Abstract

We study the behaviour of the familywise error rate (FWER) for Bonferroni-type procedure in multiple testing problem. Das and Bhandari in a recent article have shown that, in the equicorrelated normal setup, FWER asymptotically (i.e when number of hypotheses is very large) is a convex function of correlation $\rho$ and hence an upper bound on the FWER of Bonferroni-\alpha procedure is given by $\alpha (1-\rho)$. We derive upper bounds on FWER for Bonferroni method under the equicorrelated and general normal setups in asymptotic and non-asymptotic case. We show similar results for generalized familywise error rates.

1 Introduction

Simultaneous hypothesis testing has emerged as a lively area of research in statistical inference because of its importance and applicability in astronomy, genomics, brain imaging, and other modern scientific investigations. Often these hypotheses involve unknown dependence structure among variables. This dependence among observations has been one of the major problems in multiple testing. Many efforts have been made to generalize the existing methods under dependence. Sarkar [16] reviews false discovery rate (FDR) control under dependence. Efron [3] has mentioned that the correlation penalty on the summary statistics depends on the root mean square (RMS) of correlations. The relevant literature is reviewed in Efron [4]. These works shed light on the fact that any error rate criterion (FWER or FDR) should be treated more carefully when correlation is present. However, very little literature can be found which elucidates the effect of correlation on different multiple testing procedures.

In this work, we shall focus on the FWER, a widely considered frequentist approach in multiple testing. This is defined as the probability of erroneously rejecting at least one true null hypothesis in a simultaneous testing problem. Controlling this FWER has been a traditional
concern in many multiple testing problems. This tradition is reflected in the books by Hochberg and Tamhane [7], Westfall and Young [20], and the review by Tamhane [18]. The control of FWER at some level $\alpha$ requires each of the individual tests to be conducted at lower levels, as in the Bonferroni procedure where $\alpha$ is divided by the number of tests considered.

We have considered equicorrelated normal distribution at first. This distribution also has important applications in modeling the lifetimes of coherent systems [11] and visual sciences ([14], [19]). Zhang and Chen [5] have derived non-asymptotic upper bounds for FDR for an adaptive one-way grouped Benjamini-Hochberg procedure under the equicorrelated setup. Das and Bhandari [2] have shown that asymptotically (i.e for large no. of hypotheses) FWER($\rho$) is a convex function in $\rho \in [0, 1]$ and therefore, FWER in the Bonferroni-$\alpha$ procedure is bounded by $\alpha(1 - \rho)$. This suggests a necessary correlation correction in Bonferroni’s method. Here, we shall derive upper bounds on FWER for Bonferroni’s method under the equicorrelated and general normal setups in both asymptotic and non-asymptotic setups.

Order statistics for exchangable normal random variables have applications in biometrics ([14], [19]). Also, the maximum of exchangeable normal random vector can be used to model the lifetime of parallel systems conveniently. The non-asymptotic bound on FWER provided in this work actually gives a lower bound on the c.d.f. of the failure time of the parallel systems. Loperfido [11] has shown that the maximum of $n$ observations from exchangeable normal distribution follows $(n-1)$ dimensional skew normal distribution. While the c.d.f. of multivariate skew normal distribution is very difficult to deal with, a non-asymptotic bound on the c.d.f. can be obtained along the similar lines to the one in this work.

This article is organized as follows: in Section 2, we introduce the framework of our work. In Section 3, we discuss a review of the recent work of Das and Bhandari [2]. We establish upper bounds on FWER for the asymptotic and non-asymptotic case in Section 4. In Section 5, we focus on the generalized familywise error rate. Subsequently, Section 6 contains simulation studies based on the procedures described in previous sections. Finally in Section 7 we raise some questions and mention some interesting problems.

2 Description of the Problem

Let $X_1, X_2, \ldots$ be a sequence of random variables and we have a sequence of null hypotheses

$$H_{0i} : X_i \sim N(0, 1) \quad i = 1, 2, \ldots$$

Suppose we have $n$ such null hypotheses. We have considered one sided tests (i.e, $H_{0i}$ is rejected for large values of $X_i$ (say $X_i > c$ for some cut-off $c$)). A classical measure of the type-I error is FWER, which is the probability of falsely rejecting at least one null hypothesis (this happens if $X_i > c$ for some $i$ and the probability is computed under the intersection null hypothesis $H_0 = \bigcap_{i=1}^{n} H_{0i} = \ldots$
\{X_i \sim N(0, 1) \forall i = 1, 2, \ldots, n\}$. Then,

\[
FWER = P(\text{At least one false rejection}) = P(X_i > c \text{ for some } i \mid H_0) = P_{H_0}\left(\bigcup_{i=1}^{n}\{X_i > c\}\right).
\]

We have considered equicorrelated setup at first (in sections 3, 4.2), i.e,

\[
\text{Corr}(X_i, X_j) = \rho \quad \forall i \neq j \quad (\rho \geq 0).
\]

In section 4.1 and 4.3, we have considered general correlated setup:

\[
\text{Corr}(X_i, X_j) = \rho_{ij} \quad \forall i \neq j \quad (\rho_{ij} \geq 0).
\]

We shall study FWER of Bonferroni’s procedure. This method sets a single cut-off for all the \(n\) hypotheses. It rejects the \(i\)-th null hypothesis \((H_{0i})\) if \(X_i > \Phi^{-1}(1 - \frac{\alpha}{n})\) where \(\alpha\) is the desired level at which one wishes to control FWER and \(\Phi\) denotes the c.d.f of standard normal distribution.

We shall denote the family wise error rate under a correlated normal set-up with correlation matrix \(R\) by FWER\((n, \alpha, R)\). Our goal is to provide a bound on FWER\((n, \alpha, R)\) of Bonferroni’s procedure for different choices of \(R\) in terms of entries of \(R\).

We shall call the setup with very large number of hypotheses an asymptotic setup while setups with small or moderate number of hypotheses will be referred to as non-asymptotic setups. We summarize known and new results regarding bounds on FWER\((n, \alpha, \rho)\) of Bonferroni’s procedure under various dependent normal setups in the table below:

3 Literature Review

Das and Bhandari [2] consider the equicorrelated framework as described in the previous section and show that asymptotically (i.e for large no. of hypotheses) FWER is a convex function in \(\rho \in [0, 1]\). Towards this, they consider the function

\[
H(\rho) = 1 - FWER(n, \alpha, \rho) = P(X_i \leq c \quad \forall i = 1, 2, \ldots, n \mid H_0).
\]
Evidently the sequence \( \{X_m\}_{m \geq 1} \) is exchangeable under the intersection null hypothesis \( H_0 \) for the equicorrelated set-up. In other words,

\[
(X_{i_1}, \ldots, X_{i_k}) \sim N_k(0_k, (1 - \rho) I_k + \rho J_k)
\]

where \( J_k \) is the \( k \times k \) matrix of all ones. Then, for each \( i \geq 1 \), \( X_i = \theta + Z_i, \forall i \geq 1 \) where \( \theta \) is a normal random variable having mean 0 and independent of the sequence \( \{Z_n\}_{n \geq 1} \) and \( Z_i \)'s are i.i.d. normal random variables.

Since \( \text{Cov}(X_i, X_j) = \rho \), we get that \( \text{Var}(\theta) = \rho \), implying \( \theta \sim \mathcal{N}(0, \rho) \) and \( Z_i \overset{i.i.d.}{\sim} \mathcal{N}(0, 1 - \rho) \) \( \forall i \geq 1 \). Thus,

\[
H(\rho) = \mathbb{P}(\theta + Z_i \leq c \ \forall i = 1, 2, \ldots, n) = \mathbb{E}_\theta \left[ \Phi^n \left( \frac{c - \theta}{\sqrt{1 - \rho}} \right) \right]
\]

\[
= \mathbb{E} \left[ \Phi^n \left( \frac{c}{\sqrt{1 - \rho}} + \sqrt{\frac{n}{1 - \rho}} Z \right) \right] \quad \text{(where } Z \sim \mathcal{N}(0, 1)\text{)}
\]

\[
= \mathbb{E}[\Phi^n(d)] \quad \text{(where } d \text{ is the quantity it is replacing)}
\]

Das and Bhandari [2] apply dominated convergence theorem twice to obtain an expression for \( H'(\rho) \) and establish the following:

**Theorem 1.** Suppose each \( H_{0i} \) is being tested at size \( \alpha_n \). If \( \lim_{n \to \infty} n\alpha_n = \alpha \in (0, 1) \) then, as \( n \to \infty \), \( H''(\rho) \leq 0 \) and therefore \( H(\rho) \) asymptotically is a concave function in \([0, 1]\).

From Theorem 1, we get that as \( n \to \infty \), the second derivative of \( FWER(n, \alpha, \rho) \) w.r.t \( \rho \) is non-negative and therefore \( FWER(n, \alpha, \rho) \) is a convex function in \( \rho \in [0, 1] \) asymptotically. We also have the following:

- For \( \rho = 0 \) (independence), \( H(\rho) = \prod_{i=1}^n \mathbb{P}_{H_0}(X_i \leq c) = (1 - \alpha_n)^n \).

- For \( \rho = 1 \) (when \( X_i = X_j \) a.s. \( \forall i \neq j \)), \( H(\rho) = 1 - \alpha_n \).

