Abstract

The stellar dynamic models considered here are triples (f, ρ, U) of three functions: the distribution function $f = f(r, u)$, the local density $\rho = \rho(r)$ and the Newtonian potential $U = U(r)$, where $r := |x|$, $u := |v|$ ($(x, v) \in \mathbb{R}^3 \times \mathbb{R}^3$ are the space-velocity coordinates), and f is a function q of the local energy $E = U(r) + \frac{u^2}{2}$. Our first result is an answer to the following question: Given a (positive) function $p = p(r)$ on a bounded interval $[0, R]$, how can one recognize p as the local density of a stellar dynamic model of the given type (“inverse problem”)? If this is the case, we say that p is “extendable” (to a complete stellar dynamic model). Assuming that p is strictly decreasing we reveal the connection between p and F , which appears in the nonlinear integral equation $p = FU[p]$ and the solvability of Eddington’s equation between F and q (Lemma 4.1). Second, we investigate the following question (“direct problem”): Which q induce distribution functions f of the form $f = q(-E(r, u) - E_0)$ of a stellar dynamic model? This leads to the investigation of the nonlinear equation $p = FU[p]$ in an approximative and constructive way by mainly numerical methods. — The paper extends preceding work on flat galaxies [1] to the three-dimensional case. In particular, the present answer to the extendability problem is completely different as in [1]. The present paper also opens the way to further explicit solutions of the Vlasov-Poisson system beyond the classical known examples which are for instant given in [4].

Keywords Vlasov-Poisson system, stationary solutions, numerical approximation.

1 Introduction

The Vlasov–Poisson System (VPS) in 3 dimensions (stellar dynamic version) has the following form:

$$\frac{\partial f}{\partial t} + v \cdot \frac{\partial f}{\partial x} - \frac{\partial}{\partial x} U(t, x) \cdot \frac{\partial f}{\partial v} = 0, \quad (\text{V})$$

$$\Delta U(t, x) = 4\pi \rho(t, x) \quad (P_1)$$

$$\text{or } U(t, x) = - \int \frac{\rho(t, y)}{|x - y|} dy, \quad (P_2)$$

$$\rho(t, x) = \int f(t, x, v) dv. \quad (\text{D})$$

Here $f = f(t, x, v) \geq 0$ is the distribution function of the gravitating matter, $U = U(t, x) \leq 0$ the Newtonian potential and $\rho(t, x) \geq 0$ the local density. The system has been intensively investigated in many directions. For the case of time-dependent functions (initial value problem), [9] gives a survey until 2007. The stationary spherically symmetric functions are characterized by the property $f(x, v) = f(A_1 x, A_2 v)$ for all $A_1, A_2 \in SO(3)$; for a short account of this class, relevant for our work, see [1], also for references.

The aim of the present paper is twofold. Our first problem is known as the “inverse problem”: to identify those functions p , defined on a bounded interval $[0, R]$, as the local density of a stationary spherically symmetric stellar dynamic model, in which f depends on the local energy:

$$f(r, u) = q(-E - E_0), \quad \text{where } E_0 > 0 \text{ is a constant.}$$

This question occurs if one wants to determine the three quantities f , ρ , U from observation. The result of an observation generally is a brightness profile, which, by certain strategies, can be turned into a mass profile. The question which follows is the determination of the potential U and the distribution f (Sections 2–5).

Our second problem is called the direct problem. It is known that the distribution f of a stationary spherically symmetric stellar dynamic model is a function of the local energy E and the angular momentum $F := x^2 v^2 - (xv)^2$ (this fact is called Jeans’

theorem) [2]. The direct problem partially poses the opposite question, namely: which functions q admit finding functions $\rho(r)$ and $U(r)$ together with a constant $E_0 > 0$ such that $f(r, u) = q(-E - E_0)$, ρ and U form a triple of a stationary spherically symmetric stellar dynamic model (Sections 6–8). We give a short overview over the different sections.

2 The potential operator in spherical symmetry

We define the potential operator

$$Lp(x) := \int_{\mathbb{R}^3} \frac{p(y)}{|x-y|} dy, \quad x \in \mathbb{R}^3,$$

for certain functions p on \mathbb{R}^3 , which are spherically symmetric. This means (by abuse of notation) that $p(x) = p(r)$, $r := |x|$. We first conclude that Lp is also spherically symmetric. In fact, if $A \in SO(3)$, then, assuming that $y = Az$, we have

$$\begin{aligned} Lp(Ax) &= \int_{\mathbb{R}^3} \frac{p(y)}{|Ax-y|} dy = \int_{\mathbb{R}^3} \frac{p(y)}{|A(x-A^{-1}y)|} dy = \int_{\mathbb{R}^3} \frac{p(Az)}{|x-z|} dz \\ &= \int_{\mathbb{R}^3} \frac{p(z)}{|x-z|} dz = Lp(x). \end{aligned}$$

We define $\mathbb{R}_{0+} := \{r \in \mathbb{R} : r \geq 0\}$ and $\mathbb{R}_+ := \{r \in \mathbb{R} : r > 0\}$.

Definition 2.1 Let $\mathcal{D}(L)$ be the set of functions $p: \mathbb{R}_{0+} \rightarrow \mathbb{R}_{0+} \cup \{\infty\}$ with the following properties:

- (a) $p \in C(\mathbb{R}_+)$,
- (b) for all $r > 0$ we have $\int_0^r p(s)s^2 ds < \infty$, $\int_r^\infty p(s)s ds < \infty$,
- (c) there exists a $\delta > 0$ such that for all $r \in (0, \delta)$, we have $p(r) > 0$.

Lemma 2.2 For $p \in \mathcal{D}(L)$, we have:

$$1) Lp(r) = 4\pi \left[\frac{1}{r} \int_0^r p(s)s^2 ds + \int_r^\infty p(s)s ds \right], \quad r > 0, \quad (2.1)$$

$$2) Lp \in C^2(\mathbb{R}_+), \quad \text{and}$$

$$(Lp)'(r) = -\frac{4\pi}{r^2} \int_0^r p(s)s^2 ds, \quad r > 0, \quad (2.2)$$

$$(Lp)''(r) = -\frac{2}{r}(Lp)'(r) - 4\pi p(r), \quad r > 0. \quad (2.3)$$

- 3) $Lp > 0$ and $(Lp)' < 0$, that is, Lp is strictly decreasing on \mathbb{R}_+ . Because the limits

$$Lp(0) := \lim_{r \rightarrow 0} Lp(r), \quad Lp(\infty) = \lim_{r \rightarrow \infty} Lp(r)$$

exist, the function Lp has a strictly decreasing inverse

$$(Lp)^{-1}: (Lp(\infty), Lp(0)) \rightarrow (0, \infty).$$

Proof. 1) Using spherical coordinates

$$x = (r \sin \psi \cos \varphi, r \sin \psi \sin \varphi, r \cos \psi),$$

we have

$$\begin{aligned} Lp(x) &= \int_0^\pi \int_0^{2\pi} \int_0^\infty \frac{p(s) \sin \psi}{\sqrt{r^2 + s^2 - 2rs \cdot \cos \psi}} s^2 ds d\varphi d\psi \\ &= 2\pi \int_0^\pi \int_0^\infty \frac{\sin \psi}{\sqrt{r^2 + s^2 - 2rs \cdot \cos \psi}} d\psi p(s)s^2 ds. \end{aligned}$$

In the inner integral we substitute $u := \sqrt{r^2 + s^2 - 2rs \cos \psi}$ and get

$$\begin{aligned} \int_0^\pi \frac{\sin \psi}{\sqrt{r^2 + s^2 - 2rs \cdot \cos \psi}} d\psi &= \int_{\sqrt{r^2 + s^2 - 2rs}}^{\sqrt{r^2 + s^2 + 2rs}} 1 \cdot du \cdot \frac{1}{rs} \\ &= \frac{(r+s) - |r-s|}{rs} = \begin{cases} \frac{2}{r} & \text{for } s \leq r, \\ \frac{2}{s} & \text{for } s \geq r, \end{cases} \end{aligned}$$

and (2.1) follows.

2) (2.2) results from differentiating (2.1), and (2.3) follows from differentiating (2.2).

3) Inequality $Lp > 0$ is a consequence of Definition 2.1 c), and $(Lp)' < 0$ results from (2.2). The existence of the limits and of the inverse operator are direct consequences of these facts. \square

Most of our functions $p \in \mathcal{D}(L)$ will have compact support.

We define

$$\begin{aligned}\mathcal{D}_R(L) &:= \{p \in \mathcal{D}(L) : p > 0 \text{ on } [0, R), p = 0 \text{ on } [R, \infty)\}. \\ \mathcal{D}_R^-(L) &:= \{p \in \mathcal{D}_R(L) : p \text{ strictly decreasing on } [0, R)\}.\end{aligned}$$

The functions $p \in \mathcal{D}_R^-(L)$ are solutions of a nonlinear integral equation, as the following lemma shows.

Diagram 2.1 for $F(h) = p \circ (Lp)^{-1}(h)$, ($E_0 := Lp(R)$).

Lemma 2.3 Let $p \in \mathcal{D}_R^-(L)$.

Then there exists a unique strictly increasing function

$$F := F[p]: [Lp(R), Lp(0)) \rightarrow p((0, R])$$

such that

$$p(r) = F \circ Lp(r), \quad r \in (0, R].$$

Proof. Lemma 2.2 3) says that

$$Lp: (0, R] \rightarrow [Lp(R), Lp(0))$$

is strictly decreasing and has a strictly decreasing inverse

$$(Lp)^{-1}: [Lp(R), Lp(0)) \rightarrow (0, R].$$

Because p is strictly decreasing on $(0, R]$, the composition

$$F := p \circ (Lp)^{-1}: [Lp(R), Lp(0)) \rightarrow p((0, R])$$

exists and is strictly increasing (see Diagram 2.1) Then

$$F(h) = p \circ (Lp)^{-1}(h), \quad h \in [Lp(R), Lp(0))$$

implies

$$F \circ Lp(r) = p(r), \quad r \in (0, R].$$

The uniqueness of F is immediate: If G satisfies $p = G \circ Lp$, then $G = p \circ (Lp)^{-1} = F$.

□

Corollary 2.4 Let $F(h) := 0$ for $h \in (0, Lp(R))$. Then under the conditions of Lemma 2.3 we have

$$p(r) = F \circ Lp(r) \text{ on } (0, R] \iff p(r) = F \circ Lp(r) \text{ on } \mathbb{R}_+.$$

Proof. Let $p(r) = F \circ Lp(r)$ on $(0, R]$. In this case, if $R < r$, then $p(r) = 0$, and $Lp(R) > Lp(r)$ implies that $F \circ Lp(r) = 0$, i. e. $p(r) = F \circ Lp(r)$ on \mathbb{R}_+ . The inverse statement is trivial. □

Often we use the abbreviation $P := Lp$.

3 Stationary spherically symmetric solutions depending on the local energy and their properties

Definition 3.1 A triple (f, ρ, U) of functions $f = f(r, u)$, $\rho = \rho(r)$, $U = U(r)$ is called a stationary spherically symmetric E -dependent solution of the (VPS) if $\rho \in \mathcal{D}_R^-(L)$ and there exists a function $q = q(s)$ with the following property:

$$(Q) \quad q \in L_{\text{loc}}^1(\mathbb{R}), \quad q(s) = 0 \text{ for } s \in (-\infty, 0], \quad q(s) > 0 \text{ for } s \in (0, P(0) - E_0)$$

such that

$$(V) \quad f(r, u) = q(-E(r, u) - E_0),$$

$$E(r, u) := U(r) + \frac{u^2}{2}, \quad u := |v|,$$

(we write $f = f_q$),

$$(P) \quad U(r) = -L\rho(r), \quad L\rho(R) =: E_0,$$

$$(D) \quad \rho(r) = \int_{\mathbb{R}^3} f(r, |v|) dv, \quad r \in \mathbb{R}_+.$$

We note that (Q) states the properties of q , (V) refers to f 's being an integral of Vlasov's equation (i.e., being constant along the characteristics), (P) is the integrated form (P₂) of Poisson's equation, (D) is the definition of the local density.

As a preparation for the following important lemma we prove a crucial identity.

