# LAGUERRE-FREUD EQUATIONS FOR THE GENERALIZED CHARLIER, GENERALIZED MEIXNER AND GAUSS HYPERGEOMETRIC ORTHOGONAL POLYNOMIALS 

ITSASO FERNÁNDEZ-IRISARRI ${ }^{1}$ AND MANUEL MAÑAS ${ }^{2}$

#### Abstract

The Cholesky factorization of the moment matrix is considered for the generalized Charlier, generalized Meixner, and Gauss hypergeometric discrete orthogonal polynomials.

For the generalized Charlier, we present an alternative derivation of the Laguerre-Freud relations found by Smet and Van Assche. Third-order and second-order nonlinear ordinary differential equations are found for the recursion coefficient $\gamma_{n}$, that happen to be forms of the Painlevé deg- $\mathrm{P}_{\mathrm{V}}$ in disguise. Laguerre-Freud relations are also found for the generalized Meixner case, which are compared with those of Smet and Van Assche.

Finally, the Gauss hypergeometric discrete orthogonal polynomials, also known as generalized Hahn of type I, are also studied. Laguerre-Freud equations are found, and the differences with the equations found by Dominici and by Filipuk and Van Assche are provided.

## 1. Introduction

Discrete orthogonal polynomials are a distinguished and well-established part of the theory of orthogonal polynomials, and classical monographs have been devoted to this type of orthogonal polynomials. For example, the classical case is discussed in detail in [47], and the Riemann-Hilbert problem was considered to study asymptotics and applications in [15]. For an authoritative discussion of the subject, see [34, 35, 16, 51]. Semiclassical discrete orthogonal polynomials, where a discrete Pearson equation is fulfilled by the weight, have been extensively treated in the literature, see [24, 25, 22, 23], and references therein for a comprehensive account. For some specific types of weights of generalized Charlier and Meixner types, the corresponding Freud-Laguerre type equations for the coefficients of the three-term recurrence have been studied, see for example [19, 28, 29, 30, 50].

In [44], we used the Cholesky factorization of the moment matrix to study discrete orthogonal polynomials $\left\{P_{n}(x)\right\}_{n=0}^{\infty}$ on the homogeneous lattice. We considered semiclassical discrete orthogonal polynomials with weights subject to a discrete Pearson equation and, consequently, with moments constructed in terms of generalized hypergeometric functions. We introduced a banded semi-infinite matrix $\Psi$, named the Laguerre-Freud structure matrix, that models the shifts by $\pm 1$ in the independent variable of the sequence of orthogonal polynomials $\left\{P_{n}(x)\right\}_{n=0}^{\infty}$. We also showed in that paper that the contiguous relations for the generalized hypergeometric functions translate into symmetries for the corresponding moment matrix, and that the 3D Nijhoff-Capel discrete Toda lattice [46, 33] describes the corresponding contiguous shifts for the squared norms of the orthogonal polynomials. In [42], we provided an interpretation for the contiguous transformations for the generalized hypergeometric functions in terms of simple Christoffel and Geronimus

[^0]transformations. Using the Geronimus-Uvarov perturbations, we obtained determinantal expressions for the shifted orthogonal polynomials. Moreover, in [26], we explored three hypergeometric families and their associated Laguerre-Freud equations.

In this paper, we consider the generalized Charlier, generalized Meixner, and Gauss hypergeometric (also known as generalized Hahn of type I in [24, 25]) discrete orthogonal polynomials, analyze the LaguerreFreud structure matrix $\Psi$, and derive from its banded structure and its compatibility with the Toda equation and the Jacobi matrix a number of nonlinear equations for the coefficients $\beta_{n}, \gamma_{n}$ of the three-term recursion relations $z P_{n}(z)=P_{n+1}(z)+\beta_{n} P_{n}(z)+\gamma_{n} P_{n-1}(z)$ satisfied by the orthogonal polynomial sequence. These nonlinear recurrences for the recursion coefficients are of the type $\gamma_{n+1}=F_{1}\left(n, \gamma_{n}, \gamma_{n-1}, \ldots, \beta_{n}, \beta_{n-1} \ldots\right)$ and $\beta_{n+1}=F_{2}\left(n, \gamma_{n+1}, \gamma_{n}, \ldots, \beta_{n}, \beta_{n-1}, \ldots\right)$, for some functions $F_{1}, F_{2}$. Magnus [37, 38, 39, 40] named this type of relations, attending to [36, 31], as Laguerre-Freud relations. There are several papers describing Laguerre-Freud relations for the generalized Charlier, generalized Meixner, and Gauss hypergeometric cases, see [50, 19, 28, 29, 30, 22].

In all cases, whether it is generalized Charlier, generalized Meixner, or Gauss hypergeometric, we observe that the $\tau$-function, defined as the Wronskian of the modified Bessel, Kummer, and Gauss hypergeometric functions, provides a solution for each system of nonlinear equations of Laguerre-Freud type for the recursion coefficients.

The layout of the paper is as follows. After this introduction, Section 2 is devoted to the generalized Charlier orthogonal polynomials. In particular, the tridiagonal Laguerre-Freud structure matrix is given in Theorem 3, and in Proposition 12, we find a set of Laguerre-Freud equations that we prove to be equivalent to those of [50]. Here we derive third-order and second-order ODEs for the coefficient $\gamma_{n}$, see Theorems 4 and 55, respectively. As kindly informed by Peter Clarkson, these equations are the Painlevé equation deg- $\mathrm{P}_{\mathrm{V}}$ in disguise [20]. Then, in Section 3, we treat the generalized Meixner orthogonal polynomials, and in Theorem 6, we find the tetradiagonal Laguerre-Freud structure matrix, giving (after some simplifications) the corresponding Laguerre-Freud relations in Theorem 7. A comparative discussion with the LaguerreFreud equations given by Smet \& Van Assche [50] is also performed. Finally, in Section 4, we discuss the Gauss hypergeometric discrete orthogonal polynomials, see [22, 24], giving the pentadiagonal LaguerreFreud structure matrix in Theorem 8, and in Theorem 9, we discuss the corresponding Laguerre-Freud relations and its comparison with the results of Dominici [22] and Filipuk \& Van Assche [30] is given, see also [27].

Now, to complete this Introduction, we give a brief resume of the basic facts regarding discrete orthogonal polynomials and then a briefing of the relevant facts of [44].
1.1. Basics on orthogonal polynomials. Given a linear functional $\rho_{z} \in \mathbb{C}^{*}[z]$, the corresponding moment matrix is

$$
G=\left(G_{n, m}\right), \quad G_{n, m}=\rho_{n+m}, \quad \rho_{n}=\left\langle\rho_{z}, z^{n}\right\rangle, \quad n, m \in \mathbb{N}_{0}:=\{0,1,2, \ldots\},
$$

with $\rho_{n}$ the $n$-th moment of the linear functional $\rho_{z}$. If the moment matrix is such that all its truncations, which are Hankel matrices, $G_{i+1, j}=G_{i, j+1}$,
are nonsingular; i.e. the Hankel determinants $\Delta_{k}:=\operatorname{det} G^{[k]}$ do not cancel, $\Delta_{k} \neq 0, k \in \mathbb{N}_{0}$. If this is the case, we have monic polynomials

$$
\begin{equation*}
P_{n}(z)=z^{n}+p_{n}^{1} z^{n-1}+\cdots+p_{n}^{n}, \quad n \in \mathbb{N}_{0} \tag{1}
\end{equation*}
$$

with $p_{0}^{1}=0$, fulfilling the orthogonality relations

$$
\left\langle\rho, P_{n}(z) z^{k}\right\rangle=0, \quad k \in\{0, \ldots, n-1\}, \quad\left\langle\rho, P_{n}(z) z^{n}\right\rangle=H_{n} \neq 0
$$

and $\left\{P_{n}(z)\right\}_{n \in \mathbb{N}_{0}}$ is a sequence of orthogonal polynomials, i.e., $\left\langle\rho, P_{n}(z) P_{m}(z)\right\rangle=\delta_{n, m} H_{n}$ for $n, m \in \mathbb{N}_{0}$. The symmetric bilinear form $\langle F, G\rangle_{\rho}:=\langle\rho, F G\rangle$, is such that the moment matrix is the Gram matrix of this bilinear form and $\left\langle P_{n}, P_{m}\right\rangle_{\rho}:=\delta_{n, m} H_{n}$.

