.

The intersection (2.16) is contributed by those elements \((\mu, P_n)\) of \( T \) for which there exists a twisted \( k \)-differential of type \( \mu \) vanishing at the first \( n - 1 \) marked points, and a possibly distinct twisted \( k \)-differential of type \( \mu \) vanishing at \( P_n \). Hence, in addition to the contributions to (2.15), also the element \((\mu = \mu_0, P_n = Q)\) of \( T \) contributes to (2.16). After Lemma 2.2, \( \mu_0 \) is generically not the \( k \)-th power of an abelian differential when \( k \geq 2 \). It follows that \( \mu_0 \) vanishes generically with order \( n - 1 \) at \( Q \) for all \( k \geq 1 \), hence the element \((\mu_0, Q)\) contributes to (2.16) with multiplicity \( n - 1 \).

Finally, for (2.17), \( T \) intersects a locus \( E_I \) only if \( P_n \) is on a rational component. This only happens for \( P_n = Q \), in which case \( T \) intersects \( E_I \) with \( I = \{1, \ldots, n-1\} \) transversally at \((\mu = \mu_0, P_n = Q)\). \( \square \)

In the final step of the proof of Theorem 2.1, we will use the following:
Lemma 2.8. Let $k$, $g$, and $n$ be such that (2.4) holds. The class of $\mathbb{H}^k_{g,n}$ and the classes of the loci $E_I$ for all $I$ are independent in $A^n(\mathbb{P}E^k_{g,n})$.

Proof. We proceed by induction on $n$. When $n = 2$, there is only one locus $E_I$, namely $E_I$ with $I = \{1\}$. To show independence, we restrict the classes of $H^1_{g,2}$ and $E_{\{1\}}$ to a test surface. For this, consider the test surface $S_i \subset \mathbb{P}E^k_{g,n}$ with $i = 1$ appeared for $k = 1$ in the proof of Proposition 1.4. Namely, select a general element of the boundary divisor $\Delta_{1;\{1\}}$ consisting of curves with an elliptic tail containing only the first marked point. The elements of the surface $S_1 \subset \mathbb{P}E^k_{g,n}$ are obtained by varying the two marked points in their corresponding components. In particular, elements of $S_1$ have a fixed general stable differential $\mu$. When a marked point collides with the node, it gives rise to a rational bridge. For $k = 1$, $\mu$ is extended by zero on such rational bridges, while for $k \geq 2$, the restriction of $\mu$ to such rational bridges has poles of order $k$ at the two nodes on each rational bridge.

The surface $S_1$ has empty intersection with $E_{\{1\}}$. For $k = 1$, one has $S_1 \cdot \left[\mathbb{H}^1_{g,2}\right] = 2g - 4$ from (1.12). For $k \geq 2$, one has

$$S_1 \cdot \left[\mathbb{H}^k_{g,2}\right] = (k(2i - 2) + k)(k(2g - i) - 2) + k).$$

This intersection is contributed by those elements of $S_i$ where both marked points coincide with zeros of the differential $\mu$, and the intersection is transverse along all such elements. Contrary to the case $k = 1$, there is no contribution from the elements where one marked point collides with the node, creating a rational bridge. Indeed, when $k \geq 2$, the restriction of $\mu$ to a rational bridge has poles of order $k$ at both nodes and does not have any zeros for degree reasons.

It follows that $S_1$ has nonzero intersection with $\mathbb{H}^k_{g,2}$, unless $k = 1$ and $g = 2$. We conclude that the classes of $\mathbb{H}^k_{g,2}$ and $E_{\{1\}}$ are independent, unless $k = 1$ and $g = 2$.

In case $k = 1$ and $g = 2$, we arrive at a similar statement by considering the push-forward of $\mathbb{H}^1_{2,2}$ and $E_{\{1\}}$ via the forgetful map $\varphi \colon \mathbb{P}E^1_{2,2} \to \overline{M}_{2,2}$. One computes

$$\varphi_* \left[\mathbb{H}^1_{2,2}\right] = \omega_1 + \omega_2 - \lambda_1 - \delta_{0:2} - \delta_{1:0},$$

$$\varphi_* \left[E_{\{1\}}\right] = \delta_{0:2}$$

in $\text{Pic}(\overline{M}_{2,2})$. Here $\lambda_1$ is the first Chern class of the Hodge bundle; $\delta_{0:2}$ is the class of the divisor $\Delta_{0:2}$ of curves with a rational tail; and $\delta_{1:0}$ is the class of the divisor $\Delta_{1:0}$ of curves with an unmarked elliptic tail. The identity (2.19) can be shown either by using Theorem 1.2 for the class of $\mathbb{H}^1_{2,2}$, or by observing that the restriction of $\varphi$ to $\mathbb{H}^1_{2,2}$ is generically finite over the divisor of curves with marked hyperelliptic conjugate points, and the class...
of such divisor is indeed given by (2.18) [Log] (see also §8.3). The identity (2.19) follows since the restriction of \( \varphi \) to \( E_{\{1\}} \) is generically finite over \( \Delta_{0,2} \). The classes in (2.18) and (2.19) are independent in Pic \( (\overline{M}_{2,2}) \).

Hence, the classes of \( \mathbb{H}_{g,2}^k \) and \( E_{\{1\}} \) are independent for all \( k \geq 1 \) and \( g \geq 2 \). The statement for \( n = 2 \) follows.

For \( n \geq 3 \), assume that

\[
(2.20) \quad \alpha \left[ \mathbb{H}^k_{g,n} \right] + \sum_I \alpha_I \left[ E_I \right] = 0 \quad \in A^n \left( \mathbb{P}^{k}_{g,n} \right)
\]

for some coefficients \( \alpha, \alpha_I \in \mathbb{Q} \). After applying \( (\pi_i)_* \) to (2.20) for some \( 1 \leq i \leq n - 1 \) and using Lemma 2.6, we get

\[
((c - 1) \alpha + \alpha_{\{i\}}) \left[ \mathbb{H}^k_{g,n-1} \right] + c \sum_{I : i \notin I} \alpha_I \left[ E_I \right] = 0
\]

where \( c := k(2g - 2) - (n - 2) \). The loci \( E_I \subset \mathbb{P}^{k}_{g,n-1} \) thus obtained are precisely the extra loci at the \( (n - 1) \)-th step as in (2.10). By the inductive assumption, we deduce

\[
(c - 1) \alpha + \alpha_{\{i\}} = 0 \quad \text{and} \quad \alpha_I = 0 \quad \text{for all} \quad I : i \notin I.
\]

Applying \( (\pi_i)_* \) to (2.20) for all \( 1 \leq i \leq n - 1 \) shows that \( \alpha_I = 0 \) in all cases except possibly for \( I = \{1, \ldots, n - 1\} \), and thus \( \alpha = 0 \) as well.

Hence, (2.20) reduces to \( \alpha_I \left[ E_I \right] = 0 \) where \( I = \{1, \ldots, n-1\} \). Restricting to the test space from Lemma 2.7, we deduce \( \alpha_I = 0 \) as well. \( \square \)

We are now ready to complete the proof of Theorem 2.1:

**Proof of Theorem 2.1.** We proceed by induction on \( n \). For the base case \( n = 2 \), the statement holds by Theorem 1.2. For the inductive step, assume (2.4), and consider the intersection (2.8). Since this is generically transverse over \( \mathcal{M}_{g,n} \), the component \( \mathbb{H}^k_{g,n} \) contributes with multiplicity one to the intersection for all \( k \geq 1 \). From Proposition 2.4, we know that

\[
L_n = \left[ \mathbb{H}^k_{g,n} \right] + \sum_I a_{n,I} \left[ E_I \right] \quad \in A^n \left( \mathbb{P}^{k}_{g,n} \right) \quad |\mathcal{M}_{g,n}\rangle
\]

for some coefficients \( a_{n,I} \in \mathbb{Q} \). Using the exact sequence

\[
A^n \left( \mathbb{P}^{k}_{g,n} \right) \to A^n \left( \mathbb{P}^{k}_{g,n} \right) \to A^n \left( \mathbb{P}^{k}_{g,n} \right) \to A^n \left( \mathbb{P}^{k}_{g,n} \right) \to 0
\]

it follows that there exists a cycle \( B_n \) not supported over \( \mathcal{M}^g_{g,n} \) such that

\[
(2.21) \quad L_n = \left[ \mathbb{H}^k_{g,n} \right] + \sum_I a_{n,I} \left[ E_I \right] + B_n \quad \in A^n \left( \mathbb{P}^{k}_{g,n} \right)
\]

Moreover, from Proposition 2.5, one has \( B_n = 0 \) when \( n \leq k \).
It remains to show that \( a_{n,I} = |I| \) for all \( n \) and \( I \). Applying \((\pi_i)_*\) to (2.21) for some \( 1 \leq i \leq n-1 \) and using Lemma 2.6 gives
\[
c L_{n-1} = ((c - 1) + a_{n,(i)}) \left[ \mathbb{P}^{g}_{g,n-1} \right] + c \sum_{I : i \notin I} a_{n,I} \left[ E_{T} \right] + (\pi_i)_* B_n
\]
where \( c := k(2g-2) - (n-2) \). By induction, this is equal to
\[
c L_{n-1} = c \left[ \mathbb{P}^{g}_{g,n-1} \right] + c \sum_{I} |T| \left[ E_{T} \right] + c B_{n-1} \in A^{n-1} \left( \mathbb{P}^{k}_{g,n-1} \right)
\]
where the loci \( E_{T} \subset \mathbb{P}^{k}_{g,n-1} \) are as in (2.10). By Lemma 2.8, we may determine \( a_{n,I} \) by simply comparing coefficients. We deduce
\[
(c - 1) + a_{n,(i)} = c \quad \text{and} \quad a_{n,I} = |I| \quad \text{for} \quad I : i \notin I.
\]
One has \( |T| = |I| \) for \( I \) with \( i \notin I \). Applying \((\pi_i)_*\) to (2.21) for all \( 1 \leq i \leq n-1 \) shows that \( a_{n,I} = |I| \) in all cases except possibly for \( I = \{1, \ldots, n-1\} \).

To find \( a_{n,I} \) with \( I = \{1, \ldots, n-1\} \), consider the \( n \)-dimensional test space \( T \) from Lemma 2.7. The restriction of (2.21) to \( T \) gives
\[
k(2g-2) = T \cdot L_n = (c - 1) + a_{n,\{1,\ldots,n-1\}}.
\]
Thus, \( a_{n,\{1,\ldots,n-1\}} = n - 1 \). Theorem 2.1 follows.

We conclude this section by extending Theorem 2.1 to the case \( k = 2 \) and \( n = 4g - 5 \):

**Theorem 2.9.** For \( g \geq 2 \) and \( n \geq 2 \), the identity
\[
\pi_2^* \left[ \mathbb{P}^{k}_{g,n} \right] \cdot \rho_2^* \left[ \mathbb{P}^{g}_{g,1} \right] = \left[ \mathbb{P}^{g}_{g,n} \right] + \sum_{I} |I| |E_I|
\]
where the sum is over all non-empty \( I \subseteq \{1, \ldots, n-1\} \), holds in:

(i) \( A^n \left( \mathbb{P}^{k}_{g,n} \right) \) when \( 0 \leq n \leq k \)

(ii) \( A^n \left( \mathbb{P}^{k}_{g,n} \right) \) when \( n \leq k \).

**Proof.** The only case left to be discussed is \( k = 2 \) and \( n = 4g - 5 \), since all other cases are covered by Theorem 2.1. For this case, the hypothesis (2.4) does not hold, and Lemma 2.2 fails. Indeed, as discussed after Lemma 2.2, the locus \( \mathbb{P}^{2}_{g,m} \subset \mathbb{P}^{2}_{g,1} \) with \( m = (4g - 6) \) from (2.5) consists of two equidimensional components. Consequently, the extra locus \( E_I := \gamma_s \mathbb{P}^{2}_{g,m} \) with \( I = \{1, \ldots, n-1\} \) from (2.3) decomposes as
\[
E_I = E'_I \cup E''_I \subset \mathbb{P}^{2}_{g,4g-5}
\]
with \( E'_I \) parametrizing quadratic differentials which generically are *not squares* of abelian differentials, and \( E''_I \) parametrizing *squares* of abelian differentials. For both components, the general element has a genus \( g \) component.
and a rational tail containing all marked points, and the quadratic differential vanishes with order exactly $4g - 6$ at the preimage of the node on the genus $g$ component.

Consider the intersection (2.8) for $k = 2$ and $n = 4g - 5$. The argument in Lemma 2.3 shows that the component $E'_I$ is inside (2.8) but not in $\overline{\mathcal{M}}_{g,4g-5}$. Next, we argue that this holds for the component $E^a_I$ as well.

Consider first the case $g = 2$. To show that

$$E^a_I \subset \pi_3^{-1} \left( \overline{\mathcal{H}}_{2,2} \right),$$

it is enough to show that $\widehat{E}^a_I := \pi_3 \left( E^a_I \right) \subset \overline{\mathcal{H}}_{2,2}$. For this, let $\widehat{E}^a_I \subset \mathcal{P} \mathcal{E}_{2,4}^2$ be the closure of the locus consisting of elements of $\mathcal{P} \mathcal{E}_{2,4}^2$ having a genus 2 component with two rational tails, and the square of an abelian differential vanishing at both nodes on the genus 2 component. In particular, the nodes on the genus 2 component are hyperelliptic conjugates, and each rational tail has two marked points. We argue that one has an inclusion $\iota$ as in the following diagram:

$$\begin{array}{ccc}
E^a_I & \xrightarrow{\iota} & \overline{\mathcal{H}}_{2,2} \\
\downarrow & & \downarrow \pi_3,4 \\
\widehat{E}^a_I & \xrightarrow{\iota} & \overline{\mathcal{H}}_{2,2} \\
\end{array} \quad \xrightarrow{\pi_3,4} \quad \mathcal{P} \mathcal{E}_{2,2}^2, \mathcal{P} \mathcal{E}_{2,4}^2.
$$

The vertical maps are induced by the map $\pi_3,4$ obtained by forgetting the last two marked points. The inclusion $\iota$ induces the desired inclusion, denoted $\iota$ in the diagram.

To prove that $\iota$ is an inclusion, we need to show that on the general element $(C,P_1,\ldots,P_4,\mu)$ of $\widehat{E}^a_I$, there exists a twisted quadratic differential of type $\mu$ satisfying the conditions of the incidence variety compactification. For this, we consider a twisted quadratic differential $\tau$ which agrees with $\mu$ on the genus 2 component of $C$ (hence has zeros of order two at the preimage of each node on the genus 2 component), and on each rational component, has a pole of order 6 at the node and simple zeros at the two marked points. Let $\Gamma$ be the dual graph of $C$, and consider the order on $\Gamma$ assigning the maximum level to the genus 2 vertex, and equal lower level to the two rational vertices, as suggested by this figure:

![Diagram of the dual graph of C]

Then $\tau$ is compatible with this order of $\Gamma$, and satisfies the conditions required by the incidence variety compactification. In particular, the global 2-residue condition holds. Note that there is no quadratic differential on a
rational curve with a pole of order 6, with two simple zeros, and with zero 2-
residue at the pole (see [CG, §3.1], and reference therein to [GT, Thm 1.10]).
However, the condition [BCG+2, Def. 1.4(4)(v)] holds, since one can assume
that \( \tau \) has equal 2-residues at the nodes on the two rational tails. Hence
the global 2-residue condition is satisfied. It follows that \( \hat{\iota} \) is an inclusion,
hence \( \tilde{\iota} \) is an inclusion, and (2.23) holds.

For \( g \geq 3 \), the argument is quite similar. One considers a locus \( \hat{E}_{I}^{ab} \)
in \( \mathbb{P}E_{g,4g-4}^{2} \) as for \( g = 2 \), defined as the closure of the locus consisting of
elements of \( \mathbb{P}E_{g,4g-4}^{2} \) having a genus \( g \) component with a rational tail with 2
marked points and a rational tail with \( 4g-6 \) marked points, and the square
of an abelian differential vanishing at the nodes on the genus 2 component
with order 2 and \( 4g-6 \), respectively. To show that \( \hat{E}_{I}^{ab} \) is in \( H_{2g,4g-5} / \rho_{4g-5} \)
ones argues that there exists a twisted quadratic differential \( \tau \) on a general
element \( (C,P_{1},\ldots,P_{4g-4},\mu) \) of \( \hat{E}_{I}^{ab} \) satisfying the conditions of the incidence
variety compactification. The restriction of such a \( \tau \) to the two rational tails
has poles of order 6 and \( 4g-2 \) at the two nodes, respectively, and simple
zeros at all marked points. One checks that the conditions of the incidence
variety compactification are satisfied with respect to the three-level
order on the dual graph of \( C \) suggested by this figure:

Contrary to the case \( g = 2 \), the two rational tails are not at the same level.
Since the aspect of such a \( \tau \) on the rational tail with more marked points
has zero 2-residue at the pole, the condition [BCG+2, Def. 1.4(4)(v)] holds.

Showing that \( E_{I}^{ab} \) is in \( \mathbb{P}E_{g,4g-4}^{2} \) and not in \( \mathbb{P}E_{g,4g-5}^{2} \) for \( g \geq 2 \)
is easier and similar to the arguments used for Lemma 2.3. Then the proof
continues in a similar way to the proof of Theorem 2.1. We sketch here the
main points. The arguments used for Proposition 2.4 and Lemma 2.6 remain
valid for this case. The test space \( T \) from Lemma 2.7 can be replaced by two
analogous \( n \)-dimensional test spaces \( T_{1}, T_{2} \subset \mathbb{P}E_{g,n}^{2} \) such that all quadratic
differentials in \( T_{1} \) are not squares of abelian differentials, and all quadratic
differentials in \( T_{2} \) are squares of abelian differentials. Using these two test
families, one shows that the class of \( \hat{H}_{g,4g-5}^{2} \), the classes of the loci \( E_{I} \) for
all \( |I| < n-1 \), and the classes of each of the two components from (2.22)
are independent in \( A^{4g-5} (\mathbb{P}E_{g,4g-5}^{2}) \), as in Lemma 2.8. Finally, one shows
that \( E_{I}^{ab} \) is in (2.8) with multiplicity equal to \( |I| \) for all \( I \) as in the
final steps of the proof of Theorem 2.1, whence the statement.

Remark 2.10. We comment here on the case \( k \geq 2 \) and \( n = k(2g-2) \) left out
by Theorem 2.9. The locus \( \mathbb{H}_{g,m}^{k} \subset \mathbb{P}E_{g,1}^{k} \) with \( m = (k(2g-2) - 1) \) from
(2.6) consists of two equidimensional components. Consequently, the extra
locus $E_{\text{max}} := E_{I} = \gamma_{\ast} \mathbb{H}_{g,m}^{i}$ with $I = \{1, \ldots, n-1\}$ from (2.3) decomposes as

$$E_{\text{max}} = E'_{\text{max}} \cup E_{\text{ab}}_{\text{max}} \subset \mathbb{P}^{k}_{g,k(2g-2)}$$

such that the general element of $E'_{\text{max}}$ has a genus $g$ component, a rational tail containing all marked points, and a $k$-differential vanishing with order exactly $k(2g-2)-1$ at the preimage of the node on the genus $g$ component; and the general element of $E_{\text{max}}$ has a genus $g$ component, a rational tail containing all marked points, and the $k$-th power of an abelian differential vanishing with order $k(2g-2)$ at the preimage of the node on the genus $g$ component. As in the proof of Theorem 2.9, one has that both components of $E_{\text{max}}$ are contained in the intersection (2.8), although $E'_{\text{max}}$ appears with multiplicity $|I| = k(2g-2)-1$, while $E_{\text{ab}}_{\text{max}}$ with multiplicity $k(2g-2)$. It follows that for $k \geq 2$ and $n = k(2g-2)$, one has

$$\pi_{n}^{\ast}\left[\mathbb{H}_{g,n}^{k}\right] \cdot \rho_{n}^{\ast}\left[\mathbb{H}_{g,1}^{k}\right] - \sum_{I} |I| [E_{I}] = \left[\mathbb{H}_{g,n}^{k}\right] + [E'_{\text{max}}]$$

in $A^{n}\left(\mathbb{P}^{k}_{g,n}\mid \mathcal{M}_{g,n}\right)$.