Lemma 3.2 *Let $p \in \mathcal{D}(L)$, $E_0 > 0$ and q satisfy (Q). Then for $E_0 \leq h < Lp(0)$ the following equality holds:*

$$\int_{\mathbb{R}^3} q \left(h - E_0 - \frac{v^2}{2} \right) dv = 4\pi\sqrt{2} \int_0^{h-E_0} q(s) \sqrt{h - E_0 - s} ds. \quad (3.1)$$

Proof. Since $q(s) = 0$ for $s \in (-\infty, 0]$, we have

$$\begin{aligned} \int_{\mathbb{R}^3} q \left(h - E_0 - \frac{v^2}{2} \right) dv &= \int_{|v| < \sqrt{2(h-E_0)}} q \left(h - E_0 - \frac{v^2}{2} \right) dv \\ &= \int_0^\pi \int_0^{2\pi} \int_0^{\sqrt{2(h-E_0)}} q \left(h - E_0 - \frac{u^2}{2} \right) u^2 du d\varphi \sin \psi d\psi \\ &= 4\pi \int_0^{\sqrt{2(h-E_0)}} q \left(h - E_0 - \frac{u^2}{2} \right) u^2 du. \end{aligned}$$

Passing to the new variable $s := h - E_0 - \frac{u^2}{2}$, we have $u = \sqrt{2(h - E_0 - s)}$. Hence we get (3.1). \square

Lemma 3.3 (Equivalence Lemma)

(a) *Let (f_q, ρ, U) be a stationary spherically symmetric E -depending solution of the (VPS). Let $F := F[p]$ (Lemma 2.3), where $p = \rho$. Then*

$$F(h) = 4\pi\sqrt{2} \int_0^{h-E_0} q(s) \sqrt{h - E_0 - s} ds \quad \text{for } h \in [E_0, P(0)). \quad (3.2)$$

(b) *Let q satisfy (Q), and let*

$$F(h) := 4\pi\sqrt{2} \int_0^{h-E_0} q(s) \sqrt{h - E_0 - s} ds \quad \text{for } h \in [E_0, P(0)). \quad (3.3)$$

Assume the integral equation

$$p(r) = F \circ Lp(r) \quad (3.4)$$

has a solution $p \in \mathcal{D}_R^-(L)$ on \mathbb{R}_+ . We define $\rho := p$, $U(r) := -L\rho(r)$, $E_0 := Lp(R)$, and $f_q(r, u) := q(-E(r, u) - E_0)$. Then (f_q, ρ, u) is a stationary spherically symmetric E -depending solution of the (VPS).

Proof.

a) Let (f_q, ρ, U) be a stationary spherically symmetric E -depending solution. Then, by virtue of Lemma 2.3, (D), (V), and (3.1), we have

$$\begin{aligned} F \circ L\rho(r) = \rho(r) &= \int_{\mathbb{R}^3} f_q(r, |v|) dv = \int_{\mathbb{R}^3} q \left(L\rho(r) - E_0 - \frac{v^2}{2} \right) dv \\ &= 4\pi\sqrt{2} \int_0^{L\rho(r)-E_0} q(s) \sqrt{L\rho(r) - E_0 - s} ds \quad \text{for } r \in (0, R], \end{aligned}$$

and (3.2) follows.

b) Our assumptions imply that (Q), (P), (V) are satisfied. Furthermore, by virtue of (3.4), (3.3), (3.1), and (V), we have

$$\begin{aligned} \rho(r) = p(r) = F \circ L\rho(r) &= 4\pi\sqrt{2} \int_0^{L\rho(r)-E_0} q(s) \sqrt{L\rho(r) - E_0 - s} ds \\ &= \int_{\mathbb{R}^3} q \left(L\rho(r) - E_0 - \frac{v^2}{2} \right) dv \\ &= \int_{\mathbb{R}^3} f(r, u) dv, \quad r \in (0, R]. \end{aligned}$$

Hence (D) is also satisfied. \square

In the sequel, we will use the definition

$$F_0(h) := F(h + E_0) \quad \text{on } [0, P(0) - E_0].$$

Then (3.2) has the form

$$F_0(h) = 4\pi\sqrt{2} \int_0^h q(s) \sqrt{h - s} ds, \quad h \in [0, P(0) - E_0]. \quad (3.5)$$

This is an equation of the form

$$g(x) = \int_0^x f(s) \sqrt{x - s} ds,$$

which is called Eddington's equation. The results on its solvability are based on the theory for an equation of the form

$$g(x) = \int_0^x \frac{f(s)}{\sqrt{x - s}} ds,$$

which is called Abel's equation. It was Tonelli [12], who has given existence proofs for these equations (a review of his work is given in [6]).

For the sake of the completeness of the present work, the main results and their proofs are given in the Appendix.

4 The inverse problem

In this section we consider and solve the following question: Given a function $p \in \mathcal{D}_R^-(L)$, under which conditions is p the local density of a stationary spherically symmetric E -dependent solution? In this case we say “ p is extendable” (by f and U to a stationary spherically symmetric E -dependent solution).

The following proposition gives a first necessary and sufficient criterion that a given $p \in \mathcal{D}_R^-(L)$ is extendable.

Theorem 4.1 *Let $p \in \mathcal{D}_R^-(L)$. Then p is extendable if and only if Eddington’s equation (3.5) has a solution q with (Q) for $F := F[p]$ from Lemma 2.3 and $F_0(h) := F(h + E_0)$.*

Proof. Necessity: If p is extendable, then there exists q with (Q) such that

$$f(r, u) = q\left(-U(r) - E_0 + \frac{u^2}{2}\right), \quad (V) \quad \text{with}$$

$$U(r) = -Lp(r), \quad E_0 = Lp(R), \quad (P),$$

$$p(r) = \int_{\mathbb{R}^3} f(r, u) dv. \quad (D)$$

Lemma 3.3 part (a) shows then that Eddington’s equation (3.5) has the solution q with (Q).

Sufficiency: If Eddington’s equation (3.5) has a solution q with (Q) for $F := F[p]$, then $f := f_q$ satisfies (V) with $U(r) := -Lp(r)$ (P) and $E_0 = Lp(R)$. Therefore, by virtue of (V), (3.1), and (3.3) we have

$$\begin{aligned} \int_{\mathbb{R}^3} f_q(r, |v|) dv &= \int_{\mathbb{R}^3} q\left(Lp(r) - E_0 - \frac{v^2}{2}\right) dv \\ &= 4\pi\sqrt{2} \int_0^{Lp(r) - E_0} q(s) \sqrt{Lp(r) - E_0 - s} ds = F \circ Lp(r) = p(r), \end{aligned}$$

that is, (D) is also valid, and p is extendable. \square

In the next theorem, we investigate the solvability of Eddington’s equation in the form

$$F_0(h) = 4\pi\sqrt{2} \int_0^h q(s) \sqrt{h - s} ds$$

for given $F_0(h) := F(h + E_0)$, $F := F[p]$, in more detail.

The following theorem gives different conditions of extendability for a function $p \in \mathcal{D}_R^-(L)$ in explicit form. The spaces $L_{\text{loc}}^1[0, T]$ and $AC[0, T]$ are defined in the Appendix.

Theorem 4.2 *Let $p \in \mathcal{D}_R^-(L)$, $p|_{(0, R]} \in C^2(0, R]$, $F := F[p]$, $E_0 := P(R)$ and $F_0(\cdot) = F(\cdot + E_0)$. Then the following statements hold.*

1) *Eddington’s equation*

$$F_0(h) = 4\pi\sqrt{2} \int_0^h q(s) \sqrt{h - s} ds, \quad 0 \leq h < P(0) - E_0 \quad (4.1)$$

has a unique real-valued solution $q \in L^1_{\text{loc}}[0, P(0) - E_0)$, which is given by

$$q(h) := \frac{1}{4\pi\sqrt{2}} \frac{2}{\pi} \frac{d}{dh} H_{F_0'}(h), \quad 0 \leq h < P(0) - E_0,$$

where

$$H_{F_0'}(h) := \int_0^h \frac{F_0'(s)}{\sqrt{h-s}} ds \text{ lies in } AC[0, P(0) - E_0), \quad F_0 \in C^2[0, P(0) - E_0). \quad (4.2)$$

2) p is extendable if and only if $q > 0$ on $(0, P(0) - E_0)$, that is

$$\frac{d}{dh} H_{F_0'}(h) = \frac{1}{\sqrt{h}} F_0'(0) + \int_0^h \frac{F_0''(s)}{\sqrt{h-s}} ds > 0 \quad \text{on} \quad (0, P(0) - E_0) \quad (4.3)$$

$$(F_0'(0) = \frac{p'(R)}{p'(R)} \geq 0).$$

3) Sufficient conditions for the extendability of p are:

$$(a) \quad F_0''(s) > 0 \text{ on } (0, P(0) - E_0),$$

$$(b) \quad X(r) := p'(r) \cdot P''(r) - p''(r)P'(r) > 0 \text{ on } (0, R),$$

$$(c) \quad \frac{2}{r} p'(r) + p''(r) > 0 \text{ on } (0, R),$$

where (a) and (b) are equivalent and (c) implies (a) and (b).

Proof. The assumptions on p and Lemma 2.2 imply that

$$P: (0, R] \rightarrow [E_0, P(0))$$

is a strictly decreasing bijection in $C^2(0, R]$ with strictly decreasing inverse

$$P^{-1}: [E_0, P(0)) \rightarrow (0, R]$$

in $C^2[E_0, P(0))$. The composition with $p \in C^2(0, R]$:

$$F := p \circ P^{-1}: [E_0, P(0)) \rightarrow [0, p(0))$$

is strictly increasing and $F \in C^2[E_0, P(0))$, $F_0 \in C^2[0, P(0) - E_0)$, $F_0'(\cdot) = F'(\cdot + E_0)$, and $F_0''(\cdot) = F''(\cdot + E_0)$.

1) To show that (4.1) has a unique real-valued solution $q \in L^1_{\text{loc}}[0, P(0) - E_0)$, we need to verify that for $g := \frac{F_0}{4\pi\sqrt{2}}$ the assumptions (a), (i) and (ii) of Lemma A.5 (in the Appendix) are satisfied. It is sufficient to do this for $g := F_0$.

Obviously, $F_0 \in C^2[0, P(0) - E_0) \subset AC[0, P(0) - E_0)$ and

$$F_0(0) = F(E_0) = pP^{-1}(E_0) = p(R) = 0.$$

For

$$H_{F_0'}(h) := \int_0^h \frac{F_0'(s)}{\sqrt{h-s}} ds$$

(a) (i) means that we have to show $H_{F'_0} \in AC[0, P(0) - E_0]$. We observe that we have $F'_0 \in C^1[0, P(0) - E_0]$ and that

$$F'_0(0) = F'(E_0) = p'(P^{-1}(E_0)) \cdot (P^{-1})'(E_0) = \frac{p'(R)}{P'(R)} \geq 0. \quad (4.4)$$

Integrating by parts, we get

$$\begin{aligned} H_{F'_0}(h) &= -2\sqrt{h-s}F'_0(s)\Big|_0^h + 2\int_0^h F'_0(s)\sqrt{h-s}ds \\ &= 2\sqrt{h}F'_0(0) + 2\int_0^h F'_0(s)\sqrt{h-s}ds, \end{aligned}$$

and $H_{F'_0} \in AC[0, P(0) - E_0]$ follows, i.e. (i) is satisfied. Also we get $H_{F'_0}(0) = 0$, which is (a) (ii). It follows from Lemma A.5 (a) that (4.1) has a unique realvalued solution q which is given by

$$q(h) := \frac{1}{4\pi\sqrt{2}} \frac{2}{\pi} \frac{d}{dh} H_{F'_0}(h) = \frac{1}{4\pi\sqrt{2}} \frac{2}{\pi} \left[\frac{1}{\sqrt{h}} F'_0(0) + \int_0^h \frac{F'_0(s)}{\sqrt{h-s}} ds \right]. \quad (4.5)$$

2) Since $H_{F'_0} \in AC[0, P(0) - E_0]$, we have $q \in L^1_{\text{loc}}[0, P(0) - E_0]$. By Theorem 4.1, it satisfies (Q) and p is extendable if and only if $q > 0$ on $(0, P(0) - E_0)$.