Introducing $\chi(z):=\left(\begin{array}{lll}1 & z & z^{2} \ldots \ldots\end{array}\right)^{\top}$ the moment matrix is $G=\left\langle\rho, \chi \chi^{\top}\right\rangle$, and $\chi$ is an eigenvector of the shift matrix, $\Lambda \chi=x \chi$, where

$$
\Lambda:=\left[\begin{array}{cccccc}
0 & 1 & 0 & \cdots & \cdots & \cdots \\
0 & 0 & \ddots & \ddots & \ddots \\
\vdots & & \ddots & 1 & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\
\vdots & & \ddots & \ddots & \ddots & \ddots \\
\vdots & & & \ddots & \ddots & \ddots
\end{array}\right] .
$$

Hence $\Lambda G=G \Lambda^{\top}$, and the moment matrix is a Hankel matrix.
As the moment matrix symmetric its Borel-Gauss factorization is a Cholesky factorization

$$
\begin{equation*}
G=S^{-1} H S^{-\top}, \tag{2}
\end{equation*}
$$

where $S$ is a lower unitriangular matrix that can be written as

$$
S=\left[\begin{array}{cccccc}
1 & 0 & & 0 & \cdots & \cdots
\end{array}\right] .
$$

and $H=\operatorname{diag}\left(H_{0}, H_{1}, \ldots\right)$ is a diagonal matrix, with $H_{k} \neq 0$, for $k \in \mathbb{N}_{0}$. The Cholesky factorization does hold whenever the principal minors of the moment matrix; i.e., the Hankel determinants $\Delta_{k}$, do not cancel.

The components $P_{n}(z)$ of

$$
\begin{equation*}
P(z):=S \chi(z), \tag{3}
\end{equation*}
$$

are the monic orthogonal polynomials of the functional $\rho$.
Proposition 1. We have the determinantal expressions

$$
H_{n}=\frac{\Delta_{n+1}}{\Delta_{n}}, \quad \quad p_{n}^{1}=-\frac{\tilde{\Delta}_{n}}{\Delta_{n}}
$$

with the Hankel determinants given by

We introduce the lower Hessenberg semi-infinite matrix

$$
\begin{equation*}
J=S \Lambda S^{-1} \tag{4}
\end{equation*}
$$

that has the vector $P(z)$ as eigenvector with eigenvalue $z, J P(z)=z P(z)$. The Hankel condition $\Lambda G=G \Lambda^{\top}$ and the Cholesky factorization gives

$$
\begin{equation*}
J H=(J H)^{\top}=H J^{\top} \tag{5}
\end{equation*}
$$

As the Hessenberg matrix $J H$ is symmetric the Jacobi matrix $J$ is tridiagonal. The Jacobi matrix $J$ given in (4) reads

$$
J=\left[\begin{array}{cccc}
\beta_{0} & 1 & 0 & \cdots \cdots \cdots \\
\gamma_{1} & \beta_{1} & 1 & \ddots \\
0 & \gamma_{2} & \beta_{2} & \ddots \\
\vdots \vdots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots
\end{array}\right] \cdot, ~ .
$$

The eigenvalue equation $J P=z P$ is a three term recursion relation $z P_{n}(z)=P_{n+1}(z)+\beta_{n} P_{n}(z)+$ $\gamma_{n} P_{n-1}(z)$, that with the initial conditions $P_{-1}=0$ and $P_{0}=1$ completely determines the sequence of orthogonal polynomials $\left\{P_{n}(z)\right\}_{n=0}^{\infty}$ in terms of the recursion coefficients $\beta_{n}, \gamma_{n}$. The recursion coefficients, in terms of the Hankel determinants, are given by

$$
\begin{equation*}
\beta_{n}=p_{n}^{1}-p_{n+1}^{1}=-\frac{\tilde{\Delta}_{n}}{\Delta_{n}}+\frac{\tilde{\Delta}_{n+1}}{\Delta_{n+1}}, \quad \quad \gamma_{n+1}=\frac{H_{n+1}}{H_{n}}=\frac{\Delta_{n+1} \Delta_{n-1}}{\Delta_{n}^{2}}, \quad n \in \mathbb{N}_{0} \tag{6}
\end{equation*}
$$

For future use we introduce the following diagonal matrices $\gamma:=\operatorname{diag}\left(\gamma_{1}, \gamma_{2}, \ldots\right)$ and $\beta:=\operatorname{diag}\left(\beta_{0}, \beta_{1}, \ldots\right)$ and $J_{-}:=\Lambda^{\top} \gamma$ and $J_{+}:=\beta+\Lambda$, so that we have the splitting $J=\Lambda^{\top} \gamma+\beta+\Lambda=J_{-}+J_{+}$. In general, given any semi-infinite matrix $A$, we will write $A=A_{-}+A_{+}$, where $A_{-}$is a strictly lower triangular matrix and $A_{+}$an upper triangular matrix. Moreover, $A_{0}$ will denote the diagonal part of $A$.

The lower Pascal matrix is defined by

$$
B=\left(B_{n, m}\right), \quad B_{n, m}:= \begin{cases}\binom{n}{m}, & n \geq m  \tag{7}\\ 0, & n<m\end{cases}
$$

so that

$$
\begin{equation*}
\chi(z+1)=B \chi(z) \tag{8}
\end{equation*}
$$

Moreover,

$$
B^{-1}=\left(\tilde{B}_{n, m}\right), \quad \quad \tilde{B}_{n, m}:= \begin{cases}(-1)^{n+m}\binom{n}{m}, & n \geq m \\ 0, & n<m\end{cases}
$$

and $\chi(z-1)=B^{-1} \chi(z)$. The lower Pascal matrix and its inverse are explicitly given by
in terms of which we introduce the dressed Pascal matrices, $\Pi:=S B S^{-1}$ and $\Pi^{-1}:=S B^{-1} S^{-1}$, which are connection matrices; i.e.,

$$
\begin{equation*}
P(z+1)=\Pi P(z), \quad P(z-1)=\Pi^{-1} P(z) \tag{9}
\end{equation*}
$$

The lower Pascal matrix can be expressed in terms of its subdiagonal structure as follows

$$
B^{ \pm 1}=I \pm \Lambda^{\top} D+\left(\Lambda^{\top}\right)^{2} D^{[2]} \pm\left(\Lambda^{\top}\right)^{3} D^{[3]}+\cdots,
$$

where $D=\operatorname{diag}(1,2,3, \ldots)$ and $D^{[k]}=\frac{1}{k} \operatorname{diag}\left(k^{(k)},(k+1)^{(k)},(k+2)^{(k)} \ldots\right)$, in terms of the falling factorials $x^{(k)}=x(x-1)(x-2) \cdots(x-k+1)$. That is,

$$
D_{n}^{[k]}=\frac{(n+k) \cdots(n+1)}{k}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_{0}
$$

The lower unitriangular factor can be also written in terms of its subdiagonals $S=I+\Lambda^{\top} S^{[1]}+\left(\Lambda^{\top}\right)^{2} S^{[2]}+$ $\cdots$ with $S^{[k]}=\operatorname{diag}\left(S_{0}^{[k]}, S_{1}^{[k]}, \ldots\right)$. From (3) is clear the following connection between these subdiagonals entries and the coefficients of the orthogonal polynomials given in (1)

$$
\begin{equation*}
S_{n}^{[k]}=p_{n+k}^{k} . \tag{10}
\end{equation*}
$$

We will use the shift operators $T_{ \pm}$acting over the diagonal matrices as follows

$$
T_{-} \operatorname{diag}\left(a_{0}, a_{1}, \ldots\right):=\operatorname{diag}\left(a_{1}, a_{2}, \ldots\right), \quad T_{+} \operatorname{diag}\left(a_{0}, a_{1}, \ldots\right):=\operatorname{diag}\left(0, a_{0}, a_{1}, \ldots\right) .
$$

These shift operators have the following important properties, for any diagonal matrix $A=\operatorname{diag}\left(A_{0}, A_{1}, \ldots\right)$

$$
\begin{equation*}
\Lambda A=\left(T_{-} A\right) \Lambda, \quad A \Lambda=\Lambda\left(T_{+} A\right), \quad A \Lambda^{\top}=\Lambda^{\top}\left(T_{-} A\right), \quad \Lambda^{\top} A=\left(T_{+} A\right) \Lambda^{\top} . \tag{11}
\end{equation*}
$$

