Locally octahedral and locally almost square Köthe-Bochner spaces

Jan-David Hardtke

ABSTRACT. It has been proved in [19] that a Köthe-Bochner space E(X) is locally octahedral/locally almost square if X has the respective property and the simple functions are dense in E(X). Here we show that the result still holds true without the density assumption. The proof makes use of the Kuratowski-Ryll-Nardzewski Theorem on measurable selections.

1 Introduction

Let X be a real Banach space. We denote by X^* its topological dual, by B_X its closed unit ball and by S_X its unit sphere.

X is locally octahedral (LOH) if the following holds: for every $x \in S_X$ and every $\varepsilon > 0$ there exists $y \in S_X$ such that $||x \pm y|| \ge 2-\varepsilon$. This notion was introduced in [15] in connection with the so called diameter-two-properties.

X is locally almost square (LASQ) if the following holds: for every $x \in S_X$ and every $\varepsilon > 0$ there exists $y \in S_X$ such that $||x \pm y|| \le 1 + \varepsilon$. This notion was introduced in [2].

For more information on these and related properties the reader may consult [1–9, 11, 13–22, 24], [10, Theorem 2.5, p.106] and references therein.

Now consider a complete, σ -finite measure space (S, \mathcal{A}, μ) . For a set $A \subseteq S$ we denote by χ_A the characteristic function of A. Let $(E, \|\cdot\|_E)$ be a Banach space of real-valued measurable functions on S (modulo equality μ -almost everywhere) such that the following holds:

- (i) $\chi_A \in E$ for every set $A \in \mathcal{A}$ with $\mu(A) < \infty$.
- (ii) If $f \in E$ and $A \in \mathcal{A}$ with $\mu(A) < \infty$, then f is μ -integrable over A.
- (iii) If g is measurable and $f \in E$ such that $|g(t)| \leq |f(t)| \mu$ -a.e. then $g \in E$ and $||g||_E \leq ||f||_E$.

Then $(E, \|\cdot\|_E)$ is called a Köthe function space over (S, \mathcal{A}, μ) .

Keywords: Köthe-Bochner spaces; locally octahedral spaces; locally almost square spaces; measurable selections

1. Introduction

Standard examples are the spaces $L^p(\mu)$ for $1 \le p \le \infty$. More generally, Orlicz spaces with the Luxemburg norm (see [25]) are examples of Köthe function spaces.

A function $f: S \to X$ is called simple if there are finitely many pairwise disjoint sets $A_1, \ldots, A_n \in \mathcal{A}$ such that $\mu(A_i) < \infty$ for all $i = 1, \ldots, n, f$ is constant on each A_i and f(t) = 0 for every $t \in S \setminus \bigcup_{i=1}^n A_i$.

f is said to be Bochner-measurable if there exists a sequence $(f_n)_{n \in \mathbb{N}}$ of simple functions such that $\lim_{n \to \infty} ||f_n(t) - f(t)|| = 0$ μ -a.e.

According to the well-known Pettis Measurability Theorem, the following assertions are equivalent:

- (i) f is Bochner-measurable.
- (ii) $x^* \circ f$ is measurable for every $x^* \in X^*$ and there is a separable, closed subspace Y of X such that $f(s) \in Y$ for μ -a.e. $s \in S$.
- (iii) f is measurable (with respect to \mathcal{A} and the Borel- σ -algebra of X) and there is a separable, closed subspace Y of X such that $f(s) \in Y$ for μ -a.e. $s \in S$.

We denote by E(X) the space of all Bochner-measurable functions $f : S \to X$ (modulo equality a.e.) such that $||f(\cdot)|| \in E$.

We define $||f||_{E(X)} = |||f(\cdot)|||_E$ for $f \in E(X)$. Then E(X) becomes a Banach space, the so called Köthe-Bochner space induced by E and X.

For $E = L^p(\mu)$ we obtain the usual Lebesgue-Bochner spaces $L^p(\mu, X)$ for $1 \le p \le \infty$. For more information on Köthe-Bochner spaces the reader is referred to the book [23].

In [19, Theorems 4.1 and 4.5] the author proved the following results:

- (a) If X is LOH/LASQ and the simple functions are dense in E(X), then E(X) is also LOH/LASQ.
- (b) If X is LOH/LASQ, then $L^{\infty}(\mu, X)$ is also LOH/LASQ.

The proofs in [19] are based on a general reduction theorem and corresponding results for absolute sums of LOH/LASQ spaces that were obtained in [2, Proposition 5.3].