3) The proof of 3) is based on a change of variables in the integral

$$\int_0^h \frac{F'_0(s)}{\sqrt{h-s}} ds.$$

We define a C^2 -diffeomorphism Φ

$$\Phi: [0, P(0) - E_0] \rightarrow (0, R]$$

as the composition of the shift

$$T: [0, P(0) - E_0] \rightarrow [E_0, P(0)], \quad s \mapsto s + E_0,$$

with

$$P^{-1}: [E_0, P(0)] \rightarrow (0, R], \quad s \mapsto P^{-1}(s),$$

that is, $\Phi := P^{-1} \circ T$, $s \mapsto r = P^{-1}(s + E_0)$ (see Diagram 4.1). The inverse of Φ is $\Psi := T^{-1} \circ P$:

$$\Psi: (0, R] \rightarrow [0, P(0) - E_0], \quad r \mapsto s = P(r) - E_0.$$

We now represent $F'_0(s)$, $F''_0(s)$ as functions of $p'(r)$, $p''(r)$, $P'(r)$, $P''(r)$ as follows: for $s = \Psi(r)$, we have

$$\begin{aligned} F_0(s) &= F_0(\Psi(r)) = F(P(r) - E_0 + E_0) = F(P(r)) = pP^{-1}(P(r)) = p(r), \\ \frac{d}{dr} F_0(\Psi(r)) &= F'(P(r)) \cdot P'(r) = p'(r). \end{aligned}$$

Diagram 4.1 Action of Φ and Ψ 

Since $P'(r) < 0$, we obtain for $s = \Psi(r)$

$$\begin{aligned}
 F'_0(s) &= F'_0(\Psi(r)) = F'(P(r)) = \frac{p'(r)}{P'(r)}, \\
 \frac{d}{dr} F'_0(\Psi(r)) &= \frac{d}{dr} F'(P(r) - E_0 + E_0) = \frac{d}{dr} F'(P(r)) \\
 &= F''(P(r)) \cdot P'(r) = \frac{d}{dr} \frac{p'(r)}{P'(r)} \\
 &= \frac{P'(r) \cdot p''(r) - p'(r) \cdot P''(r)}{P'(r)^2}.
 \end{aligned}$$

Hence, for $s = \Psi(r)$, we have

$$F_0''(s) = F_0''(\Psi(r)) = F''(P(r)) = \frac{p'(r)P''(r) - p''(r)P'(r)}{|P'(r)|^3}.$$

Changing coordinates $s \rightarrow r$ in the integral of (4.3) by $\Phi(s) := P^{-1} \circ T(s) = P^{-1}(s + E_0) = r$, $\Phi(0) = R$, $\Phi(P(0) - E_0) = 0$, $\Phi(h) = P^{-1} \circ T(h) = P^{-1}(h + E_0)$, $ds = P'(r)dr$, and observing the negative sign of $P'(r)$, we get

$$\int_0^h \frac{F_0''(s)}{\sqrt{h-s}} ds = \int_{P^{-1}(h+E_0)}^R \frac{p'(r)P''(r) - p''(r)P'(r)}{|P'(r)|^3 \sqrt{h - (P(r) - E_0)}} |P'(r)| dr, \quad (4.6)$$

and 3) (a) or 3) (b) imply $q > 0$ in view of (4.3), (4.4).

Let 3) (c) hold. Then, by virtue of Lemma 2.3, we have

$$\begin{aligned} p'P'' - p''P' &= p' \left(-\frac{2}{r}P' - 4\pi p \right) - p''P' \\ &= 4\pi p(-p') + (-P') \left(\frac{2}{r}p' + p'' \right) > 0, \end{aligned}$$

and 3) (b) is fulfilled. \square

Remark 4.3 For later numerical calculations it is useful to write (4.3) in another form. Because $\Phi(h) = P^{-1}(h + E_0)$, we have $P(\Phi(h)) = h + E_0$ and therefore

$$h = P(\Phi(h)) - P(R),$$

and with (4.4) and (4.6) we get for (4.3)

$$\begin{aligned} \frac{d}{dh} H_{F_0'}(h) &= \frac{1}{\sqrt{P(\Phi(h)) - P(R)}} \\ &\times \left(\frac{p'(R)}{P'(R)} + \int_{\Phi(h)}^R \frac{p'(r)P''(r) - p''(r)P'(r)}{|P'(r)|^2} \sqrt{\frac{P(\Phi(h)) - P(R)}{P(\Phi(h)) - P(r)}} dr \right) \end{aligned} \quad (4.7)$$

The integrand has a singularity at $r = \Phi(h)$.

Remark 4.4 Examples in the following section will show that the conditions 3) (a), (b), and (c) are not necessary for the extendability.

5 Examples

Example 5.1

$$p(r) := \begin{cases} 1 - \left(\frac{r}{R}\right)^2, & 0 \leq r \leq R, \\ 0, & R < r, R > 0. \end{cases}$$

This example allows to compute explicitly the other functions involved in the theory: $P, P^{-1}, F, q, G_0 =: F_0^{-1}$ (which is the right hand side of the approximating nonlinear system (ANS) occurring in Section 7).

For $0 \leq r \leq R$, we have

$$p'(r) = -\frac{2}{R^2} r, \quad p''(r) = -\frac{2}{R^2},$$

hence $\frac{2}{r} p'(r) + p'' = -\frac{6}{R^2} < 0$. Therefore the sufficient condition 3) (c) in Theorem 4.2 does not hold.

Substituting p into (2.1), we obtain

$$\begin{aligned} P(r) &= 4\pi \left[\frac{1}{r} \int_0^r \left(1 - \frac{s^2}{R^2} \right) s^2 ds + \int_r^R \left(1 - \frac{s^2}{R^2} \right) s ds \right] \\ &= 4\pi \left[\frac{r^2}{3} - \frac{1}{5} \frac{r^4}{R^2} + \frac{1}{2} (R^2 - r^2) - \frac{1}{4} \frac{1}{R^2} (R^4 - r^4) \right] \\ &= 4\pi R^2 \left[\frac{1}{20} \left(\frac{r}{R} \right)^4 - \frac{1}{6} \left(\frac{r}{R} \right)^2 + \frac{1}{4} \right] = \pi R^2 \left[\frac{1}{5} \left(\frac{r}{R} \right)^4 - \frac{2}{3} \left(\frac{r}{R} \right)^2 + 1 \right] := h, \\ P'(r) &= 4\pi R^2 \left[\frac{1}{5} \frac{r^3}{R^4} - \frac{1}{3} \frac{r}{R^2} \right], \\ P''(r) &= 4\pi R^2 \left[\frac{3}{5} \frac{r^2}{R^4} - \frac{1}{3} \frac{1}{R^2} \right], \\ P(R) &= E_0 = \frac{8}{15} \pi R^2 \end{aligned}$$

and it follows

$$\begin{aligned} X(r) &= p'P'' - p''P' = -\frac{2}{R^2} r \cdot 4\pi R^2 \left[\frac{3}{5} \frac{r^2}{R^4} - \frac{1}{3} \frac{1}{R^2} \right] \\ &\quad + \frac{2}{R^2} \cdot 4\pi R^2 \left[\frac{1}{5} \frac{r^3}{R^4} - \frac{1}{3} \frac{r}{R^2} \right] = -\frac{16\pi}{5} \frac{r^3}{R^4} < 0, \end{aligned}$$

and sufficient condition 3) (b) in Theorem 4.2 is not fulfilled.

Since $P(r) = h$ and $P: [0, R] \rightarrow [E_0, P(0)] = \left[\frac{8}{15} \pi R^2, \pi R^2 \right]$ is a biquadratic form in $\frac{r}{R}$, we can calculate P^{-1} :

$$\begin{aligned} \left(\frac{r}{R} \right)^2 &= \frac{5}{3} - \sqrt{\frac{25}{9} - 5 + \frac{5}{\pi R^2} h}, \\ r = P^{-1}(h) &= R \sqrt{\frac{5}{3} - \sqrt{\frac{5}{\pi R^2} h - \frac{20}{9}}}. \end{aligned}$$

Hence we obtain

$$F(h) = p(P^{-1}(h)) = 1 - \left(\frac{P^{-1}(h)}{R} \right)^2 = 1 - \left(\frac{5}{3} - \sqrt{\frac{5}{\pi R^2} h - \frac{20}{9}} \right)^2$$

$$\begin{aligned}
&= \sqrt{\frac{5}{\pi R^2} h - \frac{20}{3}} - \frac{2}{3}, \quad h \in [E_0, P(0)], \\
F_0(h) &= F(h + E_0) = \sqrt{\frac{5}{\pi R^2} \left(h + \frac{8}{15} \pi R^2\right) - \frac{20}{9}} - \frac{2}{3} \\
&= \sqrt{ah + \frac{4}{9}} - \frac{2}{3}, \quad \text{with } a := \frac{5}{\pi R^2}, \quad h \in [0, P(0) - E_0].
\end{aligned}$$

We have

$$\begin{aligned}
F_0(0) &= 0, \quad F_0(P(0) - E_0) = F_0\left(\frac{7}{15} \pi R^2\right) = \sqrt{\frac{7}{3} + \frac{4}{9}} - \frac{2}{3} = 1, \\
F_0'(h) &= \frac{a}{2} \frac{1}{\sqrt{ah + \frac{4}{9}}}, \\
F_0'(0) &= \frac{3}{4} a, \quad F_0'(P(0) - E_0) = \frac{3a}{10}, \\
F_0''(h) &= -\frac{a^2}{4} \frac{1}{\left(\sqrt{ah + \frac{4}{9}}\right)^3}.
\end{aligned}$$

From [5, p. 306] it follows that

$$\begin{aligned}
H_{F_0'}(h) &= \int_0^h \frac{F_0'(s)}{\sqrt{h-s}} ds = \frac{a}{2} \int_0^h \frac{ds}{\sqrt{as + \frac{4}{9}} \sqrt{h-s}} \\
&= \frac{a}{2} \frac{2}{\sqrt{a}} \operatorname{arctg} \sqrt{\frac{(as + 4/9)}{a(h-s)}} \Big|_{s=0}^{s=h} = \sqrt{a} \left(\frac{\pi}{2} - \operatorname{arctg} \left(\frac{2}{3} \frac{1}{\sqrt{a}} \frac{1}{\sqrt{h}} \right) \right).
\end{aligned}$$

Differentiating the last expression, we obtain

$$\begin{aligned}
\frac{d}{dh} H_{F_0'}(h) &= -\frac{\sqrt{a}}{1 + \frac{4}{9} \frac{1}{a} \frac{1}{h}} \frac{2}{3} \cdot \frac{1}{\sqrt{a}} \left(-\frac{1}{2} \right) \frac{1}{h^{3/2}} \\
&= \frac{1}{3} \frac{1}{h + \frac{4}{9} \frac{1}{a}} \cdot \frac{1}{\sqrt{h}} > 0, \quad h \in (0, P(0) - E_0).
\end{aligned}$$

We conclude that $H_{F_0'}$ is in $AC[0, P(0) - E_0]$, $H_{F_0'}(0) = 0$ and $\frac{d}{dh} H_{F_0'}(h) > 0$ on $(0, P(0) - E_0)$. Hence, by virtue of Theorem 4.2 1) and 4.2 2), p is extendable and

$$q(h) := \frac{1}{4\pi\sqrt{2}} \frac{2}{\pi} \frac{d}{dh} H_{F_0'}(h) = \frac{\sqrt{2}}{4\pi^2} \frac{1}{3} \frac{1}{h + \frac{4}{9} \frac{1}{a}} \cdot \frac{1}{\sqrt{h}} > 0$$

is the unique solution of Eddington's equation (4.1).

This example illustrates as well the inverse problem (with known p) as the direct problem (with known q — in Section 6). It will be expanded further in Section 8.

Example 5.2

$$p(r) := \begin{cases} \left(1 - \frac{r}{R}\right)^2, & 0 \leq r \leq R, \\ 0, & R < r, R > 0. \end{cases}$$

This is an example, which allows to decide about its extendability easily by means of Theorem 4.2 3) (b). For $0 \leq r \leq R$, we have

$$p'(r) = -\frac{2}{R} + 2\frac{r}{R^2}, \quad p''(r) = \frac{2}{R^2}.$$

The function $\frac{2}{r}p'(r) + p''(r) = \frac{6}{R^2} - \frac{4}{rR}$ changes its sign at the point $\frac{2R}{3} \in (0, R)$. Thus Theorem 4.2 3) (c) is not applicable. From (2.1) we obtain

$$\begin{aligned} P(r) &= 4\pi \left[\frac{1}{r} \int_0^r \left(s^2 - \frac{2s^3}{R} + \frac{s^4}{R^2} \right) ds + \int_r^R \left(s - \frac{2s^2}{R} + \frac{s^3}{R^2} \right) ds \right] \\ &= 4\pi \left[\frac{1}{3} r^2 - \frac{1}{2} \frac{r^3}{R} + \frac{1}{5} \frac{r^4}{R^2} + \frac{1}{2} (R^2 - r^2) - \frac{2}{3} \frac{1}{R} (R^3 - r^3) + \frac{1}{4} \frac{1}{R^2} (R^4 - r^4) \right] \\ &= 4\pi \left[-\frac{1}{6} r^2 + \frac{1}{6} \frac{r^3}{R} - \frac{1}{20} \frac{r^4}{R^2} + \frac{3}{4} R^2 \right], \\ P'(r) &= 4\pi \left[-\frac{1}{3} r + \frac{1}{2} \frac{r^2}{R} - \frac{1}{5} \frac{r^3}{R^2} \right], \\ P''(r) &= 4\pi \left[-\frac{1}{3} + \frac{r}{R} - \frac{3}{5} \frac{r^2}{R^2} \right], \\ X(r) &= p'(r)P''(r) - p''(r)P'(r) \\ &= 4\pi \left[\left(-\frac{2}{R} + 2\frac{r}{R^2} \right) \left(-\frac{1}{3} + \frac{r}{R} - \frac{3}{5} \frac{r^2}{R^2} \right) - \frac{2}{R^2} \left(-\frac{1}{3} r + \frac{1}{2} \frac{r^2}{R} - \frac{1}{5} \frac{r^3}{R^2} \right) \right] \\ &= \frac{4\pi}{R} \left(\frac{2}{3} - 2\alpha + \frac{11}{5} \alpha^2 - \frac{4}{5} \alpha^3 \right) =: \frac{4\pi}{R} f(\alpha) \text{ with } \alpha := \frac{r}{R} \leq 1. \end{aligned}$$

On $[0, 1]$ we have $f'(\alpha) = -2 + \frac{22}{5} \alpha - \frac{12}{5} \alpha^2$. It is easy to see that f is decreasing on $\left[0, \frac{5}{6}\right]$, increasing on $\left[\frac{5}{6}, 1\right]$, and $f(5/6) = \frac{7}{108}$. Hence $f(\alpha) > 0$ on $[0, 1]$ and $X(r) > 0$ on $(0, R)$. Hence, by virtue of Theorem 4.2 3) (b) p is extendable.