Remark 1. Notice that the standard notation, see [47], for the differences of a sequence $\left\{f_{n}\right\}_{n \in \mathbb{N}_{0}}$,

$$
\begin{array}{ll}
\Delta f_{n}:=f_{n+1}-f_{n}, & n \in \mathbb{N}_{0}, \\
\nabla f_{n}=f_{n}-f_{n-1}, & n \in \mathbb{N},
\end{array}
$$

and $\nabla f_{0}=f_{0}$, connects with the shift operators by means of

$$
T_{-}=I+\Delta, \quad T_{+}=I-\nabla
$$

In terms of these shift operators we find

$$
\begin{equation*}
2 D^{[2]}=\left(T_{-} D\right) D, \quad 3 D^{[3]}=\left(T_{-}^{2} D\right)\left(T_{-} D\right) D=2\left(T_{-} D^{[2]}\right) D=2 D^{[2]}\left(T_{-}^{2} D\right) \tag{12}
\end{equation*}
$$

Proposition 2. The inverse matrix $S^{-1}$ of the matrix $S$ expands as follows

$$
S^{-1}=I+\Lambda^{\top} S^{[-1]}+\left(\Lambda^{\top}\right)^{2} S^{[-2]}+\cdots
$$

The subdiagonals $S^{[-k]}$ are given in terms of the subdiagonals of $S$. In particular,

$$
\begin{aligned}
& S^{[-1]}=-S^{[1]}, \\
& S^{[-2]}=-S^{[2]}+\left(T_{-} S^{[1]}\right) S^{[1]}, \\
& S^{[-3]}=-S^{[3]}+\left(T_{-} S^{[2]}\right) S^{[1]}+\left(T_{-}^{2} S^{[1]}\right) S^{[2]}-\left(T_{-}^{2} S^{[1]}\right)\left(T_{-} S^{[1]}\right) S^{[1]} .
\end{aligned}
$$

Remark 2. Corresponding expansions for the dressed Pascal matrices are

$$
\Pi^{ \pm 1}=I+\Lambda^{\top} \pi^{[ \pm 1]}+\left(\Lambda^{\top}\right)^{2} \pi^{[ \pm 2]}+\cdots
$$

with $\pi^{[ \pm n]}=\operatorname{diag}\left(\pi_{0}^{[ \pm n]}, \pi_{1}^{[ \pm n]}, \ldots\right)$.

Proposition 3 (The dressed Pascal matrix coefficients). We have

$$
\begin{gather*}
\pi_{n}^{[ \pm 1]}= \pm(n+1), \quad \pi_{n}^{[ \pm 2]}= \\
=\frac{(n+2)(n+1)}{2} \pm p_{n+2}^{1}(n+1) \mp(n+2) p_{n+1}^{1}  \tag{13}\\
 \tag{14}\\
\pi_{n}^{[ \pm 3]}= \pm \frac{(n+2)(n+1)}{2} \mp(n+1) \beta_{n+1} \mp p_{n+1}^{1}, \\
\pm(n+1) p_{n+3}^{2} \mp(n+3) p_{n+2}^{2} \pm(n+3) p_{n+2}^{1} p_{n+1}^{1} \mp(n+2) p_{n+3}^{1} p_{n+1}^{1} .
\end{gather*}
$$

Moreover, the following relations are fulfill

$$
\begin{equation*}
\pi^{[1]}+\pi^{[-1]}=0, \quad \pi^{[2]}+\pi^{[-2]}=2 D^{[2]}, \quad \pi^{[3]}+\pi^{[-3]}=2\left(\left(T_{-}^{2} S^{[1]}\right) D^{[2]}-\left(T_{-} D^{[2]}\right) S^{[1]}\right) . \tag{15}
\end{equation*}
$$

1.2. Discrete orthogonal polynomials and Pearson equation. We are interested in measures with support on the homogeneous lattice $\mathbb{N}_{0}$ as follows $\rho=\sum_{k=0}^{\infty} \delta(z-k) w(k)$, with moments given by

$$
\begin{equation*}
\rho_{n}=\sum_{k=0}^{\infty} k^{n} w(k), \tag{16}
\end{equation*}
$$

and, in particular, with 0 -th moment given by

$$
\begin{equation*}
\rho_{0}=\sum_{k=0}^{\infty} w(k) . \tag{17}
\end{equation*}
$$

The weights we consider in this paper satisfy the following discrete Pearson equation

$$
\begin{equation*}
\nabla(\sigma w)=\tau w, \tag{18}
\end{equation*}
$$

that is $\sigma(k) w(k)-\sigma(k-1) w(k-1)=\tau(k) w(k)$, for $k \in\{1,2, \ldots\}$, with $\sigma(z), \tau(z) \in \mathbb{R}[z]$. If we write $\theta:=\tau-\sigma$, the previous Pearson equation reads

$$
\begin{equation*}
\theta(k+1) w(k+1)=\sigma(k) w(k), \quad k \in \mathbb{N}_{0} \tag{19}
\end{equation*}
$$

Theorem 1 (Hypergeometric symmetries). Let the weight $w$ be subject to a discrete Pearson equation of the type (19), where the functions $\theta, \sigma$ are polynomials, with $\theta(0)=0$. Then,
i) The moment matrix fulfills

$$
\begin{equation*}
\theta(\Lambda) G=B \sigma(\Lambda) G B^{\top} . \tag{20}
\end{equation*}
$$

ii) The Jacobi matrix satisfies

$$
\begin{equation*}
\Pi^{-1} H \theta\left(J^{\top}\right)=\sigma(J) H \Pi^{\top}, \tag{21}
\end{equation*}
$$

and the matrices $H \theta\left(J^{\top}\right)$ and $\sigma(J) H$ are symmetric.
If $N+1:=\operatorname{deg} \theta(z)$ and $M:=\operatorname{deg} \sigma(z)$, and zeros of these polynomials are $\left\{-b_{i}+1\right\}_{i=1}^{N}$ and $\left\{-a_{i}\right\}_{i=1}^{M}$ we write $\theta(z)=z\left(z+b_{1}-1\right) \cdots\left(z+b_{N}-1\right)$ and $\sigma(z)=\eta\left(z+a_{1}\right) \cdots\left(z+a_{M}\right)$. According to 17) the 0 -th moment

$$
\rho_{0}=\sum_{k=0}^{\infty} w(k)=\sum_{k=0}^{\infty} \frac{\left(a_{1}\right)_{k} \cdots\left(a_{M}\right)_{k}}{\left(b_{1}+1\right)_{k} \cdots\left(b_{N}+1\right)_{k}} \frac{\eta^{k}}{k!}={ }_{M} F_{N}\left(a_{1}, \ldots, a_{M} ; b_{1}, \ldots, b_{N} ; \eta\right)={ }_{M} F_{N}\left[\begin{array}{lll}
a_{1} & \cdots & a_{M} ; \eta \\
b_{1} & \cdots & b_{N}
\end{array}\right] .
$$

is the generalized hypergeometric function, where we are using the two standard notations, see [14]. Then, according to (16), for $n \in \mathbb{N}$, the corresponding higher moments $\rho_{n}=\sum_{k=0}^{\infty} k^{n} w(k)$, are

$$
\rho_{n}=\vartheta_{\eta}^{n} \rho_{0}=\vartheta_{\eta}^{n}\left({ }_{M} F_{N}\left[\begin{array}{ccc}
a_{1} & \cdots & a_{M} ; \eta \\
b_{1} & \cdots & b_{N}
\end{array}\right]\right), \quad \vartheta_{\eta}:=\eta \frac{\partial}{\partial \eta}
$$

Given a function $f(\eta)$, we consider the Wronskian of the covector $\delta(f):=\left[\begin{array}{lll}f & \vartheta f \cdots \cdots \vartheta^{n} f\end{array}\right]$ given by

$$
\mathscr{W}_{n}(f):=\left|\begin{array}{ccc}
f & \vartheta_{\eta} f & \vartheta_{\eta}^{2} f \ldots \ldots \ldots \vartheta_{\eta}^{n} f \\
\vartheta_{\eta} f & \vartheta_{\eta}^{2} f & \ldots . \cdot \cdot \cdot \vartheta_{\eta}^{n+1} f \\
\vartheta_{\eta}^{2} f & \ldots & \ldots \\
\vdots & \ldots & \ldots \\
\vartheta_{\eta}^{n} f & \vartheta_{\eta}^{n+1} f \ldots \ldots \ldots \cdots \cdot \vartheta_{\eta}^{2 n} f
\end{array}\right|
$$