3. Cycles from weighted rational trees

Theorem 2.9 gives a recursion satisfied by the classes of the loci $H_{g,n}^{k}$. We solve this recursion in the next few sections. As a preliminary study, we consider here cycles on moduli spaces of stable pointed rational curves. After introducing the set of rational rooted trees, we define the cycles $Z_{m}^{\ast}(n,i,j)$ and $E_{I}^{\ast}(i,j)$. These will be shown to satisfy a recursive identity in §5.

3.1. Rational rooted trees. Let $G_{0,n+1} = G_{0,n+1}^{\ast}$ be the set of trees dual to strata in $\mathcal{M}_{0,n+1}$. Relabel the $(n+1)$-th leg of each tree as $h_{0}$.

Let $T \in G_{0,n+1}$. By identifying the vertex incident to $h_{0}$ as root, the tree $T$ is considered as a rooted tree. An edge $e \in E(T)$ consists of a pair of two half-edges $e = (h^{+}, h^{-})$, where $h^{+}$ (or head) is the half-edge which is further away from the leg $h_{0}$, and $h^{-}$ (or tail) is the half-edge which is closer to the leg $h_{0}$. Let

$$H^{+}(T) := \{\text{head half-edges} h^{+} \text{ of } T\} \cup \{h_{0}\},$$

$$H^{-}(T) := \{\text{tail half-edges} h^{-} \text{ of } T\},$$

$$H(T) := H^{+}(T) \cup H^{-}(T).$$

A vertex $v$ of $T$ is said to be external if there is no tail half-edge of $T$ incident to $v$.

These definitions are compatible with the ones in the introduction when $T$ arises as a rational subtree of a graph $\Gamma \in G_{g,n+}^{\ast}$ with $g > 0$ and $n^{+} \geq n$. 
3.2. Trees decorations. Next, we extend the decorations from §0.3 to rational rooted trees. The decorations will account for the special role played by $h_0$. Also, we will allow a heavier weight on one leg.

Let $T \in G_{0,n+1}$. Given $m \geq 1$, assign weight $m$ to the first leg of $T$, and weight 1 to all other legs.

For a half-edge $h$ of $T$, let $\iota(h)$ be the half-edge such that $(h, \iota(h)) \in E(T)$. For $h \in H^+(T)$, define the weighted capacity of $h$ as

$$\ell_h^m := \begin{cases} \text{sum of the weights of the legs in the maximal connected subtree containing } h, \text{ but not } \iota(h) & \text{if } h \neq h_0, \\ n - 1 + m & \text{if } h = h_0. \end{cases}$$

Consider the moduli space

$$\mathcal{M}_T := \prod_{v \in V(T)} \mathcal{M}_{0,n(v)},$$

and define the set of decorations $\Psi(T)$ of the graph $T$ as

$$\Psi(T) := \left\{ \psi = \psi_1^{d_1} \prod_{h \in H(T)} \psi_h^{d_h} \mid d_h \geq 0 \text{ for all } h, \quad d_1 \geq 0 \right\} \subset A^*(\mathcal{M}_T).$$

Let $\psi = \psi_1^{d_1} \prod_{h \in H(T)} \psi_h^{d_h}$ in $\Psi(T)$, and define accordingly the set

$$H(T, \psi) := \{(h, e) \mid h \in H^+(T), \ 0 \leq e \leq d_h \} \cup \{(h, e) \mid h \in H^-(T), \ 1 \leq e \leq d_h \} \cup \{(1, e) \mid 1 \leq e \leq d_1 \}.$$

One has

$$|H(T, \psi)| = |H^+(T)| + \deg \psi = 1 + |E(T)| + \deg \psi.$$

This uses that $H^+(T)$ contains the head half-edges together with $h_0$, hence $|H^+(T)| = 1 + |H^-(T)| = 1 + |E(T)|$.

The set of $i$-weightings of $(T, \psi)$ compatible with the legs weight is

$$w : H(T, \psi) \to \mathbb{N} :$$

$$w(h_0,0) = i,$$

$$\ell_h^m - 1 \geq w(h,0) \geq w(h,1) \geq \cdots \geq w(h,d_h)$$

for all heads $h$ or $h = h_0$,

$$1 \leq w(h^-,1) < \cdots < w(h^-,d_{h^-}) < w(\iota(h^-),0)$$

for all tails $h^-$,

$$1 \leq w(1,1) < \cdots < w(1,d_1) < m$$

For $m = 1$, we set

$$W_{T,\psi}^1 := W_{T,\psi}^m.$$

(3.2)
One has
\[(3.4) \quad \text{if } W_{T,\psi}^{i,m} \neq \varnothing, \quad \text{then } \left\{ \begin{array}{l} i < n - 1 + m, \\ d_1 < m. \end{array} \right. \]

The inequality \(i < n - 1 + m\) follows from the conditions \(i = w(h_0,0)\) and \(w(h_0,0) \leq \ell_{h_0} - 1\). In particular, there are only finitely many non-empty \(W_{T,\psi}^{i,m}\) for given \(m\) and \(T \in G_{0,n+1}, \psi \in \Psi(T)\). The inequality \(d_1 < m\) follows from the conditions on \(w(1,e)\) for \(e = 1, \ldots, d_1\).

For \(w \in W_{T,\psi}^{i,m}\), the corresponding \(i\)-weight of \((T, \psi)\) is
\[(3.5) \quad w(T, \psi) := \prod_{(h,e) \in H(T, \psi)} w(h,e). \]

Define
\[(3.6) \quad c_{T,\psi}^{i,m} := \sum_{w \in W_{T,\psi}^{i,m}} w(T, \psi). \]

Following (3.4), if this is non-zero, then \(i < n - 1 + m\) and \(d_1 < m\).

3.3. The cycles \(\text{Dec}_{n}^{i,m}(D)\) and \(Z(n, i, j)\). Let \(T \in G_{0,n+1}\). Consider the gluing map of degree one defined by \(T\):
\[(3.7) \quad \xi_T: \overline{\mathcal{M}}_T \to \overline{\mathcal{M}}_{0,n+1}. \]

For each \(\psi \in \Psi(T)\), one has
\[(3.8) \quad \deg \xi_{T*}(\psi) = |E(T)| + \deg \psi = -1 + |H^+(T)| + \deg \psi = -1 + |H(T, \psi)|. \]

The last two equalities follow from (3.1).

For a formal variable \(D\), the cycle \(\text{Dec}_{n}^{i,m}(D)\) in \(A^*(\overline{\mathcal{M}}_{0,n+1})[D^{-1}]\) is defined as
\[(3.9) \quad \text{Dec}_{n}^{i,m}(D) := \sum_{T \in G_{0,n+1}} \sum_{\psi \in \Psi(T)} (-1)^{|H^+(T)|} c_{T,\psi}^{i,m} \xi_{T*}(\psi) D^{-|H(T, \psi)|}. \]

This is a polynomial in \(D^{-1}\) with coefficients in \(A^*(\overline{\mathcal{M}}_{0,n+1})\). It will be convenient to name also its coefficients. For this, define
\[(3.10) \quad Z^{n}(n, i, j) := [\text{Dec}_n^{i,m}(D)]_{1-n-m-j+i} \quad \text{in } A^*(\overline{\mathcal{M}}_{0,n+1}) \]

where \([X]_k\) denotes the coefficient of \(D^k\) in \(X\). One has
\[(3.11) \quad Z^{n}(n, i, j) = \sum_{(T, \psi)} (-1)^{|H^+(T)|} c_{T,\psi}^{i,m} \xi_{T*}(\psi) \quad \text{in } A^{n+m-2+j-i}(\overline{\mathcal{M}}_{0,n+1}), \]

where the sum is over decorated trees \((T, \psi)\) such that \(\xi_{T*}(\psi)\) has degree \(n + m - 2 + j - i\) in \(A^*(\overline{\mathcal{M}}_{0,n+1})\). When \(m = 1\), we simply write
\[\text{Dec}_{n}^{i}(D) := \text{Dec}_{n}^{i,1}(D) \quad \text{and} \quad Z(n, i, j) := Z^1(n, i, j). \]
In Theorem 4.2, we will show that the cycles $Z(n, i, j)$ vanish for $i, j \geq 1$.

3.4. Colliding points on rational trees. Here we show that the cycles $Z^m(n, i, j)$ for arbitrary $m$ (and arbitrary $i, j$) are obtained from the case $m = 1$ by colliding points. This is a prelude to Theorem 6.2.

Theorem 3.1. For $1 \leq m < n$, let $n^− := n − m + 1$. The cycle

$$Z^m(n^−, i, j) \in A^{n^−-1+j-i} (\overline{M}_{0,n^−+1})$$

is obtained from $Z(n, i, j)$ in $A^{n^−-1+j-i} (\overline{M}_{0,n+1})$ by colliding the first $m$ marked points into the marked point $P_1$ — and relabeling the other marked points as $P_2, \ldots, P_{n^−}$.

Proof. The case $m = 1$ is trivial. Assume the statement holds for $m−1$ such that $1 \leq m−1 < n−1$. It is enough to show that the cycle $Z^m(n^−, i, j)$ in $A^{n^−-1+j-i} (\overline{M}_{0,n^−+1})$ is obtained from

$$Z^{m−1}(n^−+1, i, j) \in A^{n^−-1+j-i} (\overline{M}_{0,n−+2})$$

by colliding the first two marked points into the marked point $P_1$ — and relabeling the other marked points as $P_2, \ldots, P_{n^−}$.

To collide the points, one proceeds as follows. Let $δ_{1,2}$ be the class of the divisor of stable pointed rational curves whose general element has two rational components with one of them containing only two marked points, namely $P_1$ and $P_2$. The cycle obtained from (3.12) by colliding the first two marked points is

$$\pi_2^∗ (δ_{1,2} \cdot Z^{m−1}(n^−+1, i, j)) \in A^{n^−-1+j-i} (\overline{M}_{0,n^−+1})$$

where $\pi_2$ is the map obtained by forgetting the second marked point. We need to show that

$$\pi_2^∗ (δ_{1,2} \cdot Z^{m−1}(n^−+1, i, j)) = Z^m(n^−, i, j) \in A^{n^−-1+j-i} (\overline{M}_{0,n^−+1}).$$

For this, we analyze the various terms arising in the expansion of (3.13) and show that they match the terms in $Z^m(n^−, i, j)$. The non-zero terms arising in the expansion of (3.13) are obtained by colliding the first two marked points in the terms of (3.12) contributed by decorated trees where the first two legs are incident to the same vertex, say $v_1$. We distinguish two cases depending on the valence of $v_1$.

Case 1. Let $(\tilde{T}, \psi)$ be a decorated tree contributing to (3.12) such that the first two legs are incident to a trivalent vertex $v_1$. We show that the contribution of $(\tilde{T}, \psi)$ to (3.13) matches the contribution of $(T, \psi \cdot \psi_1)$ to $Z^m(n^−, i, j)$, where $T$ is the tree obtained from $\tilde{T}$ by removing the second leg and contracting the edge incident to the vertex $v_1$.

Using (3.11), the contribution of $(\tilde{T}, \psi)$ to (3.12) is given by

$$(-1)^{|H^+(\tilde{T})|} c_{\tilde{T},\psi}^{i,m−1} \xi_{\tilde{T}^*} (\psi).$$
By (3.6), the coefficient $c_{T,\psi}^{i,m-1}$ is the sum of $\hat{w}(\hat{T}, \psi)$ for $\hat{w}$ in $W_{\hat{T},\psi}^{i,m-1}$. By linearity, for $\hat{w} \in W_{\hat{T},\psi}^{i,m-1}$, the contribution of $(\hat{T}, \psi, \hat{w})$ to (3.12) is
\[-1)^{|W^+(\hat{T})|} \hat{w}(\hat{T}, \psi) \xi_{T*}(\psi).
Colliding the first two marked points gives rise to the following contribution of $(\hat{T}, \psi, \hat{w})$ to (3.13):
\[(3.15) (-1)^{|W^+(\hat{T})|} \hat{w}(\hat{T}, \psi) \xi_{T*} (\psi \cdot \psi_1).
The factor $-\psi_1$ decorating the first leg arises from the intersection with $\delta_{1,2}$ in (3.13). Next, we show that $\hat{w}(\hat{T}, \psi) = w(T, \psi \cdot \psi_1)$ for an appropriate $w \in W_{T,\psi}^{i,m}$.  
Let $h_1^+$ be the head half-edge in $\hat{T}$ incident to the trivalent vertex $v_1$, and let $h_1^-$ be the tail half-edge such that $(h_1^+, h_1^-) \in E(\hat{T})$. A factor $\psi_h$ with $h = h_1^-$ in the decoration $\psi$ of $\hat{T}$ induces a factor $\psi_1$ decorating $T$. Let $d_1$ be the resulting degree of $\psi_1$ in $\psi \cdot \psi_1$ decorating $T$. Then the degree of $\psi_h$ with $h = h_1^-$ in the decoration $\psi$ of $\hat{T}$ is $d_1 - 1$. For $\hat{w}$ in $W_{\hat{T},\psi}^{i,m-1}$, one has
\[\hat{w}(h_1^+, 0) \leq \ell_{h_1^+}^{m-1} - 1 = m - 1.
The conditions on $\hat{w}$ for tails give
\[1 \leq \hat{w}(h_1^-, 1) < \cdots < \hat{w}(h_1^-, d_1 - 1) < \hat{w}(h_1^+, 0).
It follows that $d_1 < m$. Consider the bijection
\[H(\hat{T}, \psi) \xrightarrow{\cong} H(T, \psi \cdot \psi_1),
\[(h_1^-, e) \mapsto (1, e),
\[(h_1^+, 0) \mapsto (1, d_1),
\[(h, e) \mapsto (h, e),
for $1 \leq e < d_1$, for $h \not\in \{h_1^-, h_1^+\}$ and all $e$.  
For all heads $h^+ \neq h_1^+$ or $h^+ = h_0$ in $\hat{T}$, the weighted capacity $\ell_{h^+}^{m-1}$ of $h^+$ in $\hat{T}$ is equal to the weighted capacity $\ell_{h^+}^{m}$ of the corresponding $h^+$ in $T$. Consider the map
\[W_{\hat{T},\psi}^{i,m-1} \to W_{T,\psi}^{i,m}, \hat{w} \mapsto w, \text{ with } \begin{cases} w(1, e) := \hat{w}(h_1^-, e), & \text{if } 1 \leq e < d_1, \\
w(1, d_1) := \hat{w}(h_1^+, 0), \\
w(h, e) := \hat{w}(h, e), & \text{otherwise.}
\end{cases}
This map is a bijection and preserves the weights, i.e.,
\[\text{if } \hat{w} \mapsto w, \text{ then } \hat{w}(\hat{T}, \psi) = w(T, \psi \cdot \psi_1).
It follows that for $\hat{w} \in W_{\hat{T},\psi}^{i,m-1}$, the contribution of $(\hat{T}, \psi, \hat{w})$ to (3.13) given by (3.15) is equal to
\[-1)^{|H^+(T)|} w(T, \psi \cdot \psi_1) \xi_{T*} (\psi \cdot \psi_1).
where $\hat{w} \mapsto w$. This matches the contribution of $(T, \psi \cdot \psi_1, w)$ to $Z^m(n^-, i, j)$.

Vice versa, a decorated tree where $\psi_1$ has positive degree can arise in the expansion of (3.13) only by colliding the first two marked points on a term of (3.12) contributed by a decorated tree where the first two legs are incident to a trivalent vertex.

It follows that the contributions to (3.13) obtained by colliding the first two marked points on decorated trees where the first two legs are incident to a trivalent vertex match the contributions to $Z^m(n^-, i, j)$ from decorated trees where $\psi_1$ has positive degree.

**Case 2.** Finally, consider a decorated tree $(\hat{T}, \psi)$ contributing to (3.12) such that the first two legs are incident to a vertex $v_1$ of valence at least four. We can assume that $\psi_1$ has degree zero in $\psi$, since otherwise the contribution of $(\hat{T}, \psi)$ to (3.13) is zero, due to the vanishing $\psi_1 \cdot \delta_{1,2} = 0$. We show that the contribution of $(\hat{T}, \psi)$ to (3.13) matches the contribution of $(T, \psi)$ to $Z^m(n^-, i, j)$, where $T$ is the tree obtained from $\hat{T}$ by merging the first two legs. In this case, the sets of edges of the trees $\hat{T}$ and $T$ are isomorphic, and moreover the weighted capacity $\ell_{h^+}$ of $h^+$ in $\hat{T}$ is equal to the weighted capacity $\ell_{h^+}$ of the corresponding $h^+$ in $T$, for all heads $h^+$ or $h^+ = h_0$. It follows that

$$c_{T, \psi}^{i,m-1} = c_{T, \psi}^{i,m}.$$

Hence, one has

$$\pi_{2*} \left( \delta_{1,2} \cdot (-1)^{|H^+(\hat{T})|} c_{T, \psi}^{i,m-1} \xi_{T*}(\psi) \right) = (-1)^{|H^+(T)|} c_{T, \psi}^{i,m} \xi_{T*}(\psi).$$

The left-hand side is the contribution of $(\hat{T}, \psi)$ to (3.13), and the right-hand side is the contribution of $(T, \psi)$ to $Z^m(n^-, i, j)$.

We conclude that the contributions to (3.13) obtained by colliding the first two marked points on decorated trees where the first two legs are incident to a vertex of valence at least four match the contributions to $Z^m(n^-, i, j)$ from decorated trees where $\psi_1$ has degree zero. This ends the proof. $\square$

### 3.5. The extra cycles $E_I$

We define here the cycles $E_I^1(D)$ and $E_I(i, j)$. These cycles are obtained as push-forward of $\text{Dec}_{n}^{\psi}(D)$ and $Z^m(n, i, j)$, and will be used to express the recursive identities in Theorems 5.1 and 5.2.

For $T \in G_{0,n+1}$, let $v_n$ be the vertex incident to the leg $n$, and let $h_0^+$ be the element in $H^+(T)$ incident to $v_n$. If $v_n$ is external, let $T \setminus v_n$ be the graph obtained from $T$ by removing the vertex $v_n$ together with the legs incident to it and the element $h_0^+$.

For $\emptyset \neq I \subseteq \{1, \ldots, n-1\}$, define the set of decorated codas as

$$\text{DC}_I := \left\{ (T, \psi) \mid T \in G_{0,n+1}, \begin{array}{l}
v_n \text{ is external with set of incident legs } I \cup \{n\}, \\
\text{and the degree of } \psi_h \text{ with } h = h_0^+ \text{ in } \psi \text{ is zero}
\end{array} \right\}.$$
For \( I = \{1, \ldots, n-1\} \), the set \( DC_I \) consists of a single decorated tree \((T,0)\) where \( T \) has only one vertex — in this case, \( T \setminus v_n = \emptyset \) and \( \psi = 0 \). For \( I \ni \{1, \ldots, n-1\} \), one has \( T \setminus v_n \neq \emptyset \) for \((T,\psi) \in DC_I \). For such decorated trees, by relabeling the tail half-edge of the edge connecting \( v_n \) to \( T \setminus v_n \) as leg 1 of \( T \setminus v_n \), and relabeling the other legs of \( T \setminus v_n \) accordingly, one has \( T \setminus v_n \in G_{0,n-\|I\|+1} \).

Let \((T,\psi) \in DC_I \) for some \( \emptyset \neq I \subseteq \{1, \ldots, n-1\} \). An element \( h^+ \) in \( H^+(T) \) is called a predecessor of \( h^+_n \) if \( h^+ \) is incident to a vertex \( v \neq v_n \) closer to \( h_0 \) than \( v_n \). Consider the subset of \( i \)-weightings

\[
W^I_{T,\psi} := \left\{ w \in W^I_{T,\psi} \mid \begin{array}{l}
w(h^+,0) \leq \ell_{h^+} - 2 \\
\text{for all predecessors } h^+ \text{ of } h^+_n \\
\text{and } w(h^+_n,0) = |I|
\end{array} \right\}.
\]

Here \( W^I_{T,\psi} \) is as in (3.3). One has

\[
(3.17) \quad \text{if } W^I_{T,\psi} \neq \emptyset, \quad \text{then } \begin{cases} 
eq n-2 \text{ and } |I| \leq n-2, \\
i = |I| = n-1. \end{cases}
\]

For \((T,\psi) \in DC_I \), define the coefficient \( d^I_{T,\psi} \) as

\[
(3.18) \quad d^I_{T,\psi} := \frac{1}{|I|} \sum_{w \in W^I_{T,\psi}} w(T,\psi).
\]

Following (3.17), one has

\[
(3.19) \quad \text{if } d^I_{T,\psi} \neq 0, \quad \text{then } \begin{cases} 
eq n-2 \text{ and } |I| \leq n-2, \\
i = |I| = n-1. \end{cases}
\]

In the case \( i = n-1 \) and \( I = \{1, \ldots, n-1\} \), one has \( d^I_{T,0} = 1 \).