In this case it is not possible to calculate P^{-1} explicitly (as in Example 5.1), because $P(r)$ is a monotone non special polynomial of degree 4.

Example 5.3

$$p(r) := \begin{cases} e^{-r} - e^{-R}, & 0 \leq r \leq R \\ 0, & R < r, R > 0. \end{cases}$$

We have for $0 < r \leq R$

$$p'(r) = -e^{-r}, \quad p''(r) = e^{-r},$$

$$\begin{aligned}
P(r) &:= 4\pi \left[\frac{1}{r} \int_0^r (e^{-s} - e^{-R}) s^2 ds + \int_r^R (e^{-s} - e^{-R}) s ds \right] \\
&= 4\pi \left[\frac{1}{r} \left(e^{-s} (-s^2 - 2s - 2) - e^{-R} \frac{s^3}{3} \right) \Big|_0^r + \left(e^{-s} (-s - 1) - e^{-R} \frac{s^2}{2} \right) \Big|_r^R \right] \\
&= 4\pi \left[-e^{-r} \left(r + 2 + \frac{2}{r} \right) + \frac{2}{r} - \frac{1}{3} r^2 e^{-R} - e^{-R} \left(R + 1 + \frac{R^2}{2} \right) \right. \\
&\quad \left. + e^{-r} (r + 1) + e^{-R} \frac{r^2}{2} \right] \\
&= 4\pi \left[-e^{-r} \left(1 + \frac{2}{r} \right) + \frac{2}{r} - e^{-R} \left(1 + R + \frac{R^2}{2} - \frac{r^2}{6} \right) \right], \\
P'(r) &= 4\pi \left[e^{-r} \left(1 + \frac{2}{r} + \frac{2}{r^2} \right) - \frac{2}{r^2} + \frac{1}{3} e^{-R} r \right], \\
P''(r) &= 4\pi \left[-e^{-r} \left(1 + \frac{2}{r} + \frac{4}{r^2} + \frac{4}{r^3} \right) + \frac{4}{r^3} + \frac{1}{3} e^{-R} \right].
\end{aligned}$$

We get on the triangle $\{(r, R); 0 < R, r \in (0, R]\}$

$$\begin{aligned}
X(r, R) &= p'(r)P''(r) - p''(r)P'(r) = -e^{-r} (P'(r) + P''(r)) \\
&= -4\pi e^{-r} \left[e^{-r} \left(1 + \frac{2}{r} + \frac{2}{r^2} \right) - \frac{2}{r^2} + \frac{1}{3} e^{-R} r - e^{-r} \left(1 + \frac{2}{r} + \frac{4}{r^2} + \frac{4}{r^3} \right) \right. \\
&\quad \left. + \frac{4}{r^3} + \frac{1}{3} e^{-R} \right] \\
&= 4\pi e^{-r} \left[\left\{ e^{-r} \left(\frac{2}{r^2} + \frac{4}{r^3} \right) + \frac{2}{r^2} \right\} - \left\{ \frac{4}{r^3} + \frac{e^{-R}}{3} (r + 1) \right\} \right] \\
&= 4\pi \frac{e^{-r}}{r^3} \left[\{ e^{-r} (2r + 4) + 2r \} - \left\{ 4 + \frac{1}{3} e^{-R} (r^4 + r^3) \right\} \right].
\end{aligned}$$

Because

$$\frac{\partial X}{\partial R}(r, R) = \frac{4\pi}{3} \frac{r+1}{e^{r+R}} > 0 \quad \text{for } 0 < R, r \in (0, R] \quad (5.1)$$

X is strictly increasing in direction of growing values of $R > 0$ and each r fixed in $[0, R]$.

It seems that X, P, P', P'' have singularities at $r = 0$. But they can be repaired, as shown for X in (5.2) and (5.3). For P, P', P'' it can be done in the same way. The last formula of $X(r, R)$ is not useful to calculate values of $X(r, R)$ with r near zero, because X is the difference of two large, positive terms, who have nearly equal values. Therefore we make the following transformation:

If $\tilde{X}(r, R) := e^{2r} r^3 (4\pi)^{-1} \cdot X(r, R)$, then we get

$$\tilde{X}(r, R) = \left[(2r + 4) - \frac{e^{r-R}}{3} r^3 (1 + r) + (2r - 4) e^r \right]$$

$$\begin{aligned}
&= \left[-\frac{e^{r-R}}{3} r^3 (1+r) + (2r+4) + (2r-4) \left(1+r + \frac{r^2}{2!} + \frac{r^3}{3!} + \frac{r^4}{4!} + \sum_{k=5}^{\infty} \frac{r^k}{k!} \right) \right] \\
&= \left[-\frac{e^{r-R}}{3} r^3 (1+r) + (2r+4) + (2r+2r^2 + \frac{2r^3}{2!} + \frac{2r^4}{3!} + \frac{2r^5}{4!}) \right. \\
&\quad \left. + (-4-4r - \frac{4r^2}{2!} - \frac{4r^3}{3!} - \frac{4r^4}{4!}) + (2r-4) \sum_{k=5}^{\infty} \frac{r^k}{k!} \right] \\
&= \left[-\frac{e^{r-R}}{3} r^3 (1+r) + r^3 (1 - \frac{4}{6}) + r^4 (\frac{2}{6} - \frac{1}{6}) + r^5 \frac{2}{4!} + (2r-4) \sum_{k=5}^{\infty} \frac{r^k}{k!} \right] \\
&= r^3 \left[-\frac{e^{r-R}}{3} (1+r) + \frac{1}{3} + \frac{r}{6} + \frac{r^2}{12} + (2r-4) r^2 \sum_{k=5}^{\infty} \frac{r^{k-5}}{k!} \right].
\end{aligned}$$

Dividing \tilde{X} by $e^{2r} r^3 (4\pi)^{-1}$ we have

$$X(r, R) = \frac{4\pi}{e^{2r}} \left[-\frac{e^{r-R}}{3} (1+r) + \frac{1}{3} + \frac{r}{6} + \frac{r^2}{12} + (2r-4) r^2 \sum_{k=5}^{\infty} \frac{r^{k-5}}{k!} \right]. \quad (5.2)$$

It follows

$$\lim_{r \rightarrow 0} X(r, R) = 4\pi \left[-\frac{1}{3e^R} + \frac{1}{3} \right] \in \left(0, \frac{4\pi}{3} \right] \quad \text{for } R > 0. \quad (5.3)$$

First we calculate $X(r, r)$

$$\begin{aligned}
X(r, r) &= \frac{4\pi}{e^{2r}} \left[-\frac{e^{r-r}}{3} (1+r) + \frac{1}{3} + \frac{r}{6} + \frac{r^2}{12} + (2r-4) r^2 \sum_{k=5}^{\infty} \frac{r^{k-5}}{k!} \right] \\
&= \frac{4\pi}{e^{2r}} r \left[\frac{r}{12} - \frac{1}{6} + (2r-4) \sum_{k=5}^{\infty} \frac{r^{k-4}}{k!} \right] \\
&\begin{cases} = 0 & \text{for } r = 2, \\ > 0 & \text{for } 2 < r, \\ < 0 & \text{for } r < 2. \end{cases} \quad (5.4)
\end{aligned}$$

A possible application of Theorem 4.2 3) (b) requires the determination of the sign of $X(r, R)$ for $0 < r < R$. We distinguish between two cases

$$(1) R \geq 2 \quad \text{and} \quad (2) R < 2$$

In case (1) and for $0 < r < 2$ we know from (5.1) and Chart (5.1) (Diagram 5.1), that

$$X(r, R) > X(r, 2) > 0,$$

for $2 \leq r < R$ we have with (5.1) and (5.4) that

$$X(r, R) > X(r, r) \geq 0.$$

It follows that for case (1) $R \geq 2$ we have $X(r, R) > 0$ for $0 < r < R$ and p is extendable by Theorem 4.2 3) (b).

In the case (2) with $0 < R < 2$, we know from (5.4) that $X(r, r) < 0$, on the other hand $X(r, 2) > 0$ for $r \in [0, 2)$. By (5.1) there exist a unique zero of $X(r, R)$ between R and 2 for each r fixed in $(0, 2)$. The zeros lie on a monotone curve produced by $X(r, R) = 0$ in the neighborhood above the diagonal (see Diagram 5.1) :

$$R(r) = -\ln \left(6 \frac{(r+2)e^{-r} + r - 2}{(r+1)r^3} \right) \text{ for } 0 < r \leq R < 2.$$

Therefore the extendability of p can be only decided with Theorem 4.2 2) or (4.7) of Remark 4.4. The integral is not calculable explicitly and the integrand is singular at the left end of the integration interval. But the integral can be approximated by a Newton-Cotes formula avoiding border points (for instance the Midpoint Rule). The error occurring by using approximation formulas has to be carefully estimated against the preceding term $p'(R)/P'(r)$ to claim the extendability of p by Theorem 4.2 2). Such a case will be treated in Example 5.6 and we leave the details here to the reader.

Chart 5.1 $X(r, 2)$ for $0 \leq r \leq 2$

r	0	10^{-5}	0.25	0.5	0.75	1	1.25	1.5	1.75	2
$X(r, 2)$	3.6220	3.6218	2.33	1.47	0.910	0.541	0.302	0.151	0.056	0

Diagram 5.1 Ranges of positive and negative values of $X(r, R)$

Example 5.4

$$p(r) := \begin{cases} r^{-b} - R^{-b}, & 0 < r \leq R \\ 0, & R < r, R > 0, 0 < b < 3. \end{cases}$$

First, we note that, if $b < 3$, then $p(r) \in \mathcal{D}_R^-(L)$.

For $0 < r \leq R$, we have

$$p'(r) = -br^{-b-1}, \quad p''(r) = b(b+1)r^{-b-2}.$$

For $1 < b < 3$ we get

$$\frac{2}{r} p'(r) + p''(r) = -2br^{-b-2} + b(b+1)r^{-b-2} = b(b-1)r^{-b-2} > 0,$$

and it follows from Theorem 4.2 3) (c) that p is extendable.

For $0 < b < 3$, $b \neq 2$ and $0 < r < R$, we have

$$\begin{aligned} P(r) &= 4\pi \left[\frac{1}{r} \int_0^r (s^{-b+2} - R^{-b}s^2) ds + \int_r^R (s^{-b+1} - R^{-b}s) ds \right] \\ &= 4\pi \left[\frac{1}{-b+3} r^{-b+2} - \frac{1}{3} R^{-b} r^2 + \left(\frac{1}{-b+2} s^{-b+2} - R^{-b} \frac{s^2}{2} \right) \Big|_r^R \right] \\ &= 4\pi \left[\frac{r^{-b+2}}{-b+3} - R^{-b} \frac{r^2}{3} + \frac{R^{-b+2}}{-b+2} - \frac{r^{-b+2}}{-b+2} - \frac{R^{-b+2}}{2} + \frac{R^{-b} r^2}{2} \right] \\ &= 4\pi \left[\frac{-r^{-b+2}}{(-b+3)(-b+2)} + \frac{1}{6} R^{-b} r^2 + \frac{b}{2(-b+2)} R^{-b+2} \right]. \end{aligned}$$

For $0 < r < R$, we have

$$\begin{aligned} \frac{X(r)}{4\pi} &= (-b)r^{-b-1} \left(\frac{b-1}{-b+3} r^{-b} + \frac{1}{3} R^{-b} \right) - b(b+1)r^{-b-2} \left(\frac{-r^{-b+1}}{-b+3} + \frac{1}{3} R^{-b} r \right) \\ &= \frac{2b}{-b+3} r^{-2b-1} - \frac{1}{3} (b^2 + 2b) R^{-b} r^{-b-1} \\ &= \frac{R^{-b} r^{-b-1}}{-b+3} \left(2b \left(\frac{R}{r} \right)^b - \frac{b^2}{3} (3-b) - \frac{2b}{3} (3-b) \right) \\ &= \frac{R^{-b} r^{-b-1}}{-b+3} \cdot b \cdot \left(2 \left(\left(\frac{R}{r} \right)^b - 1 \right) + \frac{1}{3} (b^2 - b) \right). \end{aligned}$$

For $1 \leq b < 3$, $b \neq 2$, we get $X(r) > 0$ and we conclude from Theorem 4.2 3) (b) that p is extendable.