(as one rejection would imply rejection of all null hypotheses here)

Therefore, \( H(\rho) \) is bounded below by the line \( y = \mathcal{L}(\rho) \) which joins \((0, (1 - \alpha_n)^n)\) and \((1, 1 - \alpha_n)\).

We have the following corollary regarding the asymptotic behaviour of \( H(\rho) \) as a function of \( \rho \):

**Corollary 1.** For large \( n \), \( H(\rho) \geq 1 - \alpha_n - (1 - \rho) [1 - \alpha_n - (1 - \alpha_n)^n] \).

For large \( n \), \( 1 - (1 - \alpha_n)^n \approx n\alpha_n \) implying \( H(\rho) \geq 1 - \alpha_n [n - (n - 1)\rho] \).

Bonferroni’s method suggests taking \( \alpha_n = \frac{\alpha}{n} \) if we want to control FWER at \( \alpha \) level. This choice of \( \alpha_n \) also satisfies the criterion of Theorem 1. When \( \alpha_n = \frac{\alpha}{n} \), then \( \alpha_n [n - (n - 1)\rho] \sim \alpha (1 - \rho) \). Thus, we have the following corollary:

**Corollary 2.** For Bonferroni’s procedure, \( H(\rho) \) is asymptotically bounded below by \( 1 - \alpha (1 - \rho) \).

This result has the following immediate consequence:
**Corollary 3.** For Bonferroni’s procedure, $FWER(n, \alpha, \rho)$ is asymptotically bounded by $\alpha(1 - \rho)$.

Hence, if the correlation can be estimated in a consistent manner (let $\hat{\rho}$ be that estimate of $\rho$), then to provide control FWER at level $\alpha$, the procedure should use $\frac{\alpha}{1-\hat{\rho}}$ as the corrected level of significance. Thus, the bound by Das and Bhandari [2] provides a significant gain in power for Bonferroni method for large number of hypotheses. **Corollary 3** also implies the following:

**Corollary 4.** For Bonferroni’s procedure, asymptotically, $FWER(n, \alpha, \rho) + FWER(n, \alpha, 1-\rho) \leq \alpha$.

This shows that Bonferroni procedure controls FWER at a much smaller level than $\alpha$.

4 Bounds on FWER

We establish upper bounds on FWER for the asymptotic and non-asymptotic setups in this section. This section is further split into three subsections. The first of these is concerned with finding upper bounds on FWER in the general asymptotic setup. The second subsection considers FWER in equicorrelated non-asymptotic setup while the last subsection discusses the general non-asymptotic setup.

4.1 Bound on FWER in General asymptotic Setup

Suppose we have $2n$ null hypotheses:

$$H_{0i} : X_i \sim N(0, 1), \ i = 1, 2, \ldots, 2n$$

corresponding to a sequence of $2n$ random variables $X_1, X_2, \ldots, X_{2n}$. In this section, we shall consider various dependence structures among these random variables and obtain upper bounds on FWER under those setups. We shall denote the FWER of Bonferroni’s procedure under a correlation structure $\Sigma$ by $FWER(\Sigma)$ throughout this subsection.

Firstly we consider following block equi-correlation structure among these random variables:

$$\begin{align*}
(X_1, X_2, \ldots, X_n) &\perp (X_{n+1}, X_{n+2}, \ldots, X_{2n}), \\
\text{Corr} (X_i, X_j) &= \rho_1 (\geq 0) \quad \forall i \neq j, \ i, j \in \{1, \ldots, n\} \quad \text{and} \\
\text{Corr} (X_i, X_j) &= \rho_2 (\geq 0) \quad \forall i \neq j, \ i, j \in \{n+1, \ldots, 2n\}.
\end{align*}$$

Thus $(X_1, X_2, \ldots, X_{2n})$ have the following covariance structure:

$$\Sigma_{2n}(\rho_1, \rho_2) = \begin{pmatrix}
1 & \dot{} & \rho_1 & 0 & \cdots & 0 \\
\vdots & \ddots & \vdots & \ddots & \vdots & \ddots \\
\rho_1 & \dot{} & 1 & 0 & \cdots & 0 \\
0 & \cdots & 0 & 1 & \cdots & \rho_2 \\
\vdots & \ddots & \vdots & \ddots & \ddots & \ddots \\
0 & \cdots & 0 & \rho_2 & \dot{} & 1
\end{pmatrix} = \begin{pmatrix}
M_n(\rho_1) & O_n \\
O_n & M_n(\rho_2)
\end{pmatrix}$$
where $M_n(\rho)$ denotes the $n \times n$ matrix with diagonal entries equal to 1, off-diagonal entries equal to $\rho$ and $O_n$ denotes the zero matrix of order $n$. This block-equicorrelated covariance structure has been used to explicitly model within-replicate and between-replicate correlations of observations from genome-wide data [21].

Suppose $\alpha$ is the target level at which we wish to control FWER. We shall obtain upper bound on
\[
FWER(\Sigma_{2n}(\rho_1, \rho_2)) = \mathbb{P}_{\Sigma_{2n}(\rho_1, \rho_2)} \left( \bigcup_{i=1}^{2n} \{ X_i > \Phi^{-1}(1 - \alpha/2n) \} \bigg| H_0 \right)
\]
in terms of $\rho_1$ and $\rho_2$ in the following theorem.

**Theorem 2.** Let $FWER(\Sigma_{2n}(\rho_1, \rho_2))$ be defined as above. Then, asymptotically,
\[
FWER(\Sigma_{2n}(\rho_1, \rho_2)) \leq \alpha \left( 1 - \frac{\rho_1 + \rho_2}{2} \right) - \frac{\alpha^2}{4} (1 - \rho_1)(1 - \rho_2).
\]

We need the following consequence of Corollary 2 to prove this theorem:

**Corollary 5.** Let $Z$ be a standard normal variable and $c_{n,\alpha} = \Phi^{-1}(1 - \alpha/n)$. Then, for sufficiently large $n$ and for all $\rho \in [0, 1)$,
\[
\mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha} + \sqrt{n}Z}{\sqrt{1 - \rho}} \right) \right] \geq 1 - \alpha(1 - \rho).
\]

This is immediate from Corollary 2 using the definition of $H(\rho)$ in Bonferroni procedure.

**Proof of Theorem 2:** Evidently $(X_1, X_2, \ldots, X_n)$ and $(X_{n+1}, X_{n+2}, \ldots, X_{2n})$ are two independent sets of exchangeable normal random variables. Therefore, proceeding in the same way as in the proof of Theorem 1, we get that

\[
\mathbb{P} (X_i \leq c_{n,\alpha} \forall i = 1, \ldots, n \big| H_0) = \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha} + \sqrt{\rho_1}Z_1}{\sqrt{1 - \rho_1}} \right) \right] \quad \text{(where } Z_1 \sim N(0, 1))
\]

\[
\mathbb{P} (X_i \leq c_{n,\alpha} \forall i = n + 1, \ldots, 2n \big| H_0) = \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha} + \sqrt{\rho_2}Z_2}{\sqrt{1 - \rho_2}} \right) \right] \quad \text{(where } Z_2 \sim N(0, 1))
\]

for any $c_{n,\alpha}$ where $Z_1$ and $Z_2$ are independent. Since $(X_1, X_2, \ldots, X_n)$ and $(X_{n+1}, X_{n+2}, \ldots, X_{2n})$ are independent, we obtain

\[
\mathbb{P} (X_i \leq c_{n,\alpha} \forall i = 1, \ldots, 2n \big| H_0) = \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha} + \sqrt{\rho_1}Z_1}{\sqrt{1 - \rho_1}} \right) \right] \cdot \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha} + \sqrt{\rho_2}Z_2}{\sqrt{1 - \rho_2}} \right) \right].
\]

The above identity holds for any $\alpha \in (0, 1)$. Hence, using $\alpha/2$ instead of $\alpha$, we get

\[
\mathbb{P} (X_i \leq c_{n,\alpha/2} \forall i = 1, \ldots, 2n \big| H_0) = \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha/2} + \sqrt{\rho_1}Z_1}{\sqrt{1 - \rho_1}} \right) \right] \cdot \mathbb{E} \left[ \Phi^n \left( \frac{c_{n,\alpha/2} + \sqrt{\rho_2}Z_2}{\sqrt{1 - \rho_2}} \right) \right].
\]
This gives, from Corollary 5, for sufficiently large $n$,

$$
P(X_i \leq \Phi^{-1}(1 - \alpha/2n) \ \forall i = 1, \ldots, 2n \mid H_0) \geq \left[ 1 - \frac{\alpha}{2}(1 - \rho_1) \right] \cdot \left[ 1 - \frac{\alpha}{2}(1 - \rho_2) \right].
$$

Therefore,

$$
FWER(\Sigma_{2n}(\rho_1, \rho_2)) = 1 - P(X_i \leq \Phi^{-1}(1 - \alpha/2n) \ \forall i = 1, 2, \ldots, 2n \mid H_0)
\leq 1 - \left[ 1 - \frac{\alpha}{2}(1 - \rho_1) \right] \cdot \left[ 1 - \frac{\alpha}{2}(1 - \rho_2) \right] \quad \text{(for sufficiently large $n$)}
\leq \alpha \left( 1 - \frac{\rho_1 + \rho_2}{2} \right) - \frac{\alpha^2}{4}(1 - \rho_1)(1 - \rho_2)
$$

completing the proof.

