(Dated: July 1, 2021)

The theory of non-Hermitian systems and the theory of quantum deformations have attracted a great deal of attention in the last decades. In general, non-Hermitian Hamiltonians are constructed by a \textit{ad hoc} manner. Here, we study the (2+1) Dirac oscillator and show that in the context of the $\kappa$--deformed Poincaré-Hopf algebra its Hamiltonian is non-Hermitian but having real eigenvalues. The non-Hermiticity stems from the $\kappa$--deformed algebra. From the mapping in [Bermudez et al., Phys. Rev. A 76, 041801(R) 2007], we propose the $\kappa$--JC and $\kappa$--AJC models, which describe an interaction between a two-level system with a quantized mode of an optical cavity in the $\kappa$--deformed context. We find that the $\kappa$--deformation modifies the Zitterbewegung frequencies and the collapse and revival of quantum oscillations. In particular, the total angular momentum in the $z$--direction is not conserved anymore, as a direct consequence of the deformation.

I. INTRODUCTION

The interest in non-Hermitian Hamiltonians with real spectrum have started with the seminal work of Bender and Boettcher [1]. In the last two decades, these systems have been discussed in connection with invariance under spatio-temporal reflection. A $\mathcal{PT}$--symmetric Hamiltonian is invariant under spatial reflection ($\mathcal{P}$) and time reversal ($\mathcal{T}$) symmetries [2, 3]. Many applications of $\mathcal{PT}$--symmetric Hamiltonian are found in the study of gain and loss systems [4] which may be found in different physical contexts [5]. In standard quantum mechanics, the Hermiticity, or being more precise the self-adjointness, of physical observables, in special of Hamiltonians, guarantees that the quantum evolution is unitary and the spectrum is real. If the eigenstates of Hamiltonian and the $\mathcal{PT}$--operator are the same, it is said to have an unbroken $\mathcal{PT}$--symmetry, and the $\mathcal{PT}$--symmetric Hamiltonian is also quasi-Hermitian [6, 7]. From the theory of quasi-Hermitian operators, we know that it has real eigenvalues but the time evolution is not unitary. However, for time-independent non-Hermitian Hamiltonians [8], it is possible to have a unitary evolution if we employ a similarity transformation [9] which leads to its Hermitian counterpart.

In parallel and separately, in the last decades the theory of quantum deformations based on the $\kappa$--Poincaré-Hopf algebra has also attracted great deal of attention and has been an alternative framework for studying relativistic and nonrelativistic quantum systems and represents an interesting theory due to its phenomenological applications. The $\kappa$--deformed Poincaré-Hopf algebra, established in Refs. [10–13], is based on the following commutation relations

\begin{equation}
[M_i, M_j] = i\epsilon_{ijk} M_k, \quad [M_i, L_j] = i\epsilon_{ijk} L_k,
\end{equation}

\begin{equation}
[L_i, L_j] = -i\epsilon_{ijk} \left[ M_k \cosh (\varepsilon P_0) - \frac{\varepsilon^2}{4} P_k P_l M_l \right],
\end{equation}

where $\varepsilon$ is defined by

\begin{equation}
\varepsilon = \frac{1}{\kappa} = \lim_{R \to \infty} \left( R \ln q \right),
\end{equation}

with $R$ being the de Sitter curvature and $q$ is a real deformation parameter, $P_{\mu} = (P_0, P)$ are the $\kappa$--deformed generators for energy and momenta, and $M_i$ and $L_i$ represent the spatial rotations and deformed boosts generators, respectively. The parameter $\kappa$ has the dimension of mass and was claimed from the very beginning that it must have something to do with quantum gravity, and therefore it is usually interpreted as being the Planck mass $M_P$ [14]. We also comment that in Ref. [15], it was discussed that the parameter $\kappa$ does not correspond to an observable, then its value should be inferred through some indirect measurements. For a short introduction to the $\kappa$--deformation framework, see Ref. [16]. In the context of $\kappa$--deformed theory, the physical properties of relativistic quantum mechanics can be addressed by solving the $\kappa$--deformed Dirac equation [17–20]. For instance, it has implications in the divergencelessness of the vacuum energy in quantum field theory [21], in the spin-1/2 Aharonov-Bohm problem [22] leading to additional bound states [23], as well as in the in the Landau levels [24, 25], and in the 2D and 3D Dirac oscillators [26, 27].

As stated above, although some quantum systems could be effectively described by non-Hermitian Hamiltonians as considered, for instance, in Refs. [28–30], non-Hermitian systems are usually constructed by exactly balancing loss and gain [31] and this is usually achieved in an \textit{ad hoc} manner. In the present work, we revisit the 2D Dirac oscillator, the relativistic version of the simple harmonic oscillator (see below) and show that in the context of the $\kappa$--deformed algebra, this system has a non-Hermitian Hamiltonian. Then, here we show that we obtain a non-Hermitian Hamiltonian from first principles by employing the $\kappa$--deformed algebra. Moreover, from mapping this system into a Jaynes-Cummings (JC) and

\begin{table}[h]

\caption{Parameters of Jaynes-Cummings and anti-Jaynes-Cummings models.}
\end{table}
anti-Jaynes-Cummings (AJC) models, this allows us to propose the $\kappa$-JC and $\kappa$-AJC models.