For $0 < b < 1$, X has a zero at r_0 on $(0, R)$, which is a solution of the equation

$$\left(\frac{R}{r} \right)^b - 1 - \frac{1}{6} (b - b^2) = 0.$$

It follows

$$\frac{r_0}{R} = \left(\frac{6}{6 + (b - b^2)} \right)^{\frac{1}{b}}.$$

We have $\frac{r_0}{R} = 0,9216$ for $b = \frac{1}{2}$, $\frac{r_0}{R} = 1$ for $b = 1$, and $\lim_{b \rightarrow 0} \frac{r_0}{R}(b) = e^{-1/6} \approx 0,8465$.

The existence of a zero of X requires the application of Theorem 4.2 2). We omit the details.

Example 5.5

This example is intended to illustrate the direct problem with given q and p calculated approximately in Section 8.

Let $q(s) := c\sqrt{s}$, where $c > 0$. Then, changing the variable $s = h \sin^2 t$, we have

$$F_0(h) := 4\pi\sqrt{2} \cdot c \int_0^h \sqrt{s} \sqrt{h-s} ds = \frac{\pi^2 c}{\sqrt{2}} h^2.$$

see [5, p. 307].

Example 5.6 An unextendable p .

The aim of this example is to show numerically that not all p , which satisfy the assumptions of Theorem 4.2, are automatically extendable. That is, we construct a p that will differ in important details from the extendable examples so far given: whereas all our examples p where either convex or concave on $[0, R]$, this example will be concave in the subinterval $[0, w]$ and convex in $[w, R]$ for some $0 < w < R$ ($p''(w) = 0$). Inequality (4.3) and formula (4.7) will play an important role.

We shall construct a function

$$p(r) = \begin{cases} a_0 + a_1 r + a_2 r^2 + a_3 r^3 + a_4 r^4, & r \in [0, R], \\ 0, & r > R, \end{cases}$$

such that $p \in \mathcal{D}_R^-(L)$ and $\frac{d}{dh} H_{F_0}'(h) < 0$ for some $h \in (0, P(0) - E_0)$. Then, by virtue of Theorem 4.2 2), p will be not extendable.

The condition $p \in \mathcal{D}_R^-(L)$ requires

$$p(0) > 0, \tag{5.5}$$

$$p(R) = 0, \tag{5.6}$$

We add the properties

$$p'(0) = 0, \tag{5.7}$$

$$p'(R) = 0, \tag{5.8}$$

$$p''(w) = 0 \quad \text{for some } w \in (0, R). \tag{5.9}$$

The equalities (5.8) and (4.4) imply that $F'_0(0) = 0$ and this simplifies (4.7).

A moments' reflexion shows then that (5.5), (5.6), (5.7), (5.8), (5.9) hold if and only if $a_0 > 0$, $a_1 = 0$ and

$$a_2R^2 + a_3R^3 + a_4R^4 = -a_0, \quad (5.10)$$

$$2a_2R + 3a_3R^2 + 4a_4R^3 = 0, \quad (5.11)$$

$$2a_2 + 6a_3w + 12a_4w^2 = 0. \quad (5.12)$$

Further we assume that

$$R = 2, \quad w = \frac{13}{10}, \quad a_0 = 2. \quad (5.13)$$

This choise of R, w, a_0 cannot be made arbitrarily. Tests of different values of R show that for $w \leq R/4$ or $3R/4 \leq w$ p will never be strictly monotone decreasing whatever $a_0 > 0$ may be. For $R/4 < w \leq R/2$ p is strictly decreasing, but X is nowhere zero in $(0, R)$. For $R/2 < w < 3R/4$ p is strictly decreasing and X has a zero in $(0, R)$.

The determinant of linear algebraic system (5.10)–(5.12) relatively to a_2, a_3 , and a_4 is not zero. Therefore there exists exactly one solution of system (5.10)–(5.12)

$$a_2 = -\frac{39}{146}, \quad a_3 = -\frac{107}{146}, \quad a_4 = \frac{45}{146}.$$

We now have

$$p(r) = 2 + \frac{1}{146} (-39r^2 - 107r^3 + 45r^4), \quad (5.14)$$

$$p'(r) = \frac{1}{146} (-78r - 321r^2 + 180r^3), \quad (5.15)$$

$$p''(r) = \frac{1}{146} (-78 - 642r + 540r^2), \quad (5.16)$$

(see Diagram 5.2).

From (5.15) it follows that $p'(r) < 0$ for $r \in (0, 2)$. This implies that $p \in \mathcal{D}_R^-(L)$.

In order to calculate $P(r)$, we remark that it is easy to see that

$$L(r^l) = 4\pi \left(-\frac{r^{l+2}}{(l+2)(l+3)} + \frac{R^{l+2}}{l+2} \right), \quad l = 0, 1, 2, \dots, \quad (5.17)$$

wich directly implies for $l = 0, 2, 3, 4$ the bracket terms in the following formular

$$\begin{aligned} P(r) &= Lp(r) \\ &= 4\pi \left[a_0 \left(-\frac{r^2}{6} + \frac{R^2}{2} \right) + a_2 \left(-\frac{r^4}{20} + \frac{R^4}{4} \right) + a_3 \left(-\frac{r^5}{30} + \frac{R^5}{5} \right) + a_4 \left(-\frac{r^6}{42} + \frac{R^6}{6} \right) \right] \\ &= 4\pi \left[-\frac{1}{3}r^2 + \frac{39}{2920}r^4 + \frac{107}{4380}r^5 - \frac{15}{2044}r^6 + \frac{558}{365} \right]. \end{aligned}$$

Diagram 5.2 for p, p' and p'' 

Calculating $P'(r)$ and $P''(r)$ and substituting these derivatives into the equality $X(r) = p'(r)p''(r) - p''(r)p'(r)$, we have

$$X(r) = \frac{4\pi}{746060} [-1093540r^2 + 1183812r^3 - 233688r^4 - 330515r^5 + 329025r^6 - 81000r^7].$$

It is easy to see that the function $X = X(r)$ has the zero at $r_0 = 0$ and $X(1) < 0, X(2) > 0$. Therefore there is a zero of $X(r)$ at $r_1, 1 < r_1 < 2$ with the approximate value of $r_1 \approx w + 0.0575585$ (see Diagram 5.3). (Occasionally, we work with equivalent fractions of entire numbers to avoid rounding errors of decimal representations.)

Diagram 5.3 for X, P, P' and P'' 

Our aim is to show that there exists a point $h \in (0, P(0) - E_0)$ such that $\frac{d}{dh}H_{F_0}(h) < 0$. By virtue of Theorem 4.2 2), this means that p is not extendable. Because $p'(r) = 0$,

(4.7) shows that the sign of $\frac{d}{dh}H_{F'_0}(h)$ is equal to the sign of the integral on the right side of (4.7). Therefore we have to investigate its integrand

$$J(r, h) := \frac{X(r)}{|P'(r)|^2} \sqrt{\frac{P(\Phi(h)) - P(R)}{P(\Phi(h)) - P(r)}}.$$

As it was shown in the proof of Theorem 4.2,

$$\Phi : [0, P(0) - E_0] \rightarrow (0, R], h \mapsto \Phi(h) = P^{-1}(h + E_0)$$

is a C^2 -diffeomorphism. If $r \in (\Phi(h), R)$, then $P(\Phi(h)) > P(r) > P(R)$. Hence $P(\Phi(h)) - P(r) < P(\Phi(h)) - P(R)$, i.e.

$$\frac{P(\Phi(h)) - P(R)}{P(\Phi(h)) - P(r)} > 1, \quad \text{and} \quad \lim_{r \rightarrow \Phi(h)} \frac{P(\Phi(h)) - P(R)}{P(\Phi(h)) - P(r)} = \infty,$$

and because $J(R)$ and $X(r)$ always have the same sign, that is,

$$J(r) < 0 \text{ for } \Phi(h) < r < r_1 \text{ and } J(r) > 0 \text{ for } r_1 < r < R.$$

Since Φ is a bijection from $[0, P(0) - E_0]$ onto $(0, R]$, for a given $\tilde{r} := 0.01 \in (0, R)$, there exists a unique $\tilde{h} \in [0, P(0) - E_0]$ such that $\Phi(\tilde{h}) = \tilde{r} = 0.01$.

By virtue of Lemma 2.2, $P(r) \in C^2(\mathbb{R}_+)$. Therefore, using Taylor's formula, we have $P(\Phi(\tilde{h})) - P(r) = P'(r + \theta(\Phi(\tilde{h}) - r))(\Phi(\tilde{h}) - r)$, where $0 < \theta < 1$. We denote

$$c_0 := \min_{r \in [\tilde{r}, R]} |P'(r)|, \quad c_1 := |P(\Phi(\tilde{h})) - P(R)|, \quad c_2 := \max_{r \in [\tilde{r}, R]} |X(r)|.$$

Clearly, $0 < c_i < \infty$ ($i = 0, 1, 2$). Then we have

$$J(r, \tilde{h}) \leq \frac{\sqrt{c_1 c_2}}{c_0^2} \cdot \frac{1}{\sqrt{\Phi(\tilde{h}) - r}}.$$

Therefore the function $J(r, \tilde{h})$ is integrable with respect to r over the interval $(\Phi(\tilde{h}), R)$.

Now we are going to show that $\frac{d}{dh}H_{F'_0}(h)|_{h=\tilde{h}} < 0$ by proving the following inequality:

$$\int_{\Phi(\tilde{h})}^R J(r, \tilde{h}) dr < 0. \quad (5.18)$$

To this end, we introduce two rectangular triangles

$$T_1 := \{(0.01; 0), (0.01; -4), (0.31; 0)\} \quad \text{and} \quad T_2 := \{(1.3; 0), (2; 1.21), (2; 0)\}$$

with their hypotenuses

$$g_1(r) = \frac{4}{0.3}(r - 0.31) \text{ for } r \in [0.01, 0.31] \text{ and } g_2(r) = \frac{1.21}{0.7}(r - 1.3) \text{ for } r \in [1.3, 2]$$

(see Diagram 5.4).

Numerical calculations show (see Charts 5.2 and 5.3) that

$$0 > g_1(r) > J(r, \tilde{h}) \text{ for } r \in [0.01, 0.31] \quad \text{and} \quad 0 < J(r, \tilde{h}) < g_2(r) \text{ for } r \in [1.3, 2].$$

Diagram 5.4 for integrand J , hypotenuses g_1, g_2 and triangles T_1, T_2 .**Chart 5.2** for $g_1(r) - J(r, \tilde{h})$

r	0.01	0.1	0.15	0.175	0.2	0.31
$g_1(r) - J(r, \tilde{h})$	∞	0.832	0.182	0.129	0.173	0.937

Chart 5.3 for $g_2(r) - J(r, \tilde{h})$

r	1.3	1.5	1.7	1.9	2
$g_2(r) - J(r, \tilde{h})$	0.027	0.256	0.369	0.225	0.004

The area of T_1 is 0.60 and that of T_2 is 0.4235. Therefore, substituting the values $\Phi(\tilde{h}) = 0.01$ and $R = 2$, we obtain

$$\begin{aligned}
 \int_{\Phi(\tilde{h})}^R J(r, \tilde{h}) dr &= \int_{0.01}^{0.31} J(r, \tilde{h}) dr + \int_{0.31}^w J(r, \tilde{h}) dr + \int_w^2 J(r, \tilde{h}) dr \\
 &\leq \int_{0.01}^{0.31} g_1(r) dr + 0 + \int_w^2 g_2(r) dr = -0.60 + 0.4235 = -0.1765 < 0.
 \end{aligned}$$

This finishes the proof of the unextendability of p .

It is interesting to compare for $R = 2$ F_0, F'_0, F''_0 of Example 5.1 (p extendable) on $h \in [0, 28/15\pi]$ and 5.6 (p unextendable) on $h \in [0, \approx 10]$.

Since in Example 5.1 $F'_0 > 0$ and $F''_0 < 0$, then $F_0 > 0$ is strictly increasing and F'_0 is strictly decreasing. F''_0 is strictly decreasing, as shows its formula.

In Example 5.6 it is not possible to calculate P^{-1} explicitly (as in Example 5.1), because $P(r)$ is a monotone, nonelementary polynomial of degree 4. In such a case there still exists the following possibility:

Diagram 5.5 for F_0, F'_0, F''_0 

The set $\{(P(r_k), r_k) : 0 \leq r_k \leq R; k = 1, \dots, l; l > 0\}$ is contained in the graph of P^{-1} , therefore one can approximate P^{-1} by a polynomial of degree m ($l > 2m + 1$) with the method of least squares. With this approximation, we can calculate F, F_0, F'_0, F''_0 (here we omit the calculations).