**Remark 1.** It is clear from the preceding proof that the bound provided in Theorem 2 holds for correlation matrices with odd dimensions also. In other words, we also have the following:

$$
FWER(\Sigma_{2n+1}(\rho_1, \rho_2)) \leq \alpha \left( 1 - \frac{\rho_1 + \rho_2}{2} \right) - \frac{\alpha^2}{4}(1 - \rho_1)(1 - \rho_2) \quad \text{as} \ n \to \infty.
$$

where $\Sigma_{2n+1}(\rho_1, \rho_2) = \begin{pmatrix} M_{n+1}(\rho_1) & O_n \\ O_n & M_n(\rho_2) \end{pmatrix}$.

We consider a more general setup now. Suppose $(X_1, X_2, \ldots, X_{2n})$ have the following correlation structure:

$$
\Sigma_{2n} = \begin{pmatrix} A_{n \times n} & B \\ B^T & C_{n \times n} \end{pmatrix}
$$

where $A, B, C$ have non-negative entries. Evidently, $\Sigma_{2n}$ reduces to $\Sigma_{2n}(\rho_1, \rho_2)$ when $A = M_n(\rho_1)$, $B = O_n$ and $C = M_n(\rho_2)$. We have the following generalization of Theorem 2:

**Theorem 3.** Let $\Sigma_{2n} = \begin{pmatrix} A_{n \times n} & B \\ B^T & C_{n \times n} \end{pmatrix}$ be an arbitrary correlation matrix where $A, B, C$ have non-negative entries. Suppose the least entries of $A$ and $C$ are $\rho_1$ and $\rho_2$, respectively. Then, asymptotically,

$$
FWER(\Sigma_{2n}) \leq \alpha \left( 1 - \frac{\rho_1 + \rho_2}{2} \right) - \frac{\alpha^2}{4}(1 - \rho_1)(1 - \rho_2).
$$

We shall prove this using the following well-known inequality due to Slepian:

**Theorem 4. Slepian [17]** Let $X$ be distributed according to $N(0, \Sigma)$, where $\Sigma$ is a correlation matrix. For an arbitrary but fixed real vector $a = (a_1, \ldots, a_k)'$, consider the quadrant probability

$$
g(k, a, \Sigma) = P_{\Sigma} \left[ \bigcap_{i=1}^{k} \{ X_i \leq a_i \} \right].
$$

Let $R = (\rho_{ij})$ and $T = (\tau_{ij})$ be two positive semidefinite correlation matrices. If $\rho_{ij} \geq \tau_{ij}$ holds for
all $i, j$, then $g(k, a, R) \geq g(k, a, T)$, i.e.

$$P_{\Sigma=R}\left[\bigcap_{i=1}^{k}\{X_i \leq a_i\}\right] \geq P_{\Sigma=T}\left[\bigcap_{i=1}^{k}\{X_i \leq a_i\}\right]$$

holds for all $a = (a_1, \ldots, a_k)'$. Furthermore, the inequality is strict if $R, T$ are positive definite and if the strict inequality $\rho_{ij} > \tau_{ij}$ holds for some $i, j$.

**Proof of Theorem 3:** We note that, for any $n \times n$ correlation matrix $\Sigma$, $FWER(\Sigma) = 1 - g(k, a, \Sigma)$ with $k = n$ and $a_i = \Phi^{-1}(1 - \alpha/n)$ for $1 \leq i \leq n$. Therefore,

$$FWER(\Sigma_{2n}) = 1 - g(2n, a, \Sigma_{2n}) \quad (\text{with } a_i = \Phi^{-1}(1 - \alpha/2n) \text{ for each } i)$$

$$\leq 1 - g(2n, a, \Sigma_{2n}(\rho_1, \rho_2)) \quad (\text{using Theorem 4})$$

$$= FWER(\Sigma_{2n}(\rho_1, \rho_2))$$

The rest follows from Theorem 2.

**Corollary 6.** For Bonferroni’s procedure, $FWER(\rho)$ is asymptotically bounded by

$$\alpha(1 - \rho) \left[1 - \frac{\alpha(1 - \rho)}{4}\right].$$

This follows by taking $A = C = M_n(\rho)$ and $B = \rho J_n$ (where $J_n$ is the $n \times n$ matrix all of 1’s) in Theorem 3. This is an improvement over Corollary 3.

### 4.2 Bounds on FWER in Equicorrelated Non-asymptotic Setup

In equicorrelated setups with small and moderate dimensions, the $\alpha(1 - \rho)$ bound fails (we shall see this in detail in Section 6). This is the motivation behind considering FWER in the non-asymptotic case. In the non-asymptotic set-up, we can not apply dominated convergence theorem and hence we can not proceed in the same way as in Das and Bhandari [2]. Therefore, alternative approaches to bound FWER must be considered. Previously we used $FWER(n, \alpha, \rho)$ to denote the FWER under the equicorrelated normal setup. For the rest of this work, we are concerned with Bonferroni procedure only and therefore we can safely use our previous notation $FWER(n, \alpha, \rho)$ to denote the FWER for Bonferroni’s procedure under the equicorrelated normal. So,

$$FWER(n, \alpha, \rho) = \mathbb{P}\left(\bigcup_{i=1}^{n}\{X_i > \Phi^{-1}(1 - \alpha/n)\} \mid H_0\right)$$

where $\Phi$ denotes the c.d.f of standard normal distribution. We shall prove the following:

**Theorem 5.** Under the equicorrelated normal set-up,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{2\pi} \int_{\rho}^{\rho_0} \frac{1}{\sqrt{1-z^2}} e^{-\frac{\Phi^{-1}(1-\frac{\alpha}{n})^2}{1+z^2}} dz.$$
It is noteworthy that this bound holds for any choice of \((n, \alpha)\) and any \(\rho \geq 0\). We need the following two lemmas to establish this theorem:

**Lemma 1. Kwerel [9]** Let \(A_1, A_2, \ldots, A_n\) be \(n\) events. Let \(S_1 = \sum_{i=1}^{n} P(A_i)\) and \(S_2 = \sum_{1 \leq i < j \leq n} P(A_i \cap A_j)\). Then, \(P(\bigcup_{i=1}^{n} A_i) \leq S_1 - \frac{2}{n} S_2\).

This bound on the union of \(n\) events is also called the Sobel-Uppuluri upper bound and is the optimal linear bound in \(S_1\) and \(S_2\) [1]. The second lemma is regarding the joint distribution function of a bivariate normal distribution:

**Theorem 6. Monhor [12]** Suppose \((X, Y)\) follows a bivariate normal distribution with parameters \((0, 0, 1, 1, \rho)\) with \(\rho \geq 0\). Then, for all \(x > 0\),

\[
P(X \leq x, Y \leq x) = [\Phi(x)]^2 + \frac{1}{2\pi} \int_{0}^{\rho} \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+z^2}} dz.
\]

**Proof of Theorem 5:** For \(i = 1, \ldots, n\), we define the event \(A_i = \{X_i > \Phi^{-1}(1-\alpha/n)|H_0\}\). Now,

\[
P(A_i) = P_{H_0} \left[ X_i > \Phi^{-1}(1-\alpha/n) \right] = 1 - P_{H_0} \left[ X_i \leq \Phi^{-1}(1-\alpha/n) \right] = 1 - (1-\alpha/n) = \frac{\alpha}{n}.
\]

This gives \(S_1 = \sum_{i=1}^{n} P(A_i) = n \cdot \frac{\alpha}{n} = \alpha\). Now,

\[
P(A_i \cap A_j)
\]

\[
= P_{H_0} \left[ X_i > \Phi^{-1}(1-\alpha/n), X_j > \Phi^{-1}(1-\alpha/n) \right]
\]

\[
= 1 - P_{H_0} \left[ X_i > \Phi^{-1}(1-\alpha/n) \bigcup X_j > \Phi^{-1}(1-\alpha/n) \right]
\]

\[
= 1 - P_{H_0} \left[ X_i \leq \Phi^{-1}(1-\alpha/n) \right] - P_{H_0} \left[ X_j \leq \Phi^{-1}(1-\alpha/n) \right] + P_{H_0} \left[ X_i \leq \Phi^{-1}(1-\alpha/n), X_j \leq \Phi^{-1}(1-\alpha/n) \right]
\]

\[
= 1 - (1-\alpha/n) - (1-\alpha/n) + P_{H_0} \left[ X_i \leq \Phi^{-1}(1-\alpha/n), X_j \leq \Phi^{-1}(1-\alpha/n) \right]
\]

\[
= \frac{2\alpha}{n} - 1 + (1-\alpha/n)^2 + \frac{1}{2\pi} \int_{0}^{\rho} \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+z^2}} dz \quad \text{(using Theorem 6)}
\]

\[
= \frac{\alpha^2}{n^2} + \frac{1}{2\pi} \int_{0}^{\rho} \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+z^2}} dz
\]

This gives

\[
S_2 = \left( \frac{n}{2} \right) \cdot \left[ \frac{\alpha^2}{n^2} + \frac{1}{2\pi} \int_{0}^{\rho} \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+z^2}} dz \right].
\]
Now, using Lemma 1, we obtain

$$\text{FWER} = \mathbb{P}\left(\bigcup_{i=1}^{n} A_i \leq S_1 - \frac{2}{n} S_2\right)$$

$$= \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{2\pi} \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{\phi^{-1}(1-\frac{\alpha}{n})^2}{1+z^2}} dz$$

completing the proof.