The remainder of this paper is organized as follows. In Sec. II we revise the solution of the (2+1) Dirac oscillator and the mapping of this system into the JC and AJC systems. In Sec. III we propose the $\kappa$-JC and $\kappa$-AJC models. In Sec. IV we study the symmetries of the $(\kappa\text{-})$AJC Hamiltonian. In Sec. V the dynamics of the $\kappa$-JC model is presented. Our conclusion are presented in Sec. VI.

II. THE DIRAC OSCILLATOR AND THE MAPPING ONTO THE JC AND AJC SYSTEMS

In this section, we briefly review the Dirac oscillator and the exact mapping onto the JC and AJC systems. The Dirac oscillator, first proposed by Itô et al.,[32] and then further developed by Moshinsky et al.,[33] has been a usual model for studying physical properties of systems in various branches of physics. In the non-relativistic limit, the Dirac oscillator reduces to the simple harmonic oscillator with strong spin-orbit coupling. It was shown that the Dirac oscillator can be regarded as describing a neutral particle interaction with a static linear electric field.[34] Recently, the one-dimensional Dirac oscillator has had its first experimental realization.[35] and it also was proposed as a tabletop experiment for direct observation of the corresponding analogue of virtual pair creation on quantum measurement backaction.[36] These results made the system more attractive from the point of view of applications. For a detailed approach to the Dirac oscillator see the Refs. [37, 38].

The Dirac oscillator is obtained by means of a nonminimal coupling [33]

$$ p \rightarrow p \pm i m \omega \beta r, \quad (3) $$

with $p$ the momentum operator, $m$ is the mass, $\omega$ is the oscillator frequency, $r$ is the position vector, and $\beta$ is a Dirac matrix. The double signal introduced in Eq. (3) leads us to similar results [39] and serves to map the Dirac oscillator onto the JC (AJC) model for $+$ (−) in a transparent manner. The Dirac oscillator in (2+1) dimensions, when the third spatial coordinate is absent, was studied in Refs. [40–43]. This system is achieved by writing the Dirac equation in (2+1) dimensions including the nonminimal interaction in Eq. (3),

$$ H^\pm |\psi\rangle = \left( \mathbf{\alpha} \cdot \mathbf{\pi}^\pm + \beta m c^2 \right) |\psi\rangle = E |\psi\rangle, \quad (4) $$

where $|\psi\rangle$ is a two-component spinor, $\mathbf{\alpha} = \beta \gamma$, $\mathbf{\pi}^\pm = \mathbf{p} \pm i m \omega \beta \mathbf{r}$ and the $2 \times 2$ Dirac matrices are defined in terms of the Pauli matrices [44]

$$ \beta = \gamma_0 = \sigma_z, \quad \beta \gamma_1 = \sigma_x, \quad \beta \gamma_2 = s \sigma_y. \quad (5) $$

The parameter $s$ is twice the spin value and here serves to characterize the two possible chiralities of the system, with $s = -1$ ($s = +1$) corresponding to the left (right) chirality. The approach employed here based on the matrix set (5) differs from the usual one which chooses one specific value of the chirality $s$ and has the advantage of making the results dependent on the chirality in a transparent manner. Thus, considering the two-component spinor as $|\psi\rangle = (|\psi_1\rangle, |\psi_2\rangle)^T$, from Eq. (4) we arrive at the following set of coupled equations:

$$ (E - mc^2) |\psi_1\rangle = c(\pi_x^+ - i s \pi_y^+) |\psi_2\rangle, $$

$$ (E + mc^2) |\psi_2\rangle = c(\pi_x^- + i s \pi_y^-) |\psi_1\rangle, \quad (6) $$

where $\pi_x^\pm = p_i \pm i m \omega r_i, i = x, y$. Introducing the chiral creation and annihilation operators [42]

$$ a_s^\pm = \frac{1}{\sqrt{2}}(a_x^\pm \mp i a_y^\pm), \quad (7) $$

where $a_s^+ (a_s^-)$ is the usual creation (annihilation) operators of the harmonic oscillator,

$$ a_i^+ = \frac{1}{\sqrt{2}} \left( \frac{1}{\Delta} p_i - \frac{i}{\hbar} \Delta r_i \right), \quad (8) $$

and $\Delta = \sqrt{\hbar/m \omega}$ is the ground state oscillator width, the equations (6) can be written as

$$ (E - mc^2) |\psi_1\rangle = 2 i m c^2 \sqrt{\xi} a_x^+ |\psi_2\rangle, $$

$$ (E + mc^2) |\psi_2\rangle = - 2 i m c^2 \sqrt{\xi} a_x^- |\psi_1\rangle, \quad (9) $$

with $\xi = \hbar \omega/m c^2$ representing the relativistic parameter which leads to the nonrelativistic limit when $\xi \rightarrow 0$. By squaring (9), we find

$$ (E^2 - m^2 c^4) |\psi_1\rangle = 4 m^2 c^4 \xi a_x^+ a_x^- |\psi_1\rangle, $$

$$ (E^2 - m^2 c^4) |\psi_2\rangle = 4 m^2 c^4 \xi a_x^+ a_x^- |\psi_2\rangle. \quad (10) $$

