OPERATOR-FREE SPARSE DOMINATION

ANDREI K. LERNER, EMIEL LORIST, AND SHELDY OMBROSI

Abstract. We obtain a sparse domination principle for an arbitrary family of functions $f(x, Q)$, where $x \in \mathbb{R}^n$ and $Q$ is a cube in $\mathbb{R}^n$. When applied to operators, this result recovers our recent works [36, 38]. On the other hand, our sparse domination principle can be also applied to non-operator objects. In particular, we show applications to generalized Poincaré–Sobolev inequalities, tent spaces, and general dyadic sums. Moreover, the flexibility of our result allows us to treat operators that are not localizable in the sense of [38], as we will demonstrate in an application to vector-valued square functions.

1. Introduction

Sparse domination is a recent technique allowing to estimate (in norm, pointwise or dually) many operators in harmonic analysis by simple expressions of the form

$$\sum_{Q \in S} \langle f \rangle_{p,Q} \chi_Q,$$

where $\langle f \rangle_{p,Q} = \left(\frac{1}{|Q|} \int_Q |f|^p\right)^{1/p}$ for $p \in (0, \infty)$ and $S$ is a sparse family of cubes in $\mathbb{R}^n$.

Primarily motivated by sharp quantitative weighted norm inequalities, sparse domination has quickly transformed into a very active area, dealing with various operators within and beyond the Calderón-Zygmund theory. During the last five years a number of sparse domination principles (that is, general results establishing sparse domination for a given class of operators) have appeared e.g. in the works [2, 5, 6, 8, 12, 13, 33, 34, 36, 38].

Let us consider a particular line of research in this direction, for which the starting point is the so-called local mean oscillation estimate

2020 Mathematics Subject Classification. 42B20, 42B25.

Key words and phrases. Sparse domination, Poincaré–Sobolev inequalities, tent spaces, square functions, dyadic sums.

where \( f \) is an arbitrary measurable function, and \( m_f(Q) \) and \( \omega_\lambda(f; Q) \) denote a median value and the local mean oscillation of \( f \) on the cube \( Q \), respectively. The local mean oscillation estimate can be regarded as the first operator-free sparse domination result, but its main application was to operators. Specifically, this estimate was applied by the first author in [31] to a Calderón–Zygmund operator \( T \), using \( Tf \) instead of \( f \) in (1.1). This provided norm sparse domination for \( T \), and, as a result, an alternative proof of the \( A_2 \)-theorem, which was first proven by Hytönen [21]. Later, this norm sparse domination result was improved to pointwise sparse domination simultaneously by Conde-Alonso–Rey and the first author and Nazarov in [14, 35]. The methods in [14, 35] still depended on (1.1). The drawback of this approach is that it necessitates to estimate local mean oscillations of \( T \), although \( T \) is not a well-localized operator. For this reason, the results in [14, 35] hold under the log-Dini assumption on the kernel of the Calderón–Zygmund operator \( T \).

The next step was taken by Lacey in [29], where pointwise sparse domination for \( T \) was obtained under the usual Dini assumption on the kernel of \( T \). The main new realization in [29] was that it suffices to estimate suitable truncations of \( T \), which can be done without the use of (1.1). The proof of the pointwise sparse domination result for \( T \) was subsequently simplified by the first author in [33] and the first and third authors in [36], in which a general sparse domination principle was established, allowing to deal with a vast number of “smooth” operators. The main result of [36] was afterwards extended by the second author [38] into several directions, including the setting of vector-valued functions on spaces of homogeneous type, along with the concept of \( \ell^r \)-sparse domination.

The development we have so-far described can be summarized in the following diagram:

\[
(1.1) \rightarrow [31] \rightarrow [14, 35] \rightarrow [29] \rightarrow [33] \rightarrow [36] \rightarrow [38].
\]

Starting from [29], the local mean oscillation estimate (1.1) has not played a role in the obtained sparse domination results. Therefore, this development can be viewed as an evolution from sparse domination for arbitrary functions (expressed in (1.1)) to sparse domination for operators.
In the present paper, we return sparse domination to its roots, using functions rather than operators. We will essentially use the techniques developed in [36, 38]. Our key novel point is the language in which our main results are written. This language unifies (1.1) with all the results containing in [36, 38]. More importantly, it allows us to deal with many non-operator objects, which have not yet been investigated using sparse domination techniques. This development can be seen in analogy to the development of Rubio de Francia extrapolation, which was first proven for operators, but was later realized to be much more versatile and applicable in a formulation for functions (see [15] for a discussion on this development).

Let us give a flavour of our language. Precise definitions and statements will be given in subsequent sections. We shall deal with functions \( f(x,Q) \) of two “variables”, being the points \( x \in \mathbb{R}^n \) and the cubes \( Q \subset \mathbb{R}^n \). For brevity we denote such functions by \( f_Q(x) \). Observe that the role of the cubes \( Q \) may vary. For example, one can define \( f_Q(x) := T(f\chi_{\alpha Q})(x) \), where \( T \) is a given operator. On the other hand, in the theory of tent spaces, a typical definition will be \( f_Q(x) := \int_{\Gamma_{\ell Q}(x)} f(y,t) \, d\mu(y,t) \), where \( \Gamma_{\ell Q}(x) \) is a cone in \( \mathbb{R}^{n+1}_+ \), truncated according to the side length of \( Q \).

Our main result, Theorem 3.2, provides pointwise sparse domination for \( |f_Q| \) for a fixed cube \( Q \subset \mathbb{R}^n \). The dominating sparse object is expressed in terms of \( f_P \) for dyadic subcubes \( P \) of \( Q \) and a certain family of functions \( f_{P,Q} \), which connects \( f_P \) and \( f_Q \) in a natural way. A typical example is \( f_{P,Q} := f_Q - f_P \), but, depending on the context, one can make more clever choices of \( f_{P,Q} \).

The paper is organized as follows. Section 2 contains the main definitions. In particular, our language is introduced there. Section 3 contains our main results, which are pointwise and bilinear form operator-free sparse domination principles, expressed in Theorems 3.2 and 3.4. In Section 4 we show that our new results contain a vast number of previously known sparse domination results as particular cases.

Sections 5-8 present new applications. Section 5 is devoted to generalized Poincaré–Sobolev inequalities. In a recent work on this topic [44], Pérez and Rela obtained a weighted self-improving result, assuming the \( A_\infty \)-condition on the weight. They asked whether the \( A_\infty \)-condition can be removed. Using our sparse domination principle, we give an affirmative answer to this question.

In Section 6, we give a “sparse” proof of the theorem of Coifman–Meyer–Stein [10] on the main relation between two basic operators.
in the theory of tent spaces. In particular, this improves the good-$\lambda$ inequality for these operators established in [10]. We also obtain similar results for vector-valued tent spaces.

In Section 7 we give a simplified proof of a recent result by Xu [48] about sharp bounds for the vector-valued vertical square function, which was an important ingredient in his answer to a question by Naor and Young [43] about sharp bounds for the heat semigroup on $\mathbb{R}^n$.

In Section 8 we obtain a simple sufficient condition allowing one, when dealing with the dyadic sums $\sum \alpha_Q \chi_Q$, to replace the summation over all dyadic subcubes of a given cube by the summation over a sparse family. As an application, we will generalize and provide a new proof of a result by Honzík and Jaye [20] on a sharp good-$\lambda$ inequality for the non-linear dyadic potential.

Throughout the paper we use the notation $A \lessapprox B$ if $A \leq CB$ with some independent constant $C$. We write $A \equiv B$ if $A \lessapprox B$ and $B \lessapprox A$.

2. Main definitions

2.1. Dyadic cubes. Denote by $Q$ the set of all cubes $Q \subset \mathbb{R}^n$ with sides parallel to the axes. Given a cube $Q \in Q$, denote by $\mathcal{D}(Q)$ the set of all dyadic cubes with respect to $Q$, that is, the cubes obtained by repeated subdivision of $Q$ into $2^n$ congruent subcubes.

Following [35, Def. 2.1], a dyadic lattice $\mathcal{D}$ in $\mathbb{R}^n$ is any collection of cubes such that

(i) Any child of $Q \in \mathcal{D}$ is in $\mathcal{D}$ as well, i.e. $\mathcal{D}(Q) \subseteq \mathcal{D}$.
(ii) Any $Q', Q'' \in \mathcal{D}$ have a common ancestor, i.e. there exists a $Q \in \mathcal{D}$ such that $Q', Q'' \in \mathcal{D}(Q)$.
(iii) For every compact set $K \subset \mathbb{R}^n$, there exists a cube $Q \in \mathcal{D}$ containing $K$.

Let $Q \in Q$. We say that a family of dyadic cubes $\mathcal{F} \subset \mathcal{D}(Q)$ is contracting if $\mathcal{F} = \bigcup_{k=0}^{\infty} \mathcal{F}_k$, where $\mathcal{F}_0 = \{Q\}$, each $\mathcal{F}_k$ is a family of pairwise disjoint cubes, and for $\Omega_k = \bigcup_{P \in \mathcal{F}_k} P$ we have $\Omega_{k+1} \subset \Omega_k$ and $|\Omega_k| \to 0$ as $k \to \infty$. Given a contracting family $\mathcal{F} \subset \mathcal{D}(Q)$, for $P \in \mathcal{F}_k$ with $k \in \mathbb{N} \cup \{0\}$, we denote

$$E_P := P \setminus \bigcup_{P' \in \mathcal{F}_{k+1}} P' = P \setminus \Omega_{k+1}.$$ 

Observe that the sets $\{E_P\}_{P \in \mathcal{F}}$ are pairwise disjoint.

Definition 2.1. Let $\eta \in (0,1)$ and $Q \in Q$. We say that a family $\mathcal{F} \subset \mathcal{D}(Q)$ is $\eta$-sparse if it is contracting and $|E_P| \geq \eta |P|$ for all $P \in \mathcal{F}$. 
Note that our definition of a sparse family of cubes is slightly more restrictive than the usual definition in the literature. In particular, we assume a sparse family of cubes to have exactly one maximal cube, the cube $Q$.

2.2. The $\ell^r$-condition. Consider a family of measurable functions \( \{f_Q, f_{P,Q}\} : \mathbb{R}^n \to \mathbb{R} \), where $Q \in \mathcal{Q}$, $P \in \mathcal{D}(Q)$. We note that our choice of $\mathbb{R}$ as the scalar field is inconsequential, i.e. all subsequent results hold for complex-valued functions as well.

We introduce a compatibility condition on such a family of functions, which is implicitly contained in [38]. We will elaborate on the connection to [38] in Subsection 4.2.

**Definition 2.2.** Let $r \in (0, \infty)$. We say that the family
\[
\{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)}
\]
satisfies the $\ell^r$-condition if there exists a $C_r > 0$ such that for every $Q \in \mathcal{Q}$ and every $P_1, \ldots, P_m \in \mathcal{D}(Q)$ with $P_m \subset \cdots \subset P_1$, we have for a.e. $x \in P_m$,
\[
|f_{P_1}(x)| \leq C_r \left( \sum_{k=1}^{m-1} |f_{P_{k+1}, P_k}(x)|^r + |f_{P_m}(x)|^r \right)^{1/r}.
\]

Given an arbitrary family of measurable functions $f_Q : \mathbb{R}^n \to \mathbb{R}$, a canonical choice for $f_{P,Q}$ is given by
\[
(2.1) \quad f_{P,Q} := f_Q - f_P,
\]
for which the $\ell^r$-condition holds trivially with $C_r = 1$ for $0 < r \leq 1$.