**Corollary 7.** Under the equicorrelated normal set-up, if $\rho \leq \frac{\alpha}{n}$, $\text{FWER}(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \alpha \rho$.

Hence, throughout this work, we assume that $\rho \geq \frac{\alpha}{n}$. Monhor [12] obtained the following inequality for positively correlated bivariate normal distribution function using Theorem 6:

$$\mathbb{P}(X \leq x, Y \leq x) \geq [\Phi(x)]^2 + \frac{1}{2\pi} \cdot \sin^{-1} \rho \cdot e^{-x^2} \quad \forall x > 0.$$ 

We strengthen Monhor’s inequality further for $x$ taking value in a certain region, in the following theorem:

**Theorem 7.** Suppose $(X, Y)$ follows a bivariate normal distribution with parameters $(0, 0, 1, 1, \rho)$ with $\rho \geq 0$. Then, for all $x \geq 2$,

$$\mathbb{P}(X \leq x, Y \leq x) \geq [\Phi(x)]^2 + \frac{1}{2\pi} \cdot \sin^{-1} \rho \cdot e^{-\frac{x^2}{1+\frac{x^2}{2}}}.$$ 

We shall use the following well-known inequalities to prove the above theorem:

**Lemma 2. (Chebyshev Integral Inequality)** Let $f$ and $g$ be two nonnegative integrable functions and synchronous on a bounded interval $[a, b]$, i.e

$$\forall x, y \in [a, b], \quad [f(x) - f(y)] \cdot [g(x) - g(y)] \geq 0.$$ 

Then,

$$(b - a) \cdot \int_a^b f(x)g(x)dx \geq \int_a^b f(x)dx \cdot \int_a^b g(x)dx.$$ 

**Lemma 3. (Hermite-Hadamard Integral Inequality)** Let $f : [a, b] \to \mathbb{R}$ be a convex function. Then,

$$\int_a^b f(x)dx \geq (b - a) \cdot f\left(\frac{a + b}{2}\right).$$ 

**Proof of Theorem 7:** Suppose $(X, Y)$ follows a bivariate normal distribution with parameters $(0, 0, 1, 1, \rho)$, $\rho \geq 0$. Then, from Theorem 6,

$$\forall x > 0 \quad \mathbb{P}(X \leq x, Y \leq x) = [\Phi(x)]^2 + \frac{1}{2\pi} \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{\frac{\pi^2z^2}{2}} dz.$$
It can be easily shown that the functions \( \frac{1}{\sqrt{1-z^2}} \) and \( e^{-\frac{x^2}{1+z}} \) have same monotony in \( z \in [0,1] \), i.e. are synchronous on \([0,1]\). Using Lemma 2, we get that
\[
\int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{x^2}{1+z}} \, dz \geq \frac{1}{\rho} \int_0^\rho \frac{1}{\sqrt{1-z^2}} \, dz \cdot \int_0^\rho e^{-\frac{x^2}{1+z}} \, dz.
\]

\( \implies \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{x^2}{1+z}} \, dz \geq \sin^{-1} \frac{\rho}{\rho} \cdot \int_0^\rho e^{-\frac{x^2}{1+z}} \, dz. \) \((*)\)

The function \( e^{-\frac{x^2}{1+z}} \) is convex in \( z \) if \( z \leq \frac{x^2}{2} - 1 \). Now, \( 0 \leq z \leq \rho \leq 1 \). So, \( z \leq \frac{x^2}{2} - 1 \) holds if \( x \geq 2 \).

Hence, \( e^{-\frac{x^2}{1+z}} \) is convex in \( z \in [0,1] \) for \( x \geq 2 \). Applying Lemma 3 on this function, we get,
\[
\forall x \geq 2, \quad \int_0^\rho e^{-\frac{x^2}{1+z}} \, dz \geq \rho \cdot e^{-\frac{x^2}{1+z}}.
\]

Combining this with \((*)\), we get, for \( x \geq 2 \),
\[
\int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{x^2}{1+z}} \, dz \geq \sin^{-1} \rho \cdot e^{-\frac{x^2}{1+z}}.
\]

The rest is obvious from Theorem 6.

**Corollary 8.** Under the equicorrelated normal set-up, if \( x = \Phi^{-1}(1 - \frac{\alpha}{n}) \geq 2 \),
\[
FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{2\pi} - \frac{n-1}{n} \cdot \sin^{-1} \rho \cdot e^{-\frac{x^2}{1+z}}.
\]

We shall write \( x \) for \( \Phi^{-1}(1 - \frac{\alpha}{n}) \) from now on.

We observe from simulation study that, the upper bound \( \alpha(1-\rho) \) given by Corollary 3 holds for any nonnegative value of \( \rho \) when \( n \geq 10000 \) and \( \alpha \geq 0.01 \). When \( n = 10000 \) and \( \alpha = 0.01 \), we have \( x = 4.42 \). This, along with the findings from our simulations suggest that the bound holds for \( x \geq 4.42 \). Therefore, here we restrict ourselves to the case \( x \leq 4.42 \).

We also observe that, when \( \rho \geq 0.5 \), the bound \( \alpha(1-\rho) \) works when \( n \geq 900 \) and \( \alpha \geq 0.01 \). When \( n = 900 \) and \( \alpha = 0.01 \), we have \( x = 4.23 \). This, along with the findings from our simulations suggest that, when \( \rho \geq .5 \), the bound works for \( x \geq 4.23 \). Therefore, when \( \rho \geq .5 \), we restrict ourselves to the case \( x \leq 4.23 \).

We shall also assume \( \rho \geq 0.01 \) from now on. We shall derive upper bounds on \( FWER(n, \alpha, \rho) \) in each of the following four cases separately:

- \( 4.23 \geq x \geq 2, \rho \geq .5 \)
- \( 4.42 \geq x \geq 2, .01 \leq \rho < .5 \)
- \( x \leq 2, \rho \geq .5 \)
• $x \leq 2, \rho < 0.5$

Case 1: $4.23 \geq x \geq 2, \rho \geq 0.5$

**Theorem 8.** Let $4.23 \geq x \geq 2, \rho \geq 0.5$. Then,

$$\forall x \in [x_l, x_{l+1}] \quad FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \frac{\alpha \rho}{6} \cdot C_{x_l}(n)$$

where $x_l$'s and $C_{x_l}(n)$'s are as follows:

<table>
<thead>
<tr>
<th>$l$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x_l$</td>
<td>2.00</td>
<td>2.56</td>
<td>3.06</td>
<td>3.33</td>
<td>3.71</td>
<td>3.93</td>
<td>4.23</td>
</tr>
<tr>
<td>$C_{x_l}(n)$</td>
<td>1</td>
<td>$\frac{1}{2}$</td>
<td>1</td>
<td>$\frac{1}{2\pi}$</td>
<td>$\frac{1}{\pi^2}$</td>
<td>$\frac{1}{6\pi^3}$</td>
<td>-</td>
</tr>
</tbody>
</table>

**Proof:** We have from Corollary 8, for each $x \geq 2$,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{2\pi} \cdot \sin^{-1} \rho \cdot e^{-\frac{x^2}{1+\rho}}$$

$$\leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{2\pi} \cdot \frac{2\pi \rho}{6} \cdot e^{-\frac{x^2}{1+\rho}} \quad \text{(since } \rho \geq 0.5 \text{ implies } \frac{\sin^{-1} \rho}{\rho} \geq \frac{\pi}{3}).$$

Hence it is enough to show that

$$\forall x \in [x_l, x_{l+1}] \quad e^{-\frac{x^2}{1+\rho}} \geq \frac{\alpha}{n} \cdot C_{x_l}(n).$$

Now, $\frac{\alpha}{n} = 1 - \Phi(x)$. Let, $M(x) = e^{-\frac{x^2}{1-\Phi(x)}}$. Using computational tools, we get that $\forall x \in [x_l, x_{l+1}]$, $M(x) \geq C_{x_l}(n)$ and the proof is completed.

Case 2: $4.42 \geq x \geq 2, 0.01 \leq \rho < 0.5$

**Theorem 9.** Let $4.42 \geq x \geq 2, 0.01 \leq \rho < 0.5$. Let $I_1 = [\frac{1}{3}, 0.5)$, $I_2 = [\frac{1}{2\pi}, \frac{1}{3})$ and $I_3 = [0.01, \frac{1}{2\pi})$.

Then, for $\rho \in I_i$ with $i = 1, 2, 3$ and for $x \in [x_m(i), x_{m+1}(i)]$,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{2\pi} \cdot \frac{\rho \alpha}{6} \cdot D_{x_m}(n)$$

where $x_m$'s and $D_{x_m}(n)$'s are as follows:

<table>
<thead>
<tr>
<th>$m$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>$D_{x_m}(n)$</td>
<td>1</td>
<td>$\frac{1}{2}$</td>
<td>$\frac{1}{\pi}$</td>
<td>$\frac{1}{2\pi}$</td>
<td>$\frac{1}{\pi^2}$</td>
<td>$\frac{1}{4\pi^3}$</td>
<td>$\frac{1}{6\pi^5}$</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>$x_m(1)$</td>
<td>2</td>
<td>2.3</td>
<td>2.76</td>
<td>3</td>
<td>3.36</td>
<td>3.56</td>
<td>4</td>
<td>4.42</td>
<td>-</td>
</tr>
<tr>
<td>$x_m(2)$</td>
<td>2</td>
<td>2.49</td>
<td>2.72</td>
<td>3.04</td>
<td>3.23</td>
<td>3.66</td>
<td>4.03</td>
<td>4.42</td>
<td>-</td>
</tr>
<tr>
<td>$x_m(3)$</td>
<td>2</td>
<td>2.28</td>
<td>2.5</td>
<td>2.8</td>
<td>2.97</td>
<td>3.37</td>
<td>3.72</td>
<td>4.1</td>
<td>4.42</td>
</tr>
</tbody>
</table>

The proof of this theorem is exactly similar to that of the previous theorem and hence omitted.