Introducing the chiral quanta basis

$$ |n_s^\pm\rangle = \frac{1}{\sqrt{n_{cs}^s}} (a_s^+)^{n_{cs}^s} |0\rangle, \quad (11) $$

with $n_s^+ = 0, 1, 2, \ldots$ and $n_s^- = 1, 2, 3 \ldots$ representing the eigenvalues of the number operator, $N_s = a_s^+ a_s^-$, it is possible to diagonalize both equations simultaneously. In this manner, with $|\psi_1\rangle = |n_s^+\rangle$, $|\psi_2\rangle = |n_s^-\rangle$ and due to the fact these states represent the components of the same state vector with energy $E^\pm$, we conclude that $n_s^\pm = n_{cs}^\pm \pm 1$, and the energy eigenvalues are given by

$$ E^\pm = \pm E_{n_{cs}^\pm}^\pm = \pm m c^2 \sqrt{1 + 4 \xi [n_{cs}^\pm + \Theta(\pm)]}, \quad (12) $$

where we have made use of the Heaviside step function $\Theta(\pm) = (1 \mp 1)/2$. We observe that the particle and antiparticle spectrum are symmetric and, as we shall show shortly, the deformation breaks this symmetry. These energy eigenvalues should be compared with those obtained by the directed solution of the second-order differential equation in polar coordinates that arises from the position representation of the Dirac equation. The result is seems to be [40]

$$ E^\pm = \pm E_{n_{cs}^\pm}^\pm = \pm m c^2 \sqrt{1 + 4 \xi [n + (|l| - s l)/2 + \Theta(\pm)]}, \quad (13) $$
where \( n = 0, 1, 2, \ldots \) is the radial quantum number and \( l = 0, \pm 1, \pm 2, \ldots \) is the angular momentum quantum number. So, the comparison leads to \( n^2 = n + (|l| - s)^2 \), showing the dependency on \( s \) and the high degeneracy of the (2+1) Dirac oscillator spectra [27].

The Hamiltonian \( H^\pm \) for the (2+1) Dirac oscillator can be rewritten as

\[
H^\pm = \left( \pm 2mc^2 \sqrt{\xi} a_{\pm}^* a_{\pm} \mp 2imc^2 \sqrt{\xi} a_{\pm}^* s + mc^2 \right),
\]

(14)

As shown in [42], using the notation \( \sigma_\pm = |e\rangle\langle e| - |g\rangle\langle g| \), \( \sigma^+ = |e\rangle\langle g| \) and \( \sigma^- = |g\rangle\langle e| \) in which \( \sigma^\pm \) are the standard fermionic two-level transition operators that obey the commutation relation \( \left[ \sigma^+, \sigma^- \right] = \sigma_z \), and \( |g\rangle \) and \( |e\rangle \) are, respectively, the ground and excited states of a two level quantum system, the Hamiltonian \( H^\pm \) can be mapped onto the JC model of quantum optics,

\[
H^+ = 2imc^2 \sqrt{\xi} (a^*_s |e\rangle\langle g| - a^*_s |g\rangle\langle e|) + mc^2 \sigma_z
= h (ga^*_s \sigma^- + g^* a^*_s \sigma^+) + \delta \sigma_z
= H^+_{JC},
\]

(15)

\[
H^- = h (ga^-_s \sigma^+ + g^* a^-_s \sigma^-) + \delta \sigma_z
= H^-_{JC}.
\]

(16)

Thus, the mapping onto the JC or AJC systems may be accomplished by a suitable choice of the non-minimal coupling signal in Eq. (3), which amounts to the substitution \( \omega \rightarrow -\omega \). Besides that, the substitution of the oscillator frequency turns the JC system into the AJC system with opposite chirality, which is evident when comparing (15) with (16). The results presented here are generalizations of results present in the literature. Thus using the double signal in the nonminimal coupling together with the \( s \) parameter, the mapping of the Dirac oscillator onto the JC and AJC models is now more transparent.

III. THE \( \kappa \)-JC AND THE \( \kappa \)-AJC MODELS

In this section, we present the \( \kappa \)-deformed Dirac oscillator, and using the mapping of the previous section, we propose the \( \kappa \)-deformed JC and AJC models. The deformation studied here differs from previous models proposed in the literature in the sense that it arises naturally from the \( \kappa \)-deformed algebra. It is interesting to comment that there are other proposals in the literature for deformed (AJC) models, namely the \( \gamma \)-deformed [45] and the \( f \)-deformed [46] models. Both models are based on the deformation of the commutation relations for the creation and annihilation operators and lead to Hermitian Hamiltonians. In the scenario presented here, the deformation stems from the \( \kappa \)-deformed algebra and does not affect the creation and annihilation operators and leads naturally to a non-Hermitian Hamiltonian.