2.3. Sharp maximal operators. For a measurable function $f : \mathbb{R}^n \to \mathbb{R}$ we define its standard oscillation over a cube $Q \in \mathcal{Q}$ by
\[
\text{osc}(f; Q) = \text{ess sup}_{x', x'' \in Q} |f(x') - f(x'')|.
\]
Furthermore, for $q \in (0, \infty)$ we define its $q$-oscillation over a cube $Q \in \mathcal{Q}$ by
\[
\text{osc}_q(f; Q) = \left( \frac{1}{|Q|^2} \int_{Q \times Q} |f(x') - f(x'')|^q \, dx' \, dx'' \right)^{1/q}.
\]

Using these oscillations, we can now define sharp maximal operators associated to a family $\{f_{P,Q}\}$, of which precursors can be found in [36, 38].
Definition 2.3. Given a family \( \{f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)} \), define the sharp maximal function \( m^\#_{Q} f \) for \( Q \in \mathcal{Q} \) by

\[
m^\#_{Q} f(x) = \sup_{P \in \mathcal{D}(Q) : x \in P} \text{osc}(f_{P,Q}; P), \quad x \in Q,
\]

and for \( q \in (0, \infty) \) define the sharp \( q \)-maximal function by

\[
m^\#_{Q,q} f(x) = \sup_{P \in \mathcal{D}(Q) : x \in P} \text{osc}_{q}(f_{P,Q}; P), \quad x \in Q.
\]

2.4. Non-increasing rearrangements. The non-increasing rearrangement of a measurable function \( f : \mathbb{R}^n \to \mathbb{R} \) is defined by

\[
f^*(t) = \inf \{ \alpha > 0 : |\{ x \in \mathbb{R}^n : |f(x)| > \alpha \}| \leq t \}, \quad t \in \mathbb{R}^+.
\]

Observe that \( (|f|^{\delta})^*(t) = f^*(t)^{\delta} \) for every \( \delta > 0 \). This, along with Chebyshev’s inequality \( f^*(t) \leq \frac{1}{t} \|f\|_{L^1(\mathbb{R}^n)} \), implies that

\[
(2.2) \quad f^*(t) \leq \frac{1}{t} \|f\|_{L^1(\mathbb{R}^n)}.
\]

We also have

\[
(2.3) \quad |\{ x \in \mathbb{R}^n : |f(x)| > f^*(t) \}| \leq t,
\]

which is a consequence of the fact that the distribution function is right-continuous.

3. Main results

3.1. A toy domination principle. We start our analysis by observing that the \( \ell^r \)-condition allows us to bound \( f_Q \) for every \( Q \in \mathcal{Q} \) by a sum over an arbitrary contracting family of cubes. In particular we note that we do not need a sparseness assumption in the following statement.

Proposition 3.1. Let \( r \in (0, \infty) \) and let \( \{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)} \) satisfy the \( \ell^r \)-condition. Let \( Q \in \mathcal{Q} \) and let \( \mathcal{F} \subset \mathcal{D}(Q) \) be a contracting family of cubes. Then for a.e. \( x \in Q \),

\[
|f_Q(x)|^r \leq C_r \sum_{k=0}^{\infty} \sum_{P \in \mathcal{F}_k} \left( |f_P(x)|^r \chi_{E_k}(x) + \sum_{P' \in \mathcal{F}_{k+1} : P' \subset P} |f_{P',P}(x)|^r \chi_{P'}(x) \right).
\]

Proof. Since \( |\Omega_k| \to 0 \), there is a set \( N \subset Q \) of measure zero such that, for every \( x \in Q \setminus N \), there are only finitely many \( k \in \mathbb{N} \) with \( x \in \Omega_k \).

Fix \( x \in Q \setminus N \). Then there exist \( P_k \in \mathcal{F}_k \) for \( k = 0, \ldots, m \) such that

\[
x \in P_m \subset P_{m-1} \subset \cdots \subset P_0 = Q
\]
and \( x \not\in \Omega_{m+1} \). Hence, by the \( \ell^r \)-condition,

\[
|f_Q(x)|^r \leq C_r^r \left( |f_{P_m}(x)|^r + \sum_{k=0}^{m-1} |f_{P_{k+1}, P_k}(x)|^r \right)
\]

\[
= C_r^r \left( |f_{P_m}(x)|^r \chi_{E_{P_m}}(x) + \sum_{k=0}^{m-1} |f_{P_{k+1}, P_k}(x)|^r \chi_{P_{k+1}}(x) \right).
\]

In order to make this expression independent of the particular choice of \( P_k \), we add zero terms. This allows us to write

\[
|f_{P_m}(x)|^r \chi_{E_{P_m}}(x) = \sum_{k=0}^{\infty} \sum_{P \in F_k} |f_P(x)|^r \chi_{E_P}(x)
\]

and

\[
\sum_{k=0}^{m-1} |f_{P_{k+1}, P_k}(x)|^r \chi_{P_{k+1}}(x) = \sum_{k=0}^{\infty} \sum_{P \in F_k} \sum_{P' \in F_{k+1} : P' \subset P} |f_{P', P}(x)|^r \chi_{P'}(x),
\]

which completes the proof. \( \square \)

### 3.2. A pointwise sparse domination principle.

In order to estimate the terms \( f_{P', P} \) in Proposition 3.1 effectively, we make an additional assumption on the family \( \{f_{P, Q}\}_{Q \in Q, P \in D(Q)} \). Indeed, we will assume for \( Q \in Q \) and \( P \in D(Q) \) that

\[
(3.1) \quad |f_{P, Q}| \leq |f_P| + |f_Q|.
\]

Observe that this assumption is not really restrictive. In particular, for the main example in (2.1), (3.1) holds trivially.

Our first main result is the following.

**Theorem 3.2.** Let \( r \in (0, \infty) \) and let \( \{f_Q, f_{P, Q}\}_{Q \in Q, P \in D(Q)} \) satisfy the \( \ell^r \)-condition and (3.1). For any \( Q \in Q \) and \( \eta \in (0, 1) \) there exists an \( \eta \)-sparse family \( F \subset D(Q) \) such that for a.e. \( x \in Q \),

\[
|f_Q(x)| \lesssim C_r \left( \sum_{P \in F} \gamma_P \chi_P(x) \right)^{1/r},
\]

where

\[
\gamma_P := (f_P \chi_P)^* \left( |P|^\frac{1-\eta}{2n+2} \right) + (m^# f)^* \left( |P|^\frac{1-\eta}{2n+2} \right).
\]

**Proof.** We construct the family \( F \subset D(Q) \) inductively. Set \( F_0 = \{Q\} \). Next, given a collection of pairwise disjoint cubes \( F_k \), let us describe how to construct \( F_{k+1} \).

Fix a cube \( P \in F_k \). Consider the sets

\[
\Omega_1(P) := \{ x \in P : |f_P(x)| > (f_P \chi_P)^* \left( |P|^\frac{1-\eta}{2n+2} \right) \},
\]

and
\[ \Omega_2(P) := \{ x \in P : m^\#_P f(x) > (m^\#_P f)^\ast(|P|^{\frac{1-\eta}{2n+2}}) \}, \]

and denote \( \Omega(P) := \Omega_1(P) \cup \Omega_2(P) \). Then, by (2.3), we know that \( |\Omega(P)| \leq \frac{1}{2^{n+1}}|P| \).

Apply the local Calderón-Zygmund decomposition to \( \chi_{\Omega(P)} \) at height \( \frac{1}{2^{n+1}} \). We obtain a family of pairwise disjoint cubes \( \mathcal{S}_P = \{P_j\} \), dyadic with respect to \( P \), such that for \( N_P = \Omega(P) \setminus \cup_j P_j \) we have that \( |N_P| = 0 \), and for every \( P_j \in \mathcal{S}_P \),

\[ (3.2) \quad \frac{1}{2^{n+1}}|P_j| \leq |P_j \cap \Omega(P)| \leq \frac{1}{2}|P_j|. \]

In particular, it follows from this that

\[ (3.3) \quad \sum_j |P_j| \leq 2^{n+1} |\Omega(P)| \leq (1-\eta)|P|. \]

We define \( \mathcal{F}_{k+1} = \bigcup_{P \in \mathcal{F}_k} \mathcal{S}_P \). Setting \( \mathcal{F} = \bigcup_{k=0}^{\infty} \mathcal{F}_k \), we note by (3.3) that \( \mathcal{F} \) is \( \eta \)-sparse.

Let us now prepare to apply Proposition 3.1 with the constructed family \( \mathcal{F} \). Fix \( P \in \mathcal{F}_k \) for some \( k \in \mathbb{N} \cup \{0\} \). Since \( |N_P| = 0 \), almost every point of the set \( \Omega_1(P) \) is covered by a cube \( P' \in \mathcal{F}_{k+1} \). Therefore, we have

\[ (3.4) \quad |f_P(x)| \leq (f_P \chi_P)^\ast(|P|^{\frac{1-\eta}{2n+2}}), \quad x \in E_P. \]

It remains to estimate \( |f_{P',P}| \chi_{P'} \) for \( P \in \mathcal{F}_k \) and \( P' \in \mathcal{F}_{k+1} \) with \( P' \subset P \). Denote \( G_P = P' \setminus \Omega(P) \). Then, by (3.2), we have

\[ |G_P| \geq |P'| - |P' \cap \Omega(P)| \geq \frac{1}{2}|P'|. \]

Therefore, \( |G_P \setminus \Omega(P')| > 0 \) and hence, fixing

\[ y \in G_{P'} \setminus \Omega(P') \subset P' \setminus (\Omega_1(P) \cup \Omega_1(P')) \]

and applying (3.1), we obtain for a.e. \( x \in P' \)

\[ |f_{P',P}(x)| \leq \inf_{x' \in P'} m^\#_{P'} f(x') + |f_{P',P}(y)| \leq (m^\#_{P'} f)^\ast(|P'|^{\frac{1-\eta}{2n+2}}) + |f_P(y)| + |f_{P'}(y)| \leq \gamma_P + (f_{P'} \chi_{P'})^\ast(|P'|^{\frac{1-\eta}{2n+2}}). \]

Combining this estimate with (3.4) and Proposition 3.1 yields for a.e. \( x \in Q \) that

\[ |f_Q(x)|^r \leq C_r^P \sum_{k=0}^{\infty} \sum_{P \in \mathcal{F}_k} ((f_P \chi_P)^\ast(|P|^{\frac{1-\eta}{2n+2}}))^r \chi_{EP}(x) \]
+ \sum_{P' \in \mathcal{F}_{k+1} : P' \subset P} \left( \gamma_P + (f_{P'} \chi_{P'})^* \left( |P'|^{\frac{1-\eta}{m+2}} \right) \right)^r \chi_{P'}(x) \right) \\
\leq 2(2C_r)^r \sum_{k=0}^{\infty} \sum_{P \in \mathcal{F}_k} \gamma_P^r \chi_P + (2C_r)^r \sum_{k=0}^{\infty} \sum_{P \in \mathcal{F}_k} \sum_{P' \in \mathcal{F}_{k+1} : P' \subset P} \gamma_{P'}^r \chi_{P'} \\
\leq 3(2C_r)^r \sum_{P \in \mathcal{F}} \gamma_P^r \chi_P,
which completes the proof. \hfill \square

Remark 3.3. It is easily seen from the proof that Theorem 3.2 can be stated in a, formally stronger, local version. Namely, fix a cube $Q_0 \in \mathcal{Q}$, and assume that the $\ell^r$-condition and (3.1) hold for a family of functions $\{f_Q, f_{P,Q}\}$, where $P, Q \in \mathcal{D}(Q_0)$ and $P \subseteq Q$. Then for any $\eta \in (0, 1)$ there exists an $\eta$-sparse family $\mathcal{F} \subset \mathcal{D}(Q_0)$ such that for a.e. $x \in Q_0$,

\[ |f_{Q_0}(x)| \lesssim C_r \left( \sum_{P \in \mathcal{F}} \gamma_P^r \chi_P(x) \right)^{1/r} \]

with the same $\gamma_P$ as in Theorem 3.2. In particular, the family of all cubes $Q$ in Theorem 3.2 can be replaced by an arbitrary subfamily, for example, by a dyadic lattice $\mathcal{D}$.

3.3. A bilinear form sparse domination principle. In certain applications the $m_{P,q}^* f$-term in the definition of $\gamma_Q$ in Theorem 3.2 is too large to efficiently estimate. We will therefore also prove a variant of Theorem 3.2, dominating $|f_Q|$ dually by a sparse form involving the smaller term $m_{Q,q}^* f$ for $q \in (0, \infty)$.

