#### Abstract

The 1-2-3 Conjecture, posed by Karoński, Łuczak and Thomason, asked whether every connected graph $G$ different from $K_{2}$ can be 3-edge-weighted so that every two adjacent vertices of $G$ get distinct sums of incident weights. The 1-2 Conjecture states that if vertices also receive colors and the vertex color is added to the sum of its incident edges, then adjacent vertices can be distinguished using only $\{1,2\}$. In this paper we confirm 1-2 Conjecture for 3-regular graphs. Meanwhile, we show that every 3 -regular graph can achieve a neighbor sum distinguishing edge coloring by using 4 colors, which answers 1-2-3 Conjecture positively.

## 1 Introduction

All considered graphs are finite, undirected, simple and connected. Let $N(u)$ denote the set of neighbors of vertex $u$ and $0 \leq s<t$. Let $d_{G}(v)$ be the degree of vertex $v$ of $G$. For general theoretic notations, we follow [3].

Karónski et al.[7] introduced and investigated a coloring of the edges of a graph with positive integers so that adjacent vertices have different sums of incident edge colors. More precisely, let $f: E \rightarrow[k]=$ $\{1,2, \ldots, k\}$ be an edge coloring of G (such a coloring is also called a $k$-coloring of $G$ ). For $x \in V$, set

$$
\sigma(x)=\sum_{e \ni x} f(e)
$$

A k-coloring $f$ of $G$ is called neighbor sum distinguishing edge coloring if $\sigma(x) \neq \sigma(y)$ for every edge $x y \in E(G)$. In other words, the vertex coloring $\sigma$ induced by $f$ in the above described way must be proper. The minimum integer $k$ for which there is a neighbor sum distinguishing edge coloring of a graph $G$ will be denoted by $\operatorname{gndi}_{\Sigma}(G)$.

In [7] Karónski, Łuczak and Thomason posed the following elegant problem, known as the 1-2-3 Conjecture.

Conjecture 1. Let $G$ be a connected graph and $G \neq K_{2}$. Then gndi ${ }_{\Sigma}(G) \leq 3$.

[^0]Toward the Conjecture 1, Kalkowski, Karoński and Pfender [6] showed that if $G$ is a $k$-colorable graph with $k$ odd then $G$ admits a vertex-coloring $k$-edge-weighting. So, for the class of 3 -colorable graphs, including bipartite graphs, the answer is affirmative. However, in general, this question is still open. Addario-Berry et al.[1] showed that every graph without isolated edges has a proper $k$-weighting when $k=30$. After improvements to $k=15$ in [2] and $k=13$ in [10], Kalkowski, Karónski, and Pfender [6] showed that every graph without isolated edges has a proper 5-weighting. Przybylo [9] showed that every $d$-regular graph with $d \geq 2$ admits a vertex-coloring edge 4 -weighting and every $d$-regular graph with $d \geq 10^{8}$ admits a vertex-coloring edge 3 -weighting.

In [8] the following problem related to 1-2-3 Conjecture was introduced. Let $f: E \cup V \rightarrow[k]=$ $\{1,2, \ldots, k\}$ be a total k-coloring of a graph $G=(V, E)$. For every vertex $v$, let

$$
t(v):=f(v)+\sum_{u \in N(v)} f(u v)=f(v)+\sigma(v)
$$

Thus, $t(v)$ is the sum of incident colors of $v$ and the color of $v$. We say that $f$ is a neighbor total sum distinguishing total coloring of $G$ if $t(u) \neq t(v)$ for all adjacent vertices $u, v$ in $G$. Similarly as above, the minimum value of $k$ for which there exists a total neighbor sum distinguishing coloring of a graph $G$ will be denoted by $\operatorname{tgndi}(G)$.