Case 3: $x \leq 2, \rho \geq 0.5$
Theorem 10. Let $x \leq 2, \rho \geq .5$. Then,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \frac{\alpha \rho}{6}.$$ 

Proof: We have, from Theorem 4,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \frac{\alpha \rho}{6 \pi} \cdot \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+\rho^2}} dz.$$ 

Now,

$$\frac{n-1}{2\pi} \cdot \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+\rho^2}} dz \geq \frac{n-1}{2\pi} \cdot \frac{1}{\rho} \int_0^\rho \frac{1}{\sqrt{1-z^2}} dz \cdot \int_0^\rho e^{-\frac{z^2}{1+\rho^2}} dz \quad \text{using Lemma 2}$$

$$= \frac{n-1}{2\pi} \cdot \sin^{-1} \rho \cdot \rho \cdot \int_0^\rho e^{-\frac{z^2}{1+\rho^2}} dz$$

$$= \frac{n-1}{2\pi} \cdot \sin^{-1} \rho \cdot \rho \cdot \left[ \int_0^{\rho/2} e^{-\frac{z^2}{1+\rho^2}} dz + \int_{\rho/2}^\rho e^{-\frac{z^2}{1+\rho^2}} dz \right]$$

$$\geq \frac{n-1}{2\pi} \cdot \sin^{-1} \rho \cdot \rho \cdot \frac{\rho}{2} \left[ e^{-x^2} + e^{-\frac{x^2}{1+\rho^2}} \right] \quad \text{(since $e^{-\frac{z^2}{1+\rho^2}}$ is increasing in $z$)}$$

$$= \frac{\sin^{-1} \rho}{2\pi} \cdot (n-1) \cdot \left[ \frac{e^{-x^2} + e^{-\frac{x^2}{1+\rho^2}}}{2} \right]$$

$$\geq \frac{\sin^{-1} \rho}{2\pi} \cdot (n-1) \cdot \left[ \frac{e^{-x^2} + e^{-\frac{x^2}{1+\rho^2}}}{2} \right] \quad \text{(since $\rho \geq .5$)}$$

$$= \frac{\sin^{-1} \rho}{2\pi} \cdot (n-1) \cdot G(x) \quad \text{(suppose)}$$

Now, we have $\frac{\sin^{-1} \rho}{2\pi} \geq \frac{\rho}{6}$ since $\rho \geq .5$. Also, $G(x) \geq 1 - \Phi(x) = \frac{\alpha}{n}$ for $x \leq 2.2$. The rest follows from Theorem 5.

Case 4: $x \leq 2, \rho < .5$

Theorem 11. Let $x = \Phi^{-1}(1 - \frac{\alpha}{n}) \leq 2$. Then,

$$FWER(n, \alpha, \rho) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \frac{2\alpha \rho}{5\pi}.$$ 

Proof: $\Phi^{-1}(1 - \frac{\alpha}{n}) \leq 2$ implies $\frac{\alpha}{n} \geq 1 - \Phi(2) = 0.02275$. Therefore, $\rho \geq 0.02275$. Now, along the same lines of proof of the preceding theorem, we have,

$$\frac{n-1}{2\pi} \cdot \int_0^\rho \frac{1}{\sqrt{1-z^2}} e^{-\frac{z^2}{1+\rho^2}} dz \geq \frac{\sin^{-1} \rho}{2\pi} \cdot (n-1) \cdot \left[ \frac{e^{-x^2} + e^{-\frac{x^2}{1+\rho^2}}}{2} \right]$$

13
\[ \geq \frac{\rho}{2\pi} \cdot (n - 1) \cdot \left[ e^{-x^2} + e^{-\frac{x^2}{\rho^2(1 + x^2)}} \right] \quad (\text{since } \rho \geq 0.02275) \]
\[ = \frac{\rho}{2\pi} \cdot (n - 1) \cdot H(x) \quad (\text{suppose}) \]

Now, \( H(x) \geq \frac{1}{3}(1 - \Phi(x)) = \frac{4}{5} \) for \( x \leq 2 \). The rest follows from Theorem 5.

### 4.3 Bounds on FWER in General Non-asymptotic Setup

We have considered equicorrelated normal in non-asymptotic case so far. However, problems involving variables with more general dependence structure need to be analysed with more general correlation matrices. Hence, study of behaviour of FWER in general setups becomes important.

Suppose \((X_1, X_2, \ldots, X_n)\) have covariance matrix \( R = (\rho_{ij}) \) with \( \rho_{ij} \geq 0 \) for all \( i \neq j \). Let \( FWER(n, \alpha, R) \) denote the family-wise error rate for Bonferroni’s procedure under this set-up. So,\n
\[ FWER(n, \alpha, R) = \mathbb{P}_R \left( \bigcup_{i=1}^{n} \{X_i > \Phi^{-1}(1 - \alpha/n)\} \mid H_0 \right) = \mathbb{P}_R \left( \bigcup_{i=1}^{n} A_i \right) \]

where \( A_i = \{X_i > \Phi^{-1}(1 - \frac{\alpha}{n}) \mid H_0\} \) for \( i = 1, \ldots, n \).

In the equicorrelated setup, we used Kwerel’s inequality to find an upper bound to FWER:

\[ \mathbb{P} \left( \bigcup_{i=1}^{n} A_i \right) \leq \sum_{i=1}^{n} \mathbb{P}(A_i) - \frac{2}{n} \sum_{1 \leq i < j \leq n} \mathbb{P}(A_i \cap A_j). \]

That approach can be used to obtain bounds on FWER in the arbitrarily correlated setup also. However, one observes that the above inequality gives equal importance to all the intersections. Therefore, it might be advantageous to use some other probability inequality which involves the intersections with higher probabilities only. We mention such an inequality below:

**Lemma 4. Kounias [8]** Let \( A_1, A_2, \ldots, A_n \) be \( n \) events. Then,

\[ \mathbb{P} \left( \bigcup_{i=1}^{n} A_i \right) \leq \sum_{i=1}^{n} \mathbb{P}(A_i) - \max_{1 \leq i \leq n} \sum_{j=1, j \neq i}^{n} \mathbb{P}(A_i \cap A_j). \]

Evidently Kounias’s inequality is sharper than Kwerel’s inequality and they are equivalent when \( \mathbb{P}(A_i \cap A_j) \) is same for all \( i \neq j \). We are now in a position to establish a generalization of Theorem 5:

**Theorem 12.** Consider the arbitrarily correlated normal set-up with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Then,

\[ FWER(n, \alpha, R) \leq \alpha - \frac{n - 1}{n} \cdot \frac{\alpha^2}{n} - \frac{1}{2\pi} \sum_{j=1, j \neq i}^{n} \int_{0}^{\rho_{i,j}} \frac{1}{\sqrt{1 - z^2}} e^{-\frac{(1 - \alpha)^2}{2(1 + z^2)}} dz \]
where \( i^* = \arg \max_i \sum_{j=1, j \neq i}^n \rho_{ij} \).

**Proof:** We have \( \mathbb{P}(A_i) = \frac{\alpha}{n} \) where \( A_i = \{ X_i > \Phi^{-1}(1 - \frac{\alpha}{n})|H_0\} \), for \( i = 1, \ldots, n \). One can show, along the similar lines of the proof of Theorem 5, the following:

\[
\mathbb{P}_R(A_i \cap A_j) = \frac{\alpha^2}{n^2} + \frac{1}{2\pi} \int_0^{\rho_{ij}} \frac{1}{\sqrt{1-z^2}} \frac{e^{-\Phi^{-1}(1-\frac{\alpha}{n})^2/1+z}}{1+z} dz \quad \forall i \neq j.
\]

Hence, \( \mathbb{P}_R(A_i \cap A_j) \) is an increasing function of \( \rho_{ij} \). Therefore,

\[
\arg \max_i \sum_{j=1, j \neq i}^n \mathbb{P}_R(A_i \cap A_j) = \arg \max_i \sum_{j=1, j \neq i}^n \rho_{ij} = i^* \quad \text{(say)}.
\]

Hence, applying Lemma 4, we get

\[
FWER = \mathbb{P}_R \left( \bigcup_{i=1}^n A_i \right) \leq \sum_{i=1}^n \mathbb{P}(A_i) - \max_{1 \leq i \leq n} \sum_{j=1, j \neq i}^n \mathbb{P}_R(A_i \cap A_j)
\]

\[
= \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} + \frac{1}{2\pi} \sum_{j=1, j \neq i}^n \int_0^{\rho_{ij}} \frac{1}{\sqrt{1-z^2}} \frac{e^{-\Phi^{-1}(1-\frac{\alpha}{n})^2/1+z}}{1+z} dz
\]

completing the proof.