Theorem 3.4. Let $r \in (0, \infty)$ and let $\{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)}$ satisfy the $\ell^r$-condition and (3.1) and let $q \in (r, \infty)$. For any $Q \in \mathcal{Q}$ and $\eta \in (0, 1)$ there exists an $\eta$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that for every measurable $g : \mathbb{R}^n \to \mathbb{R}_+$,

\[ \int_Q |f_Q|^r g \lesssim C_r \sum_{P \in \mathcal{F}} \alpha_P^*(g)_{(q/r)', r}|P|, \]

where

\[ \alpha_P = (f_P \chi_P)^* \left( |P|^{\frac{1-\eta}{2m+2}} \right) + (m_{P,q}^* f)^* \left( |P|^{\frac{1-\eta}{2m+2}} \right). \]

Proof. The proof is similar to the proof of Theorem 3.2 and hence some details are omitted. Construct the $\eta$-sparse family $\mathcal{F}$ exactly as in the proof of Theorem 3.2, only replacing $m_P^* f$ by $m_{P,q}^* f$ in the definition of $\Omega_2(P)$. 
By Proposition 3.1 we have
\begin{equation}
|Q|^{\gamma} \leq C^{r}_{\gamma} \sum_{P} \sum_{k=0}^{\infty} \left( \int_{E_{P}} |f_{P}|^{r} g + \sum_{P' \in P_{k+1}: P' \subset P} \int_{P'} |f_{P',P}|^{r} g \right),
\end{equation}
and by (3.4)
\begin{equation}
\int_{E_{P}} |f_{P}|^{r} g \leq \alpha_{P}^{r} \int_{P} g.
\end{equation}

It remains to estimate the second term on the right-hand side of (3.5). As in the proof of Theorem 3.2, we introduce the set $G_{P'} = P' \setminus \Omega(P)$ and observe that
\begin{equation}
|G_{P'} \setminus \Omega(P')| \geq \left( \frac{1}{2} - \frac{1}{2^{n+3}} \right) |P'| \geq \frac{1}{4} |P'|.
\end{equation}
For a.e. $g \in G_{P'} \setminus \Omega(P') \subset P' \setminus \left( \Omega_{1}(P) \cup \Omega_{1}(P') \right)$ we have
\begin{equation}
\int_{P'} |f_{P',P}|^{r} g \leq 2^{r} \int_{P'} |f_{P',P}(x) - f_{P',P}(y)|^{r} g(x) dx + 4^r (\alpha_{P'}^{r} + \alpha_{P}^{r}) \int_{P'} g.
\end{equation}
Integrating over $G_{P'} \setminus \Omega(P')$ and using (3.7), we obtain
\begin{equation}
\int_{P'} |f_{P',P}|^{r} g \leq 4 \cdot 2^{r} \frac{1}{|P'|} \int_{P'} \int_{P'} |f_{P',P}(x) - f_{P',P}(y)|^{r} g(x) dx dy + 4^r (\alpha_{P'}^{r} + \alpha_{P}^{r}) \int_{P'} g.
\end{equation}
By Hölder’s inequality,
\begin{align*}
\frac{1}{|P'|} \int_{P'} \int_{P'} |f_{P',P}(x) - f_{P',P}(y)|^{r} g(x) dx dy & \leq \text{osc}_{q}(f_{P',P}; P') \cdot \langle g \rangle_{(q/r)', P'} |P'| \\
& \leq \inf_{x' \in P'} (m_{P,q} f(x'))^{r} \langle g \rangle_{(q/r)', P'} |P'| \\
& \leq \alpha_{P'}^{r} \langle g \rangle_{(q/r)', P'} |P'|,
\end{align*}
which, along with the previous estimate, implies
\begin{equation}
\int_{P'} |f_{P',P}|^{r} g \leq 5 \cdot 4^r \left( \alpha_{P'}^{r} \langle g \rangle_{(q/r)', P'} |P'| + (\alpha_{P'}^{r} + \alpha_{P}^{r}) \int_{P'} g \right).
\end{equation}
Now note that, by Hölder’s inequality, we have
\begin{align*}
\sum_{P' \in P_{k+1}: P' \subset P} \alpha_{P'}^{r} \langle g \rangle_{(q/r)', P'} |P'| & \leq \alpha_{P}^{r} \left( \sum_{P' \in P_{k+1}: P' \subset P} \int_{P'} g^{(q/r)'} \right)^{\frac{1}{q}} \cdot \left( \sum_{P' \in P_{k+1}: P' \subset P} |P'| \right)^{\frac{r}{q}} \\
& \leq \alpha_{P}^{r} \langle g \rangle_{(q/r)', P} |P|.
\end{align*}
Combining this estimate with (3.5), (3.6) and (3.8), we obtain
\[
\int_Q |f_Q|^r g \leq 6 \cdot 4^r \cdot C_r \left( \sum_{k=0}^\infty \sum_{P \in F_k} \left( \alpha_P^r \int_P g + \sum_{P' \in F_{k+1}; P' \subset P} \alpha_{P'}^r \int_{P'} g \right) + \sum_{k=0}^\infty \sum_{P \in F_k} \alpha_P^r \langle g \rangle_{(q/r)',P} |P| \right)
\]
\[
\leq 18 \cdot 4^r \cdot C_r \sum_{P \in F} \alpha_P^r \langle g \rangle_{(q/r)',P} |P|,
\]
which completes the proof. \qed

3.4. **Sparse domination in spaces of homogeneous type.** A space of homogeneous type \((S, d, \mu)\), originally introduced by Coifman and Weiss in [11], is a set \(S\) equipped with a quasi-metric \(d\) and a doubling Borel measure \(\mu\). That is, a metric \(d\) which instead of the triangle inequality satisfies
\[
d(s, t) \leq c_d (d(s, u) + d(u, t)), \quad s, t, u \in S
\]
for some \(c_d \geq 1\), and a Borel measure \(\mu\) that satisfies the doubling ball property
\[
\mu(B(s, 2\rho)) \leq c_\mu \mu(B(s, \rho)), \quad s \in S, \quad \rho > 0
\]
for some \(c_\mu \geq 1\).

It was shown by Anderson and Vagharshakyan [1] that the sparse domination principle based on the median oscillation estimate (1.1) could be generalized from the Euclidean space \(\mathbb{R}^n\) equipped with the Lebesgue measure to a space of homogeneous type. Later, in [38], it was shown by the second author that the sparse domination principle for operators in [33, 36] also generalizes directly to spaces of homogeneous type. Doing similar adaptations as in [38], Theorems 3.2 and 3.4 also generalize to this setting.

4. **Previous known results from our sparse domination principles**

In this section we will show that Theorems 3.2 and 3.4 imply a number of the previously known results.

4.1. **The local mean oscillation estimate.** Let us start by showing that Theorem 3.2 implies (1.1), or more generally its vector-valued variant by Hänninen and Hytönen [17].
Let $X$ be a Banach space and $f: \mathbb{R}^n \to X$ be a strongly measurable function. Given $0 < \lambda < 1$, the local mean oscillation of $f$ on $Q \in \mathcal{Q}$ is defined by
\[
\omega_\lambda(f; Q) = \inf_{c \in X} \left( \|f - c\|_X \right)^* (\lambda |Q|).
\]
Moreover, for $0 < \lambda < \frac{1}{2}$, we define the quasi-optimal center of oscillation $c_\lambda(f; Q)$ as any vector $c \in X$ such that
\[
\left( \|f - c\|_X \right)^* (\lambda |Q|) \leq 2 \omega_\lambda(f; Q),
\]
see [17, Section 4] for an introduction. We will use the following property of this object: for $0 < \lambda \leq \kappa < \frac{1}{2}$ we have for any quasi-optimal center of oscillation $c_{\kappa}(f; Q)$ that
\[
(4.1) \quad \left( \|f - c_{\kappa}(f; Q)\|_X \right)^* (\lambda |Q|) \leq 4 \omega_\lambda(f; Q),
\]
see [17, Lemma 4.10].

**Theorem 4.1** ([17]). Let $X$ be a Banach space and let $f: \mathbb{R}^n \to X$ be strongly measurable. For every cube $Q \in \mathcal{Q}$ and $\eta \in (0, 1)$, there exists an $\eta$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that for any $c_{1/4}(f; Q)$ and for a.e. $x \in Q$,
\[
\|f(x) - c_{1/4}(f; Q)\|_X \lesssim \sum_{P \in \mathcal{F}} \omega_{\frac{1 - \eta}{2n+2}}(f; P) \chi_P(x).
\]

**Proof.** For $Q \in \mathcal{Q}$ and $P \in \mathcal{D}(Q)$ define
\[
\begin{align*}
f_Q &:= \|f - c_{1/4}(f; Q)\|_X, \\
f_{P,Q} &:= \|c_{1/4}(f; P) - c_{1/4}(f; Q)\|,
\end{align*}
\]
where for any cube $Q \in \mathcal{Q}$ we fix a quasi-optimal center of oscillation $c_{1/4}(f; Q)$.

The family $\{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)}$ satisfies the $\ell^1$-condition with $C_1 = 1$ by the triangle inequality, and (3.1) holds as well. Therefore, by Theorem 3.2, there exists an $\eta$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that for a.e. $x \in Q$,
\[
\|f(x) - c_{1/4}(f; Q)\|_X \lesssim \sum_{P \in \mathcal{F}} \gamma_P \chi_P(x).
\]

The function $f_{P',P}$ is a constant for every $P' \in \mathcal{D}(P)$, and therefore $m_P^\# f = 0$. Hence, by (4.1),
\[
\gamma_P = \left( \|f - c_{1/4}(f; P)\|_X \right)^* (|P|^{\frac{1 - \eta}{2n+2}}) \leq 4 \omega_{\frac{1 - \eta}{2n+2}}(f; P),
\]
which completes the proof. \qed
4.2. The $\ell^r$-sparse domination principle for operators. Next we show that Theorem 3.2 implies the main result of the second author in [38, Theorem 3.2] on pointwise $\ell^r$-sparse domination for a bounded operator $T: L^p \to L^{p,\infty}$. Moreover, due to our flexible setup, we also obtain the pointwise $\ell^r$-sparse domination result for bounded operators $T: L^p \to L^{q,\infty}$ in [38, Theorem 3.4] without any additional effort.

Let us first introduce some notation. Let $D$ be a dyadic lattice, let $X,Y$ be Banach spaces, $p,q \in (0,\infty)$ and $\alpha \geq 1$. For a bounded operator

$$T: L^p(\mathbb{R}^n; X) \to L^{q,\infty}(\mathbb{R}^n; Y)$$

we say that a family of operators $\{T_Q\}_{Q \in D}$ from $L^p(\mathbb{R}^n; X)$ to $L^{q,\infty}(Q; Y)$ is an $\alpha$-localization family of $T$ if for all $Q \in D$ and $f \in L^p(\mathbb{R}^n; X)$ we have

$$T_Q(f\chi_Q)(x) = T_Q f(x), \quad x \in Q,$$

$$\|T_Q(f\chi_Q)(x)\|_Y \leq \|T(f\chi_Q)(x)\|_Y, \quad x \in Q.$$  

The canonical example is of course $T_Q f := T_Q(f\chi_Q)$ for all $Q \in D$.

Using an $\alpha$-localization family of $T$, we can define operator variants of the $\ell^r$-condition and the sharp maximal function $m_Q^{\#} f$. Indeed, set $T_{P,Q} := T_Q - T_P$ and let $r \in (0,\infty)$. We say that $T$ satisfies a localized $\ell^r$-estimate if for every $Q \in \mathcal{Q}$ and every $P_1, \ldots, P_m \in \mathcal{D}(Q)$ with $P_m \subset \cdots \subset P_1$ and $f \in L^p(\mathbb{R}^n; X)$, we have for a.e. $x \in P_m$

$$\|T_{P,Q}(x)\|_Y \leq C_r \left( \sum_{k=1}^{m-1} \|T_{P_{k+1},P_k} f(x)\|_Y^r + \|T_{P_m} f(x)\|_Y^r \right)^{1/r}.$$  

Observe that if $r \in (0,1]$ and $T_Q f = T(f\chi_Q)$ for some $\alpha \geq 1$, then this estimate holds trivially for every (sub)linear operator $T$ with $C_r = 1$. If $T$ satisfies a localized $\ell^r$-estimate, then, setting

\begin{align*}
(4.2) \quad f_Q(x) := \|T_Q f(x)\|_Y & \quad x \in \mathbb{R}^n \\
(4.3) \quad f_{P,Q}(x) := \|T_{P,Q} f(x)\|_Y & \quad x \in \mathbb{R}^n
\end{align*}

for $Q \in D$ and $P \in \mathcal{D}(Q)$, we obtain that the $\ell^r$-condition holds.

Next, the operator analogue of the sharp maximal function $m_Q^{\#} f$ for a cube $Q \in \mathcal{Q}$ is given by

$$M_{T,Q}^\# f(x) = \sup_{P \in \mathcal{D}(Q): x \in P} \mathop{\text{ess sup}}_{x',x'' \in P} \|T_{P,Q} f(x') - T_{P,Q} f(x'')\|_Y, \quad x \in \mathbb{R}^n.$$  

For $f_{P,Q}$ as in (4.3) we have

$$|f_{P,Q}(x') - f_{P,Q}(x'')| \leq \|T_{P,Q} f(x') - T_{P,Q} f(x'')\|_Y, \quad x',x'' \in P.$$  

For $f_{P,Q}$ as in (4.3) we have
and therefore
\begin{equation}
(4.4) \quad m_Q^\# f(x) \leq M_{T,Q}^\# f(x), \quad x \in \mathbb{R}^n.
\end{equation}

We are now ready to prove the announced result from [38], which in
the diagonal case \( p = q \) generalizes the main result of [36].