Diagram 5.5 shows F_0 and F'_0, F''_0 enlarged with the factor 5, because the value sets of F_0 and F'_0, F''_0 are very different. We see $F_0 \geq 0$ and strictly monotone, $F'_0 \geq 0$ but not monotone, and F''_0 is not monotone and changes its sign.

6 The direct problem and its equivalent formulation

We have already mentioned in the introduction in connection with Jeans' theorem, what is called the direct problem: Given a function $q \in L^1_{\text{loc}}[0, T)$, $q > 0$ on $[0, T)$ for a sufficiently large interval $[0, T)$ — under which conditions do there exist functions (f_q, ρ, U) , which form a stationary spherically symmetric E -dependent solution of the (VPS)?

A first answer is given by Lemma 3.3 b): These functions exist if for the function

$$F(h) := 4\pi\sqrt{2} \int_0^{h-E_0} q(s) \sqrt{h-E_0-s} ds, \quad h \in [E_0, P(0)),$$

$$F = 0 \quad \text{on } (-\infty, E_0),$$

the integral equation

$$p(r) = F \circ Lp(r) \quad \text{on } \mathbb{R}_+ \quad (6.1)$$

has a solution $p \in \mathcal{D}_R^-(L)$. The following Lemma exhibits further properties of the functions involved.

Lemma 6.1 *We may assume $T > P(0) - E_0$ and define*

$$F_0(h) := F(h + E_0) = 4\pi\sqrt{2} \int_0^h q(s)\sqrt{h-s}ds, \quad 0 \leq h < P(0) - E_0. \quad (6.2)$$

Then F_0 is strictly increasing on $[0, P(0) - E_0]$, and so is F on $[E_0, P(0)]$. The solution $p \in \mathcal{D}_R$ of (6.1) such that $Lp(R) = E_0$ is in

Proof. It follows from Lemma A.5 (b), that $F_0 \in AC[0, P(0) - E_0]$ and F_0 is strictly increasing because

$$F_0'(h) = \frac{4\pi}{\sqrt{2}} \int_0^h \frac{q(s)}{\sqrt{h-s}} ds > 0 \quad \text{a.e. on } [0, P(0) - E_0].$$

We show that $p \in \mathcal{D}_R^-(L)$. If $0 < r_1 < r_2 < R$, then $Lp(r_1) > Lp(r_2)$ (Lemma 2.3 3)) and $p(r_1) = F \circ Lp(r_1) > F \circ Lp(r_2) = p(r_2)$, so that p is strictly decreasing on $(0, R)$. Using the relations $F(h) = 0$ for $h \in (-\infty, E_0)$, $Lp(R) = E_0$, and $Lp(r) < Lp(R)$ for $r > R$, we have $p(r) = F \circ Lp(r) = 0$ ($r > R$). \square

We see that the solution of the direct problem is closely connected with solving the nonlinear integral equation

$$p(r) = F \circ Lp(r) \quad \text{on } \mathbb{R}_+,$$

or — what is the same after Corollary 2.4 — on $(0, R]$. To make this equation accessible for numerical investigation, we are going to transform it into a slightly different form. Because

$$F_0: [0, P(0) - E_0] \rightarrow [0, p(0))$$

is a strictly increasing bijection (Lemma 6.1), it has a strictly increasing inverse

$$G_0: [0, p(0)) \rightarrow [0, P(0) - E_0]$$

and

$$F: [E_0, P(0)] \rightarrow [0, p(0))$$

has an inverse

$$G: [0, p(0)) \rightarrow [E_0, P(0)],$$

which has the form $G(h) = G_0(h) + E_0$. Then we get two equivalent statements in the following Lemma.

Lemma 6.2 *Let $p \in \mathcal{D}_R^-(L)$ as in (6.1), and $Lp(R) = E_0$. Then*

$$p = F \circ Lp \iff Lp - E_0 = G_0p \quad \text{on } [0, R].$$

Proof. \implies : Because $Lp(R) = E_0$, $r \leq R$ implies $Lp(r) \geq E_0$. We apply G to both parts of the equation $p = F \circ Lp$. Then we get $Gp = Lp$ or $Lp = G_0p + E_0$.

\impliedby : If $Lp - E_0 = G_0p$, then $Lp = G_0p + E_0 = G(p)$, and application of F yields $F \circ Lp = F \circ Gp = p$. \square

Now let the functions q and F be as in the beginning of this section. Our aim is to solve the integral equation (6.1), or, what is equivalent according to Lemma 6.2:

$$Lp(r) - Lp(R) = G_0p(r) \text{ on } [0, R]. \quad (6.3)$$

Our first aim is to consider (6.3) at the points $r = R_k$ of the equidistant partition

$$0 = R_0 < R_1 < R_2 < \dots < R_n := R, \quad R_k := k \frac{R}{n}, \quad k = 0, \dots, n, \text{ of } R.$$

To this end, we introduce the space of piecewise linear functions

$$p_{R_0 R_1 \dots R_{n-1} R_n}^{x_0 x_1 \dots x_{n-1} x_n}(r) := -\frac{r - R_k}{R_k - R_{k-1}} x_{k-1} + \frac{r - R_{k-1}}{R_k - R_{k-1}} \cdot x_k \text{ on } [R_{k-1}, R_k],$$

$k = 1, \dots, n$, with the property

$$p_{R_0 R_1 \dots R_{n-1} R_n}^{x_0 x_1 \dots x_{n-1} x_n}(R_k) = x_k, \quad k = 0, \dots, n.$$

A basis for this space is the set

$$\left\{ p_{R_{k-1} R_k R_{k+1}}^{010}, \quad k = 0, 1, \dots, n-1 \right\},$$

where for the sake of unified notation, we have defined

$$p_{R_{k-1} R_k R_{k+1}}^{010} \big|_{k=0} := p_{R_0 R_1}^{10}$$

(R_{-1} is not defined). Any piecewise linear p with $0 = p(R) = p(R_n) = x_n$ can be represented in the form

$$p(r) = \sum_{k=0}^{n-1} x_k p_{R_{k-1} R_k R_{k+1}}^{010} \quad (6.4)$$

and its image under L is

$$Lp(r) = \sum_{k=0}^{n-1} x_k Lp_{R_{k-1} R_k R_{k+1}}^{010}(r).$$

If $(x_0, x_1, \dots, x_{n-1})$ is a solution of the system

$$\sum_{k=0}^{n-1} \left(Lp_{R_{k-1} R_k R_{k+1}}^{010}(R_i) - Lp_{R_{k-1} R_k R_{k+1}}^{010}(R) \right) x_k = G_0(x_i), \quad (ANS)$$

$i = 0, 1, \dots, n-1$, and if we define p by (6.4) and $Lp(R) =: E_0$, then

$$Lp(r) - E_0 = G_0(p(r)) \text{ for } r = R_0, R_1, \dots, R_{n-1}.$$

The system is also satisfied for $r = R$ because $Lp(R) = E_0$ and $G_0(p(R)) = 0$. We call (ANS) the “approximating nonlinear system”. It will be the subject of the next section.

7 The approximating nonlinear system (ANS)

The approximating nonlinear system (ANS) has the form

$$Ax = G_0(x),$$

where for a vector $x \in \mathbb{R}^n$, we define $G_0(x) := (G_0(x_i))_{i=0}^{n-1}$ and A is the $n \times n$ matrix with coefficients A_{ik} ,

$$A_{ik} := Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_i) - Lp_{R_{k-1}R_kR_{k+1}}^{010}(R) =: B_{ik} - C_k, \quad i, k = 0, 1, \dots, n-1. \quad (7.1)$$

The expressions $Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_i)$ are composed of terms of the form

$$(i) \quad L_I p_{RS}^{01}(r) := Lp_{RS}^{01}(r), \quad 0 \leq r \leq R < S,$$

$$(ii) \quad L_I p_{ST}^{10}(r) := Lp_{ST}^{10}(r), \quad 0 \leq r \leq S < T,$$

$$(iii) \quad L_{II} p_{RS}^{01}(r) := Lp_{RS}^{01}(r), \quad 0 \leq R < S \leq r,$$

$$(iv) \quad L_{II} p_{ST}^{10}(r) := Lp_{ST}^{10}(r), \quad 0 \leq S < T \leq r,$$

where $p_{RS}^{01}(s) = \frac{s-R}{S-R} \chi_{[R,S]}(s)$, $p_{ST}^{10}(s) = \frac{s-T}{S-T} \chi_{[S,T]}(s)$. If $p \in L^\infty(R_+)$ and $sp \in L^1(R_+)$, we have

$$Lp(0) := \lim_{r \downarrow 0} Lp(r) = 4\pi \cdot \lim_{r \downarrow 0} \left[\frac{1}{r} \int_0^r p(s)s^2 ds + \int_r^\infty p(s)s ds \right] = 4\pi \int_0^\infty p(s)s ds.$$

For $a, b \in \mathbb{R}$ and $n \geq 2$, we shall apply the formula

$$a^n - b^n = (a-b)(a^{n-1} + a^{n-2}b + \dots + ab^{n-2} + b^{n-1}). \quad (7.2)$$

The calculation of the expressions (i)–(iv) requires the following lemma.

Lemma 7.1

(i) Let $0 \leq r \leq R < S$. Then we have

$$\begin{aligned} L_I p_{RS}^{01}(r) &= \frac{4\pi}{S-R} \int_R^S (s-R)s ds = \frac{4\pi}{S-R} \left(\frac{s^3}{3} - R \frac{s^2}{2} \Big|_R^S \right) \\ &= \frac{4\pi}{S-R} \left[\frac{1}{3}(S^3 - R^3) - \frac{R}{2}(S^2 - R^2) \right] \\ &= 4\pi \left[\frac{1}{3}(S^2 + SR + R^2) - \frac{R}{2}(S+R) \right] \quad \text{with (7.2)} \\ &= 4\pi \left[\frac{1}{3}S^2 - \frac{1}{6}SR - \frac{1}{6}R^2 \right] = \frac{4\pi}{3} \left[S^2 - \frac{1}{2}R(S+R) \right]. \end{aligned}$$

(ii) Let $0 \leq r \leq S < T$. Then we have

$$\begin{aligned} L_{\text{I}} p_{ST}^{10}(r) &= 4\pi \cdot \frac{(-1)}{T-S} \int_S^T (s-T)s ds = -\frac{4\pi}{T-S} \left(\frac{s^3}{3} - T \frac{s^2}{2} \right) \Big|_S^T \\ &= -\frac{4\pi}{T-S} \left[\frac{1}{3} (T^3 - S^3) - \frac{1}{2} T (T^2 - S^2) \right] \\ &= -4\pi \left[\frac{1}{3} (T^2 + TS + S^2) - \frac{1}{2} T (T + S) \right] = \frac{4\pi}{3} \left[\frac{1}{2} T (T + S) - S^2 \right]. \end{aligned}$$

(iii) Let $0 \leq R < S \leq r$. Then we have

$$\begin{aligned} L_{\text{II}} p_{RS}^{01}(r) &= \frac{4\pi}{r} \frac{1}{S-R} \int_R^S (s-R)s^2 ds = \frac{4\pi}{r} \frac{1}{S-R} \left(\frac{s^4}{4} - R \frac{s^3}{3} \right) \Big|_R^S \\ &= \frac{4\pi}{r} \frac{1}{S-R} \left[\frac{1}{4} (S^4 - R^4) - \frac{R}{3} (S^3 - R^3) \right] \\ &= \frac{4\pi}{r} \left[\frac{1}{4} (S^3 + S^2R + SR^2 + R^3) - \frac{R}{3} (S^2 + RS + R^2) \right] \\ &= \frac{\pi}{r} \left[S^3 - \frac{1}{3} (S^2R + SR^2 + R^3) \right]. \end{aligned}$$

(iv) Let $0 \leq S < T \leq r$. Then we have

$$\begin{aligned} L_{\text{II}} p_{ST}^{10}(r) &= \frac{-4\pi}{r} \frac{1}{T-S} \int_S^T (s-T)s^2 ds = -\frac{4\pi}{r} \frac{1}{T-S} \left(\frac{s^4}{4} - \frac{T s^3}{3} \right) \Big|_S^T \\ &= -\frac{4\pi}{r} \frac{1}{T-S} \left[\frac{1}{4} (T^4 - S^4) - \frac{T}{3} (T^3 - S^3) \right] \\ &= -\frac{4\pi}{r} \left[\frac{1}{4} (T^3 + ST^2 + S^2T + S^3) - \frac{T}{3} (T^2 + ST + S^2) \right] \\ &= \frac{\pi}{r} \left[\frac{1}{3} (T^3 + T^2S + TS^2) - S^3 \right]. \end{aligned}$$

In order to calculate the B_{ik} and C_k we divide the square $\{(i, k) : i, k = 0, 1, 2, \dots, n-1\}$ into subsections J_0, \dots, J_5 :

$$J_0 := \{(0, 0)\},$$

$$J_1 := \{(i, 0) : i = 1, \dots, n-1\},$$

$$J_2 := \{(0, k) : k = 1, \dots, n-1\},$$

$$J_3 := \{(i, k) : 2 \leq i \leq n-1, 1 \leq k \leq i-1\},$$

Diagram 7.1

$$J_4 := \{(i, k) : i = k = 1, \dots, n-1\},$$

$$J_5 := \{(i, k) : 1 \leq i \leq k-1, 2 \leq k \leq n-1\}.$$

Lemma 7.2 (Calculation of the $B_{ik} = Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_i)$).