Consider the cycle

\[
E^i_I(D) := \sum_{(T,\psi) \in DC_I} (-1)^{|H^+(T)|-1} d^I_{T,\psi} \xi_{T^*}(\psi) D^{-|H(T,\psi)|}
\]

in \( A^* (\overline{\mathcal{M}}_{0,n+1}) [D^{-1}] \). Similarly to (3.10), let

\[
E_I(i,j) := [E^i_I(D)]_{-n-j+i} \quad \text{in } A^{n-1+j-i}(\overline{\mathcal{M}}_{0,n+1})
\]

be its coefficients. One has

\[
E_I(i,j) = \sum_{(T,\psi)} (-1)^{|H^+(T)|-1} d^I_{T,\psi} \xi_{T^*}(\psi)
\]

in \( A^{n-1+j-i}(\overline{\mathcal{M}}_{0,n+1}) \), where the sum is over decorated trees \((T,\psi) \in DC_I \)

such that \( \xi_{T^*}(\psi) \) has degree \( n-1+j-i \).

Here we show that when \( |I| \leq n-2 \), the cycles \( E_I(i,j) \) are obtained as pushforward of cycles \( Z^m(n-m,i,j) \) with \( m = |I| \). Let

\[
\gamma: \overline{\mathcal{M}}_{0,n-m+1} \times \overline{\mathcal{M}}_{0,|I|\{n,h^+_n\}} \rightarrow \overline{\mathcal{M}}_{0,n+1}
\]
be the gluing map of degree one obtained by identifying the marked point $P_1$ on elements of $\overline{\mathcal{M}}_{0,n-m+1}$ with the marked point $h^+_{n}$ of elements in $\overline{\mathcal{M}}_{0,I\cup\{n,h^+_{n}\}}$, and relabeling the other marked points of elements in $\overline{\mathcal{M}}_{0,n-m+1}$ by elements of $\{h_0,1,\ldots,n-1\} \setminus I$.

**Lemma 3.2.** Let $\emptyset \neq I \subseteq \{1,\ldots,n-1\}$ and $m := |I| \leq n - 2$. One has

$$ E_I(D) = \gamma_* \text{Dec}^{i,m}_{n-m}(D) \in A^*(\overline{\mathcal{M}}_{0,n+1})[D^{-1}] . $$

**Proof.** We show that the coefficients of the two polynomials $E_I(D)$ and $\gamma_* \text{Dec}^{i,m}_{n-m}(D)$ in $D^{-1}$ match. Namely, using (3.10) and (3.20), we show that

$$ (3.22) \quad E_I(i, j) = \gamma_* \mathcal{Z}^m(n - m, i, j) \in A^{n-1+j-i}(\overline{\mathcal{M}}_{0,n+1}) . $$

For $(T, \psi) \in \text{DC}_I$, the gluing map $\xi_T$ factors as $\xi_T = \gamma \circ \xi_T|_{\psi_n}$, and one has

$$ \xi_{T*}(\psi) = \gamma_*(\xi_T|_{\psi_n*}(\psi)) . $$

This uses that the degree of $\psi_h$ with $h = h^+_n$ in $\psi$ is zero. Moreover, one has

$$ H^+(T) = H^+(T \setminus v_n) \cup \{h^+_n\}, $$

hence $|H^+(T)| - 1 = |H^+(T \setminus v_n)|$. Let $h^-_n$ be the tail half-edge such that $(h^+_n, h^-_n) \in E(T)$. One has a bijection

$$ H(T, \psi) \setminus \{(h^+_n, 0)\} \xrightarrow{\cong} H(T \setminus v_n, \psi) $$

$$ (h^-_n, e) \mapsto (1, e), \quad \text{for all } e, $$

$$ (h, e) \mapsto (h, e), \quad \text{for } h \notin \{h^+_n, h^-_n\} \text{ and all } e. $$

For all predecessors $h^+$ of $h^+_n$ in $T$, the number $\ell_{h^+} - 1$ for $h^+$ in $T$ is equal to the weighted capacity $\ell_{h^+}^m$ of the corresponding $h^+$ in $T \setminus v_n$. For all other heads $h^+$ in $T$, the capacity $\ell_{h^+}$ of $h^+$ in $T$ is equal to the weighted capacity $\ell_{h^+}^m$ of the corresponding $h^+$ in $T \setminus v_n$. It follows that the constraint on $w \in \mathcal{W}_{T,\psi}$ that $w(h^+, 0) \leq \ell_{h^+} - 2$ for all predecessors $h^+$ of $h^+_n$ in $T$ is equivalent to the constraint on $w \in \mathcal{W}_{T\setminus v_n,\psi}$ that $w(h^+, 0) \leq \ell_{h^+}^m - 1$ for the corresponding $h^+$ in $T \setminus v_n$.

Consider the map

$$ \mathcal{W}^i_{T,\psi} \to \mathcal{W}^i_{T\setminus v_n,\psi}, \quad \hat{w} \mapsto w, \quad \text{with } \left\{ \begin{array}{ll} w(1, e) := \hat{w}(h^-_n, e), \\ w(h, e) := \hat{w}(h, e), \end{array} \right. \quad \text{otherwise.} $$

This map is a bijection, and since $\hat{w}(h^+_n, 0) = |I|$, one has

$$ \text{if } \hat{w} \mapsto w, \text{ then } \frac{1}{|I|} \hat{w}(T, \psi) = w(T \setminus v_n, \psi). $$

Using (3.6) and (3.18), it follows that

$$ d^i_{T,\psi} = \ell^{i,m}_{T\setminus v_n,\psi}. $$
Hence (3.21) can be written as

$$E_I(i, j) = \gamma_* \left( \sum_{(T^-, \psi)} (-1)^{|H^+(T^-)|} c_{T^-, \psi}^{i, m} \xi_{T^-*}(\psi) \right) \in A^{n-1+j-i}(\overline{M}_{0, n+1})$$

where the sum is over decorated trees $(T^-, \psi)$ such that $(T^-, \psi) = (T\setminus v_n, \psi)$ for some $(T, \psi)$ in $\text{DC}_I$, and such that $\xi_{T^-*}(\psi)$ has degree $n-2+j-i$. Using (3.11), the statement follows. □

4. Vanishing cycles on moduli of pointed rational curves

Here we show how certain coefficients of the polynomial $\text{Dec}_i^n(D)$ introduced in the previous section encode relations in $A^*(\overline{M}_{0, n+1})$. This will be used in the proof of the recursive relations in §5.

Recall the cycle $\text{Dec}_i^n(D) = \text{Dec}_i^{i, 1}(D)$ from (3.9) defined as

$$\text{Dec}_i^n(D) := \sum_{T \in G_{0, n+1}} \sum_{\psi \in \Psi(T)} (-1)^{|H^+(T)|} c_{T, \psi}^i \xi_{T*}(\psi) D^{-|H(T, \psi)|}$$

in $A^*(\overline{M}_{0, n+1})[D^{-1}]$, where the coefficients $c_{T, \psi}^i = c_{T, \psi}^{i, 1}$ are as in (3.6).

**Theorem 4.1.** For $i \geq 1$, one has

$$D^{n-i} \text{Dec}_i^n(D) \in A^*(\overline{M}_{0, n+1})[D].$$

First we rewrite this statement as a vanishing statement about the coefficients of the polynomial $\text{Dec}_i^n(D)$. Recall from (3.10) the cycle

$$Z(n, i, j) := [\text{Dec}_i^n(D)]_{i-n-j} \in A^*(\overline{M}_{0, n+1})$$

where $[X]_t$ denotes the coefficient of $D^t$ in $X$. This gives

(4.1) $$Z(n, i, j) = \sum_{(T, \psi)} (-1)^{|H^+(T)|} c_{T, \psi}^i \xi_{T*}(\psi) \quad \text{in} \quad A^{n-1+j-i}(\overline{M}_{0, n+1})$$

where the sum is over decorated trees $(T, \psi)$ such that $\xi_{T*}(\psi)$ has degree $n-1+j-i$ in $A^*(\overline{M}_{0, n+1})$.

To prove Theorem 4.1, it suffices to prove the following.

**Theorem 4.2.** For $i, j \geq 1$, one has

$$Z(n, i, j) = 0 \quad \text{in} \quad A^{n-1+j-i}(\overline{M}_{0, n+1}).$$

The statement is non-trivial for $i < n$, since the coefficients $c_{T, \psi}^i$ vanish by definition otherwise, as well as for $j < i$, since the cycle vanishes for degree reasons otherwise.

This statement is proven as part (b) of Theorem 5.1 in §5.
4.1. **Examples.** Here we collect some examples of Theorem 4.2. Each graph stands for the sum of the pairwise non-isomorphic graphs obtained by all possible labeling of the unmarked legs by $1, \ldots, n$.

When $n = 3$, $i = 2$, and $j = 1$, one has

$$Z(3, 2, 1) = 2 \frac{h_0}{h_0} + 9 \frac{h_0}{h_0} - 6 \psi_{h_0} = 0 \quad \in A^1(\overline{M}_{0,4}).$$

When $n = 4$, $i = 3$, and $j = 1$, one has

$$Z(4, 3, 1) = 3 \frac{h_0}{h_0} + 18 \frac{h_0}{h_0} - 18 \psi_{h_0} = 0 \quad \in A^1(\overline{M}_{0,5}).$$

in $A^1(\overline{M}_{0,5})$. When $n = 4$, $i = 2$, and $j = 1$, one has

$$Z(4, 2, 1) = -14 \psi_{h_0}^2 - 6 \psi_{h_0} + 14 \psi_{h_0} + 6 \psi_{h_0} - 2 \psi_{h_0} = 0 \quad \in A^2(\overline{M}_{0,5}).$$

Still in $A^2(\overline{M}_{0,5})$, when $n = 4$, $i = 3$, and $j = 2$, one has

$$Z(4, 3, 2) = -75 \psi_{h_0}^2 + 21 \psi_{h_0} + 18 \psi_{h_0} - 9 \psi_{h_0} - 3 \psi_{h_0} = 0 \quad \in A^2(\overline{M}_{0,5}).$$

4.2. **Preliminary identities.** Here we start proving some identities which will help to prove Theorem 4.2 in §5. When $i = n - 1$ and $j = 1$, as in the first two examples in §4.1, the vanishing of $Z(n, i, j)$ holds due to a well-known divisorial relation on moduli spaces of stable pointed rational curves:

**Lemma 4.3.** For $n \geq 3$, one has

$$Z(n, n - 1, 1) = 0 \quad in \ A^1(\overline{M}_{0,n+1}).$$

**Proof.** From (3.8), a decorated tree $(T, \psi)$ contributes to $Z(n, n - 1, 1)$ if and only if $|E(T)| + \deg(\psi) = 1$, i.e., $|H(T, \psi)| = 2$. Recall from §3.1 that $H^+(T)$ always contains the element $h_0$. There are two cases.

If $\deg(\psi) = 1$, then the tree $T$ has only one vertex, and $\psi = \psi_{h_0}$. Hence, one has $H(T, \psi) = \{(h_0, 0), (h_0, 1)\}$. In this case, the set of $(n - 1)$-weightings
\[ W_{T,\psi}^{n-1} \] from (3.3) consists of the functions \( w \) such that \( w(h_0, 0) = n - 1 \) and \( w(h_0, 1) = a \), with \( a \in \{1, \ldots, n - 1\} \). From (3.6), it follows that \( c_{T,\psi}^{n-1} = (n-1)\binom{n}{2} \).

If \( \deg \psi = 0 \), then the tree \( T \) has exactly one edge \( e = (h^+, h^-) \). In this case, one has \( H(T, \psi) = \{(h_0, 0), (h^+, 0)\} \). The set \( W_{T,\psi}^{n-1} \) consists of the functions \( w \) such that \( w(h_0, 0) = n - 1 \) and \( w(h^+, 0) = a \), with \( a \in \{1, \ldots, \ell_{h^+} - 1\} \). It follows that \( c_{T,\psi}^{n-1} = (n-1)\binom{\ell_{h^+}}{2} \).

We deduce that one has

\[
Z(n, n-1, 1) = -(n-1)\binom{n}{2} \psi_{h_0} + (n-1) \sum_{m=2}^{n-1} \binom{m}{2} \delta_m
\]

where \( \delta_m \) is the sum of the classes of the boundary divisors in \( \overline{\mathcal{M}}_{0,n+1} \) whose general elements consist of a rational component containing the marked point \( h_0 \) and a rational component containing precisely \( m \) other marked points. The vanishing of \( Z(n, n-1, 1) \) is then due to the identity

\[
\binom{n}{2} \psi_{h_0} = \sum_{m=2}^{n-1} \binom{m}{2} \delta_m \quad \text{in } A^1(\overline{\mathcal{M}}_{0,n+1}).
\]

This identity follows from the well-known identity

\[
\psi_{h_0} = \sum_{M} \delta_M \quad \text{in } A^1(\overline{\mathcal{M}}_{0,n+1})
\]

obtained by fixing two elements \( a, b \in \{1, \ldots, n\} \), where the sum is over \( \{a, b\} \subseteq M \subseteq \{1, \ldots, n\} \) with \( |M| \leq n-1 \), and \( \delta_M \) is the class of the divisor in \( \overline{\mathcal{M}}_{0,n+1} \) whose general element consists of a rational component containing the marked point \( h_0 \) and a rational component containing precisely the marked points in \( M \). The identity (4.4) is trivial when \( n = 2 \), and it follows by induction for arbitrary \( n \), using pull-back formulas for the map obtained by forgetting one marked point. Summing over all choices of \( a \) and \( b \), the identity (4.4) implies (4.3), hence the vanishing of \( Z(n, n-1, 1) \) from (4.2).

We end this section with the following recursive identity, which will be used in the proof of Theorem 5.1(b) to deduce the vanishing of \( Z(n, i, j) \) for \( i = n - 1 \) and \( j \geq 1 \) from Lemma 4.3 and the vanishing of \( Z(n, i, j) \) for \( i = n - 2 \) and \( j \geq 1 \):

**Lemma 4.4.** For \( j \geq 2 \), one has

\[
Z(n, n-1, j) = \frac{n-1}{n-2} Z(n, n-2, j-1) + (n-1) \psi_{h_0} Z(n, n-1, j-1)
\]

in \( A^j(\overline{\mathcal{M}}_{0,n+1}) \).

**Proof.** Let \( j \geq 2 \), and let \((T, \psi)\) be a decorated tree such that \( \xi_{T^*}(\psi) \) has degree \( j \) in \( A^*\left(\overline{\mathcal{M}}_{0,n+1}\right) \). We show that the contributions of \((T, \psi)\) to the two sides of the equality in the statement match.
The maximal capacity $\ell_h = n$ for $h$ in $\mathbb{H}^+(T)$ is attained only at $h = h_0$. It follows that the only elements of $H(T, \psi)$ where an $(n-1)$-weighting can have value $n-1$ are the pairs $(h, e)$ where $h = h_0$. We distinguish two cases.

First, assume the degree of $\psi_{h_0}$ in $\psi$ is zero. In this case, $(T, \psi)$ does not contribute to $\psi_{h_0} Z(n, n - 1, j - 1)$. Moreover, the pair $(h_0, 0)$ is the only element of $H(T, \psi)$ where an $(n-1)$-weighting can have value $n-1$. It follows that the map 

$$W^{n-1}_{T, \psi} \to W^{n-2}_{T, \psi}, \quad w \mapsto \overline{w} \text{ where } \overline{w}(h, e) := \begin{cases} n - 2 & \text{if } (h, e) = (h_0, 0), \\ w(h, e) & \text{otherwise} \end{cases}$$

is a bijection. If $w \mapsto \overline{w}$, then $w$ and $\overline{w}$ only differ at $(h_0, 0)$, where $w(h_0, 0) = n - 1$ and $\overline{w}(h_0, 0) = n - 2$. Using the definition (3.5), one has $w(T, \psi) = \frac{n-1}{n-2} \overline{w}(T, \psi)$. From the definition (3.6), one has

$$c_{T, \psi}^{n-1} = \frac{n-1}{n-2} c_{T, \psi}^{n-2}.$$ 

From (4.1), it follows that $(T, \psi)$ contributes equally to the two sides of the equality in the statement.

Finally, assume the degree of $\psi_{h_0}$ in $\psi$ is positive. Let $d_0 > 0$ be the degree of $\psi_{h_0}$ in $\psi$. Then $H(T, \psi)$ contains $(h_0, e)$ precisely for $0 \leq e \leq d_0$. Consider the partition

$$W^{n-1}_{T, \psi} = W^a \sqcup W^b$$

where

$$W^a := \left\{ w \in W^{n-1}_{T, \psi} | w(h_0, 1) \leq n - 2 \right\},$$

$$W^b := \left\{ w \in W^{n-1}_{T, \psi} | w(h_0, 1) = n - 1 \right\}.$$

The map $w \mapsto \overline{w}$ from the previous case gives a bijection $W^a \cong W^{n-2}_{T, \psi}$ such that $w(T, \psi) = \frac{n-1}{n-2} \overline{w}(T, \psi)$. Next, let $\psi^- := \psi_{h_0}^{-1} \psi$. The contribution of $(T, \psi)$ to $\psi_{h_0} Z(n, n - 1, j - 1)$ equals the contribution of $(T, \psi^-)$ to $Z(n, n - 1, j - 1)$. The set $H(T, \psi^-)$ contains $(h_0, e)$ only for $0 \leq e \leq d_0 - 1$.

One has a bijection

$$W^b \to W^{n-1}_{T, \psi^-}, \quad w \mapsto w^- \text{ where } w^-(h, e) := \begin{cases} w(h_0, e + 1) & \text{if } h = h_0, \\ w(h, e) & \text{otherwise}. \end{cases}$$

Moreover, if $w \mapsto w^-$, then $w(T, \psi) = (n - 1) w^-(T, \psi^-)$. Hence one has

$$c_{T, \psi}^{n-1} = \frac{n-1}{n-2} c_{T, \psi}^{n-2} + (n - 1) c_{T, \psi^-}^{n-1}.$$ 

It follows that $(T, \psi)$ contributes equally to the two sides of the equality in the statement. This implies the statement. $\square$
5. Recursive identities on moduli of pointed rational curves

Here we prove certain recursive identities satisfied by the cycles $Z(n, i, j)$ and $\text{Dec}_i(D)$. These will be a key ingredient in the proof of Theorem 2. The proof of the recursive identities is intertwined with the proof of the vanishing statement from Theorem 4.2.

Recall the cycle $Z(n, i, j)$ in $A^*(\overline{M}_{0,n+1})$ from (4.1). Expanding the coefficients $c^i_{T,\psi} = c^{i,1}_{T,\psi}$ as in (3.6), one has

$$(5.1) \quad Z(n, i, j) = \sum_{(T,\psi, w)} (-1)^{|H^+(T)|} w(T, \psi) \xi_{T*}(\psi) \quad \text{in } A^{n-1+j-i}(\overline{M}_{0,n+1})$$

where the sum is over $(T,\psi, w)$ such that $\xi_{T*}(\psi)$ has degree $n-1+j-i$ in $A^*(\overline{M}_{0,n+1})$ and $w$ is an $i$-weighting of $(T,\psi)$. Recall that the legs of each such $T$ are labelled by $1,\ldots,n,h_0$.