We refer to this Wronskian as the $\delta$-Wronskian of $f$. Then, we have that the Hankel determinants $\Delta_{n}=$ $\operatorname{det} G^{[n]}$ determined by the truncations of the corresponding moment matrix are $\delta$-Wronskians of generalized hypergeometric functions,

$$
\begin{equation*}
\Delta_{n}=\tau_{n}, \quad \tilde{\Delta}_{n}=\vartheta_{\eta} \tau_{n} \tag{22}
\end{equation*}
$$

where

$$
\tau_{n}:=\mathscr{W}_{n}\left({ }_{M} F_{N}\left[\begin{array}{ccc}
a_{1} & \cdots & a_{M} ; \eta \\
b_{1} & \cdots & b_{N}
\end{array}\right]\right)
$$

Moreover, using Proposition 1 we get

$$
\begin{equation*}
H_{n}=\frac{\tau_{n+1}}{\tau_{n}}, \quad \quad p_{n}^{1}=-\vartheta_{\eta} \log \tau_{n}, \quad n \in \mathbb{N}_{0} \tag{23}
\end{equation*}
$$

The functions $\tau_{k}$ are the well known tau functions [33]. In terms of these $\tau$-functions we have

$$
\begin{equation*}
\beta_{n}=\vartheta_{\eta} \log \frac{\tau_{n+1}}{\tau_{n}}, \quad \gamma_{n+1}=\frac{\tau_{n+1} \tau_{n-1}}{\tau_{n}^{2}}, \quad n \in \mathbb{N}_{0} \tag{24}
\end{equation*}
$$

were we have used (22), (6) and (23).
Remark 3. Let us observe that this Wronskian structure holds not only for weights that solve Pearson's equations. In fact, the only requirement is that the weight depends on a parameter $\eta$ such that $\vartheta_{\eta} w(k)=k w(k)$, where $k \in \mathbb{N}_{0}$. In such cases, the tau function is given by $\tau_{n}=\mathscr{W}_{n}\left(\rho_{0}\right)$, where $\rho_{0}=\sum_{k=0}^{\infty} w(k)$, and Equations (22), (23), and (24) hold true.

Theorem 2 (Laguerre-Freud structure matrix). Let us assume that the weight $w$ solves the discrete Pearson equation (19) with $\theta, \sigma$ polynomials such that $\theta(0)=0, \operatorname{deg} \theta(z)=N+1$, $\operatorname{deg} \sigma(z)=M$. Then, the LaguerreFreud structure matrix

$$
\begin{align*}
\Psi & :=\Pi^{-1} H \theta\left(J^{\top}\right)=\sigma(J) H \Pi^{\top}=\Pi^{-1} \theta(J) H=H \sigma\left(J^{\top}\right) \Pi^{\top}  \tag{25}\\
& =\theta(J+I) \Pi^{-1} H=H \Pi^{\top} \sigma\left(J^{\top}-I\right), \tag{26}
\end{align*}
$$

has only $N+M+2$ possibly nonzero diagonals $(N+1$ superdiagonals and $M$ subdiagonals)

$$
\Psi=\left(\Lambda^{\top}\right)^{M} \psi^{(-M)}+\cdots+\Lambda^{\top} \psi^{(-1)}+\psi^{(0)}+\psi^{(1)} \Lambda+\cdots+\psi^{(N+1)} \Lambda^{N+1},
$$

for some diagonal matrices $\psi^{(k)}$. In particular, the lowest subdiagonal and highest superdiagonal are given by

$$
\begin{cases}\left(\Lambda^{\top}\right)^{M} \psi^{(-M)}=\eta\left(J_{-}\right)^{M} H, & \psi^{(-M)}=\eta H \prod_{k=0}^{M-1} T_{-}^{k} \gamma=\eta \operatorname{diag}\left(H_{0} \prod_{k=1}^{M} \gamma_{k}, H_{1} \prod_{k=2}^{M+1} \gamma_{k}, \ldots\right),  \tag{27}\\ \psi^{(N+1)} \Lambda^{N+1}=H\left(J_{-}^{\top}\right)^{N+1}, & \psi^{(N+1)}=H \prod_{k=0}^{N} T_{-}^{k} \gamma=\operatorname{diag}\left(H_{0} \prod_{k=1}^{N+1} \gamma_{k}, H_{1} \prod_{k=2}^{N+2} \gamma_{k}, \ldots\right) .\end{cases}
$$

The vector $P(z)$ of orthogonal polynomials fulfill the following structure equations

$$
\begin{equation*}
\theta(z) P(z-1)=\Psi H^{-1} P(z), \quad \sigma(z) P(z+1)=\Psi^{\top} H^{-1} P(z) . \tag{28}
\end{equation*}
$$

The compatibility of the recursion relation, i.e. eigenfunctions of the Jacobi matrix, and the recursion matrix leads to some interesting equations:
Proposition 4. The following compatibility conditions for the Laguerre-Freud and Jacobi matrices hold

$$
\begin{align*}
{\left[\Psi H^{-1}, J\right] } & =\Psi H^{-1},  \tag{29a}\\
{\left[J, \Psi^{\top} H^{-1}\right] } & =\Psi^{\top} H^{-1} . \tag{29b}
\end{align*}
$$

1.3. The Toda flows. Let us define the strictly lower triangular matrix

$$
\Phi:=\left(\vartheta_{\eta} S\right) S^{-1} .
$$

Proposition 5. i) The semi-infinite vector $P$ fulfills

$$
\begin{equation*}
\vartheta_{\eta} P=\Phi P . \tag{30}
\end{equation*}
$$

ii) The Sato-Wilson equations holds

$$
\begin{equation*}
-\Phi H+\vartheta_{\eta} H-H \Phi^{\top}=J H . \tag{31}
\end{equation*}
$$

Consequently, $\Phi=-J_{-}$and $n \in \mathbb{N}_{0}$ we have $\vartheta_{\eta} \log H_{n}=J_{n, n}$.
Moreover,
Proposition 6 (Toda). The following equations hold

$$
\begin{gather*}
\Phi=\left(\vartheta_{\eta} S\right) S^{-1}=-\Lambda^{\top} \gamma,  \tag{32a}\\
\left(\vartheta_{\eta} H\right) H^{-1}=\beta . \tag{32b}
\end{gather*}
$$

In particular, for $n, k-1 \in \mathbb{N}$, we have

$$
\begin{align*}
\vartheta_{\eta} p_{n}^{1}=-\gamma_{n}, \quad \vartheta_{\eta} p_{n+k}^{k} & =-\gamma_{n+k} p_{n+k-1}^{k-1},  \tag{33a}\\
\vartheta_{\eta} \log H_{n} & =\beta_{n} . \tag{33b}
\end{align*}
$$

The functions $q_{n}:=\log H_{n}, n \in \mathbb{N}$, satisfy the Toda equations

$$
\begin{equation*}
\vartheta_{\eta}^{2} q_{n}=\mathrm{e}^{q_{n+1}-q_{n}}-\mathrm{e}^{q_{n}-q_{n-1}} . \tag{34}
\end{equation*}
$$

For $n \in \mathbb{N}$, we also have $\vartheta_{\eta} P_{n}(z)=-\gamma_{n} P_{n-1}(z)$.
Proposition 7. The following Lax equation holds $\vartheta_{\eta} J=\left[J_{+}, J\right]$. The recursion coefficients satisfy the following Toda system

$$
\begin{align*}
\vartheta_{\eta} \beta_{n} & =\gamma_{n+1}-\gamma_{n},  \tag{35a}\\
\vartheta_{\eta} \log \gamma_{n} & =\beta_{n}-\beta_{n-1}, \tag{35b}
\end{align*}
$$

for $n \in \mathbb{N}_{0}$ and $\beta_{-1}=0$. Consequently, we get

$$
\begin{equation*}
\vartheta_{\eta}^{2} \log \gamma_{n}=\gamma_{n+1}-2 \gamma_{n}+\gamma_{n-1} . \tag{36}
\end{equation*}
$$