In [8] Przybylo and Wózniak posed the following problem, known as the 1-2 Conjecture.
Conjecture 2. Let $G$ be a connected graph. Then $\operatorname{tgndi}(G) \leq 2$.
Up to now, it is known that for every graph $G, \operatorname{tgndi}_{\Sigma}(G) \leq 3$ (see [5]).
This paper is organized as follows. In Section 2, we offer an important structural lemma that every connected graph $G$ contains a $m$-partite spanning subgraph $H$ such that $\left(1-\frac{1}{m}\right) d_{G}(v) \leq d_{H}(v)$. Naturally, every 3-regular graph $G$ has a maximal bipartite spanning subgraph $H$ such that $G-E(H)$ is either isolated vertices or isolated edges. Via the structural property between $H$ and $G-E(H)$, we design a coloring algorithm to compute $\operatorname{gndi}_{\Sigma}(G)$ and $\operatorname{tgndi}(G)$ for 3 -regular graphs $G$ in Section 3 and Section 4 , respectively. We show that $\operatorname{gndi}_{\Sigma}(G) \leq 4$ and $\operatorname{tgndi} \Sigma_{\Sigma}(G) \leq 2$ for any 3-regular graph $G$. Therfore, the first result answers 1-2-3 Conjecture positively and the second one confirms 1-2 Conjecture.

## 2 Structural Lemma

Lemma 3. Let $G$ be a graph on $n$ vertices. Then it exists a m-partite spanning subgraph $H$ such that $\left(1-\frac{1}{m}\right) d_{G}(v) \leq d_{H}(v)$ for all $v \in V(G)$, where $m$ is a positive integer and $m \leq n$.

Proof Let $H$ be a maximal $m$-partite spanning subgraph of $G$ with the greatest possible number of edges. Let $\left\{V_{1}, V_{2}, \ldots, V_{m}\right\}$ be the $m$-partition of $V(H)$ and let $v \in V_{1}, d_{V_{i}}(v)=\left|N_{V_{i}}(v)\right|, N_{V_{i}}(v)=$ $\left\{u: u \in V_{i}, u v \in E(G)\right\}, i=1,2, \ldots, m$. Then $d_{V_{1}}(v) \leq d_{V_{i}}(v), i=1,2, \ldots, m$. Otherwise, it exists an $i_{0}$ such that $d_{V_{1}}(v)>d_{V_{i_{0}}}(v)$, and we use $V_{1} \backslash\{v\}, V_{i_{0}} \cup\{v\}$ instead of $V_{1}, V_{i_{0}}$, respectively, and then it generates a new maximal $m$-partite spanning subgraph $H^{\prime}$ of $G$. Obviously, $\varepsilon\left(H^{\prime}\right)>\varepsilon(H)$, a contradiction. Therefore,

$$
(m-1) d_{V_{1}}(v) \leq \sum_{i=2}^{m} d_{V_{i}}(v)=d_{H}(v)
$$

where $d_{H}(v)=\left|N_{H}(v)\right|$.
Let $d_{G}(v)=\left|N_{G}(v)\right|$. Then

$$
d_{G}(v)=d_{V_{1}}(v)+d_{H}(v) \leq \frac{1}{m-1} d_{H}(v)+d_{H}(v)=\frac{m}{m-1} d_{H}(v)
$$

Hence

$$
\left(1-\frac{1}{m}\right) d_{G}(v) \leq d_{H}(v)
$$

for all $v \in V(G)$.
By Lemma 3, every 3-regular graph $G$ contains a maximal bipartite spanning subgraph $H$ such that $G-E(H)$ is either isolated vertices or isolated edges. Via the structural between $H$ and $G-E(H)$, we further study $\operatorname{gndi} i_{\Sigma}(G)$ and $\operatorname{tgndi} i_{\Sigma}(G)$ of 3-regular graphs $G$.