Define the truncated cycle

$$(5.2) \quad Z'(n, i, j) \quad \text{in } A^{n-1+j-i}(\overline{M}_{0,n+1})$$

as the cycle obtained from $Z(n, i, j)$ by restricting the sum in (5.1) to those $(T,\psi, w)$ additionally satisfying the following property:

$$(5.3) \quad \begin{cases} \text{if } h_0, \text{ the leg } n, \text{ and a tail } h^- \text{ are incident to the same trivalent vertex,} \\ \text{then } i = w(h_0,0) \geq w(i(h^-),0). \end{cases}$$

Also, for a non-empty $I \subseteq \{1,\ldots,n-1\}$, recall the cycle

$$(5.5) \quad E_I(i, j) = \sum_{(T,\psi)} (-1)^{|H^+(T)|-1} d^i_{T,\psi} \xi_{T*}(\psi) \quad \text{in } A^{n-1+j-i}(\overline{M}_{0,n+1})$$

from (3.21), where the sum is over those decorated trees $(T,\psi)$ in the set $\text{DC}_I$ from (3.16) such that $\xi_{T*}(\psi)$ has degree $n-1+j-i$, and the coefficients $d^i_{T,\psi}$ are as in (3.18).

Let $\pi_n: \overline{M}_{0,n+1} \to \overline{M}_{0,n}$ be the map obtained by forgetting the point $P_n$.

**Theorem 5.1**. (a) For $1 \leq i \leq n-2$ and $j \in \mathbb{Z}$, one has

$$(5.4) \quad \pi_n^*(Z(n-1, i, j+1)) - \sum_I |I| E_I(i, j) = Z'(n, i, j)$$

in $A^{n-1+j-i}(\overline{M}_{0,n+1})$, where the sum is over all $\emptyset \neq I \subseteq \{1,\ldots,n-1\}$.

(b) For $i, j \geq 1$, one has

$$Z'(n, i, j) = 0 \quad \text{and} \quad Z(n, i, j) = 0 \quad \text{in } A^{n-1+j-i}(\overline{M}_{0,n+1})$$

As a consequence of Theorem 5.1, we show:

**Theorem 5.2**. For all $i \geq 1$ and $j \in \mathbb{Z}$, one has

$$(5.5) \quad \pi_n^*(Z(n-1, i, j+1)) - \sum_I |I| E_I(i, j) = Z'(n, i, j)$$

in $A^{n-1+j-i}(\overline{M}_{0,n+1})$, where the sum is over all $\emptyset \neq I \subseteq \{1,\ldots,n-1\}$.
Next, we modify this statement by replacing the truncated cycles \( Z^i(n, i, j) \) via the following Lemma. Let \( \sigma_0 : \overline{\mathcal{M}}_{0,n} \to \overline{\mathcal{M}}_{0,n+1} \) be the gluing map obtained by attaching at the marked point \( h_0 \) a rational component containing the marked points \( h_0 \) and \( p_n \).

**Lemma 5.3.** For \( i \geq 1 \) and \( j \in \mathbb{Z} \), one has

\[
Z(n, i, j) = Z^i(n, i, j) - \sum_{i^+ > i} i \sigma_0 \left( Z(n - 1, i^+, j^+) \right) \in A^{n-1+j-i} \left( \overline{\mathcal{M}}_{0,n+1} \right)
\]

where for each \( i^+ \), the number \( j^+ \) is defined by \( j^+ - i^+ = j - i \).

**Proof.** Since \( j^+ - i^+ = j - i \), the cycle \( Z(n - 1, i^+, j^+) \) has degree equal to \( n - 2 + j - i \) in \( A^* \left( \overline{\mathcal{M}}_{0,n} \right) \), and thus \( \sigma_0 \left( Z(n - 1, i^+, j^+) \right) \) has degree \( n - 1 + j - i \) in \( A^* \left( \overline{\mathcal{M}}_{0,n+1} \right) \). The statement follows from the definition of \( Z^i(n, i, j) \) as the cycle obtained from \( Z(n, i, j) \) by restricting the sum in (5.1) to those triples \((T, \psi, w)\) satisfying (5.3). Hence the difference \( Z(n, i, j) - Z^i(n, i, j) \) is contributed by those \((T, \psi, w)\) which do not satisfy (5.3), i.e., \( h_0 \), the leg \( n \), and a tail \( h^- \) are incident to a trivalent vertex of \( T \) and \( i = w(h_0, 0) < w(h^-, 0) =: i^+ \). Such a triple \((T, \psi, w)\) contributes to \( i \sigma_0 \left( Z(n - 1, i^+, j^+) \right) \), and vice versa. The negative sign before \( i \sigma_0 \left( Z(n - 1, i^+, j^+) \right) \) accounts for the new edge contributed by the gluing map \( \sigma_0 \). Hence the statement. \( \square \)

By (3.10) and (3.20), the cycles \( Z(n, i, j) \) and \( E_I(i, j) \) are coefficients of the polynomials \( \text{Dec}_n^i(D) = \text{Dec}_{n+1}^i(D) \) and \( E_I^i(D) \), respectively. That is,

\[
\text{Dec}_n^i(D) = \sum_{j > i-n} Z(n, i, j) D^{i-n-j}, \quad E_I^i(D) = \sum_{j > i-n} E_I(i, j) D^{i-n-j}
\]

in \( A^* \left( \overline{\mathcal{M}}_{0,n+1} \right) [D^{-1}] \). Combining Theorem 5.2 and Lemma 5.3, we have:

**Theorem 5.4.** For \( i \geq 1 \), one has

\[
\pi_n^* \left( \text{Dec}_{n-1}^i(D) \right) - \sum_I |I| E_I^i(D) - \sum_{i^+ > i} i \sigma_0 \left( \text{Dec}_{n+1}^{i^+}(D) \right) = \text{Dec}_n^i(D)
\]

in \( A^* \left( \overline{\mathcal{M}}_{0,n+1} \right) [D^{-1}] \). The first sum is over all \( \emptyset \neq I \subseteq \{1, \ldots, n-1\} \).

This statement will be used in the proof of Theorem 7.1. The next Lemma 5.6 shows that for any given \( n \), Theorem 5.2 follows from Theorem 5.1. The latter is proven in the remainder of §5.2.

### 5.1. Partitions of \( \mathcal{G}_{0,n+1} \)

We consider here partitions of the set of rational rooted trees \( \mathcal{G}_{0,n+1} \). These will be used in the proof of Theorem 5.1.

Let \( T \in \mathcal{G}_{0,n+1} \). A vertex \( v \) of \( T \) is **external** if there is no tail half-edge of \( T \) incident to \( v \). A subtree \( T' \) of \( T \) is **external** if either \( T' = T \), or there exists an edge \((h^+, h^-)\) in \( E(T) \) such that \( T' \) is the maximal subtree of \( T \) containing the head half-edge \( h^+ \), but not the tail half-edge \( h^- \).
Let \( v_n \) be the vertex incident to the leg \( n \), and \( v_0 \) the vertex incident to \( h_0 \). Let \( h_n \) be the unique element of \( H^+(T) \) incident to \( v_n \). For a half-edge \( h \), let \( \iota(h) \) be the half-edge such that \((h, \iota(h)) \in E(T)\).

Consider the set of decorated rational trees with \( i \)-weightings:

\[
(5.6) \quad \text{DGW}_{i,0,n+1} = \{(T, \psi, w) | T \in \mathcal{G}_{0,n+1}, \psi \in \Psi(T), w \in \mathcal{W}_{T, \psi}\}.
\]

For \( 1 \leq i \leq n-2 \), let

\[
\text{DGW}_{i,0,n+1} = A_{i,0,n+1} \cup B_{i,0,n+1} \cup C_{i,0,n+1}
\]

be the partition where

\[
A_{i,0,n+1} := \left\{ (T, \psi, w) \left| \begin{array}{l}
\text{either } v_n \text{ is incident to } h_0; \\
\text{or } v_n \text{ is trivalent, adjacent to } v_0, \text{and incident to } \\
a \text{ tail } h^-, \text{ and } w(h_n, 0) < w(\iota(h^-), 0)
\end{array} \right. \right\},
\]

\[
B_{i,0,n+1} := \left\{ (T, \psi, w) \left| \begin{array}{l}
v_n \text{ is not incident to } h_0; \text{ and} \\
\text{if } v_n \text{ is trivalent, adjacent to } v_0, \text{ and incident to } \\
a \text{ tail } h^-, \text{ then } w(h_n, 0) \geq w(\iota(h^-), 0); \text{ and} \\
\text{ if } v_n \text{ is external,} \\
\text{ then the degree of } \psi_{h_n} \text{ in } \psi \text{ is positive}
\end{array} \right. \right\},
\]

\[
C_{i,0,n+1} := \left\{ (T, \psi, w) \left| \begin{array}{l}
v_n \text{ is external and not incident to } h_0, \text{ and} \\
\text{ the degree of } \psi_{h_n} \text{ in } \psi \text{ is zero}
\end{array} \right. \right\}.
\]

For \( (T, \psi, w) \in A_{i,0,n+1} \), the vertex \( v_n \) could be external. In this case, \( v_n \) is the only vertex of \( T \).

For \( n = 3 \) and \( i = 1 \), one has \( B_{1,0,n+1} = \emptyset \), and \( \mathcal{G}_{0,n+1} = A_{1,0,n+1} \sqcup C_{1,0,n+1} \).

5.2. Proof of Theorems 5.1 and 5.2. We start with two preliminary Lemmata:

Lemma 5.5. The left-hand side of \((5.4)\) expands as a \( \mathbb{Z} \)-linear combination of classes \( \xi_{T^*} (\psi) \) for \( T \in \mathcal{G}_{0,n+1} \) and \( \psi \in \Psi(T) \), as does the right-hand side.

Proof. Let us first consider \( \pi_n^* (\mathbb{Z}(n-1, i, j+1)) \). By definition, this is a \( \mathbb{Z} \)-linear combination of terms of type \( \pi_n^* (\xi_{T^*} (\psi)) \) with \( T \) in \( \mathcal{G}_{0,n} \) and \( \psi \) in \( \Psi(\overline{T}) \). Each such term expands as

\[
(5.7) \quad \pi_n^* (\xi_{T^*} (\psi)) = \sum_T \xi_{T^*} (\pi_n^* (\psi))
\]

where \( T \in \mathcal{G}_{0,n+1} \) ranges over all graphs obtained from \( \overline{T} \) by adding a leg \( n \) to one of its vertices. Let \( \overline{T} \) be one of such graphs, let \( v_n \) be the vertex incident to the leg \( n \), and \( h_n \) be the unique element of \( H^+(T) \) incident to \( v_n \).

Consider first the case when for all tail half-edges \( h^- \) incident to \( v_n \), the degree of \( \psi_{h^-} \) in \( \psi \) is zero. Pull-back formulas for \( \psi \)-classes give

\[
\xi_{T^*} (\pi_n^* (\psi)) = \xi_{T^*} (\psi) - \xi_{T^o*} (\psi^o) \quad \in A^* (\overline{\mathcal{M}}_{0,n+1})
\]
where:

\[(5.8) \quad T^0 := \begin{cases} 
\text{the tree obtained from } T \text{ by} \\
\text{splitting the vertex } v_n \text{ into two vertices } v_n^\circ \text{ and } v_n^\perp \\
such that } v_n^\circ \text{ is trivalent and incident to: the leg } n, \\
\text{the element in } H^+ (T^0) \text{ equivalent to } h_n \text{ from } T, \\
\text{and an edge incident to } v_n^\perp; \\
\end{cases}\]

\[
\psi^0 := \begin{cases} 
\text{the monomial obtained from } \psi \text{ by} \\
\text{replacing the factor } \psi_{h_n}^{d_n}, \\
\text{where } d_n \text{ is the degree of } \psi_{h_n} \text{ in } \psi, \\
\text{with } \psi_{h_n}^{d_\perp} \text{ where } h_\perp \text{ is the head half-edge incident to } v_n^\perp \\
\text{and } d_\perp := d_n - 1; \\
\text{if } d_n = 0, \text{ then one sets } \psi^0 = 0.
\end{cases}\]

An example is given in Figure 1.

\[
(T, \psi) = \xymatrix{ h_0 \ar[r]^{v_n} & \psi_{h_n}^{v_n^\circ} \ar[r] & \psi_{h_n}^{v_n^\perp} \\
^n \ar@{-}[r]^n & \ar@{-}[r]^n & }
\quad \mapsto \quad \begin{cases} 
(T^0, \psi^0) = \xymatrix{ h_0 \ar[r]^{v_n} & \psi_{h_n}^{v_n^\circ} \ar[r] & \psi_{h_n}^{v_n^\perp} \\
^n \ar@{-}[r]^n & \ar@{-}[r]^n & }
\end{cases}
\]

\[
(T^{h^-}, \psi^{h^-}) = \xymatrix{ h_0 \ar[r]^{v_n} & \psi_{h_n}^{v_n^\circ} \ar[r] & \psi_{h_n}^{v_n^\perp} \\
^n \ar@{-}[r]^n & \ar@{-}[r]^n & }
\]

**Figure 1.** An example of the decorated trees \((T^0, \psi^0)\) and \((T^{h^-}, \psi^{h^-})\).

More generally, if for some tail half-edge \(h^-\) incident to \(v_n\), the degree of \(\psi_{h^-}\) in \(\psi\) is positive, then pull-back formulas for \(\psi\)-classes give more terms:

\[
(5.10) \quad \xi_{T^*} (\pi_n^* (\psi)) = \xi_{T^*} (\psi) - \xi_{T^*} (\psi^0) - \sum_{h^-} \xi_{T^{h^-} h^-} (\psi^{h^-})
\]

where \(T^0\) and \(\psi^0\) are as in (5.8) and (5.9); the sum is over tail half-edges \(h^-\) incident to \(v_n\); and for each such tail \(h^-:\)

\[
(5.11) \quad T^{h^-} := \begin{cases} 
\text{the tree obtained from } T \text{ by} \\
\text{splitting the vertex } v_n \text{ into two vertices } v_n^{h^-} \text{ and } v_n^\perp \\
such that } v_n^{h^-} \text{ is trivalent and incident to: the leg } n, \\
\text{the tail half-edge equivalent to } h^- \text{ from } T, \\
\text{and an edge incident to } v_n^\perp; \\
\end{cases}\]

\[
\psi^{h^-} := \begin{cases} 
\text{the monomial obtained from } \psi \text{ by} \\
\text{replacing the factor } \psi_{h_n}^{d_-}, \\
\text{where } d_- \text{ is the degree of } \psi_{h_n} \text{ in } \psi, \\
\text{with } \psi_{h_n}^{d_\perp} \text{ where } h_\perp \text{ is the tail half-edge incident to } v_n^\perp \\
in the direction of } v_n^{h^-}, \text{ and } d_\perp := d_- - 1; \\
\text{if } d_- = 0, \text{ then one sets } \psi^{h^-} = 0.
\end{cases}\]

See the example in Figure 1.

Combining (5.7) and (5.10) shows the claim for the contributions arising from \( \pi^*_n(Z(n-1, i, j+1)) \).

Regarding the cycles \( E_I(i, j) \), the claim follows immediately from (3.21). We emphasize that after (3.16) and (3.19), one has (5.13)

\[
\text{if } d^j_{T, \psi} \neq 0 \text{ and } i \leq n-2, \text{ then } \left\{ \begin{array}{l}
\nu_n \text{ is external and not incident to } h_0, \\
\text{and the degree of } \psi_{h_n} \text{ in } \psi \text{ is zero.}
\end{array} \right.
\]

It follows that if \((T, \psi)\) contributes to \( E_I(i, j) \) on the left-hand side of (5.4), then \((T, \psi, w)\) for all \( i \)-weightings \( w \) is in the subset \( C_{0,n+1}^i \subseteq DGW_{0,n+1}^i \) from §5.1.

**Lemma 5.6.** For any given \( n \geq 3 \), Theorem 5.1 implies Theorem 5.2.

**Proof.** Let \( n \geq 3 \), and assume Theorem 5.1 holds for \( n \).

For \( i \geq n \), both sides of (5.5) vanish. Indeed, for the sets of \( i \)-weightings to be non-empty, one needs \( i < n \), as in (3.4). Hence, using the definitions (5.1) and (5.2), both \( Z(n-1, i, j+1) \) and \( Z^t(n,i,j) \) vanish for \( i \geq n \). Similarly, using the definition (3.21) and (3.19), one concludes the vanishing of the cycles \( E_I(i, j) \) for \( i \geq n \).

For \( i = n-1 \), we need to prove (5.5) in \( A^j(M_{0,n+1}) \) for \( j \geq 0 \). As in the previous paragraph, the cycle \( Z(n-1, n-1, j+1) \) on the left-hand side vanishes for all \( j \), since the sets of \( i \)-weightings are empty in this case. For \( j \geq 1 \), the cycle \( Z^t(n,n-1,j) \) on the right-hand side vanishes from Theorem 5.1(b). Moreover, when \( j \geq 1 \), the only cycles \( E_I(n-1,j) \) of positive degree \( j \) are those with \( |I| < n-1 \), and these vanish since all coefficients \( d^{n-1}_{T, \psi} \) in (3.21) vanish in this case using (3.19). For \( j = 0 \), using (3.19), the only non-vanishing cycle \( E_I(n-1,0) \) in (5.5) is the one with \( |I| = n-1 \). In this case, both cycles \( E_I(n-1,0) \) and \( Z^t(n,n-1,0) \) consist of only one term contributed by \((T, \psi)\) where \( T \) is the tree with only one vertex and \( \psi = 0 \). In this case, both sides of (5.5) are equal to \(-i = -(n-1)\).

Finally, for \( 1 \leq i \leq n-2 \), the identity (5.5) follows from part (a) of Theorem 5.1. Hence the statement.

We now turn to the proof of Theorem 5.1:

**Proof of Theorem 5.1.** We prove part (a) and part (b) simultaneously by induction on \( n \).

For part (b), one can assume that \( 1 \leq j < i \), since the vanishing of \( Z^t(n,i,j) \) and \( Z(n,i,j) \) in \( A^{n-1+j-i}(M_{0,n+1}) \) for \( 1 \leq i \leq j \) is trivial for degree reasons. In addition, one can assume \( i < n \), since otherwise the sets of \( i \)-weightings are empty, hence \( Z^t(n,i,j) \) and \( Z(n,i,j) \) vanish.

The base case is \( n = 3 \), where \( i = 1 \). In this case, (5.4) is an identity in \( A^{1+j}(M_{0,4}) \), hence non-trivial only for \( j \in \{-1,0\} \).
When \( j = -1 \), the only cycle \( E_I(1, -1) \) of degree zero is the one with \( |I| = n - 1 \), and this vanishes from (3.19) since \( i < n - 1 \). Both sides of (5.4) are then equal to the fundamental class of \( \overline{M}_{0,4} \).

When \( j = 0 \), the term \( \pi^*_n (Z(n - 1, i, j + 1)) \) does not contribute any cycle in dimension zero. Hence the left-hand side of (5.4) is provided only by the two \( E_I(1, 0) \), namely

\[
\begin{align*}
&h_0 \\
&\quad \quad 1 \\
&\quad \quad 3 \\
&\quad \quad 2
\end{align*}
\]

while the right-hand side of (5.4) has in addition the following terms

\[
(5.14) \quad h_0 \\
\quad \quad 1 \\
\quad \quad 3 \\
\quad \quad 2
\]

Since (5.14) vanishes in \( A^1(\overline{M}_{0,4}) \), part (a) follows.

For \( n = 3 \), the only non-trivial case of part (b) is given when \( i = 2 \) and \( j = 1 \), and it is a special case of Lemma 4.3.

Next, we show the following:

**Claim 5.7.** Assume parts (a) and (b) for \( n \), \( n - 1 \), \( n - 2 \), \ldots, 3. Then part (a) holds for \( n \), i.e., the contributions of all \((T, \psi)\) to the two sides of (5.4) match, modulo relations in \( A^*(\overline{M}_{0,n+1}) \).

**Proof of Claim 5.7.** Let \( n \geq 4 \). The right-hand side of (5.4) is \( Z^t(n, i, j) \), given by

\[
Z^t(n, i, j) = \sum_{(T, \psi, w)} (-1)^{|H^+(T)|} w(T, \psi) \xi_T^* (\psi) \quad \text{in } A^{n-1+j-i}(\overline{M}_{0,n+1})
\]

where the sum is over \((T, \psi, w)\) in the set \( DGW_{0,n+1} \) from (5.6) such that \( \xi_T^* (\psi) \) has degree \( n - 1 + j - i \) in \( A^*(\overline{M}_{0,n+1}) \) and the property (5.3) is satisfied.