$J_0 = \{0, 0\}$. By Lemma 7.1, (ii), we get

$$B_{00} = L_I p_{0R_1}^{10}(0) = \frac{4\pi}{3} \frac{1}{2} R_1^2 = \frac{2\pi}{3} \left(\frac{R}{n}\right)^2.$$

$J_1 = \{(i, 0) : i = 1, \dots, n-1\}$. By Lemma 7.1, (iv), we obtain

$$B_{i0} = L_{II} p_{0R_1}^{10}(R_i) = \frac{\pi}{i} \frac{1}{3} \left(\frac{R}{n}\right)^3 = \frac{\pi}{3} \frac{1}{i} \left(\frac{R}{n}\right)^2.$$

$J_2 = \{(0, k) : k = 1, \dots, n-1\}$. By Lemma 7.1, (i), (ii), we get

$$\begin{aligned} B_{0k} &= Lp_{R_{k-1}R_kR_{k+1}}^{010}(0) = L_I p_{R_{k-1}R_k}^{01}(0) + L_I p_{R_kR_{k+1}}^{10}(0) \\ &= \frac{4\pi}{3} \left[R_k^2 - \frac{1}{2} R_{k-1} (R_k + R_{k-1}) \right] + \frac{4\pi}{3} \left[\frac{1}{2} R_{k+1} (R_{k+1} + R_k) - R_k^2 \right] \\ &= \frac{4\pi}{3} \left(\frac{R}{n}\right)^2 \left[k^2 - \frac{1}{2} (k-1)(2k-1) + \frac{1}{2} (k+1)(2k+1) - k^2 \right] \\ &= \frac{2\pi}{3} \left(\frac{R}{n}\right)^2 [-(2k^2 - k - 2k + 1) + (2k^2 + k + 2k + 1)] = 4\pi k \left(\frac{R}{n}\right)^2. \end{aligned}$$

$J_3 = \{(i, k) : 2 \leq i \leq n-1, 1 \leq k \leq i-1\}$. By virtue of Lemma 7.1,(iii),(iv), we obtain

$$\begin{aligned}
 B_{ik} &= Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_i) = L_{\Pi}p_{R_{k-1}R_k}^{01}(R_i) + L_{\Pi}p_{R_kR_{k+1}}^{10}(R_i) \\
 &= \frac{\pi}{R_i} \left[R_k^3 - \frac{1}{3} (R_k^2 R_{k-1} + R_k R_{k-1}^2 + R_{k-1}^3) \right. \\
 &\quad \left. + \frac{1}{3} (R_{k+1}^3 + R_{k+1}^2 R_k + R_{k+1} R_k^2) - R_k^3 \right] \\
 &= \frac{\pi}{i} \frac{1}{3} \left(\frac{R}{n} \right)^2 \left[- (k^2(k-1) + k(k-1)^2 + (k-1)^3) + (k+1)^3 \right. \\
 &\quad \left. + (k+1)^2 k + (k+1)k^2 \right] \\
 &= \frac{\pi}{i} \frac{1}{3} \left(\frac{R}{n} \right)^2 [12k^2 + 2] = 4\pi \left(\frac{R}{n} \right)^2 \frac{1}{i} \left(k^2 + \frac{1}{6} \right).
 \end{aligned}$$

$J_4 = \{(i, k) : i = k = 1, \dots, n-1\}$. By virtue of Lemma 7.1,(iii),(ii), we have

$$\begin{aligned}
 B_{kk} &= Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_k) = L_{\Pi}p_{R_{k-1}R_k}^{01}(R_k) + L_{\Pi}p_{R_kR_{k+1}}^{10}(R_k) \\
 &= \frac{\pi}{R_k} \left[R_k^3 - \frac{1}{3} (R_k^2 R_{k-1} + R_k R_{k-1}^2 + R_{k-1}^3) \right] \\
 &\quad + \frac{4\pi}{3} \left[\frac{1}{2} R_{k+1} (R_{k+1} + R_k) - R_k^2 \right] \\
 &= \frac{\pi}{k} \left(\frac{R}{n} \right)^2 \left[k^3 - \frac{1}{3} (k^2(k-1) + k(k-1)^2 + (k-1)^3) \right] \\
 &\quad + \frac{4\pi}{3} \left(\frac{R}{n} \right)^2 \left[\frac{1}{2} (k+1)((k+1) + k) - k^2 \right] \\
 &= \frac{\pi}{k} \left(\frac{R}{n} \right)^2 \left[2k^2 - \frac{4}{3}k + \frac{1}{3} \right] + 4\pi \left(\frac{R}{n} \right)^2 \frac{1}{3} \left[\frac{3}{2}k + \frac{1}{2} \right] \\
 &= 4\pi \left(\frac{R}{n} \right)^2 \left[k - \frac{1}{6} + \frac{1}{12k} \right].
 \end{aligned}$$

$J_5 = \{(i, k) : 1 \leq i \leq k-1, 2 \leq k \leq n-1\}$. By virtue of Lemma 7.1,(i),(ii), we obtain

$$\begin{aligned}
 B_{ik} &= Lp_{R_{k-1}R_kR_{k+1}}^{010}(R_i) = L_{\Pi}p_{R_{k-1}R_k}^{01}(R_i) + L_{\Pi}p_{R_kR_{k+1}}^{10}(R_i) \\
 &= \frac{4\pi}{3} \left[R_k^2 - \frac{1}{2} R_{k-1} (R_k + R_{k-1}) \right] + \frac{4\pi}{3} \left[\frac{1}{2} (R_{k+1} (R_{k+1} + R_k) - R_k^2) \right] \\
 &= \frac{4\pi}{3} \left(\frac{R}{n} \right)^2 \left[k^2 - \frac{1}{2} (k-1)(2k-1) + \frac{1}{2} (k^2 + 2k + 1 + k^2 + k) - k^2 \right] \\
 &= \frac{4\pi}{3} \left(\frac{R}{n} \right)^2 \left[k^2 - \frac{1}{2} (2k^2 - k - 2k + 1) + \frac{1}{2} (2k^2 + 3k + 1) - k^2 \right] = 4\pi \left(\frac{R}{n} \right)^2 k.
 \end{aligned}$$

Lemma 7.3 (Calculation of the $C_k := Lp_{R_{k-1}R_kR_{k+1}}^{010}(R)$).
From Lemma 7.1, (iv), it follows that

$$C_0 = L_{\Pi}p_{R_0R_1}^{10}(R) = \frac{\pi}{3R} \cdot \left(\frac{R}{n}\right)^3.$$

By virtue of Lemma 7.1, (iii),(iv), we obtain

$$\begin{aligned} C_k &= Lp_{R_{k-1}R_kR_{k+1}}^{010}(R) = L_{\Pi}p_{R_{k-1}R_k}^{01}(R) + L_{\Pi}p_{R_kR_{k+1}}^{10}(R) \\ &= \frac{\pi}{R} \left[R_k^3 - \frac{1}{3} (R_k^2 R_{k-1} + R_{k-1}^2 R_k + R_{k-1}^3) \right. \\ &\quad \left. + \frac{1}{3} (R_{k+1}^3 + R_{k+1}^2 R_k + R_{k+1} R_k^2) - R_k^3 \right] \\ &= \frac{\pi}{R} \left(\frac{R}{n}\right)^3 \left[-\frac{1}{3} (k^2(k-1) + k(k-1)^2 + (k-1)^3) \right. \\ &\quad \left. + \frac{1}{3} ((k+1)^3 + (k+1)^2 k + (k+1)k^2) \right] \\ &= \frac{4\pi}{n} \left(\frac{R}{n}\right)^2 \left[k^2 + \frac{1}{6} \right]. \end{aligned}$$

Corollary 7.4 With $A_{ik} = B_{ik} - C_k$ we have

$$A_{ik}([0, R]) = R^2 A_{ik}([0, 1]).$$

8 The numerical analysis of the (ANS)

The aim of this section is to indicate some of the numerical procedures for solving the system

$$Ax = G_0(x) \quad (\text{ANS})$$

with the matrix $A = (A_{ik})_{i,k=0}^{n-1}$, $A_{ik} := B_{ik} - C_k$, $i, k = 0, \dots, n-1$,

where $G_0(x) := (G_0(x_i))_{i=0}^{n-1}$, $x \in (\mathbb{R}_+)^n$ for the scalar function $G_0: [0, p(0)) \rightarrow [0, P(0) - E_0)$. The matrix A depends on n ($A = A(n)$) and can be calculated with the formulas developed in Section 7. The solution $x = (x_0, x_1, \dots, x_{n-1})^T$ represents the values x_0, x_1, \dots, x_{n-1} of the approximation polygon $p_{R_0R_1\dots R_{n-1}}^{x_0x_1\dots x_{n-1}}$ at $R_0 < R_1 < \dots < R_{n-1}$ with $p_{R_0R_1\dots R_{n-1}}^{x_0x_1\dots x_{n-1}}(R) = 0$ and $x_0, x_1, \dots, x_{n-1}, x_n = 0$,
 $R_k := \frac{k}{n}R$, $k = 0, 1, \dots, n-1$.

To determine the solution x of the (ANS) we use Newton's method for the equation $Ax - G_0(x) = 0$. For the convergence of Newton's method a suitable choice of the starting point $x^{(0)}$ is crucial. In the sequence of partitions

$$\pi_{2^i} := \left\{ \frac{k}{2^i} R, k = 0, \dots, 2^i \right\}, \quad i = 0, 1, 2, \dots,$$

we use the solution $p_{\pi_{2^i}}$ as starting point for the next partition $\pi_{2^{i+1}}$ for

$n = 2, 4, 8, 16, 32, 64, 128$, and thus we are able to show that Kantorovich's criterion [11, Satz 5.6.3] (which much depends of $x^{(0)}$ and $\|x^{(0)} - x^{(1)}\|$) yields convergence of the sequences in the following two examples. For $n = 2^0 = 1$, $Ax - G_0(x) = 0$ is a one-dimensional nonlinear equation. To find a solution of this equation, the method of nested intervals by bisection can be used.

Example 5.1 of Section 5.

In this example we can calculate the operator G_0 explicitly. In fact, in Example 5.1 it was shown that

$$F: [E_0, P(0)] = \left[\frac{8}{15} \pi R^2, \pi R^2 \right] \rightarrow [0, 1], \text{ where}$$

$$F(h) = \sqrt{ah - \frac{20}{9}} - \frac{2}{3}, \quad a := \frac{5}{\pi R^2}.$$

It was also proved that

$$F_0: [0, P(0) - E_0] = \left[0, \frac{7}{15} \pi R^2 \right] \rightarrow [0, 1], \text{ where}$$

$$F_0(h) = \sqrt{ah + \frac{4}{9}} - \frac{2}{3}.$$

Therefore we have

$$G_0 := F_0^{-1}: [0, 1] \rightarrow \left[0, \frac{7}{15} \pi R^2 \right], \text{ where}$$

$$G_0(t) = \frac{\pi R^2}{5} \left(t^2 + \frac{4}{3} t \right).$$

With the described choice of starting points $x^{(0)}$ Newton's method converges for $n = 2, 4$; for $n = 8, 16, 32, 64, 128$ Kantorovich's criterion guarantees the convergence. For each n , we have carried out the iterations until the norm of Newton's improvement shows a relative error with respect to the last iteration of magnitude 10^{-9} — this had been achieved by less than 5 iterations.

Chart 8.1 illustrates the convergence of the polygons p_n as the solutions of the (ANS) on the interval $[0, R]$ for $R = 8$ towards the strict solution p of the equation $p(r) = FLp(r)$ or $Lp - E_0 = G_0(p)$, which in this case is known as $p(r) = 1 - \left(\frac{r}{R}\right)^2$. In the center of the chart there are listed the values $p_n(r_k)$ ($r_k = 0, 0.5, 1, \dots, 7.5, 8$) of the approximation polygons for $n = 2, 4, \dots, 128$. The last column contains the differences $p(r_k) - p_{128}(r_k)$, which are smaller than $5 \cdot 10^{-5}$, and show the pointwise convergence $p_n(r_k) \rightarrow p(r_k)$. The third line from last gives the L_2 -norms of the differences $p - p_n$, showing their convergence to 0 and in particular revealing the fact that doubling the number of supporting points results in dividing the L_2 -norm by 4. The last two lines list the values of the E_{0n} and the relative error $|E_0 - E_{0n}|/|E_0|$ in %. A doubling of supporting point results in a convergence factor of $1/4$ also here.