**Theorem 4.2 ([38]).** Let \( \mathcal{D} \) be a dyadic lattice, let \( X \) and \( Y \) be Banach
space, take \( p, q, r \in (0, \infty) \) and let \( \alpha \geq 1 \). Suppose that
\begin{itemize}
  \item \( T \) is a bounded operator from \( L^p(\mathbb{R}^n; X) \) to \( L^{q,\infty}(\mathbb{R}^n; Y) \) with \( \alpha \)-
localization family \( \{T_Q\}_{Q \in \mathcal{D}} \).
  \item \( M_{T,Q}^\# \) is bounded from \( L^p(\mathbb{R}^n; X) \) to \( L^{q,\infty}(\mathbb{R}^n) \) uniformly in \( Q \in \mathcal{D} \).
  \item \( T \) satisfies a localized \( \ell^r \)-estimate.
\end{itemize}

Then for any \( f \in L^p(\mathbb{R}^n; X) \) and \( Q \in \mathcal{D} \), there exists a \( \frac{1}{2} \)-sparse family
\( F \subset D(Q) \) such that for a.e. \( x \in Q \),
\begin{equation}
\|T_Q f(x)\|_Y \lesssim C_T C_r \left( \sum_{P \in F} |\alpha P|^{\frac{r}{p} - \frac{1}{q}} \langle \|f\|_X \rangle_{p,\alpha P} \chi_P(x) \right)^{1/r},
\end{equation}
with \( C_T := \|T\|_{L^p \to L^{q,\infty}} + \sup_{Q \in \mathcal{D}} \|M_{T,Q}^\#\|_{L^p \to L^{q,\infty}} \).

**Proof.** The essence of the proof is already contained in the discussion
preceding the theorem. Indeed, let \( \{f_Q, f_{P,Q}\}_{Q \in \mathcal{D}, P \in D(Q)} \) be as in (4.2)
and (4.3), which satisfies the \( \ell^r \)-condition, and also (3.1) holds. Hence
we are in position to apply Theorem 3.2 with \( \eta = \frac{1}{2} \) (see also Remark 3.3). It remains to estimate \( \gamma_P \) provided by this theorem.

By the assumption on \( T \) we have
\begin{equation}
(f_P \chi_P)^* (|P|/2^{n+3}) \lesssim \|T\|_{L^p \to L^{q,\infty}} \cdot |\alpha P|^{\frac{1}{p} - \frac{1}{q}} \langle \|f\|_X \rangle_{p,\alpha P}.
\end{equation}

Moreover, by the assumption on \( M_{T,P}^\# \) and (4.4), we have
\begin{equation}
(m_P^\# \chi_P)^* (|P|/2^{n+3}) \lesssim \|M_{T,Q}^\#\|_{L^p \to L^{q,\infty}} \cdot |\alpha P|^{\frac{1}{p} - \frac{1}{q}} \langle \|f\|_X \rangle_{p,\alpha P},
\end{equation}
which completes the proof. \( \square \)

**Remark 4.3.** In [38, Theorem 3.5] a sparse form domination principle
was shown for operators. Analogously to the proof of Theorem 4.2,
one can deduce [38, Theorem 3.5] from our sparse form domination
principle in Theorem 3.4.

**Remark 4.4.** Both papers [36] and [38] contain a list of known sparse
domination results for operators that fit our setting. For readers
convenience, we include a unified and extended list below.
\begin{itemize}
  \item Calderón–Zygmund operators [36] with operator-valued kernel [38].
  \item Maximally modulated Calderón–Zygmund operators [3].
  \item Variational truncations of Calderón–Zygmund operators [41, 49].
\end{itemize}
• Multilinear singular integral operators with $L^r$-Hörmander condition [37].
• Fractional integral operators with Hormández kernel [27].
• A class of pseudo-differential operators [4].
• The Rademacher [38] and the lattice Hardy–Littlewood [18] maximal operators.
• The intrinsic Littlewood–Paley square function [39].
• Non-integral operators falling outside the scope of Calderón–Zygmund theory [8] and the associated square functions [2].
• Rough homogeneous singular integrals [34].
• The Marcinkiewicz integral with rough kernel [45].

Let us note that the boundedness of the corresponding sharp maximal operator is not explicitly contained in all of the above cited works and in particular sparse domination is obtained in a self-contained way in many of these citations. However, the presented arguments often imply the boundedness of the corresponding sharp maximal operator in our setting. For more details we refer to [36, Section 5] and [38, Section 9].

The three last items from the list fit the setting of bilinear form sparse domination expressed in Theorem 3.4.

5. Generalized Poincaré–Sobolev inequalities

As a first new application of our operator-free sparse domination principle, we will study generalized Poincaré–Sobolev inequalities as in [9, 44]. In particular, we will extend and improve [44, Theorem 1.5 and 1.24] by Perez and Rela.

Let us introduce some notation. Let $p, s \in [1, \infty)$. For a functional $a: Q \to \mathbb{R}_+$ and a weight $w$ we say that $a$ satisfies the $SD^s_p(w)$-condition, and write $a \in SD^s_p(w)$, if for any cube $Q \in \mathcal{Q}$ and any family of pairwise disjoint $\{Q_j\} \subset \mathcal{D}(Q)$ we have

$$\left( \sum_j a(Q_j)^p w(Q_j) \right)^{1/p} \leq C \left( \sum_j |Q_j| \right)^{1/s} a(Q) w(Q)^{1/p}.$$ 

The least admissible constant $C \geq 1$ is denoted by $\|a\|_{SD^s_p(w)}$. We note that the $SD^s_p(w)$-condition can be thought of as a smallness preserving condition and for examples of functionals $a \in SD^s_p(w)$ we refer to [44].

Fix a cube $Q \in \mathcal{Q}$ and $f \in L^{1}_{log}(\mathbb{R}^n)$. For $m \in \mathbb{N} \cup \{0\}$, we denote by $P_Q f$ the projection of $f$ onto the space of polynomials of degree at most $m$ in $n$ variables on $Q$. We refer to [44, Section 8] for a proper introduction of this projection. Here we just note the following two properties that we will use of $P_Q f$: 

16 A.K. LERNER, E. LORIST, AND S. OMBROSI

• There is a $C_m > 0$ such that

\begin{equation}
\|P_Q f\|_{L^\infty(Q)} \leq C_m \frac{1}{|Q|} \int_Q |f|.
\end{equation}

• For any polynomial $\pi$ of degree at most $m$ in $n$ variables we have

$P_Q(\pi) = \pi$ on $Q$.

Furthermore we note that when $m = 0$, we have $P_Q f = \frac{1}{|Q|} \int_Q f$.

In this language, the main result of Perez and Rela reads as follows:

**Theorem 5.1 (44).** Let $p, s \in [1, \infty)$ and let $w \in A_\infty$. Assume that $a \in SD^s_p(w)$. Let $f \in L^1_{\text{loc}}(\mathbb{R}^n)$ be such that for all $Q \in \mathcal{Q}$,

\begin{equation}
\frac{1}{|Q|} \int_Q |f - P_Q f| \leq a(Q).
\end{equation}

Then, there is a constant $C_{n,m} > 0$ such that for any $Q \in \mathcal{Q}$

\begin{equation}
\left( \frac{1}{w(Q)} \int_Q |f - P_Q f|^p w \right)^{\frac{1}{p}} \leq C_{n,m,s} \|a\|_{SD^s_p(w)} a(Q).
\end{equation}

Note that when $m \geq 1$, the result of Perez and Rela has an additional factor $2^{\frac{s}{p+1}}$ in the conclusion, but it was observed in [9, Theorem 2.1] that this factor can be omitted.

It was asked in [44, Remark 1.6] whether the $A_\infty$ assumption in Theorem 5.1 can be removed. A partial result in this direction was provided by Martínez-Perales [42].

In order to state our main result, we assume that $X$ is a Banach function space (see e.g. [7, 40]). First we define the $s$-smallness preserving condition for an arbitrary $X$, which in the case $X = L^p_w$ coincides with the definition of the $SD^s_p(w)$-condition.

**Definition 5.2.** Let $s \in [1, \infty)$. For a functional $a : Q \to \mathbb{R}^+$ we say that $a$ satisfies the $s$-smallness preserving condition if for any cube $Q \in \mathcal{Q}$ and any family of pairwise disjoint $\{Q_j\} \subset \mathcal{D}(Q)$ we have

\begin{equation}
\left\| \sum_j a(Q_j) \chi_{Q_j} \right\|_X \leq C \left( \frac{\sum_j |Q_j|}{|Q|} \right)^{\frac{1}{s}} a(Q) \|\chi_Q\|_X.
\end{equation}

The least admissible constant $C \geq 1$ is denoted by $\|a\|_s$.

We are ready to state the main result of this section.

**Theorem 5.3.** Let $X$ be a Banach function space and let $s \in [1, \infty)$. Take an $a : Q \to \mathbb{R}^+$ satisfying the $s$-smallness preserving condition
and let $f \in L^1_{\text{loc}}(\mathbb{R}^n)$ be such that for all $Q \in \mathcal{Q}$,

$$
\frac{1}{|Q|} \int_Q |f - P_Q f| \leq a(Q).
$$

Then there is a $C_{n,m} > 0$ such that for any $Q \in \mathcal{Q}$,

$$
(f - P_Q f) \chi_Q \|_{L^1} \leq C_{n,m} \|a\|_s a(Q) \|\chi_Q\|_{L^1}.
$$

(5.4)

Taking $X = L^p(w)$, we obtain an extension of Theorem 5.1 to arbitrary weights, which provides an affirmative answer to the question posed in [44, Remark 1.6]. Moreover, we have a quantitative improvement over Theorem 5.1, even in the case $m = 0$ and $s > 1$, since (5.4) holds with the linear dependence on $\|a\|_s$, whereas one has $\|a\|_{SD^p(w)}$ in (5.2).

The key ingredient in our proof of Theorem 5.3 is the following sparse domination result in the spirit of Theorem 4.1.

**Proposition 5.4.** Let $f \in L^1_{\text{loc}}(\mathbb{R}^n)$. For any $Q \in \mathcal{Q}$ and $\eta \in (0,1)$ there exists an $\eta$-sparse family $\mathcal{F} \subset D(Q)$ such that

$$
|f - P_Q f| \chi_Q \leq C_{n,m} \|f - P_R f\|_{L^1} \chi_R.
$$

Proof. For $Q \in \mathcal{Q}$ and $R \in D(Q)$ define

$$
f_Q := f - P_Q f
$$

and

$$
f_{R,Q} := P_R f - P_Q f.
$$

The family $\{f_Q, f_{R,Q}\}_{Q \in \mathcal{Q}, R \in D(Q)}$ trivially satisfies the $\ell^1$-condition with $C_r = 1$, and (3.1) holds.