We observe that Theorem 12 reduces to Theorem 5 when \( \rho_{ij} = \rho \) for all \( i \neq j \).

**Corollary 9.** Consider the arbitrarily correlated normal setup with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Let \( i^* = \arg \max_i \sum_{j=1, j \neq i}^n \rho_{ij} \) and \( j^* = \arg \min_j \rho_{i^*j} \). Then, if \( \rho_{i^*j^*} \leq \frac{\alpha}{n} \),

\[
FWER(n, \alpha, R) \leq \alpha - \frac{n-1}{n} \cdot \alpha \rho_{i^*j^*}.
\]

Hence, we assume \( \rho_{i^*j^*} > \frac{\alpha}{n} \) from now on. Suppose \( \bar{\rho}_{i^*} = \frac{1}{n-1} \sum_{j=1, j \neq i^*}^n \rho_{i^*j} \). We have the following two generalizations of Theorem 10 and Theorem 11 respectively:

**Theorem 13.** Consider the arbitrarily correlated normal setup with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Let \( \Phi^{-1}(1-\frac{\alpha}{n}) \leq 2, \rho_{i^*j^*} \geq .5 \). Then,

\[
FWER(n, \alpha, R) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \alpha \bar{\rho}_{i^*}.
\]

**Theorem 14.** Consider the arbitrarily correlated normal setup with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Let \( \Phi^{-1}(1-\frac{\alpha}{n}) \leq 2 \). Then,

\[
FWER(n, \alpha, R) \leq \alpha - \frac{n-1}{n} \cdot \frac{\alpha^2}{n} - \frac{n-1}{n} \cdot \frac{2\alpha \bar{\rho}_{i^*}}{5\pi}.
\]

The proofs of these are exactly similar to those of Theorem 10 and Theorem 11 and hence omitted.
In the proof of Theorem 7, we showed that, for any \( \rho \geq 0 \),
\[
\forall x \geq 2, \quad \int_0^\rho \frac{1}{\sqrt{1 - z^2}} e^{-\frac{z^2}{2}} dz \geq \sin^{-1} \rho \cdot e^{-\frac{\rho^2}{2}}.
\]
This inequality leads to the following:

**Corollary 10.** Consider the arbitrarily correlated normal setup with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Let \( x = \Phi^{-1}(1 - \frac{\alpha}{n}) \geq 2 \). Then,
\[
\text{FWER}(n, \alpha, R) \leq \alpha - \frac{n - 1}{n} \cdot \frac{\alpha^2}{2} n - \frac{1}{2\pi} \sum_{j=1, j \neq i^*}^{n} \sin^{-1} \rho_{i^*j} \cdot e^{-\frac{\rho_{i^*j}^2}{2}}
\]
where \( i^* = \arg \max_i \sum_{j=1, j \neq i}^n \rho_{ij} \).

One can derive results similar to Theorem 8 or Theorem 9 using the above corollary by imposing certain conditions on the values of the correlations in the \( i^* \)-th row of \( R \). For example, we have the following if we assume that \( \rho_{i^*j} \geq 0.5 \):

**Theorem 15.** Consider the arbitrarily correlated normal setup with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Let \( 4.23 \geq x \geq 2 \) and \( \rho_{i^*j} \geq 0.5 \). Then,
\[
\forall x \in [x_l, x_{l+1}] \quad \text{FWER}(n, \alpha, R) \leq \alpha - \frac{n - 1}{n} \cdot \frac{\alpha^2}{2} n - \frac{1}{2\pi} \sum_{j=1, j \neq i^*}^{n} \sin^{-1} \rho_{i^*j} \cdot e^{-\frac{\rho_{i^*j}^2}{2}} C_{x_l}(n)
\]
where \( x_l \)'s and \( C_{x_l}(n) \)'s are as follows:

<table>
<thead>
<tr>
<th>( x_l )</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>( C_{x_l}(n) )</td>
<td>1</td>
<td>\frac{1}{2}</td>
<td>\frac{1}{3}</td>
<td>\frac{1}{4}</td>
<td>\frac{1}{5}</td>
<td>\frac{1}{6}</td>
<td>-</td>
</tr>
</tbody>
</table>

This can be established along the same lines of Theorem 8.

## 5 Bounds on k-FWER

When the number of hypotheses \( n \) is large, control of the FWER is so stringent that departures from the null hypothesis have little chance of being detected. For this reason, alternative measures of error control have been proposed in the literature.

Lehmann and Romano [10] consider the \( k \)-FWER, the probability of rejecting at least \( k \) true null hypotheses in a simultaneous testing problem. Such an error rate with \( k > 1 \) is appropriate when one is willing to tolerate one or more false rejections, provided the number of false rejections is controlled. Thus \( k \)-FWER controls false rejections less severely, but in doing so detects false null hypotheses better and consequently provides better power. \( k \)-FWER is especially relevant in those areas where the number of hypotheses is large e.g microarray data analysis.
We consider the equicorrelated normal setup. Suppose we have \( n \) null hypotheses:

\[
H_{0i} : X_i \sim N(0, 1) \quad i = 1, 2, \ldots, n
\]

corresponding to a sequence of \( n \) random variables \( X_1, X_2, \ldots, X_n \). \( H_{0i} \) is rejected if \( X_i > c \) for some pre-specified cut-off \( c \). \( k \)-FWER is defined as the probability of falsely rejecting at least \( k \) null hypothesis:

\[
\text{\( k \)}\text{-FWER} = \mathbb{P}(\text{At least \( k \) false rejection}) = \mathbb{P}(X_i > c \text{ for at least } k \text{ i's } | H_0)
\]

where \( H_0 = \bigcap_{i=1}^{n} H_{0i} \) is the intersection null hypothesis. Evidently, when \( k = 1 \), \( k \)-FWER reduces to the usual FWER. The usual Bonferroni procedure uses the cutoff \( \Phi^{-1}(1 - \frac{\alpha}{n}) \) to control FWER at level \( \alpha \). Lehmann and Romano [10] remark that control of the \( k \)-FWER allows one to decrease this cutoff to \( \Phi^{-1}(1 - \frac{k \alpha}{n}) \), and thereby greatly increase the ability to detect false hypotheses. Thus, for their Bonferroni-type procedure,

\[
\text{\( k \)}\text{-FWER} = \mathbb{P}\left(X_i > \Phi^{-1}(1 - \frac{k \alpha}{n}) \text{ for at least } k \text{ i's } | H_0\right) .
\]

We establish upper bounds on \( k \)-FWER for equicorrelated asymptotic setup and equicorrelated non-asymptotic setup in subsections 5.1 and 5.2 respectively.

### 5.1 Bounds on \( k \)-FWER in Equicorrelated Asymptotic Setup

We perform simulation study to get idea about the behaviour of \( k \)-FWER (of Lehmann and Romano’s Bonferroni-type procedure) in equicorrelated normal setup with large number of hypotheses. The simulation scheme for fixed \((n, k, \alpha)\) is given in Section 6. Figure 1 represents the behaviour of \( k \)-FWER \((k=1,2,4,8)\) as a function of \( \rho \) for \( n = 1000 \) and \( \alpha = .01, .05, .1, .3, .5, .7 \). In each of the plots, the blue straight line indicates the \( \alpha(1 - \rho) \) line. The red, green, orange and violet curves indicate \( k \)-FWER with \( k=1,2,4,8 \) respectively. We raise two questions by observing Figure 1:

**Question 1.** Consider the equicorrelated normal setup \((n, k, \alpha, \rho)\). Does there exist some \( \rho^*(k, \alpha, n) \) such that \( (k + 1)\)-FWER is less than \( k \)-FWER for \( 0 \leq \rho \leq \rho^*(k, \alpha, n) \)? In particular, does there exist some \( \rho^*(k, \alpha) \) such that for \( 0 \leq \rho \leq \rho^*(k, \alpha) \),

\[
(k + 1)\text{-FWER}(\rho) \leq k\text{-FWER}(\rho) \quad \text{as } n \to \infty
\]

**Question 2.** Consider any fixed natural number \( k \). Is \( k\text{-FWER}(\rho) \) bounded above by \( \alpha(1 - \rho) \) as \( n \to \infty \)?

We have not been able to find theoretical justifications to answer these questions. However, we have shown that at least under independence, **Question 1** has an affirmative answer.