For the sake of narrative, we fix some natation. Let $G=\left(V_{X}, V_{Y}, E_{X}, E_{Y}, E_{H}\right)$ be a 3-regular graph with vertex partition $\left(V_{X}, V_{Y}\right)$ and edge partition $\left(E_{X}, E_{Y}, E_{H}\right)$, where $E_{X}, E_{Y}$ and $E_{H}$ represent the edge sets in $V_{X}, Y_{Y}$ and $H$, respectively. The maximal spanning bipartite graph $H$ is the graph with vertex set $\left\{x_{i}: 1 \leq i \leq m\right\} \cup\left\{y_{i}: 1 \leq i \leq n\right\}$ and edge set $\left\{x_{i} y_{i}: 1 \leq i \leq m, 1 \leq i \leq n\right\}$. We use $a_{1}$ and $b_{1}$ to denote the number of vertices with degree 2 and 3 in $X$, respectively. Let $a_{2}$ and $b_{2}$ denote the number of vertices with degree 2 and 3 in $Y$, respectively. We use $e_{x_{i}}$ for $i=1,2, \ldots, \frac{a_{1}}{2}$ to represent the edge with two endpoints $v_{x_{i}}, v_{x_{i}}^{\prime}$ in $X$. Let $e_{y_{j}}$ for $j=1,2, \ldots, \frac{a_{2}}{2}$ to represent the edge with two endpoints $v_{y_{j}}, v_{y_{j}}^{\prime}$ in $Y$. In the bipartite graph $H$, let $v_{2}(x)$ and $v_{3}(x)$ be the vertex with degree 2 and 3 in $X$, respectively. Similarly, $v_{2}(y)$ and $v_{3}(y)$ denote the vertex with degree 2 and 3 in $Y$, respectively. The edge between $v_{2}(x)$ and $v_{2}(y)$ is denoted by $\widetilde{e_{2}}$, and the edge connects $v_{2}(x)$ (or $v_{3}(x)$ ) and $v_{3}(y)$ (or $v_{2}(y)$ ) is denoted by $\widetilde{e_{2-3}}$.

## $3 \operatorname{gndi}_{\Sigma}(G)$ for 3-regular graphs

Theorem 4. For any 3-regular graph $G$, gndi $(G) \leq 4$.
Proof Case $1 a_{1}=a_{2}=0$.
This case implies that $G$ is a 3-regular complete bipartite graph. This result has been proved by Chang et al. [4].

Case $2 a_{1}=b_{2}=0$ or $b_{1}=a_{2}=0$.
Suppose that $a_{1}=b_{2}=0$. We color all edges in $E_{H}$ and $E_{Y}$ with 1 and 2, respectively. Then $\sigma\left(v_{x}\right)=3, \sigma\left(v_{y}\right)=4$. To assure that $\sigma\left(v_{y_{j}}\right) \neq \sigma\left(v_{y_{j}}^{\prime}\right)$, recolor an incident edge of $v_{y_{j}}$ (or $v_{y_{j}}^{\prime}$ ) with 3 . Then $\sigma\left(v_{x}\right)$ belongs to $\{3,5,7,9\}$ and $\sigma\left(v_{y}\right)$ belongs to $\{4,6\}$.