The \( \kappa \)-deformed Dirac equation in (2+1) dimensions can be written as [23]

\[
\left\{ \gamma_0 \sigma_0 - c \gamma_1 \sigma_1 + \frac{\epsilon}{mc^2} \left[ \gamma_0 (P^2_0 - P^2_1) - mc^2 P_0 \right] \right\} |\psi\rangle = mc^2 |\psi\rangle,
\]

(17)

where \( \epsilon = mc^2 \sqrt{\xi}/2 \) is the dimensionless deformation parameter. To obtain the \( \kappa \)-Dirac oscillator equation, we can proceed by gauging Eq. (17) introducing the nonminimal coupling above. Thus gauging the above equation with the nonminimal coupling prescription in Eq. (3),

\[
P_0 \rightarrow P_0 = H = E,
\]

(18)

\[
P_1 \rightarrow \pi^\pm_1 = p_i \pm im\omega \beta r_i,
\]

(19)

we can write Eq. (17) as

\[
H |\psi\rangle = \left[ (c \gamma_1 \pi^+_1 + \gamma_0 mc^2)
- \frac{\epsilon}{mc^2} \left( H^2 - \pi^+_1 \pi^-_1 - \gamma_0 mc^2 H^+ \right) \right] |\psi\rangle.
\]

(20)

In general, non-commutative Hamiltonians should be addressed by employing the Seiberg-Witten transformation, as discussed in [47]. However, the gauge in Eq. (18) leads to a commutative Hamiltonian and, consequently, we do not need to deal with the Seiberg-Witten transformation here. Nevertheless, the above equation is quite complicated to be solved without using some sort of approximation. A common approach [18] to solve it is recognize the first term in parentheses as the undeformed Hamiltonian (see Eq. (4)), and iterate it only keeping terms up to \( O(\epsilon) \), leading to

\[
H^\pm_\epsilon |\psi\rangle = E |\psi\rangle,
\]

(21)

with

\[
H^\pm_\epsilon = H^\pm - \frac{\epsilon}{mc^2} \left[ (H^\pm)^2 - \pi^+_1 \pi^-_1 - \gamma_0 mc^2 H^+ \right].
\]

(22)

Equation (21) defines the (2+1) \( \kappa \)-Dirac oscillator [27].

We now proceed by employing the same reasoning used in the previous section. Thus using the representation of the \( \gamma \) matrices as in Eq. (5), considering a two-component spinor and also introducing the chiral creation and annihilation operators, the deformed Hamiltonian \( H^\pm_\epsilon \) can be written as

\[
H^\pm_\epsilon = h \left( ga^\pm_\epsilon \sigma^\mp_\epsilon \mu_\epsilon^\mp \right.
+ g^* a^-_\epsilon \sigma^\mp_\epsilon \mu^\pm_\epsilon
+ \delta^\pm_\epsilon \sigma_z
+ 2mc^2 \epsilon \left( 2\tilde{N}_{\pm, s} + 1 \right) \mathbb{I},
\]

(23)

with \( \delta^\pm_\epsilon = (1 \mp 2\epsilon \xi) \delta_\epsilon \), \( \mu^\pm_\epsilon = 1 \pm \epsilon \), and \( \mathbb{I} \) the identity matrix. Notice that for \( \epsilon = 0 \) we get back the Hamiltonians in Eqs. (15) and (16), i.e., the JC or AJC models, respectively. In this manner, by the mapping of the previous section, we propose the Hamiltonian in Eq. (23) as representing the \( \kappa \)-JC and \( \kappa \)-AJC models:

\[
H^\pm_{\kappa-JC} = H^\pm_\epsilon, \quad H^\pm_{\kappa-AJC} = H^-_\epsilon.
\]

(24)

It is important to note that due to the presence of \( \mu^\pm_\epsilon \) in \( H^\pm_{\kappa-AJC} \), which comes from the term \( c \gamma_0 mc^2 H^+ \) in the deformed
Hamiltonian, Eq. (22), it fails to be Hermitian, i.e., \( H^± \neq H^±\). As a consequence, \( H^± \) being non-Hermitian leads to a nonunitary time evolution. Nevertheless, the spectrum of the allowed energy eigenvalues of \( H^± \) is real, and are given by

\[
E^±_{n^¥} = \pm E^±_{n^±} - 4mc^2\xi [n^± + \Theta(±)],
\]

which coincides with the result obtained in [27] and immediately reduces to the undeformed energy eigenvalues in Eq. (12) for \( \epsilon = 0 \). We observe that the deformation causes an asymmetric energy shift in the energy eigenvalues when compared with standard (A)JC model, \( |\Delta E| = 4mc^2\xi [n^± + \Theta(±)] \), which increases with \( \xi \) and is larger for larger values of \( n^± \). In the context of the \( \kappa \)-Dirac oscillator, this asymmetry stems from the fact that the deformed Hamiltonian breaks the charge conjugation symmetry [26, 27]. The energy spectrum of the \( \kappa \)-(A)JC has a positive energy branch which is bounded from below by \( mc^2\sqrt{1+4\xi} - 4mc^2\xi \) and a negative branch bounded from above by \(-mc^2\sqrt{1+4\xi} - 4mc^2\xi \), as displayed in Fig. 1 for the JC and \( \kappa \)-JC. The graph for the AJC and \( \kappa \)-AJC looks identical. Following Ref. [27], in which an upper bound for the deformation parameter was obtained, we used value \( \epsilon = 5 \times 10^{-4} \) as the value for the dimensionless deformation parameter.