For each such \((T, \psi, w)\), the argument depends on the position of the leg \( n \) in \( T \). For this, let \( 1 \leq i \leq n - 2 \), and consider the partition of \( DGW_{0,n+1} \) from §5.1:

\[
DGW_{0,n+1} = A_{0,n+1}^i \sqcup B_{0,n+1}^i \sqcup C_{0,n+1}^i.
\]

**Contributions from \( A_{0,n+1}^i \).** Let us consider the contributions of \((T, \psi, w)\) in \( A_{0,n+1}^i \) to \( Z^t(n, i, j) \). First, we arrange such contributions in parts, and then we distinguish Subcases 1 and 2 below.

We partition the contributions from \( A_{0,n+1}^i \) to \( Z^t(n, i, j) \) as follows. The idea is that the partition is suggested by the set of decorated trees contributing to the pull-back of \( \psi \)-classes, as in (5.10), and each part consists of:

(i) a triple \((T, \psi, w)\) where the vertex \( v_n \) incident to the leg \( n \) has valence at least four and is incident to \( h_0 \);
(ii) possibly a triple \((T^o, \psi^o, w^o)\) where the vertex \(v_n^o\) incident to the leg \(n\) is trivalent and incident to \(h_0\);

(iii) possibly triples \((T^{h^-}, \psi^{h^-}, w^{h^-})\) where the vertex \(v_n^{h^-}\) incident to the leg \(n\) is trivalent and adjacent to the vertex incident to \(h_0\).

To define such parts, consider a triple \((T, \psi, w)\) in \(A_{i,0, n+1}^0\) such that the valence of the vertex \(v_n\) incident to the leg \(n\) is at least four. In particular, \(v_n\) is incident to \(h_0\).

The possible triple \((T^\circ, \psi^\circ, w^\circ)\) in the part containing \((T, \psi, w)\) is defined as follows: \(T^\circ\) is the graph obtained from \(T\) as in (5.8); \(\psi^\circ\) is the decoration obtained from \(\psi\) as in (5.9); and \(w^\circ\) is the \(i\)-weighting defined by

\[
\begin{align*}
w^\circ(h_n^o, 0) &= w(h_n, 0), \\
w^\circ(h^\perp, e) &= w(h_n, e + 1) & \text{for } 0 \leq e \leq d^\perp, \\
w^\circ(h, e) &= w(h, e) & \text{otherwise}.
\end{align*}
\]

Here, we have used the identification

\[
H(T, \psi) \simeq H(T^o, \psi^o)
\]

\[
(h_n, 0) \mapsto (h_n^o, 0),
\]

\[
(h_n, e + 1) \mapsto (h^\perp, e), & \quad \text{for } 0 \leq e \leq d^\perp, \\
(h, e) \mapsto (h, e), & \quad \text{for } h \neq h_n \text{ and all } e.
\]

The triple \((T^o, \psi^o, w^o)\) is considered only if \(\psi^o \neq 0\). Since \((T, \psi, w)\) is in \(A^i_{0, n+1}\), by definition the triple \((T^o, \psi^o, w^o)\) is in \(A^i_{0, n+1}\) as well. Moreover, one has the following equality of weights

\[(5.15) \quad w(T, \psi) = w^o(T^o, \psi^o).\]

Since a divisorial \(\psi\)-class is exchanged with an edge, the classes \(\xi_{T^o}(\psi)\) and \(\xi_{T^o^*}(\psi^o)\) have equal degree in \(A^*(\overline{M}_{0, n+1})\).

In addition, the possibly remaining triples of the part containing \((T, \psi, w)\) are triples \((T^{h^-}, \psi^{h^-}, w^{h^-})\), one for each tail half-edge \(h^-\) incident to \(v_n\) in \(T\), where: \(T^{h^-}\) is the graph obtained from \(T\) as in (5.11); \(\psi^{h^-}\) is the decoration obtained from \(\psi\) as in (5.12); and \(w^{h^-}\) is the \(i\)-weighting defined by

\[
\begin{align*}
w^{h^-}(h^\perp, e) &= w(h^-, e), & \text{for } 0 \leq e \leq d^\perp, \\
w^{h^-}(\iota(h^\perp), 0) &= w(h^-, d^\perp + 1), \\
w^{h^-}(h, e) &= w(h, e) & \text{otherwise}.
\end{align*}
\]
Here, we have used the identification
\[ H(T, \psi) \xrightarrow{\sim} H(T^{h^-}, \psi^{h^-}) \]
\[
(h^-, e) \mapsto (h^-, e), \quad \text{for } 0 \leq e \leq d^\perp,
\]
\[
(h^-, d^\perp + 1) \mapsto (\ell(h^+), 0),
\]
\[
(h, e) \mapsto (h, e), \quad \text{for } h \neq h^- \text{ and all } e.
\]

For each \( h^- \), the triple \((T^{h^-}, \psi^{h^-}, w^{h^-})\) is considered only if \( \psi^{h^-} \neq 0 \). Since \((T, \psi, w)\) is in \( A^i_{0,n+1} \), by definition the triple \((T^{h^-}, \psi^{h^-}, w^{h^-})\) is in \( A^i_{0,n+1} \) as well, and one has
\[
(5.16) \quad w(T, \psi) = w^{h^-}(T^{h^-}, \psi^{h^-}).
\]

Since a divisorial \( \psi \)-class is exchanged with an edge, the classes \( \xi_{T^*}(\psi) \) and \( \xi_{T^{h^-*}}(\psi^{h^-}) \) have equal degree in \( A^*\left(\mathcal{M}_{0,n+1}\right) \).

For \((T, \psi, w)\) to contribute to \( Z^t(n, i, j) \), the degree of \( \xi_{T^*}(\psi) \) is required to be \( n - 1 + j - i \) in \( A^*\left(\mathcal{M}_{0,n+1}\right) \). This implies that the corresponding \( \xi_{T^{h^-*}}(\psi^o) \) and all \( \xi_{T^{h^-*}}(\psi^{h^-}) \) have the same degree \( n - 1 + j - i \). In addition, \((T^o, \psi^o, w^o)\) satisfies the property (5.3) by construction; \((T, \psi, w)\) and all \((T^{h^-}, \psi^{h^-}, w^{h^-})\) trivially satisfy (5.3). This implies that if \((T, \psi, w)\) contributes to \( Z^t(n, i, j) \), then \((T^o, \psi^o, w^o)\) and all \((T^{h^-}, \psi^{h^-}, w^{h^-})\) contribute to \( Z^t(n, i, j) \) as well.

The number of head half-edges of \( T \) and corresponding \( T^o \) varies by one. Similarly, the number of head half-edges of \( T \) and each corresponding \( T^{h^-} \) varies by one. Using (5.15) and (5.16), it follows that the sum of the contributions to \( Z^t(n, i, j) \) of all triples in the part of \( A^i_{0,n+1} \) corresponding to \((T, \psi, w)\) is:
\[
(5.17) \quad (-1)^{|H^t(T)|} w(T, \psi) \left(\xi_{T^*}(\psi) - \xi_{T^{h^-*}}(\psi^o) - \sum_{h^-} \xi_{T^{h^-*}}(\psi^{h^-})\right).
\]

As in (5.10), this is
\[
(5.18) \quad (-1)^{|H^t(T)|} w(T, \psi) \xi_{T^*}(\pi_n^* \psi) \in A^*\left(\mathcal{M}_{0,n+1}\right).
\]

This is the total contribution to \( Z^t(n, i, j) \) of the part of \( A^i_{0,n+1} \) corresponding to \((T, \psi, w)\). We distinguish two subcases:

**Subcase 1.** Consider first the case when the sum of the degrees of \( \psi_h \) in \( \psi \) for \( h \) incident to \( v_n \) in \( T \) is valence\( (v_n) - 3 \). In this case, the total contribution to \( Z^t(n, i, j) \) as given in (5.18) vanishes. Indeed, our assumption implies that the sum of the degrees of \( \pi_n^* \psi_h \) in the term \( \pi_n^* \psi \) from (5.18) for \( h \) incident to \( v_n \) is valence\( (v_n) - 3 \). The product of \( \pi_n^* \psi_h \) in \( \pi_n^* \psi \) for \( h \) incident to \( v_n \) is then the pull-back via \( \pi_n \) of a cycle of degree valence\( (v_n) - 3 \) supported on a moduli space of rational curves with valence\( (v_n) - 1 \) marked points. Such cycle vanishes for degree reasons.
Similarly, no such contributions arise in $\pi^*_n(\mathbb{Z}(n - 1, i, j + 1))$. Indeed, arguing as in Lemma 5.5, contributions to $\pi^*_n(\mathbb{Z}(n - 1, i, j + 1))$ arise precisely from terms like $\xi_{T^*}(\pi^*_n \psi)$, hence they are null in this case, as in the previous paragraph. Also, since $(T, \psi, w), (T^\circ, \psi^\circ, w^\circ)$ and $(T^{h^-}, \psi^{h^-}, w^{h^-})$ are all in $A_{0,n+1}^i$, there are no contributions to the cycles $E_I(i, j)$.

It follows that the sum of the contributions of such decorated trees vanishes on both sides of (5.4).

**Subcase 2.** It remains to consider the case when the sum of the degrees of $\psi_h$ in $\psi$ for $h$ incident to $v_n$ in $T$ is less than valence$(v_n) - 3$. After (5.7), the contribution (5.18) to $Z^I(n, i, j)$ in this case matches a contribution to $(\mathbb{T}^+ | w(T, \psi) \pi^*_n (\xi_{T^*}(\psi)))$.

where $\mathbb{T}$ is the tree obtained by removing the leg $n$ from $T$. Finally, this matches the contribution

$$(\mathbb{T}, \psi) \pi^*_n (\xi_{\mathbb{T}}(\psi)),$$

to $\pi^*_n(\mathbb{Z}(n - 1, i, j + 1))$ in the left-hand side of (5.4). Indeed, recall that $h_0$ is incident to $v_n$ in $T$, and $i \leq n - 2$. In particular, removing the leg $n$ in $T$ does not affect the computation of the capacities of the head half-edges, as defined in (0.5). It follows that $(T, \psi)$ and $(\mathbb{T}, \psi)$ have the same $i$-weightings, hence $w(T, \psi) = w(\mathbb{T}, \psi)$. Also, one has $|H^+(T)| = |H^+(\mathbb{T})|$

Similarly to Subcase 1, there are no contributions to the cycles $E_I(i, j)$. Hence such decorated trees have equal contributions to the two sides of (5.4).

This concludes the discussion of the case $(T, \psi, w) \in A_{0,n+1}^i$.

**Contributions from $B_{0,n+1}^i \sqcup C_{0,n+1}^i$.** Consider $(T, \psi, w) \in B_{0,n+1}^i \sqcup C_{0,n+1}^i$ contributing to $Z^I(n, i, j)$. We define a subset $P_{T,\psi,w}$ of $B_{0,n+1}^i \sqcup C_{0,n+1}^i$ assigned to $(T, \psi, w)$, and use the inductive hypothesis to show that the sum of the contributions of the triples in $P_{T,\psi,w}$ to $Z^I(n, i, j)$ is equivalent to a contribution to the left-hand side of (5.4).

To define the set $P_{T,\psi,w}$, we proceed as follows. Consider

$T^{\text{ext}} :=$ the maximal connected subtree of $T$

containing the leg $n$, but not containing $h_0$.

Let $n^{\text{ext}}$ be the number of legs of $T$ within $T^{\text{ext}}$. One has $n^{\text{ext}} < n$.

Define $T^{\text{int}}$ to be the complement of $T^{\text{ext}}$ in $T$. There is a unique edge in $E(T)$ with tail half-edge in $T^{\text{int}}$ and head half-edge in $T^{\text{ext}}$. Let $h_0^{\text{ext}}$ be such head half-edge in $T^{\text{ext}}$.

The set $H^+(T^{\text{ext}})$ is the restriction of $H^+(T)$ to $T^{\text{ext}}$, and define similarly $H^+(T^{\text{int}})$ as the restriction of $H^+(T)$ to $T^{\text{int}}$. One has

$$H(T) = H(T^{\text{ext}}) \sqcup H(T^{\text{int}}).$$
Factoring $\psi$ as $\psi = \prod_{h \in H(T)} \psi^d_h$, consider its restrictions

$$\psi^\text{ext} := \prod_{h \in H(T)\text{ext}} \psi^d_h$$

and

$$\psi^\text{int} := \prod_{h \in H(T)\text{int}} \psi^d_h$$

to $T\text{ext}$ and $T\text{int}$, respectively. One has $\psi = \psi^\text{int} \psi^\text{ext}$. This induces the partition

$$H(T, \psi) = H(T, \psi^\text{int}) \sqcup H(T, \psi^\text{ext}).$$

The $i$-weighting $w$ in $W_i^T,\psi$ is the union of two functions

$$w = w^\text{int} \sqcup w^\text{ext},$$

where $w^\text{int}$ and $w^\text{ext}$ are the restrictions of $w$ to $H(T^\text{int}, \psi^\text{int})$ and $H(T^\text{ext}, \psi^\text{ext})$, respectively. One has

$$(5.19) \quad w^\text{int} \in W_{T,\psi^\text{int}}^{i,a} \quad \text{and} \quad w^\text{ext} \in W_{T,\psi^\text{ext}}^{a}$$

for some $a$.

Here, $W_{T,\psi^\text{int}}^{i,a}$ is as in (3.2), with the tail half-edge $\iota(h^{\text{ext}})$ in $T^\text{int}$ playing the role of the first leg in (3.2), and $W_{T,\psi^\text{ext}}^{a}$ is as in (3.3).

The function $w^\text{int}$ gives a lower bound for $a$. For this, consider the tail $h^- := \iota(h^{\text{ext}})$ which is half of the edge connecting $T^\text{int}$ and $T^\text{ext}$. If $d^-$ is the degree of $\psi^- \in \psi$, let

$$(5.20) \quad a_0 := w^\text{int} \left(h^-, d^-ight).$$

By the definition of the weighting $w$, one has $w^\text{ext}(h^{\text{ext}}, 0) = a$ for some $a > a_0$.

Since $(T, \psi, w)$ is in $B_{0,n+1}^i \sqcup C_{0,n+1}^i$, one has that $w^\text{ext}$ is an $a$-weighting of $(T^\text{ext}, \psi^\text{ext})$, for some $a$, satisfying the property (5.3).

The set $P_{T,\psi, w}$ consists of those triples $(T', \psi', w')$ in $B_{0,n+1}^i \sqcup C_{0,n+1}^i$ contributing to $Z^i(n, i, j)$ which are obtained by fixing $T^\text{int}, \psi^\text{int}, w^\text{int}$, and varying $T^\text{ext}, \psi^\text{ext}, w^\text{ext}$. Namely, define $P_{T,\psi, w} \subseteq B_{0,n+1}^i \sqcup C_{0,n+1}^i$ as

$$P_{T,\psi, w} := \left\{ (T', \psi', w') \left| T^\text{int} = T^\text{int}, \quad \psi^\text{int} = \psi^\text{int}, \quad w^\text{int} = w^\text{int}, \quad \deg \xi_{T'}(\psi') = n - 1 + j - i \quad \text{in} \ A^*(\mathcal{M}_{0,n+1}) \right. \right\}.$$ 

Since $P_{T,\psi, w} \subseteq B_{0,n+1}^i \sqcup C_{0,n+1}^i$, for each $(T', \psi', w')$ in $P_{T,\psi, w}$ one has that

$$w^\text{ext} \in W_{T^\text{ext},\psi^\text{ext}}^{a}$$

for some $a > a_0$

and $w^\text{ext}$ satisfies the property (5.3).

The sum of the contributions of all $(T', \psi', w')$ in $P_{T,\psi, w}$ to $Z^i(n, i, j)$ consists of the following term:

$$(5.21) \quad \sum_{(T', \psi', w') \in P_{T,\psi, w}} (-1)^{|H^+(T')}| w'(T', \psi') \xi_{T'}(\psi').$$

We need to show that (5.21) is equivalent to a contribution to the left-hand side of (5.4). For this, we first rewrite (5.21) so that we can apply the inductive hypothesis for the triples $(T^\text{ext}, \psi^\text{ext}, w^\text{ext})$. 

For \((T', \psi', w') \in P_{T, \psi, w}\), the \(i\)-weighting \(w' \in W_{T', \psi'}\) is the union of two functions \(w' = w^{\text{int}} \sqcup w^{\text{ext}}\) such that

\[ w^{\text{int}} \in W_{T^{\text{int}}, \psi^{\text{int}}}^{i, a} \quad \text{and} \quad w^{\text{ext}} \in W_{T^{\text{ext}}, \psi^{\text{ext}}}^{a}\]

for some \(a > a_0\) as in (5.19). From (3.5), the corresponding \(i\)-weight of \((T', \psi')\) factors as

\[ w'(T', \psi') = w^{\text{int}}(T^{\text{int}}, \psi^{\text{int}}) w^{\text{ext}}(T^{\text{ext}}, \psi^{\text{ext}}). \]

We can thus rewrite (5.21) as

\[ w^{\text{int}}(T^{\text{int}}, \psi^{\text{int}}) \sum_{(T', \psi', w') \in P_{T, \psi, w}} (-1)^{|H^+(T')}| w^{\text{ext}}(T^{\text{ext}}, \psi^{\text{ext}}) \xi_{T'}(\psi'). \]

One has

\[ (5.23) \quad H^+(T') = H^+(T^{\text{int}}) \sqcup H^+(T^{\text{ext}}). \]

Moreover, each map \(\xi_{T'}\) factors as \(\xi_{T'} = \zeta_T \circ \xi_{T^{\text{ext}}}\), where

\[ \zeta_T : \overline{M}_{0, n^{\text{ext}}+1} \times \prod_{v \in V(T^{\text{int}})} \overline{M}_{0, n(x)} \to \overline{M}_{0, n+1} \]

is the gluing map of degree one defined by \(T^{\text{int}}\) and the edge connecting \(T^{\text{int}}\) and \(T^{\text{ext}}\). Hence we have

\[ (5.24) \quad \xi_{T'}(\psi') = \zeta_T(\psi^{\text{int}}) \xi_{T^{\text{ext}}}^{\ast}(\psi^{\text{ext}}). \]

By definition of the truncated cycles \(Z^t(n^{\text{ext}}, a, b)\), we have

\[ (5.25) \quad \sum_{(T', \psi', w') \in P_{T, \psi, w}} (-1)^{|H^+(T^{\text{ext}})|} w^{\text{ext}}(T^{\text{ext}}, \psi^{\text{ext}}) \xi_{T^{\text{ext}}}^{\ast}(\psi^{\text{ext}}) = \sum_{a > a_0} Z^t(n^{\text{ext}}, a, b) \]

where for each \(a\), the number \(b\) is determined by

\[ n^{\text{ext}} - 1 + b - a = \deg \xi_{T^{\text{ext}}}^{\ast}(\psi^{\text{ext}}). \]

Since \(W_{T^{\text{ext}}, \psi^{\text{ext}}}^{a} = \emptyset\) for \(a \geq n^{\text{ext}}\), the sum on the right-hand side of (5.25) is finite.

Using (5.23), (5.24), and (5.25), it follows that (5.22) can be rewritten as

\[ (5.26) \quad (-1)^{|H^+(T^{\text{int}})|} w^{\text{int}}(T^{\text{int}}, \psi^{\text{int}}) \sum_{a > a_0} \zeta_T(\psi^{\text{int}}) Z^t(n^{\text{ext}}, a, b). \]

Formula (5.26) expresses the term of the right-hand side of (5.4) contributed by all triples in \(P_{T, \psi, w}\).

Since \(n^{\text{ext}} < n\), the induction hypothesis together with Lemma 5.6 for \(n^{\text{ext}}\) imply that for each \(a\), one has

\[ (5.27) \quad \pi^{\ast}_{n^{\text{ext}}}(Z(n^{\text{ext}} - 1, a, b + 1)) - \sum_I |I| E_I(a, b) = Z^t(n^{\text{ext}}, a, b) \]
in $A^{\text{ext}}_{n-1+b-a}(\mathcal{M}_{0,n-1})$. In the above sum, $I$ ranges over all non-empty subsets of the restriction of the set of legs $L(T) \setminus \{n\}$ to $T^{\text{ext}}$.