Case $3 b_{1}=b_{2}=0$.
Form Lemma 3, $G$ contains a maximal bipartite spanning subgraph $H$ such that $G-E(H)$ is either isolated vertices or isolated edges. We color all edges in $E_{H}$ and $E_{X}$ with 1 , and color all edges in $E_{Y}$ with 2. For any edge $v_{x_{i}} v_{x_{i}}^{\prime}$ in $X$, select one edge $e_{z}$ from $E_{H}$ such that $v_{x_{i}}$ (or $v_{x_{i}}^{\prime}$ ) is an endpoints of $e_{z}$ and recolor edge $e_{z}$ with 3. Assume that $v_{x_{i}}$ and $v_{y_{j}}$ are connected by $e_{z}$ and all incident edges (except for $e_{z}, v_{x_{i}} v_{x_{i}}^{\prime}, v_{y_{j}} v_{y_{j}}^{\prime}$ ) of $v_{x_{i}}, v_{x_{i}}^{\prime}, v_{y_{j}}, v_{y_{j}}^{\prime}$ keep the color 1 as before, and we call these edges being dominated, see Fig.1. Suppose that $v_{x_{i}}^{\prime}$ and $v_{y_{j}}$ are connected by $e_{z}$. Then $\sigma\left(v_{x_{i}}\right)=5, \sigma\left(v_{x_{i}}^{\prime}\right)=3$, $\sigma\left(v_{y_{j}}\right)=6, \sigma\left(v_{y_{j}}^{\prime}\right)=4$. Continue this procedure $\frac{a_{1}}{2}$ times until the weights of all adjacent vertices in $G$ are distinct. Now we prove it feasibility, namely, it verifies that there exists at least one edge in $E_{H}$ which can not be dominated after $\frac{a_{1}}{2}-1$ operations. Suppose that all edges in $H$ are dominated after $\frac{a_{1}}{2}-1$ operations, and if there still exists a pair of adjacent vertices $v_{x_{k}}$ and $v_{x_{k}}^{\prime}$ (or $v_{y_{k}}$ and $v_{y_{k}}^{\prime}$ ) having the same weights, then the four incident edges of $v_{x_{k}}$ and $v_{x_{k}}^{\prime}$ in $H$ must receive the same color 1. By our coloring rule, it is impossible.

Case $4 a_{1} \neq a_{2}, b_{1} \neq b_{2}$ and they are positive integers.

Fig.1: Edges labelled by solid line are dominated.

We color all edges in $E_{H}$ with 1, color all edges in $E_{X}$ with 2 and color all edges in $E_{Y}$ with 3 . By the technique in Case 3, we can distinguish all adjacent vertices whose joined by $\widetilde{e_{2}}$. But we still need to distinguish adjacent vertices whose joined by $\widetilde{e_{2-3}}$. Select an incident edge from $\widetilde{e_{2-3}}$ and color it with 3 , it deduces that $\sigma\left(v_{x_{i}}\right) \neq \sigma\left(v_{x_{i}}^{\prime}\right)$ and $\sigma\left(v_{y_{j}}\right) \neq \sigma\left(v_{y_{j}}^{\prime}\right)$. Moreover, $\sigma\left(v_{2}(x)\right)=4$ or $6, \sigma\left(v_{2}(y)\right)=5$ or 7 , $\sigma\left(v_{3}(x)\right)$ belongs to set $\{3,5,7,9\}$ and $\sigma\left(v_{3}(y)\right)$ belongs to set $\{3,5,7,9\}$. Possibly, there may exist some cases that the weight of adjacent vertices can not distinguish. We deal with it as follows.

Case $4.1 \sigma\left(v_{3}(x)\right)=3$.
Case 4.1.1 Vertex $v_{3}(x)$ connects two vertices of degree 2 and one vertex of degree 3 in Y. Let $N\left(v_{3}(x)\right)=\left\{v_{2}\left(y_{1}\right), v_{2}\left(y_{2}\right), v_{3}\left(y_{3}\right)\right\}$. Then $\sigma\left(v_{3}(x)\right)=\sigma\left(v_{3}\left(y_{3}\right)\right)=3$.

1. Vertex $v_{2}\left(y_{1}\right)$ or $v_{2}\left(y_{2}\right)$ has weight 7. Assume that $\sigma\left(v_{2}\left(y_{1}\right)\right)=7$. Recolor $v_{3}(x) v_{2}\left(y_{1}\right)$ with 2 , then $\sigma\left(v_{3}(x)\right)=4, \sigma\left(v_{2}\left(y_{1}\right)\right)=8$.
2. $\sigma\left(v_{2}\left(y_{1}\right)\right)=\sigma\left(v_{2}\left(y_{2}\right)\right)=5$. We may recolor any incident edge of $v_{2}\left(y_{1}\right)$ or $v_{2}\left(y_{2}\right)$. Assume that recolor $v_{3}(x) v_{2}\left(y_{1}\right)$ with 4 , then $\sigma\left(v_{3}(x)\right)=4$ and $\sigma\left(v_{2}\left(x_{1}\right)\right)=8$.