IV. SYMMETRIES AND THE NON-HERMITICITY OF THE \( \kappa \)-JC AND \( \kappa \)-AJC MODELS

As we stated above, \( H^± \) is non-Hermitian and it leads to a nonunitary evolution. In fact, the \( \kappa \)-deformed Hamiltonian is not even \( \mathcal{PT} \)-symmetric, but it is quasi-Hermitian. We can check this by first looking at the effects of parity and time reversal symmetry operations on \( \alpha \)'s and \( \sigma \)'s operators [48]:

\[
\mathcal{P} a^± \mathcal{P}^{-1} = a^±, \quad \mathcal{P} \sigma^± \mathcal{P}^{-1} = \sigma^±, \quad \mathcal{T} a^± \mathcal{T}^{-1} = -a^±, \quad \mathcal{T} \sigma z \mathcal{T}^{-1} = -\sigma z, \quad \mathcal{T} \sigma_± \mathcal{T}^{-1} = \sigma_±.
\]

Through this, one notes that the deformed Hamiltonian in Eq. (23) is not \( \mathcal{PT} \)-symmetric since

\[
\mathcal{PT} H^±_c (\mathcal{PT})^{-1} = h \left( ga^±_s \sigma^± \mu^±_c + g^* a^±_c \sigma^± \mu^±_s \right) - \delta^±_c \sigma z + mc^2\xi (2N^±_c + 1) \mathbb{I} \\
\neq H^±_c.
\]

However, the Hamiltonian is invariant under the transformation \( \mathcal{P} \sigma_± \), so that

\[
\mathcal{P} \sigma_± H^±_c (\mathcal{P} \sigma_±)^{-1} = H^±_c.
\]

This symmetry was also observed in a similar system in Ref. [49]. Another interesting transformation is given by

\[
\mathcal{T} \sigma z H^±_c (\mathcal{T} \sigma z)^{-1} = h \left( ga^±_s \sigma^± \mu^±_c + g^* a^±_c \sigma^± \mu^±_s \right) + \delta^±_c \sigma z + mc^2\xi (2N^±_c + 1) \mathbb{I},
\]

which leads to the original Hamiltonian but with the chirality changed, \( s \to -s \). Although the Hamiltonian is not \( \mathcal{PT} \)-symmetric, it is quasi-Hermitian since its eigenvalues are real [7]. Therefore, the Hamiltonian satisfies a quasi-Hermiticity relation

\[
H^±_c = \eta_± H^±_c \eta_±^{-1},
\]

for some positive-defined operator \( \eta_± \) [50], the so-called metric operator, which defines the inner-product

\[
\langle \cdot, \cdot \rangle_\eta_± = \langle \cdot, \eta_± \cdot \rangle,
\]

with respect to which the Hamiltonian is said to be Hermitian since

\[
\langle \phi, H^±_c \psi \rangle_\eta_± = \langle \phi | \eta_± H^±_c | \psi \rangle = \langle \phi | H^±_c \eta_± | \psi \rangle = \langle H^±_c \phi | \eta_± \psi \rangle,
\]

for all \( \phi \) and \( \psi \) in the domain of \( H^±_c \). Thus, decomposing the metric operator as \( \eta_± = \rho_± \rho_±^{-1} \), Eq. (29) allows us define a Hermitian counterpart associated with the non-Hermitian one,

\[
\rho_± = \rho_± H^±_c \rho_±^{-1},
\]
in such a way that $h_x^\pm = h_x^{\pm \dagger}$. The expected values in both representations are the same

$$
\langle H^\pm_x \rangle_{\eta, \Phi} = \langle \Phi | h^\pm_x | H^\pm_x | \Phi \rangle
= \langle \Phi | \rho \pm \dagger h^\pm_x \rho \pm | \Phi \rangle
= \langle \Phi | h^\pm_x | \Psi \rangle
= \langle h^\pm_x \rangle \Psi,
$$

with $| \Psi \rangle = \rho \pm | \Phi \rangle$.

\section{V. \textbf{SYSTEM DYNAMICS}}

Until now we have worked with both $\kappa$–JC and $\kappa$–AIC systems simultaneously. For the sake of clarity, in what follows we focus our discussion on the $\kappa$–JC Hamiltonian, $H^\pm = H_{kJC}$. Consequently, to simplify the notation, we drop the $\pm$ sign in our equations. We also observe that the results for the $\kappa$–AIC can be obtained similarly. To obtain the Hermitian operator associated with $H^{\ast}_{kJC}$, a suitable similarity transformation is given by the operator

$$
\rho = e^{\alpha \sigma_- a^{-} - \alpha \sigma^+ a^+} e^{\alpha \sigma_- a^{-} + \alpha \sigma^+ a^+},
$$

satisfying $\rho^\dagger \rho = \eta$. Note that this operator reduces to the identity operator for $\epsilon = 0$. Thus, the Hermitian operator can be obtained from the similarity transformation

$$
h_{\kappa JC}^\ast = \rho H_{kJC}^\ast \rho^{-1},
$$

with $\rho^\dagger \rho = \eta$, and can be written as

$$
h_{\kappa JC}^\ast = h(g \sigma^- a^- + g^* \sigma^+ a^+ + (1 - 2\epsilon \xi) \delta \sigma_z + \epsilon h(g \sigma^- a^- + g^* \sigma^+ a^+) + mc^2 \epsilon \xi (2N_e + 1) \mathbb{I}).
$$