For the compatibility of (9) and (30), that is for the compatibility of the systems

$$
\left\{\begin{array}{l}
P(z+1)=\Pi P(z), \\
\vartheta_{\eta}(P(z))=\Phi P(z) .
\end{array}\right.
$$

we obtain $\vartheta_{\eta}(\Pi)=[\Phi, \Pi]$. In the general case the dressed Pascal matrix $\Pi$ is a lower unitriangular semiinfinite matrix, that possibly has an infinite number of subdiagonals. However, for the case when the weight $w(z)=v(z) \eta^{z}$ satisfies the Pearson equation (19), with $v$ independent of $\eta$, that is $\theta(k+1) v(k+1) \eta=$ $\sigma(k) v(k)$, the situation improves as we have the banded semi-infinite matrix $\Psi$ that models the shift in the $z$ variable as in (28). From the previous discrete Pearson equation we see that $\sigma(z)=\eta \kappa(z)$ with $\kappa, \theta$ $\eta$-independent polynomials in $z$

$$
\begin{equation*}
\theta(k+1) v(k+1)=\eta \kappa(k) v(k) . \tag{37}
\end{equation*}
$$

Proposition 8. Let us assume a weight $w$ satisfying the Pearson equation (19). Then, the Laguerre-Freud structure matrix $\Psi$ given in 25 satisfies

$$
\begin{align*}
\vartheta_{\eta}\left(\eta^{-1} \Psi^{\top} H^{-1}\right) & =\left[\Phi, \eta^{-1} \Psi^{\top} H^{-1}\right]  \tag{38a}\\
\vartheta_{\eta}\left(\Psi H^{-1}\right) & =\left[\Phi, \Psi H^{-1}\right] \tag{38b}
\end{align*}
$$

Relations 38a and 38b are gauge equivalent.

## 2. Generalized Charlier weights

A particular simple case is when $\sigma$ does not depend upon $z$, that we name as extended Charlier weights. The generalized Charlier, which is the main example of these extended Charlier weights, corresponds to the choice $\sigma(z)=\eta$ and $\theta(z)=z(z+b)$. In fact, a weight that satisfies the Pearson equation

$$
(k+1)(k+1+b) w(k+1)=\eta w(k)
$$

is proportional to the generalized Charlier weight

$$
w(z)=\frac{\Gamma(b+1) \eta^{z}}{\Gamma(z+b+1) \Gamma(z+1)}=\frac{1}{(b+1)_{z}} \frac{\eta^{z}}{z!}
$$

The finiteness of the moments requires $b>-1$ and $\eta>0$, see [24]. The generalized Charlier 0-th moment, as we have discussed, is the confluent hypergeometric limit function $\rho_{0}(\eta)={ }_{0} F_{1}(; b+1 ; \eta)$.
Remark 4. Is well known the relation of this function with the Bessel functions $J_{\nu}$ and $I_{\nu}$ :

$$
\frac{\left(\frac{\eta}{2}\right)^{b}}{\Gamma(b+1)} \rho_{0}\left(-\frac{\eta^{2}}{4}\right)=J_{b}(\eta), \quad \frac{\left(\frac{\eta}{2}\right)^{b}}{\Gamma(b+1)} \rho_{0}\left(\frac{\eta^{2}}{4}\right)=I_{b}(\eta)
$$

Here $J_{\nu}$ is the $\nu$-th Bessel function and $I_{\nu}$ the $\nu$-th modified Bessel, both are connected: $\mathrm{e}^{ \pm \mathrm{i} \frac{\nu \pi}{2}} I_{\nu}(x)=J_{\nu}\left(\mathrm{e}^{ \pm \mathrm{i} \frac{\nu \pi}{2}} x\right)$. Thus, in terms of these modified Bessel functions, we can write, see [24]

$$
\begin{equation*}
\rho_{0}(\eta)=\frac{\Gamma(b+1)}{\sqrt{\eta}^{b}} I_{b}(2 \sqrt{\eta}) \tag{39}
\end{equation*}
$$

Remark 5. From 39) and 24 we get that in terms of the following $\delta$-Wronskian of a modified Bessel function

$$
\tau_{n}:=\mathscr{W}_{n}\left(\frac{\Gamma(b+1)}{\sqrt{\eta}^{b}} I_{b}(2 \sqrt{\eta})\right)
$$

we get explicit expressions for the recursion coefficients

$$
\beta_{n}=\vartheta_{\eta} \log \frac{\tau_{n+1}}{\tau_{n}}, \quad \quad \gamma_{n+1}=\frac{\tau_{n+1} \tau_{n-1}}{\tau_{n}^{2}}, \quad n \in \mathbb{N}_{0}
$$

Remark 6. The non generalized Charlier polynomials or Poisson-Charlier polynomials were discussed by Charlier in [18].

Proposition 9. Let us consider an extended Charlier type weight w, i.e. $\theta(k+1) w(k+1)=\eta w(k)$ with $\theta(0)=0$. Then, the semi-infinite matrix $H \theta\left(J^{\top}\right)$ admits the Cholesky factorization

$$
\begin{equation*}
\theta(J) H=H \theta\left(J^{\top}\right)=\Theta^{-1} H \Theta^{-\top}=\Pi H \Pi^{\top} \tag{40}
\end{equation*}
$$

with the dressed Pascal semi-infinite matrix $\Pi=\Theta^{-1}$ being a lower unitriangular semi-infinite matrix with only its first $\operatorname{deg} \theta$ subdiagonals different from zero.
Proof. From 25 we have $\Pi^{-1} H \theta\left(J^{\top}\right)=H \Pi^{\top}$; i.e. $H \theta\left(J^{\top}\right)=\Pi H \Pi^{\top}$ and given the uniqueness of the Cholesky factorization and its band structure we deduce the result.

Proposition 10. For an extended Charlier type weight, with the choice $\sigma=\eta$ and $\theta(z)=z\left(z^{N-1}+\cdots+\theta_{1}\right)$, we have the following subdiagonal structure for the dressed Pascal matrix $\Pi=\sum_{k=0}^{N}\left(\Lambda^{\top}\right)^{k} \pi^{[k]}$ with the main diagonal and first subdiagonals given by $\pi^{[0]}=I$ and $\pi^{[1]}=D=\operatorname{diag}(1,2,3, \cdots)$, and the lowest subdiagonal

$$
\left(\Lambda^{\top}\right)^{N} \pi^{[N]}=\left(J_{-}\right)^{N}, \quad \pi^{[N]}=\prod_{k=0}^{N-1} T_{-}^{k} \gamma=\operatorname{diag}\left(\prod_{k=1}^{N} \gamma_{k}, \prod_{k=2}^{N+1} \gamma_{k}, \ldots\right)=\operatorname{diag}\left(\frac{H_{N}}{H_{0}}, \frac{H_{N+1}}{H_{1}}, \ldots\right) .
$$

Proof. The only new fact to prove is the explicit expression for the lowest subdiagonal, that obviously will come from the lowest diagonal of $\theta(J)$ that is $J_{-}^{N}$.
Theorem 3 ( The generalized Charlier Laguerre-Freud structure matrix). For a generalized Charlier weight, i.e. $\sigma=\eta$ and $\theta=z(z+b)$, the Laguerre-Freud structure matrix is