Case 4.1.2 Vertex $v_{3}(x)$ connects two vertices of degree 3 and a vertex of degree 2 in $Y$. Let $N\left(v_{3}(x)\right)=\left\{v_{3}\left(y_{1}\right), v_{3}\left(y_{2}\right), v_{2}\left(y_{3}\right)\right\}$. Then $v_{3}(x)$ and its two neighbors all have weight 3 and $\sigma\left(v_{2}\left(y_{3}\right)\right)=5$ (or 7). Recolor $v_{3}(x) v_{2}\left(y_{3}\right)$ with 2 (or 4 ). Then $\sigma\left(v_{3}(x)\right)=4$ or $6, \sigma\left(v_{2}\left(y_{3}\right)\right)=8$.

Case 4.1.3 Vertex $v_{3}(x)$ connects three vertices of degree 3 in $Y$. Denoted by $v_{3}\left(y_{1}\right), v_{3}\left(y_{2}\right)$ and $v_{3}\left(y_{3}\right)$, respectively. If three neighbors of $v_{3}(x)$ have the same weight 3 , then recolor all incident edges of $v_{3}(x)$ with 3 , it follows that $\sigma\left(v_{3}(x)\right)=9$ and $\sigma\left(v_{3}\left(y_{1}\right)\right)=\sigma\left(v_{3}\left(y_{2}\right)\right)=\sigma\left(v_{3}\left(y_{3}\right)\right)=5$.

Case $4.2 \sigma\left(v_{3}(y)\right)=5$.
Vertex $v_{3}(x)$ connects a vertex of degree 2 with weight 7 in $Y$. Denote the vertex of degree 2 by $v_{2}\left(y_{0}\right)$. Recolor $v_{3}(x) v_{2}\left(y_{0}\right)$ with 4 . Then $\sigma\left(v_{3}(x)\right)=6$ and $\sigma\left(v_{2}\left(y_{0}\right)\right)=8$.

Case $4.3 \sigma\left(v_{3}(x)\right)=7$.
Vertex $v_{3}(x)$ must connect two vertices of degree 2 in $Y$. Let $N\left(v_{3}(x)\right)=\left\{v_{2}\left(y_{1}\right), v_{2}\left(y_{2}\right), v_{k}\right\}$. Here we need not consider the weight of $v_{k}$. Recolor $v_{3}(x) v_{2}\left(y_{1}\right)$ and $v_{3}(x) v_{2}\left(y_{2}\right)$ with 4 . Then $\sigma\left(v_{3}(x)\right)=9$ and $\sigma\left(v_{2}\left(y_{1}\right)\right)=\sigma\left(v_{2}\left(y_{2}\right)\right)=8$.

Przybylo [9] showed that every $d$-regular graph with $d \geq 2$ admits a vertex-coloring edge 4 -weighting and every $d$-regular graph with $d \geq 10^{8}$ admits a vertex-coloring edge 3 -weighting. From the proof of Theorem 4, we characterize the structural that some edges of 3-regular graphs receive color 4 when $a_{1} \neq a_{2}$ and $b_{1} \neq b_{2}$. In other words, if Conjecture 1 is true for every 3-regular graph, then it requires a method to deal with these edges which are colored by 4 .

## $4 \operatorname{tgndi}_{\Sigma}(G)$ for 3-regular graphs

Theorem 5. For any 3-regular graph $G$, tgndi ${ }_{\Sigma}(G) \leq 2$.
Proof Case $1 a_{1}=a_{2}=0$.

This case implies that $G$ is a 3-regular complete bipartite graph. We color all vertices in $X$ with 1 , color all vertices in $Y$ with 2 and color all edges in $E_{H}$ with 1 . Then $t\left(v_{x}\right)=4$ and $t\left(v_{y}\right)=5$.