The spectrum of the Hermitian operator $h_{\kappa JC}^\ast$ is given by (25) as it shares the spectrum with the non-Hermitian operator $H_{kJC}^\ast$. To find the associated deformed energy eigenstates for the positive and negative deformed energy eigenvalues of $h_{\kappa JC}^\ast$, we first solve the eigenvalue equation for the non-Hermitian operator, $H_{kJC}^\ast | E_n^\ast \rangle = E_n^\ast | E_n^\ast \rangle$, then apply the transformation $\rho$. In this manner, using the Pauli spinors $| \uparrow \rangle = (1, 0)^\dagger$ and $| \downarrow \rangle = (0, 1)^\dagger$, the deformed energy eigenstates of $H_{kJC}^\ast$ can be written as

$$
| \pm E_n^\ast \rangle = \sqrt{\frac{E_n \pm mc^2}{2E_n}} | n_s \rangle | \uparrow \rangle
d \pm i \sqrt{\frac{E_n \pm mc^2}{2E_n}} (1 - \epsilon) | n_s + 1 \rangle | \downarrow \rangle,
$$

and by applying the transformation $\rho$, we obtain

$$
| + \tilde{E}_n^\ast \rangle = \rho | + E_n^\ast \rangle
= \alpha | n_s \rangle | \uparrow \rangle + \beta | n_s + 1 \rangle | \downarrow \rangle + \epsilon \alpha | n_s \rangle | \uparrow \rangle - \epsilon \beta | n_s + 1 \rangle | \downarrow \rangle
$$

and

$$
| - \tilde{E}_n^\ast \rangle = \rho | - E_n^\ast \rangle
= \beta | n_s \rangle | \uparrow \rangle - \alpha | n_s + 1 \rangle | \downarrow \rangle + \epsilon \beta | n_s \rangle | \uparrow \rangle + \epsilon \alpha | n_s + 1 \rangle | \downarrow \rangle
$$

with

$$
\alpha_{n_s} = \sqrt{\frac{E_n + mc^2}{2E_n}}, \quad \beta_{n_s} = \sqrt{\frac{E_n - mc^2}{2E_n}},
$$

and $c_{n_s} = \sqrt{n_s(n_s - 1)}$. Note that the eigenstates in (38) and (39) are normalized up to first order in $\epsilon$ and, as observed in [42], these eigenstates show that the spin and angular momentum are entangled. Moreover, the presence of deformation gives rise to new entangled states. Equations (38) and (39) allow us to write an initial state $| \Psi(0) \rangle = | n_s \rangle | \uparrow \rangle$ in terms of the positive- and negative-energy eigenstates, namely

$$
| \Psi_{n_s}(0) \rangle = \alpha_{n_s} | + \tilde{E}_n^\ast \rangle + \beta_{n_s} | - \tilde{E}_n^\ast \rangle
$$

This superposition of the positive- and negative-energy eigenstates is a signature of the Zitterbewegung, which is a relativistic quantum effect understood as a trembling motion of relativistic particles [51], difficult of be measured, but can be simulated experimentally in one dimension [52]. We observe again the deformation introduces more eigenstates in the superposition and for $\epsilon = 0$ our results immediately reduce to the ones in Ref. [42].

Now that we have a Hermitian operator and their eigenstates, we can proceed to study the system dynamics. Thus starting with (41), it leads to a state at time $t$ given by
$$|\Psi_{n_s}(t)\rangle = \alpha_{n_s} \left[ + \hat{E}_{n_s}^+ e^{-i\omega_{n_s}^+ t} + \beta_{n_s} \left| - \hat{E}_{n_s}^- \right] e^{-i\omega_{n_s}^- t} \right.$$

$$- \epsilon c_{n_s} \alpha_{n_s-2} \left| + \hat{E}_{n_s-2}^+ \right] e^{-i\omega_{n_s-2}^+ t} - \epsilon c_{n_s} \beta_{n_s-2} \left| - \hat{E}_{n_s-2}^- \right] e^{-i\omega_{n_s-2}^- t}$$

$$+ \epsilon c_{n_s+2} \alpha_{n_s+2} \left| + \hat{E}_{n_s+2}^+ \right] e^{-i\omega_{n_s+2}^+ t} + \epsilon c_{n_s+2} \beta_{n_s+2} \left| - \hat{E}_{n_s+2}^- \right] e^{-i\omega_{n_s+2}^- t},$$