Proof. For the structure matrix $\Psi$ we have that, see (27), $\Psi=\psi^{(0)}+\psi^{(1)} \Lambda+\psi^{(2)} \Lambda^{2}$. Let us find these diagonal matrix coefficients. In the one hand, as

$$
\begin{equation*}
\Psi=\eta H \Pi^{\top}=\underbrace{\eta H}_{\text {main diagonal }}+\underbrace{\eta H D \Lambda}_{\text {first superdiagonal }}+\underbrace{\eta H \pi^{[2]} \Lambda^{2}}_{\text {second superdiagonal }}+\cdots, \tag{41}
\end{equation*}
$$

we get from the main diagonal that $\psi^{(0)}=\eta H$, and from the first superdiagonal that $\psi^{(1)}=\eta H D$. In the other hand, we observe that

$$
\begin{aligned}
& \Psi= \Pi^{-1} H\left(\left(J^{\top}\right)^{2}+b J^{\top}\right) \\
&=\left(I-\Lambda^{\top} D+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]}+\cdots\right) H \\
& \quad \times\left(\left(\Lambda^{\top}\right)^{2}+\Lambda^{\top}\left(\beta+T_{-} \beta+b I\right)+\gamma+T_{+} \gamma+\beta^{2}+b \beta+\left(\beta+T_{-} \beta+b I\right) \gamma \Lambda+\left(T_{-} \gamma\right) \gamma \Lambda^{2}\right)
\end{aligned}
$$

so that

$$
\begin{align*}
\Psi=\cdots+\underbrace{H\left(\gamma+T_{+} \gamma+\beta^{2}+b \beta\right)-}_{\text {main diagonal }} & \Lambda^{\top} D H\left(\beta+T_{-} \beta+b I\right) \gamma \Lambda+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]} H\left(T_{-} \gamma\right) \gamma \Lambda^{2}  \tag{42}\\
& +\underbrace{H\left(\beta+T_{-} \beta+b I\right) \gamma \Lambda-\Lambda^{\top} D H\left(T_{-} \gamma\right) \gamma \Lambda^{2}}_{\text {first superdiagonal }}+\underbrace{H\left(T_{-} \gamma\right) \gamma \Lambda^{2},}_{\text {second superdiagonal }}
\end{align*}
$$

and the result is proven.
Proposition 11 (Compatibility). For a generalized Charlier weight the recursion coefficients fulfill

$$
\begin{equation*}
n \eta\left(\beta_{n}-\beta_{n-1}-1\right)=\left(-\gamma_{n+1}+\gamma_{n-1}\right) \gamma_{n}, \tag{43}
\end{equation*}
$$

for $n \in \mathbb{N}$ and $\gamma_{0}=0$. Alternative forms of this equation are

$$
\begin{align*}
n \vartheta_{\eta}\left(\frac{\eta}{\gamma_{n}}\right) & =\gamma_{n+1}-\gamma_{n-1},  \tag{44a}\\
\vartheta_{\eta}\left(\frac{\gamma_{n} \gamma_{n+1}}{\eta}\right) & =(n+1) \gamma_{n}-n \gamma_{n+1}, \tag{44b}
\end{align*}
$$

for $n \in \mathbb{N}$ and $\gamma_{0}=0$. We also have

$$
\begin{equation*}
\beta_{n}-\beta_{n-2}-1=\eta\left(n \gamma_{n}^{-1}-(n-1) \gamma_{n-1}^{-1}\right), \quad n \geq 2 . \tag{45}
\end{equation*}
$$

Proof. Recalling $\gamma=\left(T_{-} H\right) H^{-1}$ we write

$$
\begin{aligned}
\Psi H^{-1} & =\eta+\eta H D \Lambda H^{-1}+H\left(T_{-} \gamma\right) \gamma \Lambda^{2} H^{-1}=\eta+\eta H\left(T_{-} H\right)^{-1} D \Lambda+H\left(T_{-}^{2} H\right)^{-1}\left(T_{-} \gamma\right) \gamma \Lambda^{2} \\
& =\eta+\eta \gamma^{-1} D \Lambda+\Lambda^{2} \\
& =\left[\begin{array}{ccccc}
\eta & \frac{\eta}{\gamma_{1}} & 1 & 0 & \cdots \\
0 & \eta & \frac{2 \eta}{\gamma_{2}} & 1 & \ddots \\
0 & \ddots \\
0 & 0 & \eta & \frac{3 \eta}{\gamma_{3}} & \ddots \\
0 & & & \ddots \\
\vdots & 0 & 0 & & \ddots \\
\vdots & \ddots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots & \ddots \\
\hline
\end{array}\right] .
\end{aligned}
$$

The compatibility equation (29b), $\left[\Psi H^{-1}, J\right]=\Psi H^{-1}$, reads

$$
\begin{aligned}
& +\left[\begin{array}{cccccc}
\eta & \frac{\eta}{\gamma_{1}} & 1 & 0 & \cdots \\
0 & \eta & \frac{2 \eta}{\gamma_{2}} & 1 & \ddots & \ddots \\
0 & 0 & \eta & \frac{3 \eta}{\gamma_{3}} & \ddots & \ddots \\
0 & 0 & 0 & \eta & \ddots \\
\vdots & \ddots & \ddots & \ddots & \ddots
\end{array}\right]\left[\begin{array}{ccccc}
\beta_{0} & 1 & 0 & \ldots & \cdots
\end{array}\right]\left[\begin{array}{llll}
\gamma_{1} & \beta_{1} & 1 & \ddots \\
0 & \gamma_{2} & \beta_{2} & \ddots \\
\vdots & \ddots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots
\end{array}\right]
\end{aligned}
$$

and, consequently, we get (43) on the first superdiagonal and from the second superdiagonal we get 45).
Let us look to the alternative expression (44a). First, using the Toda system (35b) we see that (44a) is equivalent to (43). Indeed, from (35b we get

$$
n \vartheta_{\eta}\left(\frac{\eta}{\gamma_{n}}\right)=\frac{n \eta}{\gamma_{n}}-\frac{n \eta \vartheta_{\eta} \gamma_{n}}{\gamma_{n}^{2}}=-\frac{n \eta\left(\beta_{n}-\beta_{n-1}-1\right)}{\gamma_{n}}
$$

and the statement follows. An alternative proof for (44a) is obtained from the compatibility condition (38b), i.e.,

Equation (38a) with

$$
\Pi=\eta^{-1} \Psi^{\top} H^{-1}=\left[\begin{array}{cccccc}
1 & 0 & & 0 & \cdots & \cdots \\
1 & 1 & & 0 & \ddots & \\
\frac{\gamma_{2} \gamma_{1}}{\eta} & 2 & & & \ddots & \ddots \\
0 & & & \ddots & \\
\vdots \vdots & \frac{\gamma_{3} \gamma_{2}}{\eta} & & \ddots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\
\hline & \ddots & & \ddots & &
\end{array}\right]
$$

gives 44b.
Theorem 4 (Third order ODE for generalized Charlier). The recursion coefficient $\gamma_{n}$ of the generalized Charlier polynomials is subject to the following third order nonlinear ODE

$$
\begin{equation*}
\vartheta_{\eta}\left(\frac{\gamma_{n}}{\eta}\left(\vartheta_{\eta}^{2} \log \gamma_{n}+2 \gamma_{n}\right)+n^{2} \frac{\eta}{\gamma_{n}}\right)=2 \gamma_{n} \tag{46}
\end{equation*}
$$

Proof. In the one hand, Equation (44b) can be written as follows

$$
\pm \vartheta_{\eta}\left(\frac{\gamma_{n} \gamma_{n \pm 1}}{\eta}\right)=(n \pm 1) \gamma_{n}-n \gamma_{n \pm 1},
$$

and, consequently, we find

$$
\begin{aligned}
\vartheta_{\eta}\left(\frac{\gamma_{n} \gamma_{n+1}+\gamma_{n-1} \gamma_{n}}{\eta}\right) & =(n+1) \gamma_{n}-n \gamma_{n+1}-(n-1) \gamma_{n}+n \gamma_{n-1}=2 \gamma_{n}-n\left(\gamma_{n+1}-\gamma_{n-1}\right) \\
& =2 \gamma_{n}-n^{2} \vartheta_{\eta}\left(\frac{\eta}{\gamma_{n}}\right)
\end{aligned}
$$

where (44a) has been used. In the other hand,

$$
\vartheta_{\eta}\left(\frac{\gamma_{n} \gamma_{n+1}+\gamma_{n-1} \gamma_{n}}{\eta}\right)=\vartheta_{\eta}\left(\frac{\gamma_{n}}{\eta}\left(\gamma_{n+1}+\gamma_{n-1}\right)\right)=\vartheta_{\eta}\left(\frac{\gamma_{n}}{\eta}\left(\vartheta_{\eta}^{2} \log \gamma_{n}+2 \gamma_{n}\right)\right),
$$

where the Toda equation (36) for the $\gamma$ 's has been used. Hence, comparing the previous equations we get Equation (46).