Case $2 a_{1}=b_{2}=0$ or $b_{1}=a_{2}=0$.
Without loss of generality, assume that $a_{1}=b_{2}=0$. We color all vertices in $H$ with 1 , color all edges in $E(H)$ with 1, and color all edges in $E_{Y}$ with 2. To assure that $t\left(v_{y_{j}}\right) \neq t\left(v_{y_{j}}^{\prime}\right)$, recolor $v_{y_{j}}$ (or $\left.v_{y_{j}}^{\prime}\right)$ with 2 . Then $t\left(v_{x}\right)=4$ and $t\left(v_{y}\right)$ is 5 or 6 .

Case $3 b_{1}=b_{2}=0$.
We color all vertices in $X$ with 1, color all vertices in $Y$ with 2, color all edges in $E_{H}$ and $E_{X}$ with 1 , and color all edges in $E_{Y}$ with 2. For any edge $v_{x_{i}} v_{x_{i}}^{\prime}$ in $G$, select one edge $e_{z}$ from $E_{H}$ such that $v_{x_{i}}$ (or $v_{x_{i}}^{\prime}$ ) is an endpoints of $e_{z}$ and recolor edge $e_{z}$ with 2, meanwhile, all incident edges (except for $e_{z}, v_{x_{i}} v_{x_{i}}^{\prime}, v_{y_{j}} v_{y_{j}}^{\prime}$ ) of $v_{x_{i}}, v_{x_{i}}^{\prime}, v_{y_{j}}, v_{y_{j}}^{\prime}$ keep the color 1 as before, namely they are dominated, see Fig.1. Without loss of generality, assume that $v_{x_{i}}$ and $v_{y_{j}}$ are connected by $e_{z}$. Then $t\left(v_{x_{i}}\right)=5, t\left(v_{x_{i}}^{\prime}\right)=4$, $t\left(v_{y_{j}}\right)=6, t\left(v_{y_{j}}^{\prime}\right)=7$. Continue this procedure $\frac{a_{1}}{2}$ times until the weights of all adjacent vertices in $G$ are distinct. The feasibility of this method is similar to Case 3 in Theorem 4.

Case $4 a_{1} \neq a_{2}, b_{1} \neq b_{2}$ and they are positive integers.
We color all vertices in $X$ with 1, color all vertices in $Y$ with 2, color all edges in $E_{H}$ with 2, color all edges in $E_{X}$ with 1 and color all edges in $E_{Y}$ with 2. Using the technique in Case 3 again, we change the color of $e_{z}$ from 2 to 1 , and change the weight of vertices which are connected only by $\widetilde{e_{2}}$. By this way, we can distinguish all adjacent vertices whose are connected by $\widetilde{e_{2}}$. But we still need to distinguish adjacent vertices whose joined by $\widetilde{e_{2-3}}$. Select an incident edge from $\widetilde{e_{2-3}}$ and color it with 1, it deduces that $t\left(v_{x_{i}}\right) \neq t\left(v_{x_{i}}^{\prime}\right)$ and $t\left(v_{y_{i}}\right) \neq t\left(v_{y_{i}}^{\prime}\right)$. Meanwhile, $t\left(v_{2}(x)\right)=5$ or $6, t\left(v_{2}(y)\right)=7$ or $8, t\left(v_{3}(x)\right)$ belongs to set $\{7,6,5,4\}$ and $t\left(v_{3}(y)\right)$ belongs to set $\{8,7,6,5\}$. Possibly, it still exist some cases that vertex can not distinguish. We deal it as follows.

Case $4.1 t\left(v_{3}(y)\right)=5$. Vertex $v_{3}(y)$ must join three vertices of degree 2 in $X$. Recolor $v_{3}(y)$ with 1 , then $t\left(v_{3}(y)\right)=4$ and $t\left(v_{2}(x)\right)=5$.