Chart 8.1 Example 5.1 of Section 5:

Approximations $p_n(r)$ of $p(r) = 1 - \left(\frac{r}{R}\right)^2$ for $R = 8$ and $n = 2, 4, 8, 16, 32, 64, 128$

Diagram 8.1 to Chart 8.1: Polygon p_{128} 

Diagram 8.2 to Chart 8.2: Polygon p_{128} **Example 5.5 of Section 5.**

First we have to compute $G_0(t) = F_0^{-1}(h)$. The equality $F_0(h) = \frac{\pi^2 c}{\sqrt{2}} h^2$ implies that

$G_0(t) = \frac{\sqrt[4]{2}}{\pi\sqrt{c}} \sqrt{t}$. To obtain comparable and clearly representable values x of the solutions in Chart 8.2 we choose $c = \sqrt{2}/(4^2 \pi^4 1000)$.

In this example we calculate the solutions p_n as in the first example with Newton's method. Again Kantorovich's criterion guarantees its convergence for $n = 4, 8, \dots, 128$.

The results are shown in Chart 8.2, which differ from Chart 8.1 in the following:

1. The last column shows the relative error (in %) of $|p_{128}(r_k) - p_{64}(r_k)| / p_{128}(r_k) \cdot 100$.
2. The third line from last reads $\text{Norm-Error}\% = 100 \cdot \left| \|p_n\|_2 - \|p_{2n}\|_2 \right| / \|p_{2n}\|_2$.
3. The last line reads $E_0 - \text{Error}\% = 100 \cdot |E_{0,n} - E_{0,2n}| / E_{0,2n}$.

9 Appendix: Abel's and Eddington's equations

The goal of this section is the existence proof for Eddington's equation. It is based on the existence proof for Abel's equation, which we treat first.

We shall use the following notation. For an interval $[0, T)$, we let

$$L_{\text{loc}}^1[0, T) := \{p: [0, T) \rightarrow \mathbb{R}; \quad p|_{[0, a]} \in L^1[0, a] \text{ for all } a \in [0, T)\},$$

$$AC[0, T) := \{p: [0, T) \rightarrow \mathbb{R}; \quad p|_{[0, a]} \text{ is absolutely continuous on } [0, a] \\ \text{for all } a \in [0, T)\} \quad [9, \text{ p. 106}].$$

We begin with two lemmas and then turn to Abel's equation.

Chart 8.2 Example 5.4 of Section 5:Approximations of $p(r)$ for $G_0(r) = 4\pi\sqrt{1000}\sqrt{r}$ for $R = 8$ and $n = 2, 4, 8, 16, 32, 64, 128$

Lemma A.1 Let $f \in L^1_{\text{loc}}[0, T)$. Then the function

$$g(x) := \int_0^x \frac{f(s)ds}{\sqrt{x-s}}, \quad x \in [0, T)$$

belongs to $L^1_{\text{loc}}[0, T)$.**Proof.** We may assume that $f \geq 0$. Using the equality

$$\int_a^b \frac{d\sigma}{\sqrt{b-\sigma}\sqrt{\sigma-a}} = \pi, \quad 0 \leq a < b,$$

and Fubini's Theorem, we obtain

$$\infty > \int_0^x f(s)ds = \frac{1}{\pi} \int_0^x f(s) \int_s^x \frac{1}{\sqrt{x-\sigma}\sqrt{\sigma-s}} d\sigma ds$$

$$\begin{aligned}
&= \frac{1}{\pi} \int_0^x \left(\int_0^\sigma \frac{f(s)}{\sqrt{\sigma-s}} ds \right) \frac{1}{\sqrt{x-\sigma}} d\sigma \\
&= \frac{1}{\pi} \int_0^x g(\sigma) \frac{1}{\sqrt{x-\sigma}} d\sigma.
\end{aligned}$$

It follows $\left(\sigma \rightarrow g(\sigma) \frac{1}{\sqrt{x-\sigma}} \right) \in L^1_{\text{loc}}[0, T)$ and $g \in L^1_{\text{loc}}[0, T)$. \square

Lemma A.2 Let $f, g \in L^1_{\text{loc}}[0, T)$. Then we have

$$\int_0^x \frac{f(s)}{\sqrt{x-s}} ds = g(x) \quad \text{a.e. on } (0, T) \quad (\text{A.1})$$

if and only if

$$\int_0^x f(s) ds = \frac{1}{\pi} \int_0^x \frac{g(s)}{\sqrt{x-s}} ds \quad \text{on } (0, T). \quad (\text{A.2})$$

Proof. Let (A.1) hold. Then

$$\begin{aligned}
\int_0^x \frac{g(s)}{\sqrt{x-s}} ds &= \int_0^x \left(\int_0^s \frac{f(\sigma)}{\sqrt{s-\sigma}} d\sigma \right) \frac{1}{\sqrt{x-s}} ds \\
&= \int_0^x f(\sigma) \left(\int_\sigma^x \frac{1}{\sqrt{x-s}\sqrt{s-\sigma}} ds \right) d\sigma = \pi \int_0^x f(\sigma) d\sigma,
\end{aligned}$$

i.e., (A.2) is fulfilled.

Now assume (A.2). Let $h(x) := \int_0^x \frac{f(s)}{\sqrt{x-s}} ds - g(x)$. We need to show $h = 0$. Lemma A.1 gives $h \in L^1_{\text{loc}}[0, T)$. As in the first part of the proof, using (A.2), we have

$$\begin{aligned}
\int_0^x \frac{h(s)}{\sqrt{x-s}} ds &= \int_0^x \frac{1}{\sqrt{x-s}} \int_0^s \frac{f(\sigma)}{\sqrt{s-\sigma}} d\sigma ds - \int_0^x \frac{g(s)}{\sqrt{x-s}} ds \\
&= \int_0^x \left(\int_\sigma^x \frac{ds}{\sqrt{x-s}\sqrt{s-\sigma}} \right) f(\sigma) d\sigma - \int_0^x \frac{g(s)}{\sqrt{x-s}} ds = \\
&= \pi \int_0^x f(\sigma) d\sigma - \int_0^x \frac{g(s)}{\sqrt{x-s}} ds = 0.
\end{aligned}$$

Hence

$$\begin{aligned}
\pi \int_0^x h(s) ds &= \int_0^x h(s) \int_s^x \frac{1}{\sqrt{x-\sigma}\sqrt{\sigma-s}} d\sigma ds = \\
&= \int_0^x \frac{1}{\sqrt{x-\sigma}} \left(\int_0^\sigma h(s) ds \right) d\sigma = 0, \quad x \in [0, T),
\end{aligned}$$

and $h = 0$ follows. \square

We now consider the solvability of Abel's equation.

Lemma A.3 (Existence and uniqueness for Abel's equation).

(a) Let $g \in L^1_{\text{loc}}[0, T)$ and assume

$$(i) \ G \in AC[0, T), \text{ where } G(x) := \int_0^x \frac{g(s)}{\sqrt{x-s}} ds,$$

$$(ii) \ G(0) = 0.$$

Then f defined by

$$f(x) := \frac{1}{\pi} G'(x)$$

is the unique solution of Abel's equation

$$g(x) = \int_0^x \frac{f(s)}{\sqrt{x-s}} ds, \quad x \in [0, T). \quad (\text{A.3})$$

(b) Conversely, if $f \in L^1_{\text{loc}}[0, T)$ and g satisfies (A.3), then $g \in AC[0, T)$, (i), (ii) hold, and

$$f(x) = \frac{1}{\pi} G'(x), \quad x \in [0, T).$$

Proof. (a) By assumption, $f \in L^1_{\text{loc}}[0, T)$, and we have

$$\int_0^x f(s) ds = \frac{1}{\pi} \int_0^x G'(s) ds = \frac{1}{\pi} (G(x) - 0) = \frac{1}{\pi} \int_0^x \frac{g(s)}{\sqrt{x-s}} ds, \quad x \in (0, T).$$

Lemma A.2 then shows that f solves (A.3). The uniqueness follows from (b).

(b) It follows from Lemma A.1 that $g \in L^1_{\text{loc}}[0, T)$. We define

$$G(x) := \int_0^x \frac{g(s)}{\sqrt{x-s}} ds.$$

Since f satisfies (A.3), Lemma A.2 gives

$$\int_0^x f(s) ds = \frac{1}{\pi} G(x), \quad x \in [0, T).$$

Hence $G \in AC[0, T)$, $G(0) = 0$, and $f(x) = \frac{1}{\pi} G'(x)$, $x \in (0, T)$, which proves the uniqueness assertion in (a). \square

Remark A.4 The example $g(s) = \frac{1}{\sqrt{s}}$, $G(x) = \int_0^x \frac{ds}{\sqrt{s}\sqrt{x-s}} = \pi$ shows that (ii) does not necessarily follow from (i).

Now we treat the solvability of Eddington's equation.

Lemma A.5 (Existence and uniqueness for Eddington's equation).

(a) Let $g \in AC[0, T)$, $g(0) = 0$, and assume that

$$(i) \ H_{g'} \in AC[0, T), \text{ where } H_{g'}(x) := \int_0^x \frac{g'(s)}{\sqrt{x-s}} ds,$$

$$(ii) \ H_{g'}(0) = 0.$$

Then f defined by

$$f(x) := \frac{2}{\pi} H'_{g'}(x) \quad (\text{A.4})$$

is the unique solution of Eddington's equation

$$g(x) = \int_0^x f(s) \sqrt{x-s} ds. \quad (\text{A.5})$$

(b) Conversely, if $f \in L^1_{\text{loc}}[0, T)$, and g satisfies (A.5), then $g \in AC[0, T)$, $g(0) = 0$, (i), (ii) hold, and f has the representation (A.4). In addition, $g'(x) = \frac{1}{2} \int_0^x \frac{f(s)}{\sqrt{x-s}} ds$.

Proof. (a) Equation (A.4), partial integration, (i) (ii), and Fubini's theorem yield

$$\begin{aligned} \int_0^x f(s) \sqrt{x-s} ds &= \frac{2}{\pi} \int_0^x H'_{g'}(s) \sqrt{x-s} ds = \frac{1}{\pi} \int_0^x \frac{H_{g'}(s)}{\sqrt{x-s}} ds \\ &= \frac{1}{\pi} \int_0^x \frac{1}{\sqrt{x-s}} \left(\int_0^s \frac{g'(\sigma)}{\sqrt{s-\sigma}} d\sigma \right) ds \\ &= \frac{1}{\pi} \int_0^x \left(\int_\sigma^x \frac{ds}{\sqrt{x-s} \sqrt{s-\sigma}} \right) g'(\sigma) d\sigma = g(x), \end{aligned}$$

that is, (A.5). Uniqueness follows from (b).

(b) Let $f \in L^1_{\text{loc}}[0, T)$, and g satisfy (A.5). We show that $g \in AC[0, T)$ and $g(0) = 0$. We formally define

$$h(x) := \int_0^x \frac{f(s)}{\sqrt{x-s}} ds.$$

By Lemma A.1, h exists a.e. on $[0, T)$ and $h \in L^1_{\text{loc}}[0, T)$. In fact, equality (A.5) and Fubini's theorem imply

$$\begin{aligned} 2g(x) &= 2 \int_0^x f(\sigma) \sqrt{x-\sigma} d\sigma = \int_0^x f(\sigma) \left(\int_\sigma^x \frac{ds}{\sqrt{s-\sigma}} \right) d\sigma \\ &= \int_0^x \left(\int_0^s \frac{f(\sigma)}{\sqrt{s-\sigma}} d\sigma \right) ds = \int_0^x h(s) ds. \end{aligned}$$

Hence $g \in AC[0, T)$, and $g(0) = 0$. Furthermore,

$$2g'(x) = h(x) = \int_0^x \frac{f(s)}{\sqrt{x-s}} ds,$$

and from Lemma A.5 it follows that

$$\int_0^x f(s) ds = \frac{2}{\pi} \int_0^x \frac{g'(s)}{\sqrt{x-s}} ds = \frac{2}{\pi} H_{g'}(x).$$

Hence $H_{g'} \in AC[0, T)$, and $H_{g'}(0) = 0$. Differentiating the last equality, we get (A.4), which also shows the uniqueness in (a). \square

10 Suggestions for further work

In Example 5.6 it was constructed a function p satisfying the assumptions of Theorem 4.2 such that according to numerical calculations the function q can have negative values, i.e. p is nonextendable. It would be interesting to give a rigorous proof of this result.

A further question is the extension of the present work to the case of cylindrical symmetry.