The assumption that the simple functions are dense in E(X) holds true whenever E is order continuous, in particular for $E = L^p(\mu)$ with $1 \le p < \infty$.

Here we will show that the result is still true without any additional assumptions on E or X. The proof makes use of the Kuratowski-Ryll-Nardzewski Theorem on the existence of measurable selections, which we will recall in the next section.

2 Measurable selections

Let (S, \mathcal{A}) be a measurable space and (Y, d) a metric space. Denote by $\mathcal{P}(Y)$ the power-set of Y and by $\mathcal{B}(Y)$ the Borel- σ -Algebra of (Y, d). For a subset $M \subseteq Y$ we denote by \overline{M} the closure of M in (Y, d).

Let $F: S \to \mathcal{P}(Y)$ be a set-valued map. For $M \subseteq Y$ we put

$$F_{-}(M) := \{ s \in S : F(s) \cap M \neq \emptyset \}.$$

F is said to be weakly \mathcal{A} -measurable if $F_{-}(U) \in \mathcal{A}$ for every open set $U \subseteq Y$. If $F_{-}(C) \in \mathcal{A}$ for every closed set $C \subseteq Y$, then F is called \mathcal{A} -measurable. \mathcal{A} -measurability of F implies weak \mathcal{A} -measurability (this follows from the fact that every open subset in a metric space is an F_{σ} -set).

The following standard lemma follows directly from the definition.

Lemma 2.1. Suppose that $F, G : S \to \mathcal{P}(Y)$ are two set-valued maps such that $F(s) \subseteq G(s) \subseteq \overline{F(s)}$ for every $s \in S$. Then F is weakly \mathcal{A} -measurable if ond only if G is weakly \mathcal{A} -measurable.

The next lemma is also standard but we include a sketch of the proof here for the reader's convenience.

Lemma 2.2. Suppose that (Y,d) is separable and $g : S \times Y \to \mathbb{R}$ is a Carathéodory function, *i. e.*

- (i) $g(s, \cdot)$ is continuous for every $s \in S$,
- (ii) $g(\cdot, y)$ is \mathcal{A} -measurable for every $y \in Y$.

Let $\alpha \in \mathbb{R}$ and put

$$F(s) := \{ y \in Y : g(s, y) > \alpha \} \quad for all \ s \in S.$$

Then $F: S \to \mathcal{P}(Y)$ is A-measurable.

Proof. Let $C \subseteq Y$ be nonempty and closed. Choose a sequence $(y_n)_{n \in \mathbb{N}}$ such that $C = \overline{\{y_n : n \in \mathbb{N}\}}$ and put $A_n := \{s \in S : g(s, y_n) > \alpha\}$ for every $n \in \mathbb{N}$. Then we have $A_n \in \mathcal{A}$ for each n and it is easy to see that $F_-(C) = \bigcup_{n \in \mathbb{N}} A_n$. Thus $F_-(C) \in \mathcal{A}$.

A classical result on the existence of measurable selections is the Kuratowski-Ryll-Nardzewski Theorem (see for instance [12, Theorem 2.1]).

Theorem 2.3 (Kuratowski-Ryll-Nardzewski Selection Theorem). Let (S, \mathcal{A}) be a measurable space and (Y, d) a complete, separable metric space. Let $F : S \to \mathcal{P}(Y)$ be a weakly \mathcal{A} -measurable set-valued map such that F(s)is non-empty and closed in Y for every $s \in S$. Then there is an \mathcal{A} - $\mathcal{B}(Y)$ measurable map $f : S \to Y$ such that $f(s) \in F(s)$ for every $s \in S$.

3 LOH and LASQ Köthe-Bochner spaces

Now we are ready to prove the general stability result.

Theorem 3.1. Let (S, \mathcal{A}, μ) be a complete, σ -finite measure space and let E be a Köthe function space over (S, \mathcal{A}, μ) . If X is a real Banach space which is LOH/LASQ, then the Köthe-Bochner space E(X) is also LOH/LASQ.

Proof. 1) Assume that X is LOH. Fix $\varepsilon > 0$ and $f \in E(X)$ with $||f||_{E(X)} =$ 1. Since $f : S \to X$ is Bochner-measurable there is a separable, closed subspace Y of X such that $f(s) \in Y$ for μ -a.e. $s \in S$ (Pettis Measurability Theorem). Without loss of generality we may assume that this holds even for all $s \in S$.

Put $S' := \{s \in S : f(s) \neq 0\}.$

Since Y is separable the unit sphere S_Y is also separable. We fix a sequence $(y_n)_{n \in \mathbb{N}}$ which is dense in S_Y .