## Remark 7. Using the relations

$$
\vartheta_{\eta}^{2} \log \gamma_{n}=\vartheta_{\eta}\left(\frac{\eta}{\gamma_{n}}\right) \frac{\mathrm{d} \gamma_{n}}{\mathrm{~d} \eta}+\frac{\eta^{2}}{\gamma_{n}} \frac{\mathrm{~d}^{2} \gamma_{n}}{\mathrm{~d} \eta^{2}}, \quad \vartheta_{\eta}\left(\frac{\eta}{\gamma_{n}}\right)=\frac{\eta}{\gamma_{n}}-\frac{\eta^{2}}{\gamma_{n}^{2}} \frac{\mathrm{~d} \gamma_{n}}{\mathrm{~d} \eta}
$$

we write (46) as follows

$$
\frac{\mathrm{d}}{\mathrm{~d} \eta}\left(\eta \mathcal{P}_{I I, n}^{\prime}\left(\gamma_{n}\right)\right)=2 \frac{\gamma_{n}}{\eta}, \quad \quad \mathcal{P}_{I I I, n}^{\prime}\left(\gamma_{n}\right):=\frac{\mathrm{d}^{2} \gamma_{n}}{\mathrm{~d} \eta^{2}}-\frac{1}{\gamma_{n}}\left(\frac{\mathrm{~d} \gamma_{n}}{\mathrm{~d} \eta}\right)^{2}+\frac{1}{\eta} \frac{\mathrm{~d} \gamma_{n}}{\mathrm{~d} \eta}+\frac{2 \gamma_{n}^{2}}{\eta^{2}}+\frac{n^{2}}{\gamma_{n}} .
$$

The notation here is motivated by the Okamoto's, see [49], alternative form $P_{\text {III }}^{\prime}$ of the Painlevé III equation $\left(\mathcal{P}_{\text {III,n }}^{\prime}(u)=\right.$ 0), listed as 32.2 .9 in the Digital Library of Mathematical Functions (DLMF) at NIST, with the following choice of parameters given there: $\alpha=8, \gamma=\beta=0$ and $\delta=4 n^{2}$. The Okamoto's notation in [49] is $P_{I I I^{\prime}}$. In fact, the corresponding Painlevé equation is, after suitable rescaling of dependent and independent variable, the $P_{\text {III' }}(D 7)$ equation (9) with $\beta=0$ in [48]. See Theorem 1 (iv) in 48] and the comment immediately after. For the connection with $P_{\text {III }}$ see [50, 51] and [19]. In particular, Remark 4.5 in [19] gives the functions $p, q$ of the Hamiltonian system $\mathcal{H}_{\text {III' }}$, see [49], in terms of $S_{n}=-p_{n}^{1}=\vartheta_{\eta} \tau_{n}$

$$
q=\frac{\eta \frac{\mathrm{d}^{2} S_{n}}{\mathrm{~d} \eta^{2}}-2(n+b) \frac{\mathrm{d} S_{n}}{\mathrm{~d} \eta}+2 n}{4 \frac{\mathrm{~d} S_{n}}{\mathrm{~d} \eta}\left(1-\frac{\mathrm{d} S_{n}}{\mathrm{~d} \eta}\right)}
$$

$$
p=\frac{\mathrm{d} S_{n}}{\mathrm{~d} \eta}
$$

with parameters $\theta_{0}=n+b$ and $\theta_{\infty}=n-b$. In terms of $\gamma_{n}=\eta \frac{\mathrm{d} S_{n}}{\mathrm{~d} \eta}$ we have

$$
q=\frac{\eta^{2} \frac{\mathrm{~d} \gamma_{n}}{\mathrm{~d} \eta}-(2 n+2 b+1) \eta \gamma_{n}+2 n \eta^{2}}{4 \gamma_{n}\left(\eta^{2}-\gamma_{n}\right)}, \quad p=\frac{\gamma_{n}}{\eta}
$$

From [19, §2.4] we conclude that $q$ satisfies $P_{\text {III' }}$ with $\alpha=-4(n-b), \beta=4(n+b+1), \gamma=4$ and $\delta=-4$, in 32.2 .9 at DLMF, or Equation (2.4) in [19] with $A=-2 \theta_{\infty}=-2(n-b)$ and $B=2\left(\theta_{0}+1\right)=2(n+b+1)$,

$$
\frac{\mathrm{d}^{2} q}{\mathrm{~d} \eta^{2}}=\frac{1}{q}\left(\frac{\mathrm{~d} q}{\mathrm{~d} \eta}\right)^{2}-\frac{1}{\eta} \frac{\mathrm{~d} q}{\mathrm{~d} \eta}-(n-b) \frac{q^{2}}{\eta^{2}}+\frac{n+b+1}{\eta}+\frac{q^{3}}{\eta}-\frac{1}{q}
$$

Notice also [19, 49] that $p_{n}^{1}$ is a solution to the $P_{I I I^{\prime}} \sigma$-equation.
Remark 8. In terms of $p=\frac{\gamma_{n}}{\eta}=-\frac{\mathrm{d} p_{n}^{1}}{\mathrm{~d} \eta}$, Equation (46) can be written as follows

$$
\vartheta_{\eta}\left(\vartheta_{\eta}^{2} p-\frac{\left(\vartheta_{\eta} p\right)^{2}}{p}+2 \eta p^{2}+\frac{n^{2}}{p}\right)=2 \eta p
$$

that expands to

$$
p^{2} \vartheta_{\eta}^{3} p-2 p\left(\vartheta_{\eta} p\right)\left(\vartheta_{\eta}^{2} p\right)+\left(\vartheta_{\eta} p\right)^{3}+\left(2 \eta p^{3}-n^{2}\right) \vartheta_{\eta} p+2 p^{3}(p-\eta)=0
$$

In [19] it is shown that $\frac{p-1}{p}$ satisfies an instance of Painlevé $V$.
Remark 9 (The appearance of deg- $\mathrm{P}_{\mathrm{V}}$ ). After all these observations, one is lead to conjecture that Equation 46) should have the Painlevé property, and probably is solved in terms of the $P_{\text {III }}$ transcendents. This is indeed the case as was recently shown by Peter Clarkson in [20] in where an integration of this equation leads to [20, Equation (83)] which is equivalent to deg-P ${ }_{V}$, i.e. [20, Equation (38)].

Proposition 12 (Laguerre-Freud relations for the generalized Charlier case). For $n \in \mathbb{N}_{0}$, we find that the recursion coefficients satisfy the following Laguerre-Freud relations

$$
\begin{align*}
& \beta_{n+1}=\frac{\eta(n+1)}{\gamma_{n+1}}-\beta_{n}+n-b  \tag{47a}\\
& \gamma_{n+1}=\eta-\gamma_{n}-\beta_{n}^{2}-b \beta_{n}+\frac{\gamma_{n-1} \gamma_{n}}{\eta}+\frac{\eta n^{2}}{\gamma_{n}}, \quad \gamma_{-1}=\gamma_{0}=0 \tag{47b}
\end{align*}
$$

For $n \in \mathbb{N}$, the following expression for the coefficient of the subleading term

$$
\begin{equation*}
p_{n}^{1}=\frac{n(n+1)}{2}-n \beta_{n}-\frac{\gamma_{n} \gamma_{n+1}}{\eta} \tag{48}
\end{equation*}
$$

holds, as a function of near neighbors recursion coefficients holds.

Proof. From (41) and (42), using (11), we get two different expressions for the first superdiagonal involving only the recursion coefficients that we must equate, i.e.

$$
\begin{equation*}
\eta H D=H\left(\beta+T_{-} \beta+b I\right) \gamma-T_{+}\left(D H\left(T_{-} \gamma\right) \gamma\right) \tag{49}
\end{equation*}
$$

so that

$$
\begin{equation*}
\eta D \gamma^{-1}=\beta+T_{-} \beta+b I-\left(T_{+} D\right)\left(T_{+} T_{-}^{2} H\right)\left(T_{-} H\right)^{-1}=\beta+T_{-} \beta+b I-T_{+} D, \tag{50}
\end{equation*}
$$

where we used $\gamma=\left(T_{-} H\right) H^{-1}$, that component wise is 47a). Alternatively, notice that Equation (45), after summing and dealing with a telescopic series on the RHS, gives 47a.