Case $4.2 t\left(v_{3}(y)\right)=6$. Vertex $v_{3}(y)$ must connect two vertices of degree 2 in $X$, denoted by $v_{2}\left(x_{1}\right)$ and $v_{2}\left(x_{2}\right)$, respectively. Set $v_{0} \in N\left(v_{3}(x)\right)-\left\{v_{2}\left(x_{1}\right), v_{2}\left(x_{2}\right)\right\}$. Let $v_{0}^{\prime}$ be the neighbor of $v_{0}$.

Case 4.2.1 $t\left(v_{0}\right)=t\left(v_{3}(y)\right)=6$ and $t\left(v_{0}^{\prime}\right) \neq 6$. Recolor $v_{3}(y), v_{0} v_{3}(y)$ with 1 and $v_{0}$ with 2 , then we have $t\left(v_{3}(y)\right)=4$ and $t\left(v_{0}\right)=6$.

Case 4.2.2 $t\left(v_{0}\right)=t\left(v_{3}(y)\right)=t\left(v_{0}^{\prime}\right)=6$. If $d_{H}\left(v_{0}\right)=2$, then $v_{0}$ connects two vertices with degree 3 in $Y$ and denoted by $v_{3}\left(y_{1}\right)$ and $v_{3}\left(y_{2}\right)$, respectively. Recolor $v_{0}$ with 2 , it gets that $t\left(v_{0}\right)=7$. If $d_{H}\left(v_{0}\right)=3$, then $v_{0}$ connects two vertices of degree 3 in $Y$ and denoted by $v_{3}\left(y_{3}\right)$ and $v_{3}\left(y_{4}\right)$, respectively. Denote $v_{1} \in N\left(v_{0}\right)-\left\{v_{3}\left(y_{3}\right), v_{3}\left(y_{4}\right)\right\}$. Recolor $v_{0}$ and $v_{0} v_{1}$ with 2 , and recolor $v_{1}$ with 1 . Then $t\left(v_{0}\right)=8$ and $t\left(v_{1}\right)=7$.

Case 4.3 $t\left(v_{3}(x)\right)=7$. Suppose that $N\left(v_{3}(x)\right)=\left\{v_{y_{1}}, v_{y_{2}}, v_{y_{3}}\right\}$. Let $v_{x_{1}}, v_{x_{1}}^{\prime}$ be two neighbors of $v_{y_{1}}$ and $v_{x_{2}}, v_{x_{2}}^{\prime}$ be two neighbors of $v_{y_{2}}$. Then the following cases may appear adjacent vertices having the same weight.

Case 4.3.1 $t\left(v_{y_{1}}\right), t\left(v_{y_{2}}\right)$ and $t\left(v_{y_{3}}\right)$ are not equal to 8 . Then it exists a vertex of $N\left(v_{3}(x)\right)$ having weight 7 (otherwise, $v_{3}(x)$ and its neighbors can be distinguished immediately). Recolor $v_{3}(x)$ with 2 , it follows that $t\left(v_{3}(x)\right)=8$.

Case 4.3.2. One of $\left\{v_{y_{1}}, v_{y_{2}}, v_{y_{3}}\right\}$ has weight 8 and another two vertices have weight 7 . Without loss of generality, suppose that $t\left(v_{y_{3}}\right)=8$ and $t\left(v_{y_{1}}\right)=t\left(v_{y_{2}}\right)=7$.

Case 4.3.2.1 $d_{H}\left(v_{y_{1}}\right)=d_{H}\left(v_{y_{2}}\right)=2$.