(42)

where

$$\omega_{n_s}^\pm = \pm \omega_{n_s} - \phi_{n_s}^\pm,$$

(43)

is the $\kappa$-deformed Zitterbewegung frequency, with $\omega_{n_s} = E_{n_s}^+/\hbar$, and $\phi_{n_s}^\pm = 4m^2 e^4 \xi(n_s+1)/\hbar$. Now, writing the evolved state in the language of Pauli spinors, we have

$$|\Psi_{n_s}(t)\rangle = e^{i\phi_{n_s}^+ t} \left( f_{n_s}(t) |n_s\rangle |\uparrow\rangle + g_{n_s}(t) |n_s + 1\rangle |\downarrow\rangle \right)$$

$$+ \epsilon e^{i\phi_{n_s}^- t} \left[ c_{n_s} f_{n_s}(t) |n_s - 2\rangle |\uparrow\rangle + c_{n_s+1} g_{n_s}(t) |n_s - 1\rangle |\downarrow\rangle \right]$$

$$- \epsilon e^{i\phi_{n_s}^- t} \left( c_{n_s+2} f_{n_s}(t) |n_s + 2\rangle |\uparrow\rangle - c_{n_s+3} g_{n_s}(t) |n_s + 3\rangle |\downarrow\rangle \right)$$

$$- \epsilon c_{n_s} e^{i\phi_{n_s}^- t} \left( f_{n_s-2}(t) |n_s - 2\rangle |\uparrow\rangle + g_{n_s-2}(t) |n_s - 1\rangle |\downarrow\rangle \right)$$

$$+ \epsilon c_{n_s+2} e^{i\phi_{n_s}^- t} \left( f_{n_s+2}(t) |n_s + 2\rangle |\uparrow\rangle + g_{n_s+2}(t) |n_s + 3\rangle |\downarrow\rangle \right),$$

(44)

where

$$f_{n_s}(t) = \cos(\omega_{n_s} t) - \frac{i \sin(\omega_{n_s} t)}{\sqrt{1 + 4\xi(n_s + 1)}},$$

(45)

and

$$g_{n_s}(t) = 2 \sin(\omega_{n_s} t) \alpha_{n_s} \beta_{n_s},$$

(46)

with $|f_{n_s}(t)|^2 + |g_{n_s}(t)|^2 = 1$.

We can appreciate the modifications caused by the $\kappa$-deformation by evaluating the expectation values of the $z$ component of the spin, orbital and total angular momentum observables, which are defined by

$$S_z = \frac{\hbar}{2} \sigma_z, \quad L_z = \hbar(N_s - N_{-s}), \quad J_z = L_z + S_z,$$

(47)

respectively. Surprisingly, even though the $\kappa$ deformation modifies the energy eigenvalues, it gives rise to new entangled states with different quantum numbers, and modifies the Zitterbewegung frequency, there is no first-order correction on the expectation values of the $\kappa$-JC. This kind of result was already observed in the $\kappa$-Dirac-Coulomb problem [18], where the first-order correction on this system is identical zero.

On the other hand, we can observe first-order effects of the $\kappa$-deformation on the scenario of collapse and revival of probabilities in the $\kappa$-JC model by employing a coherent state as an initial state. So, considering the initial state as $|\Psi_{n_s}(0)\rangle = |\alpha\rangle |\uparrow\rangle$, with

$$|\alpha\rangle = e^{-|\alpha|^2} \sum_{n_s=0}^{\infty} \frac{\alpha^{n_s}}{\sqrt{n_s!}} |n_s\rangle,$$

(48)

the $\kappa$-deformed expectation values are given by

$$\langle S_z^\pm \rangle = \frac{\hbar}{2} - \hbar \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s} e^{-\langle n_s \rangle}}{n_s!} S_{n_s}(t)$$

$$+ \hbar \epsilon \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s+1} e^{-\langle n_s \rangle}}{n!} [S_{n_s}(t) - S_{n_s+2}(t)],$$

(49)

$$\langle L_z^\pm \rangle = \hbar \langle n_s \rangle + \hbar \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s} e^{-\langle n_s \rangle}}{n_s!} S_{n_s}(t)$$

$$- \hbar \epsilon \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s+1} e^{-\langle n_s \rangle}}{n!} [S_{n_s}(t) - S_{n_s+2}(t)]$$

$$+ \hbar \epsilon \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s+1} e^{-\langle n_s \rangle}}{n!} \mathcal{L}_{n_s}(t),$$

(50)

and

$$\langle J_z^\pm \rangle = \hbar \left[ \langle n_s \rangle + \frac{1}{2} \right] + \hbar \epsilon \sum_{n_s=0}^{\infty} \frac{\langle n_s \rangle^{n_s+1} e^{-\langle n_s \rangle}}{n!} \mathcal{L}_{n_s}(t),$$

(51)

where $\langle n_s \rangle = |\alpha|^2$,

$$S_{n_s}(t) = \frac{4\xi(n_s+1)}{[1 + 4\xi(n_s + 1)]} \sin^2(\omega_{n_s} t),$$

(52)
FIG. 2. (Color online) Behavior of the expectation values (a) $\langle S^z \rangle$, (b) $\langle L^z \rangle$, and (c) $\langle J^z \rangle$ as a function of time for a system with mean photon number $\langle n_s \rangle = 25$ for $\epsilon = 5 \times 10^{-4}$ (blue solid line) and $\epsilon = 0$ (orange dotted line) using units such as $m = h = \omega = c = 1$. In (a), the two curves are superposed and the inset shows the difference between them. In (c), the inset shows the asymptotic behavior of the $\Delta \langle J^z \rangle$.