For any $R' \in D(R)$ we have by (5.1)

$$
\|f_{R',R}\|_{L^\infty(P)} = \|P_{R'}(f - P_R f)\|_{L^\infty(R')} \leq C_m \frac{1}{|R'|} \int_{R'} |f - P_R f|,
$$

which implies

$$
m^\#_{R'} f(x) \leq 2C_m M((f - P_R f) \chi_R)(x), \quad x \in \mathbb{R}^n.
$$

Therefore, by Chebyshev’s inequality and the weak $L^1$-boundedness of $M$, we have for any $\eta \in (0,1)$,

$$
(f_R \chi_R)^*(|R|^{\frac{n}{2(m+1)}}) + (m^\#_{R'} f)^*(|R|^{\frac{n}{2(m+1)}}) \leq C_{n,m} \frac{1}{1-\eta} \frac{1}{|R|} \int_{R'} |f - P_R f|,
$$

which, by Theorem 3.2, completes the proof. \qed
Proof of Theorem 5.3. Fix a cube $Q \in \mathcal{Q}$. Let $\eta \in (0, 1)$. By the main hypothesis of Theorem 5.3 combined with Proposition 5.4, there exists an $\eta$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that for a.e. $x \in Q$,

\begin{equation}
|f - P_Qf| \leq C_{n,m} \frac{1}{1 - \eta} \sum_{R \in \mathcal{F}} a(R) \chi_R.
\end{equation}

Write $\mathcal{F} = \bigcup_{k=0}^{\infty} \mathcal{F}_k$, where $\mathcal{F}_k$ is as in the definition of a contracting family of dyadic cubes. Since $\mathcal{F}$ is $\eta$-sparse, for any $k \in \mathbb{N} \cup \{0\}$ we have

$$\sum_{R \in \mathcal{F}_k} |R| \leq (1 - \eta)^k |Q|,$$

which, along with the $s$-smallness preserving condition, implies

$$\left\| \sum_{R \in \mathcal{F}_k} a(R) \chi_R \right\|_X \leq \|a\|_s (1 - \eta)^{k/s} a(Q) \|\chi_Q\|_X.$$

Therefore,

$$\left\| \sum_{R \in \mathcal{F}} a(R) \chi_R \right\|_X \leq \sum_{k=0}^{\infty} \left\| \sum_{R \in \mathcal{F}_k} a(R) \chi_R \right\|_X \leq \|a\|_s \frac{1}{1 - (1 - \eta)^{1/s}} a(Q) \|\chi_Q\|_X.$$

From this and (5.5), we obtain

$$\left\| (f - P_Qf) \chi_Q \right\|_X \leq C_{n,m} \frac{1}{1 - \eta} \frac{1}{1 - (1 - \eta)^{1/s}} \|a\|_s a(Q) \|\chi_Q\|_X.$$

Taking $\eta = 1 - \left( \frac{s}{s+1} \right)^s$ completes the proof. \hfill \square

Remark 5.5. Using the Aoki-Rolewicz theorem (see [28]), one can show that Theorem 5.3 remains true for quasi-Banach function spaces, although the precise constant will depend on $X$.

Remark 5.6. Observe that the term $\|\chi_Q\|_X$ does not play any role in the proof of Theorem 5.3. Therefore, if we consider a functional $b: \mathcal{Q} \to \mathbb{R}_+$ and replace $\|\chi_Q\|_X$ by $b(Q)$ in the right-hand side of the $s$-smallness preserving condition (5.3), we obtain Theorem 5.3 with $b(Q)$ instead of $\|\chi_Q\|_X$ in the right hand side of (5.4). Other examples of functionals $b$ are $b(Q) = \|\chi_{2Q}\|_X$ or $b(Q) = \|M(\chi_Q)\|_X$, which could in certain circumstances yield a more general condition than our current $s$-smallness preserving condition.
6. Tent spaces

As our second new application, we will use our sparse domination principle to prove the main relation between two basic operators in the theory of tent spaces.

Let $\mathbb{R}_{+}^{n+1} = \{(y, t) : y \in \mathbb{R}^n, t > 0\}$ and, given $\alpha > 0$, let $\Gamma_\alpha(x)$ denote the cone in $\mathbb{R}_{+}^{n+1}$ with vertex in $x \in \mathbb{R}^n$ of aperture $\alpha$, i.e.

$$\Gamma_\alpha(x) = \{(y, t) \in \mathbb{R}_{+}^{n+1} : |x - y| < \alpha t\}.$$  

Given a ball $B = B(x, r)$ in $\mathbb{R}^n$, denote the tent over $B$ by

$$\hat{B} = \{(y, t) \in \mathbb{R}_{+}^{n+1} : |x - y| + t < r\}.$$ 

For a measurable function $f : \mathbb{R}_{+}^{n+1} \to \mathbb{R}$ define

$$A^{(\alpha)}(f)(x) := \left(\int_{\Gamma_\alpha(x)} |f(y, t)|^2 \frac{dydt}{t^{n+1}}\right)^{1/2}, \quad x \in \mathbb{R}^n,$$

$$C(f)(x) := \sup_{B \ni x} \left(\frac{1}{|B|} \int_{B} |f(y, t)|^2 \frac{dydt}{t}\right)^{1/2}, \quad x \in \mathbb{R}^n,$$

where the supremum is taken over all balls $B \subset \mathbb{R}^n$ containing $x$.

In [10], Coifman, Meyer and Stein defined the tent space $T^p_\alpha$ for $p \in (0, \infty)$ and $\alpha > 0$ as the space of all measurable $f : \mathbb{R}_{+}^{n+1} \to \mathbb{R}$ such that

$$\|f\|_{T^p_\alpha} := \|A^{(\alpha)}(f)\|_{L^p(\mathbb{R}^n)} < \infty.$$  

It was shown in [10] that $T^p_\alpha = T^p_\beta$ for $\alpha, \beta > 0$ and thus it suffices to study $T^p := T^p_1$. Furthermore, they deduced

\begin{align*}
  &\|f\|_{T^p} \lesssim \|C(f)\|_{L^p(\mathbb{R}^n)} & p \in (0, \infty), \quad (6.1) \\
  \|C(f)\|_{L^p(\mathbb{R}^n)} & \lesssim \|f\|_{T^p} & p \in (2, \infty). \quad (6.2)
\end{align*}

To prove these inequalities, it is useful to define a truncated version of $A^{(\alpha)}$, i.e. for $h > 0$ set

$$A^{(\alpha)}_h(f)(x) := \left(\int_0^h \int_{|y - x| < \alpha t} |f(y, t)|^2 \frac{dydt}{t^{n+1}}\right)^{1/2}, \quad x \in \mathbb{R}^n,$$

and note that, using Fubini’s theorem, we can reformulate $C(f)(x)$ for $x \in \mathbb{R}^n$ as follows

\begin{align*}
  C(f)(x) & \asymp \sup_{y \ni B} \left(\frac{1}{|B|} \int_0^{|r(B)|} \int_{|y - x| \leq \alpha t} |B(y, \alpha t)| \frac{dydt}{t^{n+1}}\right) \\
  & \asymp \sup_{y \ni B} \left(\frac{1}{|B|} \int_0^{|r(B)|} \int_{|y - z| \leq \alpha t} |f(y, t)|^2 \frac{dydt}{t^{n+1}} dz\right)^{1/2} \quad (6.3) \\
  & = \sup_{y \ni B} \left(\frac{1}{|B|} \int_B A^{(\alpha)}_r(B)(f)(z)^2 dz\right)^{1/2}.
\end{align*}
where \( r(B) \) denotes the radius of the ball \( B \) and the implicit constants depend on \( \alpha > 0 \).

From (6.3) it is clear that \( C(f)^2 \lesssim M(A(f)^2) \), which directly implies (6.2) by the boundedness of the maximal operator. We will give a “sparse” proof of the converse in (6.1).

**Theorem 6.1.** Take \( \alpha > 0 \) and let \( f : \mathbb{R}^{n+1}_+ \to \mathbb{R} \) be measurable. For every cube \( Q \in \mathcal{Q} \) there exists a \( \frac{1}{2} \)-sparse family \( \mathcal{F} \subset \mathcal{D}(Q) \) such that for a.e. \( x \in Q \),

\[
A_{|Q|}^{(\alpha)}(f)(x) \lesssim \left( \sum_{P \in \mathcal{F}} \frac{1}{|P|} \int_P A_{|P|}^{(4\alpha+\sqrt{m})}(f)^2 \cdot \chi_P(x) \right)^{1/2}.
\]

Combining Theorem 6.1 with (6.3), we obtain for \( \delta \in (0,2] \) and \( g \in L^{p'}(\mathbb{R}^n) \),

\[
\int_Q A_{|Q|}^{(1)}(f)^\delta g \lesssim \sum_{P \in \mathcal{F}} \left( \frac{1}{|P|} \int_P A_{|P|}^{(4\alpha+\sqrt{m})}(f)^2 \right)^{\delta/2} \int_P g \lesssim \sum_{P \in \mathcal{F}} \int_{E_P} (C(f))^\delta \cdot Mg \lesssim \|C(f)^\delta\|_{L^p(\mathbb{R}^n)}\|g\|_{L^{p'}(\mathbb{R}^n)}.
\]

By duality and the monotone convergence theorem, this yields (6.1).

**Proof of Theorem 6.1.** Let \( \Phi \) be a smooth function such that \( \chi_{B(0,1)} \leq \Phi \leq \chi_{B(0,2)} \) and for \( Q \in \mathcal{Q} \) define

\[
f_Q(x) := \left( \int_0^{|Q|} \int_{\mathbb{R}^n} |f(y,t)|^2 \cdot \Phi\left( \frac{x-y}{\alpha t} \right)^2 \frac{dydt}{t^{n+1}} \right)^{1/2}, \quad x \in Q.
\]

Observe that \( A_{|Q|}^{(\alpha)}(f) \leq f_Q \leq A_{|Q|}^{(2\alpha)}(f) \). For \( P \in \mathcal{D}(Q) \) set

\[
f_{P,Q}(x) := \left( \int_{|P|} \int_{\mathbb{R}^n} |f(y,t)|^2 \cdot \Phi\left( \frac{x-y}{\alpha t} \right)^2 \frac{dydt}{t^{n+1}} \right)^{1/2}, \quad x \in P.
\]

The family \( \{f_Q,f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)} \) trivially satisfies the \( \ell^2 \)-condition with \( C_2 = 1 \), and condition (3.1) holds as well. Therefore, by Theorem 3.2, there exists a \( \frac{1}{2} \)-sparse family \( \mathcal{F} \subset \mathcal{D}(Q) \) such that for a.e. \( x \in Q \),

\[
A_{|Q|}^{(\alpha)}(f)(x) \leq f_Q(x) \lesssim \left( \sum_{P \in \mathcal{F}} \gamma_P^2 \chi_P(x) \right)^{1/2},
\]

where

\[
\gamma_P = (f_P \chi_P)^*\left( |P|/2^{n+3} \right) + (m_P^\#f)^*\left( |P|/2^{n+3} \right).
\]
We start by analysing \( m_P^f \). Fix \( P \in \mathcal{F} \) and \( x \in P \). Let \( R \in \mathcal{D}(P) \) be such that \( x \in \mathbb{R} \) and take \( N \in \mathbb{N} \) such that \( 2^N \ell_R = \ell_P \). We have for \( \xi, \eta \in R \)

\[
|f_{R,P}(\xi) - f_{R,P}(\eta)| \leq \left( \int_{\ell_R}^{\ell_P} \int_{\mathbb{R}^n} |f(y,t)|^2 \cdot \left( \Phi \left( \frac{\xi-y}{\alpha t} \right) - \Phi \left( \frac{\eta-y}{\alpha t} \right) \right) \frac{2 \, dy \, dt}{t^{n+1}} \right)^{1/2} \\
\leq \sum_{k=1}^{N} \left( \int_{2^{k-1}\ell_R}^{2^k\ell_R} \int_{\mathbb{R}^n} |f(y,t)|^2 \cdot \left( \Phi \left( \frac{\xi-y}{\alpha t} \right) - \Phi \left( \frac{\eta-y}{\alpha t} \right) \right) \frac{2 \, dy \, dt}{t^{n+1}} \right)^{1/2} \\
\leq \sum_{k=1}^{N} \frac{\|\xi - \eta\|}{\alpha 2^k \ell_R} \left( \int_{2^{k-1}\ell_R}^{2^k\ell_R} \int_{|x-y| \leq 4\alpha t + \sqrt{\pi} \ell_R} |f(y,t)|^2 \frac{dy \, dt}{t^{n+1}} \right)^{1/2} \\
\leq \sum_{k=1}^{N} \frac{1}{2^k} \left( \int_0^{\ell_P} \int_{|x-y| < (4\alpha + \sqrt{\pi})t} |f(y,t)|^2 \frac{dy \, dt}{t^{n+1}} \right)^{1/2} \\
\leq A_{\ell_P}^{(4\alpha + \sqrt{\pi})} f(x).
\]

Therefore \( m_P^f(x) \lesssim A_{\ell_P}^{(4\alpha + \sqrt{\pi})} f(x) \) for \( x \in P \). Since we already noted that \( f_P \leq A_{\ell_P}^{(2\alpha)} f \), we obtain by (2.2),

\[
\gamma_P \leq \left( \frac{2^{n+3}}{|P|} \int_P f_P(z)^2 \, dz \right)^{1/2} + \left( \frac{2^{n+3}}{|P|} \int_P m_P^f(z)^2 \, dz \right)^{1/2} \\
\lesssim \left( \frac{1}{|P|} \int_P A_{\ell_P}^{(4\alpha + \sqrt{\pi})}(f)(z)^2 \, dz \right)^{1/2}.
\]

Combined with (6.4), this finishes the proof. \( \square \)

### 6.1. An improved good-\( \lambda \) inequality

The estimate (6.1) was shown in [10] using the equivalence of tent spaces with different apertures and the following good-\( \lambda \) estimate: there exists a fixed \( \alpha > 1 \) and a constant \( c > 0 \) so that for all \( \lambda > 0 \) and \( 0 < \gamma \leq 1 \),

\[
\left| \{x \in \mathbb{R}^n : A(f)(x) > 2\lambda, C(f)(x) \leq \gamma \lambda \} \right| \leq c \gamma^2 \left| \{x \in \mathbb{R}^n : A^{(\alpha)}(f)(x) > \lambda \} \right|.
\]

where we abbreviated \( A(f) := A^{(1)}(f) \). Using Theorem 6.1, we can show that the quadratic dependence on \( \gamma \) in (6.5) can be improved to quadratic exponential dependence.