1. If $t\left(v_{x_{1}}\right)=t\left(v_{x_{2}}\right)=5$, recolor $v_{y_{1}} v_{3}(x)$ and $v_{y_{2}} v_{3}(x)$ with 1 , then $t\left(v_{y_{1}}\right)=t\left(v_{y_{2}}\right)=6, t\left(v_{y_{3}}\right)=8$ and $t\left(v_{x_{1}}\right)=t\left(v_{x_{2}}\right)=t\left(v_{3}(x)\right)=5$.
2. Without loss of generality, assume that $t\left(v_{x_{1}}\right)=6$. Recolor $v_{y_{1}}$ and $v_{y_{1}} v_{3}(x)$ with 1 . Then $t\left(v_{y_{1}}\right)=5$ and $t\left(v_{3}(x)\right)=6$.

Case 4.3.2.2 $d_{H}\left(v_{y_{1}}\right)=2$ and $d_{H}\left(v_{y_{2}}\right)=2$ hold not at the same time. Assume that $d_{H}\left(v_{y_{1}}\right)=3$ and $t\left(v_{x_{1}}^{\prime}\right)=5$. Recolor $v_{y_{1}} v_{x_{1}}, v_{y_{1}} v_{3}(x)$ and $v_{y_{1}}$ with 1 , and recolor $v_{x_{1}}$ with 2 , then $t\left(v_{y_{1}}\right)=4, t\left(v_{3}(x)\right)=6$ and $t\left(v_{x_{1}}\right)$ keep the same as before.

Case 4.3.3 $\left\{t\left(v_{y_{1}}\right), t\left(v_{y_{2}}\right), t\left(v_{\left.y_{3}\right)}\right\}=\{6,7,8\}\right.$. Assume that $t\left(v_{y_{1}}\right)=8, t\left(v_{y_{2}}\right)=6$ and $t\left(v_{y_{3}}\right)=7$. Recolor $v_{y_{2}} v_{3}(x)$ and $v_{y_{2}}$ with 1. Then $t\left(v_{y_{2}}\right)=4$ and $t\left(v_{3}(x)\right)=6$.

Case 4.3.4 Two of $\left\{v_{y_{1}}, v_{y_{2}}, v_{y_{3}}\right\}$ have weights 8 and the remaining one has weight 7 . Assume that $t\left(v_{y_{1}}\right)=8, t\left(v_{y_{2}}\right)=7$ and $t\left(v_{y_{3}}\right)=8$.

1. If $d_{H}\left(v_{y_{2}}\right)=2$ and $t\left(v_{x_{2}}\right)=5$, recolor $v_{y_{2}} v_{3}(x)$ with 1 and recolor $v_{3}(x)$ with 2 , then $t\left(v_{3}(x)\right)=7$ and $t\left(v_{y_{2}}\right)=6$.
2. If $d_{H}\left(v_{y_{2}}\right)=2$ and $t\left(v_{x_{2}}\right)=6$, recolor $v_{y_{2}} v_{3}(x)$ and $v_{y_{2}}$ with 1 , then $t\left(v_{3}(x)\right)=6$ and $t\left(v_{y_{2}}\right)=5$.
3. If $d_{H}\left(v_{y_{2}}\right)=3$, recolor $v_{y_{2}} v_{x_{2}}, v_{y_{2}} v_{3}(x)$ and $v_{y_{2}}$ with 1 and recolor $v_{x_{2}}$ with 2 , then $t\left(v_{y_{2}}\right)=4$, $t\left(v_{3}(x)\right)=6$ and the weight of $v_{x_{2}}$ does not change.

Note that Theorem 5 implies that 1-2 Conjecture is valid for 3-regular graphs. By Lemma 3, if $G$ is 4-regular, then there exists a bipartite graph $H$ such that $2 \leq d_{H}(u) \leq 4$ for all $u \in V(G)$. Let $v \in V(G-E(H))$. Then $0 \leq d_{G-E(H)}(v) \leq 2$. Suppose that $X$ and $Y$ are the two partitions of $V(H)$, then the vertex-induced subgraph of $X$ (or $Y$ ) consists of cycles or isolated vertices or isolated edges or paths. Therefore, it may offer an idea to solve 1-2-3 Conjecture and 1-2 Conjecture for 4-regular graphs.