Because X is LOH we can find a sequence $(z_n)_{n\in\mathbb{N}}$ in S_X such that $||y_n \pm z_n|| \ge 2 - \varepsilon/2$ for every $n \in \mathbb{N}$. We put $Z := \overline{\operatorname{span}}\{z_n : n \in \mathbb{N}\}$. This is again a separable, closed subspace of X.

Next we define $F: S' \to \mathcal{P}(S_Z)$ by

$$F(s) := \overline{\left\{z \in S_Z : \left\|\frac{f(s)}{\|f(s)\|} \pm z\right\| > 2 - \varepsilon\right\}} \quad \text{for all } s \in S'.$$

We have $F(s) \neq \emptyset$ for every $s \in S'$. To see this note that $f(s)/||f(s)|| \in S_Y$ and hence there is some index $N \in \mathbb{N}$ such that $||f(s)/||f(s)|| - y_N|| < \varepsilon/2$. It follows that

$$\left\|\frac{f(s)}{\|f(s)\|} \pm z_N\right\| \ge \|y_N \pm z_N\| - \left\|\frac{f(s)}{\|f(s)\|} - y_N\right\| > 2 - \frac{\varepsilon}{2} - \frac{\varepsilon}{2} = 2 - \varepsilon.$$

If we define

$$g(s,z) := \min\left\{ \left\| \frac{f(s)}{\|f(s)\|} + z \right\|, \left\| \frac{f(s)}{\|f(s)\|} - z \right\| \right\} \text{ for } s \in S', \ z \in S_Z,$$

then $F(s) = \{z \in S_Z : g(s, z) > 2 - \varepsilon\}$ and since g is a Carathéodory function, it follows from Lemma 2.2 and Lemma 2.1 that F is weakly measurable.

Thus by the Kuratowski-Ryll-Nardzewski Selection Theorem there exists a measurable function $\tilde{f}: S' \to S_Z$ such that $\tilde{f}(s) \in F(s)$ for every $s \in S'$. Note that by Pettis Measurability Theorem \tilde{f} is also Bochner-measurable. We put $h(s) := ||f(s)||\tilde{f}(s)$ for $s \in S'$ and h(s) := 0 for $s \in S \setminus S'$. Then h is Bochner-measurable and ||h(s)|| = ||f(s)|| for every $s \in S$ and thus $||h||_{E(X)} = ||f||_{E(X)} = 1$.

We further have $||f(s) \pm h(s)|| \ge (2 - \varepsilon)||f(s)||$ for every $s \in S$. This implies $||f \pm h||_{E(X)} \ge (2 - \varepsilon)||f||_{E(X)} = 2 - \varepsilon$.

This proves that E(X) is LOH.

References

2) Now assume that X is LASQ. We take ε , f, Y, S' and $(y_n)_{n \in \mathbb{N}}$ as in part 1). Since X is LASQ there is a sequence $(z_n)_{n \in \mathbb{N}}$ in S_X such that $||y_n \pm z_n|| \le 1 + \varepsilon/2$ for every $n \in \mathbb{N}$ and we put $Z := \overline{\operatorname{span}}\{z_n : n \in \mathbb{N}\}$ and

$$F(s) := \overline{\left\{z \in S_Z : \left\|\frac{f(s)}{\|f(s)\|} \pm z\right\| < 1 + \varepsilon\right\}} \quad \text{for all } s \in S'.$$

Analogously to the proof in part 1) we can see that each set F(s) is nonempty and also that F is weakly measurable. For the latter, put

$$g(s,z) := \max\left\{ \left\| \frac{f(s)}{\|f(s)\|} + z \right\|, \left\| \frac{f(s)}{\|f(s)\|} - z \right\| \right\} \text{ for } s \in S', \ z \in S_Z.$$

Then g is a Carathéodory function and $F(s) = \overline{\{z \in S_Z : g(s, z) < 1 + \varepsilon\}}.$

By the Kuratowski-Ryll-Nardzewski Selection Theorem we find a measurable function $\tilde{f}: S' \to S_Z$ such that $\tilde{f}(s) \in F(s)$ for every $s \in S'$. Then if we define h as in 1), we find that $h \in S_{E(X)}$ and $||f(s)\pm h(s)|| \leq ||f(s)||(1+\varepsilon)$ for every $s \in S$. This implies $||f\pm h||_{E(X)} \leq 1+\varepsilon$ and the proof is finished. \Box