**Theorem 6.2.** Let \( f : \mathbb{R}^n_{+1} \to \mathbb{R} \) be measurable. There exist constants \( \alpha > 1 \) and \( c > 0 \) so that for all \( \lambda > 0 \) and \( 0 < \gamma \leq 1 \),

\[
\left| \{x \in \mathbb{R}^n : A(f)(x) > 2\lambda, C(f)(x) \leq \gamma \lambda \} \right|
\]
Before proving this lemma, we establish the following simple proposition.

**Proposition 6.3.** Let $Q \in \mathcal{Q}$ and let $\mathcal{F} \subset \mathcal{D}(Q)$ be an $\eta$-sparse family. Then we have for any $\alpha > 0$

$$|\{x \in Q : \sum_{P \in \mathcal{F}} \chi_P(x) > \alpha\}| \leq \frac{1}{1 - \eta} e^{-\alpha \log \frac{1}{1 - \eta}} |Q|.$$

**Proof.** Write $\mathcal{F} = \bigcup_{k=0}^{\infty} \mathcal{F}_k$ as in the definition of a contracting family of cubes. By $\eta$-sparseness, we have $|\Omega_k| \leq (1 - \eta)^k |Q|$. Thus, it follows that

$$|\{x \in Q : \sum_{P \in \mathcal{F}} \chi_P(x) > \alpha\}| = \sum_{k=1}^{\infty} |\Omega_{k-1} \setminus \Omega_k| \chi_{(k-1,k]}(\alpha)$$

$$\leq |Q| \sum_{k=1}^{\infty} (1 - \eta)^k \chi_{(k-1,k]}(\alpha) \leq (1 - \eta)^{a-1} |Q|,$$

which completes the proof. \qed

**Proof of Theorem 6.2.** As in [10], we consider a Whitney decomposition $\{Q_j\}_j$ of the open set $\{x \in \mathbb{R}^n : A^{(\alpha)}(f)(x) > \lambda\}$, where $\alpha > 1$ will be chosen later on. Then it suffices to prove that for every $Q_j$,

(6.6) \quad $|\{x \in Q_j : A(f)(x) > 2\lambda, Cf(x) \leq \gamma \lambda\}| \leq c_1 e^{-\alpha^2/\gamma^2} |Q_j|.$

Define $f_{Q_j}(y, t) := f(y, t) \chi_{(\ell_{Q_j}, \infty)}(t)$ and note that

$$A(f) \leq A(f_{Q_j}) + A_{\ell_{Q_j}}(f).$$

Consider $A(f_{Q_j})(x)$ for $x \in Q_j$. By the properties of the Whitney cubes, there exist $z \in Q_j$ and $x_j \in \mathbb{R}^n$ such that $|z - x_j| \leq 4 \sqrt{n} \ell_{Q_j}$ and $A^{(\alpha)}(f)(x_j) \leq \lambda$. Hence, for $(y, t) \in \mathbb{R}_+^{n+1}$ with $|y - x| < t$ and $t \geq \ell_{Q_j}$, we obtain

$$|y - x_j| \leq |y - x| + |x - z| + |z - x_j|$$

$$< t + 5 \sqrt{n} \ell_{Q_j} \leq (5 \sqrt{n} + 1) t.$$ 

Therefore, if $\alpha = 5 \sqrt{n} + 1$, then $A(f_{Q_j})(x) \leq A^{(\alpha)}(f)(x_j) \leq \lambda$ for all $x \in Q_j$. It follows that the left-hand side of (6.6) is bounded by

(6.7) \quad $|\{x \in Q_j : A_{\ell_{Q_j}}(f)(x) > \lambda, C(f)(x) \leq \gamma \lambda\}|.$
By Theorem 6.1 and (6.3), there exists a $\frac{1}{2}$-sparse family $F_j \subset D(Q_j)$ such that
\[
A_{tQ_j}(f)(x)^2 \lesssim C(f)(x)^2 \sum_{P \in F_j} \chi_P(x), \quad x \in Q_j.
\]
Combined with Proposition 6.3 this implies that the expression in (6.7) is at most
\[
|\{x \in Q_j : \sum_{P \in F_j} \chi_P(x) \gtrsim 1/\gamma^2\}| \leq 2e^{-c/\gamma^2}|Q_j|,
\]
which completes the proof of (6.6) and therefore of the theorem. □

6.2. Vector-valued tent spaces. Reinterpreting and extending the formulation of tent spaces by Harboure, Torrea and Viviani in [19], Hytönen, van Neerven and Portal [23] extended tent spaces to the vector-valued setting. In this subsection we will point out how the arguments of the preceding subsection extend to this setting.

In order to give the definition of these vector-valued tent spaces, we first need to introduce some notation. For a Banach space $X$ and a Hilbert space $H$, denote the space of $\gamma$-radonifying operators by $\gamma(H, X) \subseteq L(X, H)$. For an introduction to these spaces we refer to [25, Chapter 9].

For the remainder of this section, set $H := L^2(\mathbb{R}^{n+1}_{+}; \frac{dydt}{t^{n+1}})$. Then the space $\gamma(H, X)$ can be thought of as a square function space, since $\gamma(H, L^p(\mathbb{R}^d)) = L^p(\mathbb{R}^d; L^2(\mathbb{R}^{n+1}_{+}; \frac{dydt}{t^{n+1}}))$, $p \in [1, \infty)$.

Let $f: \mathbb{R}^{n+1}_{+} \to X$ be strongly measurable. If $\langle f, x^* \rangle \in H$ for all $x^* \in X^*$, we can define the operator $I_f \in L(H, X)$ by
\[
I_f \varphi := \int_{\mathbb{R}^{n+1}_{+}} f(y, t) \varphi(y, t) \frac{dydt}{t^{n+1}}, \quad \varphi \in H,
\]
where the integral is interpreted in the Pettis sense (see [24, Theorem 1.2.37]). If $I_f \in \gamma(H, X)$, we write with slight abuse of notation $f \in \gamma(H, X)$ and $\|f\|_{\gamma(H, X)} := \|I_f\|_{\gamma(H, X)}$. Moreover, if $I_f \notin \gamma(H, X)$ or $\langle f, x^* \rangle \notin H$ for some $x^* \in X^*$, we set $\|f\|_{\gamma(H, X)} = \infty$.

We are now ready to define the vector-valued tent spaces introduced in [23]. For $\alpha > 0$ and a strongly measurable $f: \mathbb{R}^{n+1}_{+} \to X$ define
\[
A^{(\alpha)}(f)(x) := \|f \cdot \chi_{\Gamma_{\alpha}}(x)\|_{\gamma(H, X)}, \quad x \in \mathbb{R}^n
\]
\[
A_h^{(\alpha)}(f)(x) := \|f \cdot \chi_{\Gamma_{\alpha}}(x) \cdot \chi_{\mathbb{R}^n \times (0, h)}\|_{\gamma(H, X)}, \quad x \in \mathbb{R}^n, \quad h > 0.
\]
Since $\gamma(H, \mathbb{R}) = H$, this definition coincides with the scalar-valued definitions of $A^{(\alpha)}$ and $A_h^{(\alpha)}$. Therefore it makes sense to define $T^p_\alpha(X)$
as the completion of the space of all strongly measurable \( f: \mathbb{R}^{n+1}_+ \to X \) such that

\[
\|f\|_{T^p_{\alpha}(X)} := \|A^{(\alpha)}(f)\|_{L^p(\mathbb{R}^n)} < \infty.
\]

It was shown in [23, Theorem 4.3] that, as in the scalar case, \( T^p_{\alpha}(X) = T^p_{\beta}(X) \) for \( \alpha, \beta > 0 \) when \( p \in (1, \infty) \) and \( X \) has the so-called UMD property (see [24, Chapter 4]).

The scalar-valued definition of \( C(f) \) does not make sense in the vector-valued setting. However, its reformulation using (6.3) does. Following the work of Hytönen and Weis [26], we slightly generalize this formulation. Fix \( q \in (0, \infty) \), \( \alpha > 0 \) and for a strongly measurable \( f: \mathbb{R}^{n+1}_+ \to X \) define

\[
C^{(\alpha)}_{q}(f)(x) := \sup_{B \ni x} \left( \frac{1}{|B|} \int_B A^{(\alpha)}_{r(B)}(f)^q \right)^{1/q}, \quad x \in \mathbb{R}^n.
\]

If \( X = \mathbb{R} \) and \( q = 2 \), we have \( C^{(\alpha)}_{2}(f) \approx C(f) \) by (6.3).

The equivalence between \( A^{(\alpha)}(f) \) and \( C^{(\alpha)}(f) \) was proven in [26, Theorem 4.4], using a vector-valued analogue of the good-\( \lambda \) inequality (6.5). Since this uses the equivalence of vector-valued tent spaces with different apertures, this result is limited to \( p \in (1, \infty) \) and UMD Banach spaces.

We will, as in the scalar-valued setting, give a “sparse” proof the equivalence between \( A^{(\alpha)}(f) \) and \( C^{(\alpha)}(f) \). In the proof we will not use the equivalence of vector-valued tent spaces with different apertures, which allows us the treat \( p \in (0, \infty) \) and arbitrary Banach spaces. The price we pay is that we have to increase the aperture of \( C^{(\alpha)}(f) \). Of course, if \( p \in (1, \infty) \) and \( X \) has the UMD property, one can afterwards use the equivalence of vector-valued tent spaces with different apertures to recover [26, Theorem 4.4].

We refer to [25, Chapter 7] for the definition of (Rademacher) type \( r \in [1, 2] \) with constant \( \tau_{r,X} \) used in the following theorem. Let us note here that any Banach space has type 1 with constant \( \tau_{1,X} = 1 \).

**Theorem 6.4.** Let \( X \) be a Banach space with type \( r \in [1, 2] \), take \( q \in (0, \infty) \) and let \( \alpha > 0 \). Let \( f: \mathbb{R}^{n+1}_+ \to X \) be strongly measurable. For every cube \( Q \in Q \) there exists a \( \frac{1}{2} \)-sparse family \( F \subset D(Q) \) such that for a.e. \( x \in Q \),

\[
A^{(\alpha)}_{Q}(f)(x) \lesssim \tau_{r,X} \left( \sum_{P \in F} \left( \frac{1}{|P|} \int_P A^{(4\alpha+\sqrt{m})}_{t_P}(f)^q \right)^{r/q} \cdot \chi_P(x) \right)^{1/r}.
\]
Proof. As in the proof of Theorem 6.1, let $\Phi$ be a smooth function such that $\chi_{B(0,1)} \leq \Phi \leq \chi_{B(0,2)}$ and for $Q \in \mathcal{Q}$ and $P \in \mathcal{D}(Q)$ define

\[
 f_Q(x) := \| (y,t) \mapsto f(y,t) \cdot \Phi\left(\frac{x-y}{\alpha t}\right) \cdot \chi_{(0,\ell_Q)}(t) \|_{\gamma(H,X)}, \quad x \in Q,
\]

\[
 f_{P,Q}(x) := \| (y,t) \mapsto f(y,t) \cdot \Phi\left(\frac{x-y}{\alpha t}\right) \cdot \chi_{(\ell_P,\ell_Q)}(t) \|_{\gamma(H,X)}, \quad x \in P.
\]

For the family $\{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)}$ the $\ell^r$-condition holds with $\tau_{r,X} = \tau_{r,\gamma}$ by [25, Proposition 9.4.13]. The rest of the proof follows the lines of the proof of Theorem 6.1. The only alterations are the following:

- We replace pointwise estimates by the fact that for $f \in \gamma(H,X)$ and $g \in L^\infty(\mathbb{R}^{n+1})$ we have
  \[
  \| f \cdot g \|_{\gamma(H,X)} \leq \| g \|_{L^\infty(\mathbb{R}^{n+1})} \| f \|_{\gamma(H,X)}.
  \]
- We use Theorem 3.2 with $r = r$ instead of $r = 2$.
- In the concluding estimate, we use (2.1) for $q$ instead of 2. \(\square\)

As in the scalar-valued setting, as a direct corollary of Theorem 6.4, we obtain: For $p, q \in (0, \infty)$, $\alpha > 0$, a Banach space $X$ and any strongly measurable $f : \mathbb{R}^{n+1} \to X$ we have

\[
 \| f \|_{T^p(X)} \lesssim \| C^q(f) \|_{L^p(\mathbb{R}^n)}, \quad p \in (0, \infty).
\]

Moreover, since $C^q(f) \lesssim M(A^q(f))$, we have

\[
 \| C^q(f) \|_{L^p(\mathbb{R}^n)} \lesssim \| f \|_{T^p(X)}, \quad 0 < q < p < \infty.
\]

As noted before, this recovers [26, Theorem 4.4] if $p \in (1, \infty)$ and $X$ is a UMD Banach space.