**Theorem 16.** For any fixed natural number \( k \), \( (k + 1)\text{-FWER}(0) \leq k\text{-FWER}(0) \quad \text{as } n \to \infty \).
Figure 1: Plots of $k$-FWER ($k = 1, 2, 4, 8$) vs $\rho$ for $n = 1000$ and $\alpha = .01, .05, .1, .3, .5, .7$

Given a positive integer $m$ and a real number $p \in (0, 1)$, we denote by $\text{Bin}(m,p)$ a binomial random variable with parameters $m$ and $p$. Moreover, given a positive real number $\lambda$, $\text{Poi}(\lambda)$ denotes a Poisson random variable with mean $\lambda$. We shall use the following result by Fokkink et al. [6] to prove Theorem 16:

**Theorem 17.** Fix a real number $\lambda \in (0,1]$. Then it holds

$$\mathbb{P}(\text{Poi}(\lambda k) \geq k) \geq \mathbb{P}(\text{Poi}(\lambda (k + 1)) \geq k + 1), \text{ for all } k \geq 1.$$  

**Proof of Theorem 16:** Suppose the random variables $X_1, X_2, \ldots, X_n$ are independent. Then,
\[ 1 - k\text{-FWER} = \mathbb{P}(\text{at most } (k - 1) \text{ false rejections}) \]
\[ = \sum_{j=0}^{k-1} \mathbb{P}_{H_0}(\text{exactly } j \text{ false rejections}) \]
\[ = \sum_{j=0}^{k-1} \binom{n}{j} \left[ \mathbb{P}_{H_0}(X_1 > \Phi^{-1}(1 - k\alpha/n)) \right]^j \left[ \mathbb{P}_{H_0}(X_1 \leq \Phi^{-1}(1 - k\alpha/n)) \right]^{n-j} \quad \text{(as } X_i\text{'s are iid under } H_0) \]
\[ = \sum_{j=0}^{k-1} \binom{n}{j} \left( \frac{k\alpha}{n} \right)^j \left( 1 - \frac{k\alpha}{n} \right)^{n-j} \]
\[ = \mathbb{P}(\text{Bin}(n, k\alpha/n) < k). \]

The random variable \( \text{Bin}(n, k\alpha/n) \) converges in distribution to \( \text{Poi}(k\alpha) \) as \( n \to \infty \). This implies, from above, \( \lim_{n \to \infty} 1 - k\text{-FWER} = \mathbb{P}(\text{Poi}(k\alpha) < k) \). Consequently,
\[ \lim_{n \to \infty} k\text{-FWER} = \mathbb{P}(\text{Poi}(k\alpha) \geq k). \]

The rest is immediate from Theorem 17.

We note that an affirmative answer to Question 2 will result in a generalization of Corollary 3.

### 5.2 Bounds on k-FWER in Equicorrelated Non-asymptotic Setup

We have previously seen that \( k\text{-FWER} \) can be regarded as \( \mathbb{P}(\text{at least } k \text{ out of } n A_i\text{'s occur}) \) for suitably defined events \( A_i, 1 \leq i \leq n \). Accurate computation of this probability is difficult because, in practice (as in multiple testing), the complete dependence between the events \( (A_1, \ldots, A_n) \) is often unknown or unavailable, unless the events \( A_j \) are independent of each other. The available information is often the marginal probabilities and joint probabilities up to level \( m (m << n) \). In these situations, it is preferable/desirable to compute a lower or upper bound using only a limited amount of information.

Towards finding such an easily computable upper bound on the probability that at least \( k \) out of \( n \) events occur, we generalize Kounias’s inequality (Lemma 4) in the following theorem:

**Lemma 5.** Let \( A_1, A_2, \ldots, A_n \) be \( n \) events. Then,
\[ \mathbb{P}(\text{at least } k \text{ out of } n A_i\text{'s occur}) \leq \frac{1}{k} \cdot \sum_{i=1}^{n} \mathbb{P}(A_i) - \frac{1}{k} \cdot \max_{1 \leq i \leq n} \left[ \sum_{j=1, j \neq i}^{n} \mathbb{P}(A_i \cap A_j) - (k-1)\mathbb{P}(A_i) \right]. \]

**Proof:** Let \( I_i(w) \) be the indicator random variable of the event \( A_i \) for \( 1 \leq i \leq n \). Then the random variable \( \max I_{i_1}(w) \cdots I_{i_k}(w) \) is the indicator of the event that at least \( k \) out of \( n \) \( A_i\)’s occur. Now, for any \( i = 1, \ldots, n \),
\[ \max I_{i_1}(w) \cdots I_{i_k}(w) \leq \frac{1}{k} \left[ 1 - I_i(w) \right] \sum_{j=1}^{n} I_j(w) + I_i(w). \]
Taking expectations in above, we obtain

\[ P(\text{at least } k \text{ out of } n \text{ } A_i \text{’s occur}) \leq \frac{1}{k} \cdot \sum_{j=1}^{n} P(A_j) - \frac{1}{k} \cdot \sum_{j=1, j \neq i}^{n} P(A_i \cap A_j) + P(A_i) \cdot \frac{k-1}{k}. \]

The rest follows by observing that the above holds for any \( i = 1, \ldots, n. \)

Suppose \((X_1, X_2, \ldots, X_n)\) have covariance matrix \(R = ((\rho_{ij}))\) with \(\rho_{ij} \geq 0\) for all \( i \neq j \). Let \( k\)-FWER\((n, \alpha, R)\) denote the family-wise error rate for Bonferroni’s procedure under this set-up. We define \( A_i = \{X_i > \Phi^{-1}(1 - k\alpha/n)\} \) for \( 1 \leq i \leq n \). This means

\[ k\text{-FWER}(n, \alpha, R) = P_R(\text{at least } k \text{ } A_i \text{’s occur}). \]

Now,

\[ P(A_i) = P_{H_0} \left[ X_i > \Phi^{-1}(1 - k\alpha/n) \right] = 1 - P_{H_0} \left[ X_i \leq \Phi^{-1}(1 - k\alpha/n) \right] = 1 - (1 - k\alpha/n) = k\alpha/n. \]

So, \( \sum_{i=1}^{n} P(A_i) = k\alpha \). One can show, along the similar lines of the proof of Theorem 5, the following:

\[ P_R(A_i \cap A_j) = \frac{k\alpha^2}{n^2} + \frac{1}{2\pi} \int_{0}^{\rho_{ij}} \frac{1}{\sqrt{1 - z^2}} e^{-\frac{\varphi^{-1}(1 - \frac{k\alpha}{n})^2}{1 + z}} dz \quad \forall i \neq j. \]

Hence, \( P_R(A_i \cap A_j) \) is an increasing function of \( \rho_{ij} \). Therefore,

\[ \arg \max_{i} \sum_{j=1, j \neq i}^{n} P_R(A_i \cap A_j) = \arg \max_{i} \sum_{j=1, j \neq i}^{n} \rho_{ij} = i^* \quad \text{(say)}. \]

We apply Lemma 5 to obtain the following generalization of Theorem 12:

**Theorem 18.** Consider the arbitrarily correlated normal set-up with covariance matrix \( R \). Suppose \( R \) has non-negative entries. Then,

\[ k\text{-FWER}(n, \alpha, R) \leq \alpha + \frac{k - 1}{n} \cdot \alpha - \frac{n - 1}{n} \cdot k\alpha^2 - \frac{1}{2\pi k} \sum_{j=1, j \neq i^*}^{n} \int_{0}^{\rho_{ij}} \frac{1}{\sqrt{1 - z^2}} e^{-\frac{\varphi^{-1}(1 - \frac{k\alpha}{n})^2}{1 + z}} dz \]

where \( i^* = \arg \max_{i} \sum_{j=1, j \neq i}^{n} \rho_{ij}. \)

It is mention-worthy that Theorem 18 is the most general theorem in the non-asymptotic setup, because it handles both more than one false rejections and general correlation matrices simultaneously. We have the following immediate corollary under the equicorrelated setup, i.e when \( \rho_{ij} = \rho \) for all \( i \neq j \):

**Corollary 11.** Consider the equicorrelated normal set-up with correlation \( \rho \geq 0 \). Then,

\[ k\text{-FWER}(n, \alpha, R) \leq \alpha + \frac{k - 1}{n} \cdot \alpha - \frac{n - 1}{n} \cdot k\alpha^2 - \frac{n - 1}{2\pi k} \int_{0}^{\rho} \frac{1}{\sqrt{1 - z^2}} e^{-\frac{\varphi^{-1}(1 - \frac{k\alpha}{n})^2}{1 + z}} dz. \]
One can establish upper bounds on $k$-FWER in general and equicorrelated normal setups using Theorem 18 and Corollary 11 respectively, in the same way as in section 4.2.

6 Simulations and Discussion

The bound by Das and Bhandari [2] provides a significant gain in power for Bonferroni method for large number of hypotheses. However, for equicorrelated setups with small or moderate dimensions, their bound fails as mentioned earlier. We verify this through simulations. Our simulation scheme, for fixed $(n, k, \alpha)$ is as follows: For each $\rho \in \{0, .025, .050, .075, \ldots, 1\}$, we generate 10000 $n$-variate equicorrelated multivariate normal observations (each with mean 0, variance 1; common correlation being $\rho$). For each $\rho$, in each of the 10000 replications, we note whether at least $k$ many of the generated $n$ components exceeds the cutoff $\Phi^{-1}(1 - k\alpha/n)$. For each $\rho$, the estimated $k$-FWER (for that $\rho$) is obtained accordingly from the 10000 replications.