Using (5.27) to replace $Z^{\text{ext}}(n^{\text{ext}}, a, b)$ in (5.26), we have that the term of the right-hand side of (5.4) contributed by all triples $(T', \psi', w')$ in $\mathcal{P}_{T, \psi, w}$ is

\begin{equation}
(5.28) \quad (-1)^{|H^+(T^{\text{int}})|} w^{\text{int}}(T^{\text{int}}, \psi^{\text{int}}) \times \sum_{a > a_0} \zeta_{T^*} \left( \psi^{\text{int}} \left( \pi_{n^{\text{ext}}}^{\text{int}}(Z(n^{\text{ext}} - 1, a, b + 1)) - \sum I |E_I(a, b)\right) \right). 
\end{equation}

Next, we verify that (5.28) matches a contribution to the left-hand side of (5.4). For this, we proceed by considering four subcases. This will conclude the proof of Claim 5.7.

Let $(T', \psi', w') \in \mathcal{P}_{T, \psi, w}$. Let $v'_n$ be the vertex of $T'$ incident to the leg $n$, and $h'_n$ be the head half-edge incident to $v'_n$. Let $T^{\text{ext}}_0$ be the maximal subtree of $T^{\text{ext}}$ containing $v'_n$ such that for every vertex $v$ of $T^{\text{ext}}$, the sum of the degrees of $\psi_h$ in $\psi'$ for $h$ incident to $v$ is $\text{valence}(v) - 3$. In particular, one has $T^{\text{ext}}_0 \neq \emptyset$ if and only if the sum of the degrees of $\psi_h$ in $\psi'$ for $h$ incident to $v'_n$ is equal to $\text{valence}(v'_n) - 3$. For instance, $T^{\text{ext}}_0 \neq \emptyset$ when $v'_n$ is trivalent — in this case, the degree of $\psi_h$ in $\psi'$ for $h$ incident to $v'_n$ is necessarily zero, otherwise $\xi_{T^*}(\psi') = 0$.

\textbf{Subcase 3.} Assume first that $T^{\text{ext}}_0 \neq \emptyset$, and if trivalent, then $v'_n$ is adjacent only to vertices in $T^{\text{ext}}_0$. Moreover, assume that $v'_n$ is not trivalent and external in $T'$ — the case when $v'_n$ is trivalent and external will be treated in Subcase 5. Following the proof of Lemma 5.5, there is no contribution from such $(T', \psi')$ to the left-hand side of (5.4). Indeed, the conditions that $T^{\text{ext}}_0 \neq \emptyset$ and a trivalent $v'_n$ be adjacent only to vertices in $T^{\text{ext}}_0$ imply that such a decorated tree does not contribute to $\pi_{n^{\text{ext}}}^*(Z(n - 1, i, j + 1))$; moreover, the conditions that $T^{\text{ext}}_0 \neq \emptyset$ and $v'_n$ is not trivalent and external in $T'$ imply that such a decorated tree does not contribute to the cycles $E_I(i, j)$. Similarly, the decorated tree $(T^{\text{ext}}', \psi'^{\text{ext}})$ does not contribute to the left-hand side of (5.27). Hence, the decorated tree $(T', \psi')$ contributes neither to the left-hand side of (5.4), nor to (5.28), as desired.

\textbf{Subcase 4.} Consider $(T', \psi', w') \in B_{0,n+1}$. Then from (5.13), $(T', \psi')$ does not contribute to the classes $E_I(i, j)$ in the left-hand side of (5.4). Assume that either $T^{\text{ext}}_0 = \emptyset$, or $v'_n$ is trivalent and adjacent to at least one vertex not in $T^{\text{ext}}_0$. In these cases, $(T', \psi')$ contributes to $\pi_{n^{\text{ext}}}^*(Z(n - 1, i, j + 1))$ in the left-hand side of (5.4).

When $T^{\text{ext}}_0 = \emptyset$, the total contribution of $(T', \psi')$ to the left-hand side of (5.4) is

\begin{equation}
(5.29) \quad (-1)^{|H^+(T')|} \xi_{T^*}(\psi').
\end{equation}
where \((\mathbf{T}', \psi')\) is the decorated tree with \(\mathbf{T}'\) obtained by removing the leg \(n\) from \(T'\). Similarly, consider the decorated tree \((\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}})\) where \(\mathbf{T}'^{\text{ext}}\) is the graph obtained by removing the leg \(n\) from \(T'^{\text{ext}}\).

The term in (5.29) can be decomposed as follows. As in (5.19), an \(i\)-weighting of \((\mathbf{T}', \psi')\) decomposes as \(\overline{w} = w^{\text{int}} \cup \overline{w}^{\text{ext}}\), where \(w^{\text{int}}\) is an \(i\)-weighting of \((\mathbf{T}^{\text{int}}, \psi^{\text{int}})\) and \(\overline{w}^{\text{ext}}\) is an \(a\)-weighting of \((\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}})\) for some \(a\). Hence, we have

\[
\tilde{c}_{\mathbf{T}', \psi'} = \sum_{w^{\text{int}}} w^{\text{int}} (\mathbf{T}^{\text{int}}, \psi^{\text{int}}) \sum_{a > a_0} \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi').
\]

The number \(a_0\) is determined by each \(w^{\text{int}}\), as in (5.20).

Fixing \(w^{\text{int}}\), consider the triples \((T', \psi', \overline{w}')\) for all \(\overline{w}'\) whose restriction to \((\mathbf{T}^{\text{int}}, \psi^{\text{int}})\) is \(w^{\text{int}}\). Restricting (5.29), the contribution of all such triples to the left-hand side of (5.4) is

\[
w^{\text{int}} (\mathbf{T}^{\text{int}}, \psi^{\text{int}}) \sum_{a > a_0} (-1)^{|\mathcal{H}^{\text{int}}(T')|} \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi').
\]

Using (5.23) and (5.24), this is

\[
(-1)^{|\mathcal{H}^{\text{int}}(T')|} w^{\text{int}} (\mathbf{T}^{\text{int}}, \psi^{\text{int}}) \times \sum_{a > a_0} \xi_{\mathbf{T}^{\text{int}}, \psi^{\text{int}}} (w^{\text{int}}) (-1)^{|\mathcal{H}^{\text{ext}}(\overline{w}')|} \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi'^{\text{ext}}).
\]

This formula gives the contribution to the left-hand side of (5.4) of the triples \((T', \psi', \overline{w}')\) for all \(\overline{w}'\) whose restriction to \((\mathbf{T}^{\text{int}}, \psi^{\text{int}})\) is \(w^{\text{int}}\). Here the term

\[
(-1)^{|\mathcal{H}^{\text{ext}}(\overline{w}')|} \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi'^{\text{ext}})
\]

matches the contribution of \((\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}})\) to \(\pi^{\text{ext}}_{\mathbf{T}'^{\text{ext}}} (\mathbf{Z}(n^{\text{ext}} - 1, a, b + 1))\).

It follows that the contribution to the left-hand side of (5.4) of the triples \((T', \psi', \overline{w}')\) for all \(\overline{w}'\) with fixed \(w^{\text{int}}\) matches the contribution to (5.28) of \((T', \psi', w')\) for all \(w'\) with fixed \(w^{\text{int}}\), as desired.

When \(v'_n\) is trivalent, the term in (5.29) has to be replaced by

\[
(-1)^{|\mathcal{H}^{\text{int}}(T')|} \left( c_{\mathbf{T}', \psi^{+}} + c_{\mathbf{T}', \psi^{-}} \right) \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi'.
\]

where: the tree \(\mathbf{T}'\) is obtained from \(T'\) by removing the leg \(n\) and contracting an edge to stabilize; the decoration \(\psi^{+}\) is defined so that \(\psi'\) is obtained from \(\psi^{+}\) as in (5.9); and \(\psi^{-}\) is defined so that \(\psi'\) is obtained from \(\psi^{-}\) as in (5.12). If \(v'_n\) is trivalent and adjacent to \(v_0\), then the contribution \(c_{\mathbf{T}', \psi^{-}} \xi_{\mathbf{T}'^{\text{ext}}, \psi'^{\text{ext}}}(\psi')\)

arises as in (5.17), and so it has already been discussed in Subcases 1–2. For all the other contributions, the argument then continues as in the case when \(T'^{\text{ext}} = \emptyset\).

**Subcase 5.** Next, consider \((T', \psi', w') \in \mathcal{C}_{0, n+1}\), and assume that \(v'_n\) is trivalent and external in \(T'\). In this case, \((T', \psi')\) contributes to the class \(\mathcal{E}_I(i, j)\)
such that $\mathcal{I} \sqcup \{n\}$ is the set of the two legs incident to $v'_n$, but does not contribute to the class $\pi^*_n(\mathcal{Z}(n-1, i, j+1))$ in the left-hand side of (5.4). Using (3.21), it follows that the total contribution of $(\mathcal{T}', \psi')$ to the left-hand side of (5.4) is

$$
(5.32) \quad - (-1)^{|\mathcal{H}^+|} \cdot |\mathcal{I}| \sum_{a > a_0} d_{T', \psi'}^a \xi_{T's} (\psi').
$$

As in (5.30), we have

$$
d_{T', \psi'}^a = \sum w^{\text{int}} \left( T^{\text{int}}, \psi^{\text{int}} \right) \sum_{a > a_0} d_{T'^{\text{ext}}, \psi'^{\text{ext}}}^a.
$$

Here as well, the number $a_0$ is determined by each $w^{\text{int}}$ as in (5.20). Using this with (5.23) and (5.24), the contribution to the left-hand side of (5.4) of $(\mathcal{T}', \psi')$ for a fixed $w^{\text{int}}$ becomes

$$
(5.33) \quad - (-1)^{|\mathcal{H}^+|} \cdot |\mathcal{I}| \sum_{a > a_0} \xi_{T's} \left( \psi^{\text{int}} \right) (-1)^{|\mathcal{H}^+|} \cdot |\mathcal{I}| \sum_{a > a_0} d_{T'^{\text{ext}}, \psi'^{\text{ext}}}^a \xi_{T'^{\text{ext}}s} (\psi'^{\text{ext}}).
$$

This is the summand of (5.32) corresponding to a fixed $w^{\text{int}}$. Here the term

$$
(5.33) \quad - (-1)^{|\mathcal{H}^+|} \cdot |\mathcal{I}| \sum_{a > a_0} d_{T'^{\text{ext}}, \psi'^{\text{ext}}}^a \xi_{T'^{\text{ext}}s} (\psi'^{\text{ext}})
$$

matches the contribution of $(\mathcal{T}'^{\text{ext}}, \psi'^{\text{ext}})$ to $-|\mathcal{I}| \mathcal{E}_I(a, b)$.

Hence the contribution to the left-hand side of (5.4) of $(\mathcal{T}', \psi')$ for a fixed $w^{\text{int}}$ matches the contribution to (5.28) of $(\mathcal{T}', \psi')$ for a fixed $w^{\text{int}}$, as desired.

**Subcase 6.** Finally, it remains to discuss the case when $(\mathcal{T}', \psi', w') \in \mathcal{C}_{0,n+1}$ and the external vertex $v'_n$ has valence at least four. In this case, $(\mathcal{T}', \psi')$ contributes both to $\pi^*_n(\mathcal{Z}(n-1, i, j+1))$ and to the cycle $\mathcal{E}_I(i, j)$ where $\mathcal{I} \sqcup \{n\}$ is the set of the legs incident to $v'_n$. Then, the total contribution of $(\mathcal{T}', \psi')$ to the left-hand side of (5.4) is

$$
(5.33) \quad - (-1)^{|\mathcal{H}^+|} \left( \xi_{\mathcal{T}'s} + |\mathcal{I}| \sum_{a > a_0} d_{T', \psi'}^a \xi_{T's} (\psi') \right).
$$

This is the sum of terms similar to (5.29) and (5.32). Hence, as above, for a fixed $w^{\text{int}}$ this reduces to the sum of (5.31) and (5.33), and this matches the contribution to (5.28), as desired.

This concludes the proof of Claim 5.7. △

Finally, we show the following.

**Claim 5.8.** Part (b) for $n-1$ and part (a) for $n$ imply part (b) for $n$.

**Proof of Claim 5.8.** As argued at the beginning of the proof of Theorem 5.1, one can assume that $1 \leq j < i < n$, since the vanishing of $\mathcal{Z}(n, i, j)$ and $\mathcal{Z}(n, i, j)$ is otherwise trivial.

For $2 \leq i \leq n-2$, assume part (b) for $n-1$. Specifically, assume the vanishing $\mathcal{Z}(n-1, i, j) = 0$ in $A^{n-1+j-i}(\mathcal{M}_{0,n})$ for $j \geq 1$. Using Theorem 3.1, this implies the vanishing of all cycles $\mathcal{Z}'(n-m, i, j)$ obtained from
$Z(n - 1, i, j)$ by colliding points. Using (3.22), by pushing forward, this implies the vanishing of all cycles $E_I(i, j)$ in $A^{n - 1 + j - i}(\overline{M}_{0,n+1})$ for $j \geq 1$.

Then part (a) for $n$ implies

$$Z(n, i, j) = 0 \text{ in } A^{n - 1 + j - i}(\overline{M}_{0,n+1}) \text{ for } 1 \leq j < i \leq n - 2.$$  

(5.34)

We note that in part (a) with $j = 0$, while $Z(n-1, i, 1)$ vanishes, the cycles $E_I(i, 0)$ are non-zero, and so is $Z^t(n, i, 0)$.

Regarding the cycle $Z(n, i, j)$, the vanishing

$$Z(n, i, j) = 0 \text{ in } A^{n - 1 + j - i}(\overline{M}_{0,n+1}) \text{ for } 1 \leq j < i \leq n - 2$$

follows from Lemma 5.3, (5.34), and the vanishing of $Z(n - 1, i^+, j^+)$ for $i^+ > i$ and $j^+ - i^+ = j - i$. Indeed, since $j^+ \geq 1$ for all $i^+ > i$ and $j \geq 1$, the cycles $Z(n - 1, i^+, j^+)$ in Lemma 5.3 vanish by the induction hypothesis.

It remains to establish the case $i = n - 1$, i.e., the vanishing of $Z^t(n, n - 1, j)$ and $Z(n, n - 1, j)$ in $A^j(\overline{M}_{0,n+1})$ for $1 \leq j \leq n - 2$. First we note that $Z^t(n, n - 1, j) = Z(n, n - 1, j)$, since for any $i$-weighting $w$ with $i = n - 1$, one has that $w(h_0, 0) = n - 1$ is the maximal value of $w$, hence the condition (5.3) is automatically satisfied. The case $j = 1$ is proven by Lemma 4.3. For $j \geq 2$, assume the vanishing of $Z(n, n - 1, j - 1)$. The case $i = n - 2$ discussed above establishes the vanishing of $Z(n, n - 2, j - 1)$. Then Lemma 4.4 implies the vanishing of $Z(n, n - 1, j)$ in $A^j(\overline{M}_{0,n+1})$. Hence the case $i = n - 1$ follows for all $j \geq 1$.

This concludes the proof of Claim 5.8. \quad \Box

Combining Claims 5.7 and 5.8, Theorem 5.1 follows by induction. \quad \Box

6. Colliding points on rational tail trees

We introduce the cycle $F^k_{g,m}$ in Definition 6.1 generalizing $F^k_{g,n}$ from Definition 1. As shown in Theorem 6.2, $F^k_{g,m}$ is obtained from a cycle $F^k_{g,n}$ by colliding marked points. The cycle $F^k_{g,m}$ will feature in Theorem 7.1, a generalization of Theorem 2.

Let $m = (m_1, \ldots, m_n)$ be an $n$-tuple of positive integers. Let $g > 0$ and $\Gamma \in \mathcal{G}^r_{g,n}$. The $n$-tuple $m$ induces a weight on the legs of $\Gamma$, i.e., let the leg $\ell$ have weight $m_\ell$ for all $\ell = 1, \ldots, n$.

Define the set of decorations $\Psi(\Gamma)$ of the graph $\Gamma$ as

$$\Psi(\Gamma) := \left\{ \psi = \prod_{\ell=1}^n \psi^d_{\ell} \prod_{h \in H(\Gamma)} \psi^d_{h} \bigg| \begin{array}{c} d_h \geq 0 \text{ for all } h, \\
\quad d_\ell \geq 0 \text{ for all } \ell \end{array} \right\} \subset A^*(\overline{M}_\Gamma).$$

Let $\psi = \prod_{\ell=1}^n \psi^d_{\ell} \prod_{h \in H(\Gamma)} \psi^d_{h}$ in $\Psi(\Gamma)$, and define accordingly the set $H(\Gamma, \psi)$ as

$$H(\Gamma, \psi) := \{(\ell, e) \mid \ell \in L(\Gamma), 1 \leq e \leq d_\ell \}$$
$$\quad \cup \{(h, e) \mid h \in H^{-}(\Gamma), 1 \leq e \leq d_h \}$$
$$\quad \cup \{(h, e) \mid h \in H^{+}(\Gamma), 0 \leq e \leq d_h \}.$$
One has $|H(\Gamma, \psi)| = |E(\Gamma)| + \deg \psi$.

For a half-edge $h$ of $\Gamma$, let $\imath(h)$ be the half-edge such that $(h, \imath(h)) \in E(\Gamma)$. For $h^+ \in H^+(\Gamma)$, define the weighted capacity $\ell^m_{h^+}$ of $h^+$ as:

$$\ell^m_{h^+} := \begin{cases} \text{sum of the weights of the legs of } \Gamma \text{ in the maximal} \\ \text{connected subtree containing } h^+, \text{ but not } \imath(h^+). \end{cases}$$

The set of weightings of $(\Gamma, \psi)$ compatible with the legs weight is

$$\mathcal{W}^m_{\Gamma, \psi} := \left\{ w : H(\Gamma, \psi) \to \mathbb{N} : \begin{align*} &\ell^m_{h^+} - 1 \geq w(h^+, 0) \geq w(h^+, 1) \geq \cdots \geq w(h^+, d_{h^+}) \\ &\text{for all heads } h^+, \\ &1 \leq w(h^-, 1) < \cdots < w(h^-, d_{h^-}) < w(\imath(h^-), 0) \\ &\text{for all tails } h^-, \\ &1 \leq w(\ell, 1) < \cdots < w(\ell, d_{\ell}) < m_{\ell} \\ &\text{for all legs } \ell \end{align*} \right\}.$$ 

One has

(6.1) \quad \text{if } \mathcal{W}^m_{\Gamma, \psi} \neq \emptyset, \text{ then } d_{\ell} < m_{\ell} \text{ for all legs } \ell.

For each leg $\ell$, the inequality $d_{\ell} < m_{\ell}$ follows from the conditions on $w(\ell, e)$ for $e = 1, \ldots, d_{\ell}$.

For $w \in \mathcal{W}^m_{\Gamma, \psi}$, the corresponding weight of $(\Gamma, \psi)$ is

$$w(\Gamma, \psi) := \prod_{(h, e) \in H(\Gamma)} w(h, e).$$

Define the coefficient $c^m_{\Gamma, \psi}$ as:

$$c^m_{\Gamma, \psi} := \sum_{w \in \mathcal{W}^m_{\Gamma, \psi}} w(\Gamma, \psi).$$

For $\psi = \prod_{\ell=1}^n \psi^d_{\ell} \prod_{h \in H(\Gamma)} \psi^d_h$ in $\Psi(\Gamma)$, define

$$\beta^m_{\Gamma, \psi} := \prod_{\ell=1}^n (k \omega_\ell - \eta)^{d_{\ell}} \prod_{h \in H^+(\Gamma)} (k \omega_h - \eta)^{1+d_h} \prod_{h \in H^-(\Gamma)} (k \omega_h - \eta)^{d_h}$$

in $R^* \left( \mathbb{P}^{k}_{g,m} \right)$. One has $\deg \beta^m_{\Gamma, \psi} = |E(\Gamma)| + \deg \psi$.