To conclude this subsection, let us note that, doing similar adaptations to the proof of Theorem 6.2 as we did in the proof of Theorem 6.4, we can improve the vector-valued good-$\lambda$ inequality in [26, Theorem 4.4] to exponential dependence on $\gamma^r$.

7. Vector-valued square functions

In a recent paper by Xu [48], vector-valued Littlewood–Paley–Stein theory was developed using Littlewood–Paley theory and functional calculus methods, which vastly improves earlier approaches. In this section we will simplify the technical core of [48], using our pointwise sparse domination principle.

To introduce the main result of [48], let $p \in (1, \infty)$, let $(\Omega, \mu)$ be a $\sigma$-finite measure space and let $X$ be a Banach space with martingale cotype $q \in [2, \infty)$ with constant $c_{q,X}^{\text{mart}}$. We refer to [24, Section 3.5.d] for an introduction to martingale (co)type. For a strongly continuous semigroup of regular operators $\{T_t\}_{t \geq 0}$ on $L^p(\Omega)$ and its subordinated
Poisson semigroup \( \{P_t\}_{t \geq 0} \), one of the main results of [48] states that for \( f \in L^p(\Omega; X) \) one has

\[
\left\| \left( \int_0^\infty \left\| t \frac{\partial}{\partial t} P_t(f) \right\|_X^q \right\|_{L^p(\Omega)}^{1/q} \right\| \lesssim \max\{p^\frac{1}{p'}, p'\} \cdot c_{q,X} \cdot \|f\|_{L^p(\Omega; X)}.
\]

The converse of this estimate is shown to hold under a martingale type assumption. Moreover, using functional calculus techniques, similar estimates with \( \{T_t\}_{t \geq 0} \) instead of \( \{P_t\}_{t \geq 0} \) are obtained under an analyticity assumption. The growth order in \( p \) in most of these estimates is sharp for \( p \to 1 \) and \( p \to \infty \). When \( \{T_t\}_{t \geq 0} \) is the heat semigroup on \( \mathbb{R}^n \), these results answer a question raised by Naor and Young in the appendix of [43].

The most technical part of the argument in [48] is a sharp estimate for a vector-valued variant of the vertical square function. For \( \varepsilon, \delta > 0 \) let \( H_{\varepsilon,\delta} \) be the class of all \( \varphi: \mathbb{R}^n \to \mathbb{R} \) such that

\[
\int_{\mathbb{R}^n} \varphi = 0 \quad \text{and} \quad |\varphi(x) - \varphi(x')| \leq \frac{|x - x'|^\delta}{(1 + \min\{|x|, |x'\}|)^{d+\varepsilon}}, \quad x, x' \in \mathbb{R}^n.
\]

For \( \varphi \in H_{\varepsilon,\delta} \) and \( f \in L^1(\mathbb{R}^n; X) \) define

\[
G_{q,\varphi}(f)(x) = \left( \int_0^\infty \left\| \varphi_t * f(x) \right\|_X^q \frac{dt}{t} \right)^{1/q}, \quad x \in \mathbb{R}^n,
\]

where \( \varphi_t(x) = \frac{1}{t^d} \varphi(\frac{x}{t}) \). In [48] the main result (7.1) follows from

\[
\|G_{q,\varphi}(f)\|_{L^p(\mathbb{R}^n)} \lesssim \max\{p^\frac{1}{p'}, p'\} \cdot c_{q,X} \cdot \|f\|_{L^p(\mathbb{R}^n; X)},
\]

by representing the left-hand side of (7.1) for the Poisson semigroup subordinated to the translation group on \( \mathbb{R} \) by \( G_{q,\varphi}(f) \) for some \( \varphi \in H_{\varepsilon,\delta} \) and afterwards using a transference argument for general semigroups.

The case \( p < q \) of (7.4) follows quite easily from the case \( p = q \), using classical Calderón–Zygmund theory. The case \( p > q \) with optimal dependence on \( p \) is harder, for which delicate results on conical and intrinsic square functions and weighted estimates, developed in the scalar-valued case by Wilson [46, 47], are adapted to the vector-valued setting in [48, Section 6]. We will prove (7.4) without the use of this machinery, instead opting to use our sparse domination principle.

As a starting point we will use following weak \( L^1 \)-estimate for \( G_{q,\varphi} \), which is implicitly contained in [48].
Proposition 7.1. Let $q \in [2, \infty)$, let $X$ be a Banach space with martingale cotype $q$ and let $\varphi \in \mathcal{H}_{\varepsilon, \delta}$ for $\varepsilon, \delta > 0$. Then we have for $f \in L^1(\mathbb{R}^n; X)$,
\[
\|G_{q, \varphi}(f)\|_{L^{1, \infty}(\mathbb{R}^n)} \lesssim c_{\text{mart}}^{q,X} \|f\|_{L^1(\mathbb{R}^n; X)},
\]
with the implicit constant only depending on $\varepsilon, \delta, n$.

Proof. The estimate
\[
\|G_{q, \varphi}(f)\|_{L^q(\mathbb{R}^n)} \lesssim c_{\text{mart}}^{q,X} \|f\|_{L^q(\mathbb{R}^n; X)}
\]
follows directly from [48, Lemma 5.6], see the first half of Step 1 of the proof of [48, Theorem 1.5]. The proposition then follows by viewing $G_{q, \varphi}$ as a Calderón–Zygmund operator using [48, Lemma 5.4].

For $\varphi \in \mathcal{H}_{\varepsilon, \delta}$ for $\varepsilon, \delta > 0$ define the localization
\[
G_{h, q, \varphi}(f)(x) = \left( \int_0^h \|\varphi_t * f(x)\|_X^q \frac{dt}{t} \right)^{1/q}, \quad x \in \mathbb{R}^n
\]
for $h > 0$. Since the support of $\varphi$ is not necessarily compact, the support of $G_{h, q, \varphi}(f)$ is not localized to (a multiple of) the support of $f$. Therefore, for arbitrary $f \in L^1(\mathbb{R}^d; X)$, one can not estimate $G_{h, q, \varphi}(f)$ by a local expression of the form
\[
(7.5) \quad \left( \sum_{P \in \mathcal{F}} \left\langle \|f\|_X^q \right\rangle_{1, \alpha P} \chi_P(x) \right)^{1/q}, \quad \alpha \geq 1.
\]
This in particular means that the precursor of Theorem 3.2 in [38], i.e. Theorem 4.2, is not applicable to the localization $G_{h, q, \varphi}(f)$.

Thanks to the flexible formulation of Theorem 3.2, we are able to compensate the non-local behaviour of $G_{h, q, \varphi}(f)$ by adding a convergent series of dilations of $P$ to (7.5). The main result of this section reads as follows:

Theorem 7.2. Let $q \in [2, \infty)$, let $X$ be a Banach space with martingale cotype $q$ and let $\varphi \in \mathcal{H}_{\varepsilon, \delta}$ with $\varepsilon, \delta > 0$. For any $f \in L^1(\mathbb{R}^n; X)$ and $Q \in \mathcal{Q}$ there exists a $\frac{1}{2}$-sparse collection of cubes $\mathcal{F} \subset \mathcal{D}(Q)$ such that for a.e. $x \in Q$,
\[
G_{q, \varphi}(f)(x) \lesssim c_{\text{mart}}^{q,X} \left( \sum_{P \in \mathcal{F}} \sum_{m=1}^\infty \frac{1}{2^m \varepsilon} \left\langle \|f\|_X^q \right\rangle_{1, 2^m P \chi_P(x)} \right)^{1/q},
\]
with the implicit constant depending only on $\varepsilon, \delta, n$. 
Using Hölder’s inequality and the boundedness of the maximal operator, Theorem 7.2 yields for $p > q$ and any $g \in L^{(p/q)'}(\mathbb{R}^n)$ that

$$
\int_Q G_{q,\varphi}^\ell(f)^q g \lesssim (c_{q,X}^{\text{mart}})^q \sum_{P \in \mathcal{F}} \sum_{m=1}^\infty \frac{1}{2m^e} \langle \|f\|_X \rangle_{1,2m^e}^q \int_P g
\lesssim (c_{q,X}^{\text{mart}})^q \sum_{P \in \mathcal{F}} \int_{E_P} M(\|f\|_X)^q M g
\lesssim (c_{q,X}^{\text{mart}})^q \cdot \frac{p}{q} \cdot \|f\|_{L^{p}(\mathbb{R}^n;X)} \|g\|_{L^{(p/q)'}(\mathbb{R}^n)}.
$$

This yields (7.4) by duality and the monotone convergence theorem.

Moreover, one can deduce sharp weighted estimates for $G_{q,\varphi}^\ell(f)$ for weights in the Muckenhoupt $A_p$-class, using [33, Lemma 4.5] and an argument as in [32, Section 4].

Proof of Theorem 7.2. For $Q \in \mathcal{Q}$ and $P \in \mathcal{D}(Q)$ define

$$
f_Q(x) := G_{q,\varphi}^\ell(f)(x), \quad x \in \mathbb{R}^n,
$$

$$
f_{P,Q}(x) := \left( \int_{E_P} \|\varphi_t \ast f(x)\|_X^q \frac{dt}{t^q} \right)^{1/q}, \quad x \in \mathbb{R}^n.
$$

The family $\{f_Q, f_{P,Q}\}_{Q \in \mathcal{Q}, P \in \mathcal{D}(Q)}$ trivially satisfies the $\ell^q$-condition with $C_q = 1$, and condition (3.1) holds as well. Therefore, by Theorem 3.2, there exists a $\frac{1}{2}$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that

$$
G_{q,\varphi}^\ell(f)(x) \lesssim \left( \sum_{P \in \mathcal{F}} \gamma_P^{q} \chi_P(x) \right)^{1/q}, \quad x \in Q.
$$

Thus it suffices to show

$$
(7.6) \quad \gamma_P \lesssim c_{q,X}^{\text{mart}} \cdot \left( \sum_{m=1}^\infty \frac{1}{2m^e} \langle \|f\|_X \rangle_{1,2m^e}^q \right)^{1/q} := c_{q,X}^{\text{mart}} \cdot \mathcal{M}_P
$$

for $P \in \mathcal{F}$.