\begin{equation}
\mathcal{L}^z_{ns}(t) = \frac{4c_{ns+2}}{\sqrt{(n_s+2)!}} w_{ns}(t) \cos(\Phi^\prime t) - \frac{2c_{ns+2}}{\sqrt{(n_s+2)!}} s_{ns}(t) \sin(\Phi^\prime t) - \frac{2c_{ns+3}}{\sqrt{(n_s+2)!}} p_{ns}(t) \cos(\Phi^\prime t),
\end{equation}

with

\begin{equation}
\Phi^\prime = \phi^\prime_{ns} - \phi^\prime_{ns+2} = -8m^2c^4\xi \epsilon,
\end{equation}

\begin{equation}
w_{ns}(t) = 2 \cos(\omega_n t) \cos(\omega_{n+2} t) + \frac{2\sin(\omega_n t) \sin(\omega_{n+2} t)}{\sqrt{[1 + 4\xi(n_s + 1)][1 + 4\xi(n_s + 3)]}},
\end{equation}

\begin{equation}s_{ns}(t) = \frac{2\cos(\omega_n t) \sin(\omega_{n+2} t)}{\sqrt{1 + 4\xi(n_s + 1)}} - \frac{2\cos(\omega_n t) \sin(\omega_{n+2} t)}{\sqrt{1 + 4\xi(n_s + 3)}},
\end{equation}

and

\begin{equation}
p_{ns}(t) = 2\alpha_n \alpha_{n+2} \sin(\omega_n t) \sin(\omega_{n+2} t).
\end{equation}

We can observe that the deformation modifies all the expectation values. To help us analyze the effects of the deformation on the expectation values, let us define

\begin{equation}
\Delta \langle O \rangle = \langle O^\prime \rangle - \langle O \rangle,
\end{equation}

as the difference between the $\kappa$-deformed expectation value of the observable $O$ and the usual (undeformed) one. Figure 2 shows the results for the expectation values as a function of time $t$ for a system with mean photon number $\langle n_s \rangle = 25$ using units such as $m = h = \omega = c = 1$ and $\epsilon = 5 \times 10^{-4}$ (blue solid lines) and for $\epsilon = 0$ (orange dotted lines). In Fig. 2(a) we show $\langle S^z \rangle$ and it shows the well-known initial collapse followed by the revival of the spin inversion. The inset shows $\Delta \langle S^z \rangle$ and we observe that the expectation value is slightly modified by the deformation. On the other hand, in Fig. 2(b) we show the $\langle L^z \rangle$ and we can also observe collapse and revival, but now the orbital angular momentum is noticeably more affected by the deformation than the spin angular momentum. As a result, we observe that $\langle J^z \rangle$ is not constant of motion anymore when the deformation is present, as we can see in Fig. 2(c). So, the $\kappa$-deformed expectation value of the $z$ component of the total angular momentum is not a conserved quantity. This result can be understood by noting that $J_z$ fails to commute with $h_{\kappa,\text{JC}}^z$,

\begin{equation}[h_{\kappa,\text{JC}}^z, J_z] = 4\hbar g(\sigma^- \hat{a}_s^z + \sigma^+ \hat{a}_s^z),
\end{equation}

and this failure is a direct consequence of the deformation. We can also observe that deformation displaces the expectation value of the $J_z$ (see the inset in Fig 2(c)) and for large values of $t$ it converges to a fixed amount, $\Delta \langle J^z \rangle \big|_{t \to \infty} \sim 5 \times 10^{-2}$. It is easy to see that for $\epsilon = 0$, $J_z$ commutes with the Hamiltonian and we recover all the results of the usual JC system, as it should be. We conclude this section by commenting that similar results are obtained for the $\kappa$-AJC system.

VI. CONCLUSION

In conclusion, we have revisited the Dirac oscillator in $(2+1)$ dimensions and its mapping onto the JC and AJC models. The mapping is now transparent as we have made the connection between the non-minimal coupling signal + (−)
of the Dirac oscillator Hamiltonian and the JC (AJC) model. We have also introduced the parameter \( s = \pm 1 \) to characterize the two possible chiralities, allowing to discuss them simultaneously. By considering the (2+1) Dirac oscillator in the context of the \( \kappa \)-deformed algebra and using the above mapping, we have proposed the \( \kappa \)-JC and the \( \kappa \)-AJC models. We have shown that the \( \kappa \)-deformation leads naturally to a non-Hermitian Hamiltonian, something that leads to a non-unitary time evolution. Moreover, the \( \kappa \)-(A)JC Hamiltonian is not even \( PT \)-symmetric, but is quasi-Hermitian as it possesses a real spectrum, and by employing the theory of quasi-Hermitian Hamiltonians, we have found its Hermitian counterpart, allowing us to study the dynamics of the \( \kappa \)-deformed system. Although the displacement caused by the deformation on the eigenenergies, and consequently, on the Zitterbewegung frequencies, we have observed no first-order effects on the expectation values of \( S_z, L_z \) and \( J_z \), when considering an initial state such as \( |\psi_n(0)\rangle = |n\rangle \langle \uparrow \rangle \). On the other hand, when considering a coherent initial state, we have observed modifications on the well-known collapse and revival behavior, as all as on the above expectation values. In special, we have observed that the expectation value of the total angular momentum in the \( z \) direction, \( J_z \), is not a constant of motion anymore as a direct consequence of the \( \kappa \)-deformation. Given the possible experimental realizations of the Dirac oscillator, we hope that some future experiment might be able to detect the effects of the deformation presented here.