We obtain the following plots after running these simulations for $(n, k, \alpha) = (100, 1, .01)$ and $(500, 1, .05)$ (the blue line represents the straight line $\alpha(1 - \rho)$):

![Figure 2: FWER Plots for $(n, \alpha)$=(100,.01) and (500,.05)](image)

We can see that the $\alpha(1 - \rho)$ bound fails in these cases. Also, FWER is not a convex function of $\rho$ in these cases. We present the simulation results for some choices of $(n, \alpha, \rho)$ along with our proposed bounds (given by theorems derived in preceding section) below:

<table>
<thead>
<tr>
<th>$(n, \alpha)$</th>
<th>$x$</th>
<th>$\rho$</th>
<th>0.1</th>
<th>0.3</th>
<th>0.5</th>
<th>0.7</th>
<th>0.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>(10, 0.3)</td>
<td>1.8808</td>
<td>FWER($\rho$)</td>
<td>.2132</td>
<td>.2053</td>
<td>.1688</td>
<td>.1242</td>
<td>.0733</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bound</td>
<td>.2156</td>
<td>.2087</td>
<td>.1965</td>
<td>.1875</td>
<td>.1785</td>
</tr>
<tr>
<td>(100, 0.05)</td>
<td>3.2905</td>
<td>FWER($\rho$)</td>
<td>.0456</td>
<td>.0355</td>
<td>.0265</td>
<td>.0153</td>
<td>.0005</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bound</td>
<td>.0475</td>
<td>.0474</td>
<td>.0462</td>
<td>.0457</td>
<td>.0452</td>
</tr>
<tr>
<td>(500, 0.05)</td>
<td>3.7190</td>
<td>FWER($\rho$)</td>
<td>.0451</td>
<td>.0319</td>
<td>.0198</td>
<td>.0081</td>
<td>.0028</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bound</td>
<td>.0475</td>
<td>.0475</td>
<td>.0471</td>
<td>.0469</td>
<td>.0467</td>
</tr>
</tbody>
</table>

It is mention worthy that in each case the estimated FWER is smaller than our proposed bounds.

One can see that our bounds (derived in section 4.2) give good results for small values of equicorrelation $\rho$ and tend to become naive for large values of $\rho$. This is in contrast to the method of Das and Bhandari [2] whose bound works in the large $\rho$ case. This can also be seen in Figure 2.
Therefore, in a way, bounds derived in Section 4.2 and the \( \alpha(1 - \rho) \) bound are complementary to each other in depicting the behavior of FWER in equicorrelated normal setups. We present the simulation results for \( k \)-FWER for different values of \( k \) and \( (n = 100, \alpha = 0.05) \) along with our proposed bounds (given by Corollary 11) below:

<table>
<thead>
<tr>
<th>( k )</th>
<th>( \rho )</th>
<th>0.1</th>
<th>0.3</th>
<th>0.5</th>
<th>0.7</th>
<th>0.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>( k )-FWER(( \rho ))</td>
<td>.0104</td>
<td>.0177</td>
<td>.0172</td>
<td>.0137</td>
<td>.0069</td>
</tr>
<tr>
<td></td>
<td>Bound</td>
<td>.0455</td>
<td>.045</td>
<td>.044</td>
<td>.0403</td>
<td>.0333</td>

<td>.0115</td>
</tr>
<tr>
<td></td>
<td>Bound</td>
<td>.0335</td>
<td>.0324</td>
<td>.08</td>
<td>.0254</td>
<td>.0164</td>
</tr>
</tbody>
</table>

Simulation results for \( k \)-FWER for different values of \( k \) and \( (n = 500, \alpha = 0.05) \) along with our proposed bounds (given by Corollary 11) are presented in the following table:

<table>
<thead>
<tr>
<th>( k )</th>
<th>( \rho )</th>
<th>0.1</th>
<th>0.3</th>
<th>0.5</th>
<th>0.7</th>
<th>0.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>( k )-FWER(( \rho ))</td>
<td>.0121</td>
<td>.0169</td>
<td>.0127</td>
<td>.0082</td>
<td>.0027</td>
</tr>
<tr>
<td></td>
<td>Bound</td>
<td>.0451</td>
<td>.0449</td>
<td>.0442</td>
<td>.0422</td>
<td>.0373</td>
</tr>
<tr>
<td>4</td>
<td>( k )-FWER(( \rho ))</td>
<td>.0027</td>
<td>.0117</td>
<td>.0110</td>
<td>.0090</td>
<td>.0038</td>
</tr>
<tr>
<td></td>
<td>Bound</td>
<td>.0403</td>
<td>.040</td>
<td>.0390</td>
<td>.037</td>
<td>.0308</td>
</tr>
<tr>
<td>8</td>
<td>( k )-FWER(( \rho ))</td>
<td>.0003</td>
<td>.0086</td>
<td>.0105</td>
<td>.0097</td>
<td>.0051</td>
</tr>
<tr>
<td></td>
<td>Bound</td>
<td>.0307</td>
<td>.0302</td>
<td>.029</td>
<td>.026</td>
<td>.0192</td>
</tr>
</tbody>
</table>

It is seen from the last two tables that in each case the estimated \( k \)-FWER is much smaller than our proposed bounds. We also note that the estimated values of \( k \)-FWER decrease in \( k \) for small values of \( \rho \) , whereas increase in \( k \) for large values of \( \rho \). Thus, our simulations provide empirical evidence in support of an affirmative answer to Question 1.

7 Future Scope

In this section, we raise some questions and mention some interesting problems. Let \( FWER(\Sigma_n) \) denote the family-wise error rate of Bonferroni procedure under a correlation matrix \( \Sigma_n \).

Theorem 1 states that \( FWER(M_n(\rho)) \) is convex in \( \rho \in [0, 1] \) as \( n \to \infty \). It is also known that \( FWER(M_n(\rho)) \) is a decreasing function in \( \rho \in [0, 1] \). Let \( det(A) \) denote the determinant of a real matrix \( A \). One can show that

\[
det(M_n(\rho)) = (1 - \rho)^{n-1} [1 + (n - 1)\rho] .
\]

Evidently \( det(M_n(\rho)) \) is a decreasing and convex function in \( \rho \in [0, 1] \) for \( n \geq 3 \). Therefore, the functions \( FWER \) and \( det \) behave similarly for equicorrelated matrices. More precisely, \( FWER \)
and determinant are increasing functions of each other in the set \( \{ M_n(\rho) : \rho \in [0,1], n \geq 3 \} \). This is expected since both FWER and determinant can serve as useful general indicators of the degree of dependence among the variables. Naturally, the following question arises:

**Question 3.** Do FWER and determinant behave similarly (i.e., one is an increasing function of the other) in the set of all correlation matrices of order \( n, n \geq 3 \)?

Olkin (2014) [13] proved the following determinantal inequality for correlation matrices:

**Theorem 19.** Let \( R = (r_{ij}) \) denote an \( n \times n \) correlation matrix, and \( \tilde{R} = (\tilde{r}_{ij}) \), where \( \tilde{r}_{ii} = 1, \tilde{r}_{ij} = \tilde{r} \) for all \( i \neq j \), and \( \tilde{r} = \sum_{i \neq j} r_{ij} / n(n - 1) \). Then, \( \det(R) \leq \det(\tilde{R}) \).

By virtue of the above result, if the answer to **Question 3** is affirmative then we would have the following generalization of Corollary 3:

Let \( \Sigma_n = (\rho_{ij}) \) denote an \( n \times n \) correlation matrix with non-negative entries. Suppose \( \bar{\rho} = \sum_{i \neq j} \rho_{ij} / n(n - 1) \). Then, as \( n \to \infty \),

\[
\text{FWER}(\Sigma_n) \leq \alpha(1 - \bar{\rho}).
\]

It is mention worthy that if the answer in **Question 3** is affirmative then in the set

\[
\left\{ R_n : R_n = ((\rho_{ij})) \text{ is a correlation matrix with non-negative entries, } \rho = \frac{1}{n(n - 1)} \sum_{i \neq j} \rho_{ij} \right\}
\]

FWER\( (R_n) \) is maximized at \( R_n = M_n(\rho) \).

From the results derived in section 4.3, one may ask the following regarding the bound on FWER in general asymptotic setup:

**Question 4.** Let \( R_n = ((\rho_{ij})) \) denote an \( n \times n \) correlation matrix with non-negative entries. Let \( i^* = \arg \max_i \sum_{j=1,j \neq i}^n \rho_{ij} \) and \( \bar{\rho}_{i^*} = \frac{1}{n-1} \sum_{j=1,j \neq i^*}^n \rho_{i^*j} \). Does the inequality

\[
\text{FWER}(R_n) \leq \alpha(1 - \bar{\rho}_{i^*})
\]

hold as \( n \to \infty \)?

**Question 1** and **Question 2**, raised in Section 5.1, are concerned with the probability that at least \( k \) out of \( n \) events occur. Computation of this probability arises in various contexts. For example, in the reliability problem of communication networks, where each arc fails with a certain probability, \( \mathbb{P}(\text{at least } k \text{ out of } n \text{ A}_i\text{'s occur}) \) can be used to compute or approximate the node-to-node reliability of the system. Qiu et al [15] mention this probability can also be viewed as a risk measure for a system with possible failures or security issues on its components, such as the overloading risk on multiple transmission lines in power system operations. Inequalities involving \((k + 1)\)FWER and \(k\)FWER under the equicorrelated setup in asymptotic and non-asymptotic
cases would be interesting to find. Such results might be useful in establishing new probability
inequalities regarding \( P( \text{at least } k \text{ out of } n \ A_i \text{'s occur}) \).

Bounds on \( K\text{-FWER} \) in general asymptotic setup are yet to be established. Throughout the
text, we have considered multivariate normal setup. Behaviour of familywise error rate and general-
ized familywise error rates may be studied under other or more general distributional assumptions.

Acknowledgement

The author would like to thank Professor Subir Kumar Bhandari, ISI Kolkata, for illuminating
discussions on controlling error rates in multiple hypothesis testing and for verification of proofs of
the results.