Fix $P \in \mathcal{F}$. For any $z \in P$ we have by (7.2) and Hölder’s inequality

$$
(7.7) \quad G_{q,\varphi}^\ell(f \chi_{\mathbb{R}^n \setminus 2P})(z)
\leq \left( \int_0^{\ell_P} \left( \sum_{m=1}^\infty \int_{(2m+1)^{d} \setminus (2m)^{d}} \frac{1}{|z-y|^{d+\varepsilon}} \|f(y)\|_X \, dy \right)^q \frac{dt}{t^{1-q^\varepsilon}} \right)^{\frac{1}{q}}
\lesssim \sum_{m=2}^\infty \frac{1}{2m^e} \langle \|f\|_X \rangle_{1,2m^e} \cdot \left( \ell_P^{q} \int_0^{\ell_P} \frac{dt}{t^{1-q^\varepsilon}} \right)^{\frac{1}{q}} \lesssim \mathcal{M}_P.
$$
Therefore, we have by the weak $L^1$-boundedness of $G_{q, \varphi}$ in Proposition 7.1, that
\[
(f_P \chi_P)^*(|P|/2^{n+3}) \lesssim \left( G_{q, \varphi}(f \chi_{2P}) \chi_P \right)^*(|P|/2^{n+3}) + M_P \\
\lesssim \varepsilon_{q, \varphi}^\text{mart} \cdot \langle \|f\|_X \rangle_{1,2P} + M_P \lesssim \varepsilon_{q, X}^\text{mart} \cdot M_P.
\]

Now let us turn to $(m_P^{#} f)^*(|P|/2^{n+3})$. Fix $x \in P$ and $R \in \mathcal{D}(P)$ such that $x \in R$. We will split
\[
(7.8) \quad f = f \chi_{\mathbb{R} \setminus 2P} + f \chi_{2P \setminus 2R} + f \chi_{2R}.
\]

For $\xi, \eta \in R$ we note that by (7.3) and [16, Theorem 2.1.10] we have
\[
\left( \int_{\ell_R} | \varphi_t * f \chi_{2P \setminus 2R}(\xi) - \varphi_t * f \chi_{2P \setminus 2R}(\eta) |^q \frac{dt}{t^q} \right)^{1/q} \lesssim \left( \int_{\ell_R} |\xi - \eta|^\delta \int_{\mathbb{R}^n \setminus B(x, \ell_R/2)} \frac{\|f(y) \chi_{2P}(y)\|_X}{|x - y|^{n+\frac{\delta}{2}}} \, dy \right)^{\frac{q}{2}} \frac{dt}{t^{1+\frac{\delta}{2}}} \right)^{1/q} \lesssim \varepsilon_{\ell_R} \cdot \left( \frac{X_{\setminus B(0, \ell_R/2)}}{|.|^{n+\frac{\delta}{2}}} \right)_{L^1(\mathbb{R}^n)} \cdot \int_{\ell_R} \frac{dt}{t^{1+\frac{\delta}{2}}} \cdot M(\|f \chi_{2P}\|_X)(x) \lesssim M(\|f \chi_{2P}\|_X)(x).
\]

Furthermore, by (7.2) we have for $\xi \in R$
\[
\left( \int_{\ell_R} | \varphi_t * f \chi_{2P}(\xi) |^q \frac{dt}{t^q} \right)^{1/q} \leq \int_{2R} \|f(y)\|_X \, dy \cdot \left( \int_{\ell_R} \frac{dt}{t^{1+qn}} \right)^{1/q} \lesssim M(\|f \chi_{2P}\|_X)(x).
\]

Splitting as in (7.8), combining these estimates with (7.7) and using the weak $L^1$-boundedness of the maximal operator, we therefore obtain
\[
(m_P^{#} f)^*(|P|/2^{n+3}) \lesssim \left( M(\|f \chi_{2P}\|_X) \right)^*(|P|/2^{n+3}) + M_P \lesssim \langle \|f\|_X \rangle_{1,2P} + M_P \lesssim M_P.
\]

This finishes the proof of (7.6) and thus the proof of the theorem.

\section*{8. An application to dyadic sums}

In this final section we will give a condition on a sequence $\{\alpha_R\}_{R \in \mathcal{D}(Q)}$ for $Q \in Q$ that allows to control a dyadic sum of the form $\sum_{R \in \mathcal{D}(Q)} \alpha_R \chi_R$ by a sum over a sparse family $\mathcal{F} \subset \mathcal{D}(Q)$. As an application, we will generalize and provide a new proof of a good-$\lambda$ inequality of Honzík and Jaye [20].
Theorem 8.1. Let $Q \in \mathcal{Q}$ and let $\{\alpha_R\}_{R \in \mathcal{D}(Q)}$ be a sequence of non-negative numbers. Suppose that there exist $C > 0$ and $0 < \delta \leq 1$ such that for every cube $Q' \in \mathcal{D}(Q)$,

\begin{equation}
\sum_{R \in \mathcal{D}(Q')} \alpha_R^\delta |R| \leq C \alpha_{Q'}^\delta |Q'|.
\end{equation}

Then there exists a $\frac{1}{2}$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that for a.e. $x \in Q$,

$$\sum_{R \in \mathcal{D}(Q)} \alpha_R \chi_R(x) \lesssim C \sum_{P \in \mathcal{F}} \alpha_P \chi_P(x).$$

Proof. For $Q' \in \mathcal{D}(Q)$ denote

$$f_{Q'}(x) = \sum_{R \in \mathcal{D}(Q')} \alpha_R \chi_R(x), \quad x \in Q',$n

and for $P \in \mathcal{D}(Q')$ set $f_{P,Q'} = f_{Q'} - f_P$. Then $\{f_{Q'}, f_{P,Q'}\}_{Q' \in \mathcal{D}(Q), P \in \mathcal{D}(Q')}$ trivially satisfies the $\ell^1$-condition (with $C_1 = 1$) and condition (3.1).

Observe that $f_{P,Q}$ is a constant on $P$, and therefore $m_P^# f \equiv 0$. Hence, by the local version of Theorem 3.2 (see Remark 3.3), there exists a $\frac{1}{2}$-sparse family $\mathcal{F} \subset \mathcal{D}(Q)$ such that, for a.e. $x \in Q$,

$$\sum_{R \in \mathcal{D}(Q)} \lambda_R \chi_R(x) \leq \sum_{P \in \mathcal{F}} (f_{P} \chi_P)^* (|P|/2^{n+3}) \chi_P(x).$$

By (2.2),

$$\left(f_{P} \chi_P\right)^* (|P|/2^{n+3}) \leq \left(\frac{2^{n+3}}{|P|} \int_P f_P^\delta\right)^{1/\delta},$$

and, by (8.1),

$$\int_P f_P^\delta \leq \sum_{R \in \mathcal{D}(P)} \alpha_R^\delta |R| \leq C \alpha_P^\delta |P|.$$

Combining these three estimates completes the proof. \qed

Let $\mathcal{D}$ be a dyadic lattice in $\mathbb{R}^n$. Given a sequence of non-negative numbers $\alpha = \{\alpha_Q\}_{Q \in \mathcal{D}}$, define the following two objects associated with $\alpha$:

$$S_q(\alpha) := \left(\sum_{Q \in \mathcal{D}} \alpha_Q^q \chi_Q\right)^{1/q}, \quad q \in (0, \infty),$$

$$M(\alpha) := \sup_{Q \in \mathcal{D}} \alpha_Q \chi_Q.$$
Corollary 8.2. Let $q \in (0, \infty)$. Suppose that there exist $C > 0$ and $0 < \delta \leq q$ such that for every cube $Q \in \mathcal{D}$,

$$(8.2) \quad \sum_{R \in \mathcal{D}(Q)} \alpha_R^\delta |R| \leq C \alpha_Q^\delta |Q|.$$  

Then there exists $K = K(q, \delta, C)$ such that for all $\lambda > 0$ and $0 < \varepsilon < 1$,

$$(8.3) \quad \left| \{ x \in \mathbb{R}^n : S_q(\alpha)(x) > 2\lambda, M(\alpha)(x) \leq \varepsilon \lambda \} \right| \leq 2 e^{-K/\varepsilon^q} \left| \{ x \in \mathbb{R}^n : S_q(\alpha)(x) > \lambda \} \right|.$$  

Proof. By a standard limiting argument, it sufficed to prove (8.3) for $S^F_q(A)$ instead of $S_q(A)$, where

$$S^F_q(\alpha) = \left( \sum_{Q \in F} \alpha_Q^q \chi_Q \right)^{1/q}$$

for an arbitrary finite family of cubes $F \subset \mathcal{D}$.

Write the set $\{ x \in \mathbb{R}^n : S^F_q(\alpha)(x) > \lambda \}$ as the union of its maximal cubes $Q_j \in F$. Then it suffices to prove that

$$(8.4) \quad \left| \{ x \in Q_j : S_q^F(\alpha)(x) > 2\lambda, M(\alpha)(x) \leq \varepsilon \lambda \} \right| \leq 2 e^{-K/\varepsilon^q} |Q_j|.$$  

Denote the set on the left-hand side of (8.4) by $E_j$ and fix $x \in E_j$. By maximality of $Q_j$,

$$\sum_{R \in F : Q_j \subset R} \alpha_R^q \chi_R(x) \leq \lambda^q,$$

and hence

$$\sum_{R \in F : R \subset Q_j} \alpha_R^q \chi_R(x) = S^F_q(\alpha)(x)^q - \sum_{R \in F : Q_j \subset R} \alpha_R^q \chi_R(x) > (2^q - 1) \lambda^q.$$  

On the other hand, applying Theorem 8.1 to $\{ \alpha_R^q \}_{R \in \mathcal{D}(Q_j)}$, there exists a $\frac{1}{2}$-sparse family $F \subset \mathcal{D}(Q_j)$ such that for a.e. $x \in E_j$

$$\sum_{R \in F : R \subset Q_j} \alpha_R^q \chi_R(x) \leq \sum_{P \in F} \alpha_P^q \chi_P(x) \leq (\varepsilon \lambda)^q \sum_{P \in F} \chi_P(x).$$  

So we have $\sum_{P \in F} \chi_P(x) \geq \frac{1}{\varepsilon^q}$ and therefore, by Proposition 6.3,

$$|E_j| \leq \left| \left\{ x \in Q_j : \sum_{P \in F} \chi_P(x) \geq \frac{1}{\varepsilon^q} \right\} \right| \leq 2 e^{-K/\varepsilon^q} |Q_j|,$$

i.e. (8.4) holds and the proof is complete. \qed
Example 8.3. Let $\mu$ be a non-negative Borel measure. Given $0 < \gamma < n$ and $q \in (0, \infty)$, define the non-linear dyadic potential by

$$T_{q, \gamma}(\mu) := \left( \sum_{Q \in \mathcal{D}} \left( \frac{\mu(Q)}{|Q|^{1-\gamma/n}} \right)^q \chi_Q \right)^{1/q}$$

Define also the fractional maximal operator by

$$M_{\gamma}(\mu) := \sup_{Q \in \mathcal{D}} \frac{\mu(Q)}{|Q|^{1-\gamma/n}} \chi_Q.$$  

In [20], Honzík and Jaye established the following good-$\lambda$ inequality: there exists $C_1, C_2 > 0$ such that for all $\lambda > 0$ and $0 < \varepsilon < 1$,

$$\left| \{ x \in \mathbb{R}^n : T_q(\mu)(x) > 2\lambda, M_\gamma(\mu)(x) \leq \varepsilon \lambda \} \right| \leq C_1 e^{-C_2/\varepsilon^q} \left| \{ x \in \mathbb{R}^n : T_q(\mu)(x) > \lambda \} \right|.$$  

Let us show that this result can be deduced from Corollary 8.2. Indeed, set $\alpha_Q = \mu(Q)/|Q|^{1-\gamma/n}$ for $Q \in \mathcal{D}$. It suffices to show that (8.2) holds for $\delta = \min(q, 1)$. Write $\mathcal{D}(Q) = \cup_{k=0}^\infty \mathcal{D}_k$, where $\mathcal{D}_k$ is the $k$-th generation of dyadic subcubes of $Q$. First suppose that $q \geq 1$. Then $\delta = 1$ and we have

$$\sum_{R \in \mathcal{D}(Q)} \alpha_R \delta |R| = \sum_{R \in \mathcal{D}(Q)} \mu(R) |R|^{\gamma/n} = |Q|^{\gamma/n} \sum_{k=0}^\infty 2^{-k\gamma} \sum_{P \in \mathcal{D}_k} \mu(P) = C_\gamma \cdot \mu(Q) |Q|^{\gamma/n} = C_\gamma \cdot \alpha_Q \delta |Q|.$$  

Now suppose that $q < 1$. Since $\#\{Q \in \mathcal{D}_k\} = 2^{kn}$, we have by Hölder’s inequality

$$\sum_{P \in \mathcal{D}_k} \mu(P)^q \leq 2^{nk(1-q)} \mu(Q)^q.$$  

Hence, as $\delta = q$,

$$\sum_{R \in \mathcal{D}(Q)} \alpha_R \delta |R| = |Q|^{1-q(1-\gamma/n)} \sum_{k=0}^\infty 2^{nk(1-\gamma/n)q-1} \sum_{P \in \mathcal{D}_k} \mu(P)^q \leq \left( \frac{\mu(Q)}{|Q|^{1-\gamma/n}} \right)^q |Q| \sum_{k=0}^\infty 2^{nk(1-\gamma/n)q-1} 2^{nk(1-q)} = \alpha_Q^q |Q| \sum_{k=0}^\infty 2^{-k\gamma q} = C_{\gamma,q} \alpha_Q^q |Q|.$$  

Thus, we have verified (8.2), and therefore (8.5) holds.