**Definition 6.1.** For $m = (m_1, \ldots, m_n)$ with $n^+ := \sum_{\ell=1}^n m_{\ell}$, define $\mathcal{F}^k_{g,m}$ in $R^{n^+} \left( \mathbb{P}^{k}_{g,m} \right)$ as

$$\mathcal{F}^k_{g,m} := \sum_{\Gamma \in \mathcal{G}_{g,m}} (-1)^{|E(\Gamma)|} \xi^m_{\Gamma, \psi} \left[ \prod_{\ell=1}^n (k \omega_\ell - \eta)^{m_{\ell}} \sum_{\psi \in \Psi(\Gamma)} c^m_{\Gamma, \psi} \beta^{-1}_{\Gamma, \psi} \right].$$

For $m = (1, \ldots, 1) = 1^n$, the cycle $\mathcal{F}^k_{g,m}$ specializes to the cycle $\mathcal{F}^k_{g,n}$ from Definition 1.
Theorem 6.2. The cycle \( F_{g,m}^k \) in \( R^{n^+} \left( \mathbb{P} \mathbb{E}_{g,n}^k \right) \) is obtained from \( F_{g,n}^k \) in \( R^{n^+} \left( \mathbb{P} \mathbb{E}_{g,n}^k \right) \) by colliding the first \( m_1 \) marked points into the marked point \( P_1 \), the next \( m_2 \) marked points into the marked point \( P_2 \), etc.

Proof. The argument is similar to the one for Theorem 3.1. Here, trees have a positive genus vertex, and more than one leg can be decorated with \( \psi \)-classes. However, these differences do not basically alter the argument used for Theorem 3.1.

Namely, it is enough to show that the cycle \( F_{g,m}^k \) in \( R^{n^+} \left( \mathbb{P} \mathbb{E}_{g,n}^k \right) \) for

\[
m = (m_1, \ldots, m_{i-1}, m_i, 1^{n-i}) \quad \text{with} \quad i \leq n
\]

is obtained from \( F_{g,m^-}^k \) in \( R^{n^+} \left( \mathbb{P} \mathbb{E}_{g,n+1}^k \right) \) with

\[
m^- := (m_1, \ldots, m_{i-1}, m_i - 1, 1^{n-i+1})
\]

by colliding the points \( P_i \) and \( P_{i+1} \). Here \( 1^a = (1, \ldots, 1) \) is an \( a \)-tuple of elements 1 for \( a \geq 0 \). In other words, we show that

\[
(6.2) \quad \pi_{i+1*} \left( \delta_{0;\{i,i+1\}} \cdot F_{g,m^-}^k \right) = F_{g,m}^k \subset R^{n^+} \left( \mathbb{P} \mathbb{E}_{g,n}^k \right)
\]

where \( \pi_{i+1}: \mathbb{P} \mathbb{E}_{g,n+1}^k \rightarrow \mathbb{P} \mathbb{E}_{g,n}^k \) is the map obtained by forgetting the point \( P_{i+1} \), and \( \delta_{0;\{i,i+1\}} \) is the class of the divisor in \( \mathbb{P} \mathbb{E}_{g,n+1}^k \) which is the preimage of the divisor in \( \overline{M}_{g,n+1} \) whose general element is a nodal curve with two components such that one component is rational and contains only two marked points, namely \( P_i \) and \( P_{i+1} \).

The non-zero terms arising in the expansion of the left-hand side of (6.2) are obtained by colliding \( P_i \) and \( P_{i+1} \) on the terms of \( F_{g,m^-}^k \) contributed by decorated graphs where the legs \( i \) and \( i + 1 \) are incident to the same vertex, say \( v_i \). The argument then continues as in the proof of Theorem 3.1. Namely, the contributions to the left-hand side of (6.2) obtained by decorated graphs where the valence of \( v_i \) is three match the contributions to \( F_{g,m}^k \) where the degree of \( \psi_i \) is positive, as in Case 1 of the proof of Theorem 3.1. Similarly, the contributions to the left-hand side of (6.2) obtained by decorated graphs where the valence of \( v_i \) is at least four match the contributions to \( F_{g,m}^k \) where the degree of \( \psi_i \) is zero, as in Case 2 of the proof of Theorem 3.1. The statement follows. \( \square \)

7. Proof of Theorem 2

Here we complete the proof of Theorem 2. We prove more generally the following statement. Given an \( n \)-tuple \( m = (m_1, \ldots, m_n) \) of positive integers, define

\[
(7.1) \quad \mathbb{H}_{g,m}^k \subset \mathbb{P} \mathbb{E}_{g,n}^k
\]

as the locus consisting of stable \( n \)-pointed genus \( g \) curves \( (C, P_1, \ldots, P_n) \) together with the class of a stable \( k \)-differential having a zero of order at least \( m_\ell \) at the marked point \( P_\ell \) for each \( \ell = 1, \ldots, n \).
Let \( n^+ := |m| = \sum_{\ell=1}^n m_\ell \). Unless \( k \geq 2 \), \( n^+ = k(2g - 2) \) and \( k \mid m_\ell \) for all \( \ell \), the locus \( \mathbb{H}^k_{g,m} \) has pure codimension \( n^+ \) in \( \mathbb{P} \mathcal{E}^k_{g,n} \).

For \( m = (1, \ldots, 1) = 1^n \), the locus \( \mathbb{H}^k_{g,m} \) specializes to \( \mathbb{H}^k_{g,n} \) from (0.1).

**Theorem 7.1.** Let \( g \geq 2 \) and \( m = (m_1, \ldots, m_n) \) with \( |m| = n^+ \). One has

\[
\left[ \mathbb{H}^k_{g,m} \right] = F^k_{g,m}
\]

in:

(i) \( A^{n^+} \left( \mathbb{P} \mathcal{E}^k_{g,n} \mid \mathcal{M}^g_{g,n} \right) \) when

\[
\left\{ \begin{array}{ll}
   k = 1; & \text{or} \\
   k \geq 2 \text{ and } n^+ \leq k(2g - 2) - 1; 
\end{array} \right.
\]

(ii) \( A^{n^+} \left( \mathbb{P} \mathcal{E}^k_{g,n} \right) \) when \( n^+ \leq k \).

One recovers Theorem 2 when \( m = (1, \ldots, 1) = 1^n \). When \( k = 1 \) and \( n^+ = 2g - 2 \), the statement gives all strata classes in the projectivized Hodge bundle over curves with rational tails.

Sometimes, the locus (7.1) is the union of multiple components. In this case, (7.2) implies that all components have the same dimension, and the class given in Theorem 7.1 is a weighted sum of the classes of the components. For instance, see the example in (8.3)–(8.4).

The key steps of the proof are provided by Theorems 2.9, 5.4, 6.2, and the next Theorem 7.2. This next statement is a recursive identity about the cycle \( F^k_{g,n} \) which is the counterpart of Theorem 2.9. For this, we first define the cycles \( E_I \). For a non-empty \( I \subseteq \{1, \ldots, n-1\} \) of size \( |I| = m \), recall the gluing map of degree one

\[
\gamma: \mathbb{P} \mathcal{E}^k_{g,n-m} \times \overline{\mathcal{M}}_{0,|I|+\{n\}} \to \mathbb{P} \mathcal{E}^k_{g,n}
\]

from (2.2). Let

\[
E_I := \gamma_* F^k_{g,m} \quad \text{where} \quad m = (m,1^{n-m-1}).
\]

Recall the map \( \pi_n: \mathbb{P} \mathcal{E}^k_{g,n} \to \mathbb{P} \mathcal{E}^k_{g,n-1} \) obtained by forgetting the point \( P_n \), and the map \( \rho_n: \mathbb{P} \mathcal{E}^k_{g,n} \to \mathbb{P} \mathcal{E}^k_{g,1} \) obtained by forgetting all but the point \( P_n \).

**Theorem 7.2.** For \( n \geq 2 \), one has

\[
\pi_n^* \left( F^k_{g,n-1} \right) \cdot \rho_n^* \left( F^k_{g,1} \right) - \sum_I \left| I \right| E_I = F^k_{g,n} \in R^n \left( \mathbb{P} \mathcal{E}^k_{g,n} \right)
\]

where the sum is over all non-empty \( I \subseteq \{1, \ldots, n-1\} \).

**Proof.** We verify that the contributions of each graph \( \Gamma \) in \( \mathcal{G}^r_{g,n} \) to the two sides of (7.4) match, modulo tautological relations. For this, we distinguish two cases, depending on the position of the leg \( n \) in each graph.
In the second case, it will be convenient to expand \( F_{g,n}^{k} \in R^{n}(\mathbb{P}^{k}_{g,n}) \) as

\[
F_{g,n}^{k} = \sum_{(\Gamma, \psi, w)} (-1)^{|E(\Gamma)|} w(\Gamma, \psi) \xi_{\Gamma}^{*} \left[ \psi \beta_{\Gamma, \psi}^{-1} \prod_{\ell=1}^{n} (k \omega_{\ell} - \eta) \right]
\]

where the sum is over triples \((\Gamma, \psi, w)\) such that \(\Gamma \in G_{g,n}^{rt}, \psi \in \Psi(T), \) and \(w \in W_{\Gamma, \psi}.\) This formula follows by expanding the coefficients \(c_{\Gamma, \psi}\) in Definition 1.

**Case 1.** Consider \(\Gamma \in G_{g,n}^{rt}\) where the leg \(n\) is incident to the genus \(g\) vertex. On the left-hand side of (7.4), the graph \(\Gamma\) contributes only to \(\pi_{n}^{*}(F_{g,n}^{k} - 1) \cdot \rho_{n}^{*}(F_{g,1}^{k}),\) and using Definition 1, the contribution is

\[
(-1)^{|E(\Gamma)|} \xi_{\Gamma}^{*} \left[ \prod_{\ell=1}^{n-1} (k \omega_{\ell} - \eta) \sum_{\psi \in \Psi(\Gamma)} c_{\Gamma, \psi} \psi \beta_{\Gamma, \psi}^{-1} \right] \cdot (k \omega_{n} - \eta).
\]

Rearranging factors, this is

\[
(-1)^{|E(\Gamma)|} \xi_{\Gamma}^{*} \left[ \prod_{\ell=1}^{n} (k \omega_{\ell} - \eta) \sum_{\psi \in \Psi(\Gamma)} c_{\Gamma, \psi} \psi \beta_{\Gamma, \psi}^{-1} \right] \]

thus matching the contribution of \(\Gamma\) to \(F_{g,n}^{k}\) in the right-hand side of (7.4).

**Case 2.** Consider \(\Gamma \in G_{g,n}^{rt}\) where the leg \(n\) is incident to a rational vertex. We argue by applying Theorem 5.4 locally to a rational subgraph of \(\Gamma\) containing the leg \(n.\)

Namely, let \(T\) be the maximal rational subgraph of \(\Gamma\) which contains the leg \(n,\) and let \(\Gamma_{0} := \Gamma \setminus T\) be its complement. If \(e = (h_{0}, t_{0}) \in E(\Gamma)\) is the edge connecting the genus \(g\) vertex in \(\Gamma_{0}\) and the tree \(T,\) then the head \(h_{0}\) is in \(T\) and the tail \(t_{0} = \iota(h_{0})\) is in \(\Gamma_{0}\).

Let \(G_{\Gamma_{0}}\) be the subset of \(G_{g,n}^{rt}\) consisting of graphs obtained by fixing \(\Gamma_{0}\) and varying \(T.\) This is:

\[
G_{\Gamma_{0}} := \left\{ \tilde{\Gamma} := \Gamma_{0} \sqcup e \ T' \in G_{g,n}^{rt} \mid T' \in G_{0,n'+1} \right\}
\]

where \(n'\) is the number of legs of \(\Gamma\) within \(T.\) For each \(\tilde{\Gamma} = \Gamma_{0} \sqcup e \ T'\) in \(G_{\Gamma_{0}},\) the gluing map \(\xi_{\tilde{\Gamma}}\) from (0.10) factors as \(\xi_{\tilde{\Gamma}} = \zeta_{\Gamma} \circ \xi_{T'}\) where \(\xi_{T'}\) is as in (3.7) and

\[
\zeta_{\Gamma}: \mathcal{M}_{0,n'+1} \times \mathbb{P}^{k}_{g,n(g)} \times \prod_{v \in V_{0}(\Gamma_{0})} \mathcal{M}_{0,n(v)} \longrightarrow \mathbb{P}^{k}_{g,n}
\]

is the gluing map of degree one defined by \(\Gamma_{0}\) and the edge \(e.\) The map \(\zeta_{\Gamma}\) extends the \(k\)-differentials of elements of \(\mathbb{P}^{k}_{g,n(g)}\) by zero on the attached rational tails. Recall that \(n(g)\) is the valence of the genus \(g\) vertex, and \(V_{0}(\Gamma_{0})\) is the set of rational vertices of \(\Gamma_{0}.\)
Consider a triple \((\hat{\Gamma}, \hat{\psi}, \hat{w})\) with \(\hat{\Gamma} \in G_{\Gamma_o}, \hat{\psi} \in \Psi(\hat{\Gamma}),\) and \(\hat{w} \in W_{\hat{\Gamma}, \hat{\psi}}.\) The contribution of \((\hat{\Gamma}, \hat{\psi}, \hat{w})\) to \(F^k_{g,n}\) as given in (7.5) is

\[
(7.6) \quad (-1)^{|E(\hat{\Gamma})|} \hat{w}(\hat{\Gamma}, \hat{\psi}) \xi_{\Gamma^*} \left[ \hat{\psi} \beta_{\Gamma, \psi}^{-1} \prod_{\ell=1}^n (k \omega_{\ell} - \eta) \right].
\]

Given the decomposition \(\hat{\Gamma} = \Gamma_o \sqcup T',\) let \(\psi_o\) and \(\psi'\) be the restrictions of \(\hat{\psi}\) to \(\Gamma_o\) and \(T'\) respectively. Similarly, let \(w_0\) and \(w'\) be the restrictions of \(\hat{w}\) to \((\Gamma_o, \psi_o)\) and \((T', \psi')\), respectively. If \(d_0\) is the degree of \(\psi_{t_0}\) in \(\psi_o,\) let

\[
i_0 := w_0(t_0, d_0).
\]

By definition of the weighting \(\hat{w},\) one has that \(w'(i_0, 0) = i\) for some \(i > i_0,\) i.e., \(w' \in W_{T', \psi'}\) for some \(i > i_0.\)

Decomposing as

\[
|E(\hat{\Gamma})| = |E(\Gamma_o)| + |H^+(T')|,
\]

\[
\hat{w}(\hat{\Gamma}, \hat{\psi}) = w_0(\Gamma_o, \psi_o) w'(T', \psi'),
\]

\[
\xi_{\Gamma^*} = \xi_{\Gamma_o} \circ \xi_{T'},
\]

\[
\hat{\psi} = \psi_o \psi',
\]

\[
\beta_{\Gamma, \psi} = \beta_{\Gamma_o, \psi_o} \beta_{T', \psi'},
\]

and using the identity

\[
\xi_{\Gamma^*} \left[ \alpha \beta_{T', \psi'}^{-1} \prod_{\ell=1}^n (k \omega_{\ell} - \eta) \right] = \xi_{\Gamma^*} \left[ \alpha (k \omega_{i_0} - \eta)^{-|H'(T', \psi')|} \prod_{\ell=1}^n (k \omega_{\ell} - \eta) \right]
\]

in \(A^*(\mathbb{P}^n_{g,n(k)})\) for an arbitrary cycle \(\alpha,\) the contribution in (7.6) is

\[
(-1)^{|E(\Gamma_o)|} w_0(\Gamma_o, \psi_o) \xi_{\Gamma^*} \left[ \psi_o \beta_{\Gamma_o, \psi_o}^{-1} \prod_{\ell=1}^n (k \omega_{\ell} - \eta) \right]
\]

\[
\times (-1)^{|H^+(T')|} w'(T', \psi') \xi_{T'}(\psi') (k \omega_{i_0} - \eta)^{-|H'(T', \psi')|}.
\]

Summing over all \((\psi_o, w_0)\) and \((T', \psi', w'),\) one has

\[
(7.8) \quad \sum_{(\psi_o, w_0)} (-1)^{|E(\Gamma_o)|} w_0(\Gamma_o, \psi_o) \xi_{\Gamma^*} \left[ \psi_o \beta_{\Gamma_o, \psi_o}^{-1} \prod_{\ell=1}^n (k \omega_{\ell} - \eta) \right]
\]

\[
\times \sum_{i > i_0} \text{Dec}^{i}_{w}(k \omega_{i_0} - \eta)
\]

where for each \(i\)

\[
\text{Dec}^{i}_{w}(D) = \sum_{(T', \psi', w')} (-1)^{|H^+(T')|} w'(T', \psi') \xi_{T'}(\psi') D^{-|H'(T', \psi')|}
\]

in \(A^*(\mathbb{P}^n_{g,n'+1})\) \([D^{-1}]\), as in (3.9) with \(\text{Dec}^{i}_{w}(D) = \text{Dec}^{i,1}_{w}(D).\) The index \(i_0\) appearing in (7.8) is determined by \(w_o,\) as in (7.7).
From Theorem 5.4, we have

\[(7.9)\]
\[
\pi^*_n (\text{Dec}^i_{n'-1}(D)) - \sum_I |I| E_I(D) - \sum_{i^+ > i} i \sigma_{0*} \left( \text{Dec}^i_{n'-1}(D) \right) = \text{Dec}^i_{n'}(D).
\]

We next verify that the sum of the contributions of all \(\hat{\Gamma} \in \mathcal{G}_{\mathcal{R}_o}\) to \(F^k_{g,n}\), as given by the expression obtained by replacing \((7.9)\) for \(i > i_0\) in \((7.8)\), matches the sum of the contributions of such graphs to the left-hand side of \((7.4)\).

Indeed, the sum of the contributions of all \(\hat{\Gamma} \in \mathcal{G}_{\mathcal{R}_o}\) to \(\pi^*_{n} (F^k_{g,n-1}) \cdot \rho^*_n (F^k_{g,1})\) is computed as follows. Consider the term of \(\pi^*_{n} (F^k_{g,n-1}) \cdot \rho^*_n (F^k_{g,1})\) given by

\[(7.10)\]
\[
\sum_{(\Gamma, \psi, \pi)} (-1)^{|E(\Gamma)|} w(\Gamma, \psi) \pi^*_{n} \left( \xi_{\Gamma, \psi} \frac{1}{\psi^*_{\Gamma, \psi} \beta_{0, \psi}^{-1} \prod_{\ell=1}^{n-1} (k \omega_\ell - \eta)} \right) \cdot (k \omega_n - \eta)
\]

where the sum is over: the graphs \(\Gamma\) obtained from the graphs \(\hat{\Gamma} \in \mathcal{G}_{\mathcal{R}_o}\) by removing the leg \(n\) (and contracting an edge if the vertex \(v_n\) incident to the leg \(n\) is trivalent); the decorations \(\psi\) of \(\Gamma\); and the weightings \(\pi\) of \((\Gamma, \psi)\).

For \(\hat{\Gamma} = \Gamma_0 \sqcup e T'\) in \(\mathcal{G}_{\mathcal{R}_o}\), the graph obtained by removing the leg \(n\) can be decomposed as \(\Gamma = \Gamma_0 \sqcup T\'), where \(T'\) is the tree obtained from \(T'\) by removing the leg \(n\) (and contracting an edge when necessary, as before).

As in \((5.7)\) and \((5.10)\), the expansion of \((7.10)\) consists of a sum of the decorated graphs obtained by first adding the leg \(n\) to all vertices of each \(\Gamma\), and then expanding the decorations \(\pi^*(\psi)\) accordingly. The sum of the terms obtained by adding the leg \(n\) to the subtree \(\overline{T'}\) of each \(\Gamma\), and expanding the decorations \(\pi^*(\psi)\) accordingly, is

\[(7.11)\]
\[
\sum_{(\psi_0, \omega_0)} (-1)^{|E(\Gamma_0)|} w_0(\Gamma_0, \psi_0) \xi_{\Gamma_0, \psi_0} \left( \psi_0 \beta_{0, \psi_0}^{-1} \prod_{\ell=1}^{n} (k \omega_\ell - \eta) \right) \prod_{i > i_0} \pi^*_{n} (\text{Dec}^i_{n'-1}(k \omega_{t_0} - \eta))
\]

When adding the leg \(n\) to the genus \(g\) vertex of a graph \(\Gamma\), the expansion of each decoration \(\pi^*(\psi)\) consists of \(\psi\) decorating the graph with the leg \(n\) attached to genus \(g\) vertex (this case has been treated in Case 1), minus additional terms contributed by the pull-back of \(\psi\)-classes decorating the tails incident to the genus \(g\) vertex. In particular, when the degree of \(\psi_{t_0}\) in \(\psi\) is positive, the expansion of \(\pi^*(\psi)\) includes the term corresponding to a decorated graph \((\hat{\Gamma}, \hat{\psi})\) where \(\Gamma = \Gamma_0 \sqcup v_n \sqcup T'\) is obtained from \(\Gamma = \Gamma_0 \sqcup e T'\) with \(e = (\overline{h_0}, t_0)\) by inserting a trivalent vertex \(v_n\) incident to the leg \(n\), attached to the genus \(g\) vertex in \(\Gamma_0\) via an edge with tail equal to \(t_0\), and attached to \(T'\) via an edge with head equal to \(h_0\). The decoration \(\hat{\psi}\) is obtained from \(\psi\) by decreasing the degree of \(\psi_{t_0}\) by one, i.e., \(\hat{\psi} \cdot \psi_{t_0} = \psi\).
A weighting \( \varpi \) of such \((\Gamma, \psi)\) can be decomposed as follows. Let \( \psi_0 \) and \( \psi' \) be the restrictions of \( \psi \) to \( \Gamma_0 \) and \( \Gamma' \), respectively, so that \( \psi = \psi_0 \psi' \), and thus \( \psi = \psi_0 \psi_{00} \psi' \). Let \( d_0 \) be the degree of \( \psi_{00} \) in \( \psi_0 \), so that \( d_0 + 1 \) is the degree of \( \psi_{00} \) in \( \psi' \). Similarly, let \( w_0 \) and \( \psi' \) be the restrictions of \( \varpi \) to \((\Gamma_0, \psi_0)\) and \((\Gamma', \psi')\), respectively. One has the decomposition

\[
\varpi(\Gamma, \psi) = w_0 (\Gamma_0, \psi_0) \cdot i \cdot \psi' (\Gamma', \psi')
\]

for some \( i > i_0 \)

where \( i_0 = \varpi(t_0, d_0) \) as in (7.7) and \( i = \varpi(t_0, d_0 + 1) \). Moreover, one concludes that

\[
\psi' \in \mathcal{W}^i_{\Gamma_0, \psi\psi'}
\]

for some \( i^+ > i \).

The inequalities \( i^+ > i > i_0 \) follow from the definition of the weighting \( \varpi \).

The gluing map \( \xi_\Gamma \) for such \( \hat{\Gamma} = \Gamma_0 \sqcup v_n \sqcup \Gamma' \) factors as

\[
\xi_\Gamma = \xi_\Gamma \circ \sigma_0 \circ \xi_{\Gamma'},
\]

where \( \sigma_0 : \bar{\mathcal{M}}_{0, n'} \to \bar{\mathcal{M}}_{0, n' + 1} \) is the map obtained by attaching at \( \eta_0 \) a rational component containing the leg \( n \) and \( h_0 \).

Summing over all \((\psi_0, w_0)\) and \((\Gamma_0, \psi')\), one obtains

\[
(7.12) \quad \sum_{(\psi_0, w_0)} (-1)^{|E(\Gamma_0)|} w_0 (\Gamma_0, \psi_0) \varpi_0 \left[ \psi_0 \beta_{\Gamma_0, \psi_0}^{-1} \prod_{\ell=1}^n (k \omega_\ell - \eta) \right. \\
\left. \times \left( - \sum_{i^+ > i > i_0} i \sigma_0 \left( \text{Dec}_{n' - 1}^i (D) \right) \right) \right].
\]

Finally, after (7.3) and Definition 6.1, and applying Lemma 3.2 when \(|I| < n' - 1 \), the sum of the contributions of all \( \Gamma' \in \mathcal{G}_{r_2} \) to \( E_I \) is

\[
(7.13) \quad \sum_{(\psi_0, w_0)} (-1)^{|E(\Gamma_0)|} w_0 (\Gamma_0, \psi_0) \varpi_0 \left[ \psi_0 \beta_{\Gamma_0, \psi_0}^{-1} \prod_{\ell=1}^n (k \omega_\ell - \eta) \sum_{i^+ > i > i_0} \right] \text{E}_{\hat{\Gamma}} \left( k \omega_0 - \eta \right).
\]

The sum of (7.11) and (7.12) gives the contribution of all \( \hat{\Gamma} \in \mathcal{G}_{r_2} \) to \( \pi_n^* \left( \mathcal{F}_{g,n-1}^k \cdot \rho_n^* \left( \mathcal{F}_{g,1}^k \right) \right) \). Additionally, using (7.13) for each \( I \), one obtains that the sum of the contributions of all \( \hat{\Gamma} \in \mathcal{G}_{r_2} \) to the left-hand side of (7.4) matches the sum of the contributions of such graphs to \( \mathcal{F}_{g,n}^k \), as given by the expression obtained by replacing (7.9) for \( i > i_0 \) in (7.8).

This ends the proof.

We now complete the proof of Theorem 7.1:

**Proof of Theorem 7.1.** First we argue that the case \( m = (1, \ldots, 1) \) implies the case of arbitrary \( m \). Precisely, assume the statement holds for a given \( n \) and \( m = (1, \ldots, 1) \), so that if (7.2) holds, then one has

\[
(7.14) \quad \left[ \prod_{g,n} \mathcal{F}_{g,n}^k \right] \in \mathcal{E}^n \left( \mathcal{E}_{g,n}^k \right)
\]
and if \( n \leq k \), then (7.14) extends over \( \overline{\mathcal{M}}_{g,n} \). Given a sequence \( \mathbf{m} = (m_1, \ldots, m_n) \) with \( |\mathbf{m}| = n \) of length \( n^- < n \), the locus \( \mathbb{P}^k_{g,n} \) in \( \mathbb{P}E^k_{g,n} \) is obtained from the locus \( \mathbb{P}_{g,n}^k \) by colliding the first \( m_1 \) marked points into the marked point \( P_1 \), the next \( m_2 \) marked points into the marked point \( P_2 \), etc. From Theorem 6.2, our assumption implies the statement for \( \mathbf{m} \).

Next, we proceed by recursion on \( n \) to show the case \( \mathbf{m} = (1, \ldots, 1) \). The base case \( n = 1 \) is established by Lemma 1.1. Assume (7.2) and assume the statement holds for \( n^- \), i.e., one has

\[
[\mathbb{P}^k_{g,n^-}] = F^k_{g,n^-} \in A^{n^-} \left( \mathbb{P}E^k_{g,n^-}, \mathcal{M}^n_{g,n^-} \right)
\]

and this extends over \( \overline{\mathcal{M}}_{g,n^-} \) when \( n^- \leq k \). The argument in the previous paragraph shows that given \( \mathbf{m} = (m, 1, \ldots, 1) \) with \( |\mathbf{m}| = n^- \) of length \( (n^-)^- = n^- - m \leq n^- \), one has

\[
\left[\mathbb{P}^k_{g,m} \right] = F^k_{g,m} \in A^{n^-} \left( \mathbb{P}E^k_{g,n^-}, \mathcal{M}^n_{g,n^-} \right)
\]

and this extends over \( \overline{\mathcal{M}}_{g,n^-} \) when \( n^- \leq k \). The assumption (7.2) allows us to use Theorem 2.9. Then the statement for \( n \) and \( \mathbf{m} = (1, \ldots, 1) \) follows from Theorems 2.9 and 7.2. This ends the proof. □

Remark 7.3. In the case \( k \geq 2 \), \( n = k(2g - 2) \), and \( \mathbf{m} = (1, \ldots, 1) \), the proof of Theorem 7.1 together with (2.24) show that

\[
F^k_{g,n} = \left[\mathbb{P}^k_{g,n} \right] + \left[ E_{\max}^{ab} \right] \in A^n \left( \mathbb{P}E^k_{g,n}, \mathcal{M}^n_{g,n} \right).
\]

8. Examples

We collect here some examples of the cycle \( F^k_{g,n} \) from Definition 1 and more generally \( F^k_{g,m} \) from Definition 6.1, and verify our results in some special cases.
8.1. The case \( n = 3 \). The cycle \( F^k_{g,3} \in R^3(\mathbb{P}E^k_{g,3}) \) is

\[
F^k_{g,3} = \frac{g \omega_1 - \eta}{g} \frac{g \omega_2 - \eta}{g} \frac{g \omega_3 - \eta}{g} \frac{(g \omega - \eta)^2}{g} - 7 \frac{g \omega - \eta}{g} \psi - 2 \frac{g \psi}{g} - 6 \frac{g \psi}{g} + 3 \frac{g \psi}{g} + 2 \frac{g \psi}{g} .
\]

8.2. A vanishing cycle. Specializing the above cycle at \( g = 2 \) and \( k = 1 \), we obtain the vanishing cycle

\[
F^1_{1,3} = 0 \in R^3(\mathbb{P}E^1_{2,3}|_{M^*_{2,3}}).
\]

This is a special case of Corollary 1, and can be verified as follows. Since \( \eta^2 = \eta \lambda_1 - \lambda_2 \in A^*(\mathbb{P}E^1_{1,3}) \) where \( \lambda_i := c_i(E^1_{2,3}) = 0 \) in \( A^*(M^*_{2,3}) \), all terms with a factor of \( \eta^2 \) vanish. The coefficient of \( \eta \) is a cycle in \( R^2(M^*_{2,3}) \) which recovers the restriction of the new relation in \( A^2(M^*_{2,3}) \) from [BP] plus the pull-back of a relation in \( A^2(M^*_{2,2}) \) from [Get]. Finally, the constant term in \( \eta \) is in \( R^3(M^*_{2,3}) \). The degree three is the socle of the Gorenstein algebra \( R^*(M^*_{2,3}) \), and the vanishing of the constant term in \( \eta \) is due to known relations (see e.g., [Tav]).

8.3. The Logan divisor. Here we verify how the cycle \( F^k_{g,n} \) for \( n = g \) and \( k = 1 \) recovers a well-known divisor on moduli spaces of curves.

The Logan divisor \( \mathcal{L}_g \) in \( M_{g,g} \) is the locus of \( g \)-pointed genus \( g \) curves \( (C, P_1, \ldots, P_g) \) such that the divisor \( P_1 + \cdots + P_g \) moves in a pencil [Log]. Equivalently, via the Riemann-Roch theorem, the \( g \) marked points are required to be zeros of a common abelian differential. Hence the Logan divisor is the push-forward of the incidence locus \( \mathbb{P}^1_{g,g} \) via the forgetful map \( \varphi: \mathbb{P}E_{g,g} \to \overline{M}_{g,g} \), and one has

\[
[\mathbb{P}^1_{g,g}] = \varphi_*[\mathbb{P}^1_{g,g}] \in \text{Pic}(\overline{M}_{g,g}).
\]

As a check on Theorem 2, we verify that \( \varphi_* F^1_{g,g} \) matches the restriction on \( M^*_{g,g} \) of the class of the Logan divisor from [Log]. The cycle \( F^1_{g,g} \) is a polynomial in \( \eta \) of degree \( g \). First, we replace \( (-\eta)^g \) via the relation

\[
(-\eta)^g = -\lambda_1(-\eta)^{g-1} + \cdots \in A^*(\mathbb{P}E^1_{g,g}).
\]

Then we use that \( \varphi_*((-\eta)^d) = 1 \)
if \( d = g - 1 \), and vanishes if \( d < g - 1 \). It follows that

\[
\varphi_* F^1_{g,g} = [F^1_{g,g}]_{g-1} - \lambda_1 [F^1_{g,g}]_g
\]

where \([X]_i\) if the coefficient of \((-\eta)^i\) in \(X\). Hence we have

\[
\left[\overline{X}_g\right] = \varphi_* F^1_{g,g} = \sum_{i=1}^g \omega_i - \lambda_1 - \sum_{i=2}^g \binom{i}{2} \delta_{0,i} \in \text{Pic} (\mathcal{M}^{rt}_{g,g}).
\]

This checks with the restriction on \(\mathcal{M}^{rt}_{g,g}\) of the divisor class from [Log]. Here \(\delta_{0,i}\) is the class of the divisor whose general element has an elliptic tail containing \(i\) marked points.

Additionally, for \(g = 2\), using Theorem 1.2 for the class of \(H^1_{g,m}\) over the whole \(\overline{\mathcal{M}}_{2,2}\), one checks that indeed \(\varphi_* H^1_{g,m}\) matches the Logan divisor over \(\overline{\mathcal{M}}_{2,2}\), as we did in (2.18).

### 8.4. The case of one heavy marked point.

When \(m = (a)\) for some positive \(a\), the cycle \(F^k_{g,m}\) from Definition 6.1 is

\[
F^k_{g,(a)} = \sum_{b=0}^{a-1} e_b (1, \ldots, a-1) (k \omega_1 - \eta)^{a-b} \psi_1^{b} \in R^a \left(\mathbb{P}E^k_{g,1}\right)
\]

where \(e_b(x_1, \ldots, x_{a-1})\) is the \(b\)-th elementary symmetric function in \(a - 1\) variables, here evaluated at \(1, \ldots, a - 1\). Since \(\omega_1 = \psi_1\) in \(R^* (\mathbb{P}E^k_{g,1})\), this cycle can be rewritten as

\[
F^k_{g,(a)} = \prod_{b=0}^{a-1} ((k + b) \psi_1 - \eta) \in R^a \left(\mathbb{P}E^k_{g,1}\right).
\]

Theorem 7.1 shows that

\[
\left[\overline{H}^k_{g,(a)}\right] = F^k_{g,(a)} \in A^a \left(\mathbb{P}E^k_{g,1}, \mathcal{M}_{g,1}\right)
\]

when either \(k = 1\), or \(k \geq 2\) and \(a \leq k(2g - 2) - 1\), and this holds in \(A^a \left(\mathbb{P}E^k_{g,1}\right)\) when \(a \leq k\).

For instance, when \(a = k = g = 2\), the locus \(\overline{H}^2_{2,(2)}\) consists of two equidimensional components:

\[
\overline{H}^2_{2,(2)} = \overline{H}^2_{2,1}(2,1,1) \cup \overline{H}^{2,\text{ab}}_{2,1}(2,2) \subseteq \mathbb{P}E^2_{2,1}
\]

where \(\overline{H}^2_{2,1}(2,1,1)\) consists of quadratic differentials that have generically a double zero at the marked point and two simple zeros elsewhere, and \(\overline{H}^{2,\text{ab}}_{2,1}(2,2)\) consists of squares of abelian differentials that have generically double zeros at both the marked point and its (unmarked) hyperelliptic conjugate point. In this case, the class of \(\overline{H}^2_{2,(2)}\) decomposes as:

\[
F^2_{2,(2)} = \left[\overline{H}^2_{2,1}(2,1,1)\right] + \left[\overline{H}^{2,\text{ab}}_{2,1}(2,2)\right] \in A^2 \left(\mathbb{P}E^2_{2,1}\right).
\]
As a check, one has $\varphi_* F_{2,(2)}^2 = \varphi_* (\eta^2) = 1$, where $\varphi : \mathbb{P}E_{2,1}^2 \to \overline{\mathcal{M}}_{2,1}$ is the forgetful map. Indeed, the restriction of $\varphi$ to $\mathbb{H}^{2,ab}_{2,1}(2,2)$ has degree one, while $\varphi$ has positive-dimensional fibers when restricted to the other component.

8.5. **The case of one heavy unmarked point.** By forgetting the marked point, the locus $\mathbb{H}^k_{g,(a)}$ gives rise to the stratum $\mathbb{H}^k_g(a) \subseteq \mathbb{P}E^k_g$ consisting of $k$-differentials vanishing with order at least $a$ at some point.

Let $\pi : \mathbb{P}E^k_{g,1} \to \mathbb{P}E^k_g$ be the map obtained by forgetting the marked point, and let $\kappa_b := \pi_* (\psi^{b+1})$. We deduce the following:

**Corollary 8.1.** For $g \geq 2$, one has

$$\left[ \mathbb{H}^k_g(a) \right] = \sum_{b=1}^{a} (-1)^{a-b} e_b(k, \ldots, k + a - 1) \kappa_{b-1} \eta^{a-b}$$

in:

(i) $A^{a-1} \left( \mathbb{P}E^k_g|_{\mathcal{M}_g} \right)$ when

$$\begin{cases} k = 1; \text{ or} \\ k \geq 2 \text{ and } a \leq k(2g-2) - 1; \end{cases}$$

(ii) $A^{a-1} \left( \mathbb{P}E^k_g \right)$ when $a \leq k$.

**Proof.** The hypotheses allow one to use Theorem 7.1 to conclude that (8.2) holds when either $k = 1$, or $k \geq 2$ and $a \leq k(2g-2) - 1$, and holds in $A^a \left( \mathbb{P}E^k_{g,1} \right)$ when $a \leq k$. It remains to compute the push-forward of this cycle via the forgetful map $\pi : \mathbb{P}E^k_{g,1} \to \mathbb{P}E^k_g$. Expanding $F_{g,(a)}^k$ from (8.1) as a polynomial in $\psi_1$, one has

$$\pi_* \left( \mathbb{P}E^k_{g,(a)} \right) = \sum_{b=1}^{a} (-1)^{a-b} e_b(k, \ldots, k + a - 1) \kappa_{b-1} \eta^{a-b} \in R^{a-1} \left( \mathbb{P}E^k_g \right).$$

Hence the statement.

For instance, when $a = 2$ and $k \geq 2$, one has

$$\left[ \mathbb{H}^2_g(2) \right] = k(k+1) \kappa_1 - (2k+1)(2g-2) \eta \in \text{Pic} \left( \mathbb{P}E^k_g \right).$$

This recovers the class of the divisorial stratum for $k \geq 2$ computed in [KSZ]. When $a = k = g = 2$, the locus $\mathbb{H}^2_g(2)$ is the union of the two divisors $\mathbb{H}^2_g(2,1,1)$ and $\mathbb{H}^{2,ab}_2(2,2)$ obtained by forgetting the marked point on the two components in (8.3), and (8.5) decomposes as the weighted sum

$$\left[ \mathbb{H}^2_g(2) \right] = \left[ \mathbb{H}^2_g(2,1,1) \right] + 2 \left[ \mathbb{H}^{2,ab}_2(2,2) \right] \in \text{Pic} \left( \mathbb{P}E^2_g \right).$$
Here the factor of 2 in front of the second summand is due to the fact that the restriction of \( \pi \) to \( \mathcal{H}_2 \) has generically degree 2, corresponding to the 2 zeros of the square differentials.

When \( a = 2 \) and \( k = 1 \), Corollary 8.1 only holds over \( \mathcal{M}_g \). One has a better result by considering the class of \( \mathcal{H}_1^{g,(2)} \subset \mathcal{P}^1_{g,1} \) from Theorem 1.2. Colliding the two marked points to get the class of \( \mathcal{H}_1^{g,(2)} \subset \mathcal{P}^1_{g,1} \), and then forgetting the marked point, this gives

\[
\left[ \mathcal{H}_1^g(2) \right] = 2\kappa_1 - (6g - 6)\eta - \delta_{\text{dis}} \in \text{Pic} \left( \mathcal{P}^1_{g} \right)
\]

where \( \delta_{\text{dis}} \) is the pull-back of the class of the divisor of curves with a disconnecting node in \( \mathcal{M}_g \). This recovers the class of the divisorial stratum for \( k = 1 \) computed with alternative methods in [KZ, Sau1].

For \( a = 3 \) and \( k = 1 \), one has

\[
\left[ \mathcal{H}_1^{g}(3) \right] = \pi_* \left( F_1^{g,(3)} \right) = 6(2g - 2)\eta^2 - 11\kappa_1 \eta + 6\kappa_2 \in A^* \left( \mathcal{P}^1_{g} | \mathcal{M}_g \right).
\]

This recovers the restriction over \( \mathcal{M}_g \) of the class computed in [Sau1, §6.1].