From the main diagonal and the second superdiagonal, again using (11), we get the following two expressions,

$$
\begin{align*}
\eta H & =H\left(\gamma+T_{+} \gamma+\beta^{2}+b \beta\right)-T_{+}\left(D H\left(\beta+T_{-} \beta+b I\right) \gamma\right)+T_{+}^{2}\left(\pi^{[-2]} H\left(T_{-} \gamma\right) \gamma\right),  \tag{51}\\
\eta H \pi^{[2]} & =H\left(T_{-} \gamma\right) \gamma . \tag{52}
\end{align*}
$$

From (52) and (13) we obtain (48). Again, using $\gamma=\left(T_{-} H\right) H^{-1}$ we get

$$
\begin{aligned}
\eta & =\gamma+T_{+} \gamma+\beta^{2}+b \beta-\left(T_{+} D\right)\left(T_{+} H\right) H^{-1} T_{+}\left(\beta+T_{-} \beta+b I\right)\left(T_{+} T_{-} H\right) T_{+}\left(H^{-1}\right)+T_{+}^{2}\left(\pi^{[-2]} T_{-}^{2} H\right) H^{-1} \\
& =\gamma+T_{+} \gamma+\beta^{2}+b \beta-\left(T_{+} D\right) T_{+}\left(\eta D \gamma^{-1}+T_{+} D\right)+T_{+}^{2}\left(\pi^{[-2]}\right) \\
& =\gamma+T_{+} \gamma+\beta^{2}+b \beta-\left(T_{+} D\right)\left(T_{+}^{2} D\right)-\eta\left(T_{+} D\right)^{2} T_{+}\left(\gamma^{-1}\right)+T_{+}^{2} \pi^{[-2]} .
\end{aligned}
$$

Noticing that $2 D^{[2]}=D T_{-} D$, we see that 15) implies $\pi^{[-2]}=D\left(T_{-} D\right)-\pi^{[2]}$, and (52) gives $\pi^{[-2]}=$ $D\left(T_{-} D\right)-\eta^{-1}\left(T_{-}^{2} H\right) H^{-1}$. Hence, $T_{+}^{2} \pi^{[-2]}=\left(T_{+}^{2} D\right)\left(T_{+} D\right)-\eta^{-1} H T_{+}\left(H^{-1}\right)$ and we obtain

$$
\begin{aligned}
\eta & =\gamma+T_{+} \gamma+\beta^{2}+b \beta-\left(T_{+} D\right)\left(T_{+}^{2} D\right)-\eta\left(T_{+} D\right)^{2} T_{+}\left(\gamma^{-1}\right)+\left(T_{+}^{2} D\right)\left(T_{+} D\right)-\eta^{-1} H T_{+}\left(H^{-1}\right) \\
& =\gamma+T_{+} \gamma+\beta^{2}+b \beta-\eta\left(T_{+} D\right)^{2} T_{+}\left(\gamma^{-1}\right)-\eta^{-1} H T_{+}^{2}\left(H^{-1}\right) .
\end{aligned}
$$

We finally find

$$
\gamma+T_{+} \gamma+\beta^{2}+b \beta-\eta=\eta\left(T_{+} D\right)^{2} T_{+}\left(\gamma^{-1}\right)+\eta^{-1} H T_{+}^{2}\left(H^{-1}\right),
$$

that component wise gives 47b.
Remark 10. Smet $\mathcal{E}$ Van Assche found, see [50, Theorem 2.1], for the generalized Charlier weight that the corresponding recursion coefficients satisfy (in the notation of this paper) 47a) and, instead of 47b), the following relation

$$
\begin{equation*}
\left(\gamma_{n+1}-\eta\right)\left(\gamma_{n}-\eta\right)=\eta\left(\beta_{n}-n\right)\left(\beta_{n}-n+b\right) . \tag{53}
\end{equation*}
$$

Notice that (53) is an equation of the form $\gamma_{n+1}=g\left(\gamma_{n}, \beta_{n}\right)$ which only involves a step backwards in $n$. In this sense, is better than (47b) which is of the form $\gamma_{n+1}=f\left(\gamma_{n}, \gamma_{n-1}, \beta_{n}\right)$. However, (43) gives $\gamma_{n-1}=$ $F\left(\gamma_{n+1}, \gamma_{n}, \beta_{n}, \beta_{n-1}\right)$, but (47a) gives $\beta_{n-1}=G\left(\beta_{n}, \gamma_{n}\right)$, so combining both we get $\gamma_{n-1}=F\left(\gamma_{n+1}, \gamma_{n}, \beta_{n}, G\left(\beta_{n}, \gamma_{n}\right)\right)$ and we finally get a relation involving only $\gamma_{n+1}, \gamma_{n}$ and $\beta_{n}$.
Proposition 13. If (43) holds then, equations 47a) and 47b) are equivalent to 47a) and (53).
Proof. We rewrite 43) and 47a) as indicated

$$
\begin{align*}
\gamma_{n-1} & =\gamma_{n+1}+\frac{n \eta\left(\beta_{n}-\beta_{n-1}-1\right)}{\gamma_{n}}, & n \geq 1 .  \tag{54}\\
\beta_{n-1}+1 & =-\beta_{n}+\frac{\eta n}{\gamma_{n}}+n-b . & \tag{55}
\end{align*}
$$

Hence, for $n \geq 1$ and taking $\gamma_{-1}=\gamma_{0}=0$ we can write 47b as follows

$$
\gamma_{n+1}=\eta-\gamma_{n}-\beta_{n}^{2}-b \beta_{n}+\frac{\gamma_{n}}{\eta}\left(\gamma_{n+1}+\frac{n \eta\left(\beta_{n}-\beta_{n-1}-1\right)}{\gamma_{n}}\right)+\frac{\eta n^{2}}{\gamma_{n}}
$$

$$
\begin{align*}
& =\eta+\frac{\gamma_{n} \gamma_{n+1}}{\eta}-\gamma_{n}+\frac{\eta n^{2}}{\gamma_{n}}-\beta_{n}^{2}-b \beta_{n}+n\left(\beta_{n}-\beta_{n-1}-1\right) \\
& =\eta+\frac{\gamma_{n} \gamma_{n+1}}{\eta}-\gamma_{n}+\frac{\eta n^{2}}{\gamma_{n}}-\beta_{n}^{2}-b \beta_{n}+n\left(2 \beta_{n}-\frac{\eta n}{\gamma_{n}}-n+b\right) \\
& =\eta+\frac{\gamma_{n} \gamma_{n+1}}{\eta}-\gamma_{n}-\beta_{n}^{2}-b \beta_{n}+2 n \beta_{n}-n^{2}+b n . \tag{56}
\end{align*}
$$

that is (53). The inverse statement is easily proven to hold. If we assume (53), (47a) and (43) to be true, we can go backwards in the chain of equalities leading to (56) and get the stated result.
Corollary 1. The $\beta$ 's are subject to the nonlinear recursion

$$
\frac{\eta(n+1)}{\beta_{n+1}+\beta_{n}-n+b}=\eta+\left(\frac{n-1}{\beta_{n-1}+\beta_{n-2}-n+2+b}-1\right) \frac{\eta n}{\beta_{n}+\beta_{n-1}-n+1+b}-\beta_{n}^{2}-b \beta_{n} .+n\left(\beta_{n}+\beta_{n-1}-n+1+b\right) . ~ \$ ~ \begin{array}{r}
+n+1 \tag{57}
\end{array}
$$

Proof. Notice that we can write 47a) as follows

$$
\begin{equation*}
\gamma_{n+1}=\frac{\eta(n+1)}{\beta_{n+1}+\beta_{n}-n+b}, \tag{58}
\end{equation*}
$$

that we can introduce in (47b) to get (57).
We now seek for a second order ODE for $\gamma_{n}$. From the above results it easily follows that (this was previously found in [28]),

Lemma 1. The recursion coefficients $\beta_{n}$ and $\gamma_{n}$ satisfy the following system of first order nonlinear ODEs

$$
\begin{align*}
\vartheta_{\eta} \beta_{n} & =\eta \frac{\eta+(b-n) n+\left(2 n-b-\beta_{n}\right) \beta_{n}-\gamma_{n}}{\eta-\gamma_{n}}-\gamma_{n}  \tag{59a}\\
\vartheta_{\eta} \gamma_{n} & =\left(b-n+1+2 \beta_{n}\right) \gamma_{n}-n \eta . \tag{59b}
\end{align*}
$$

Proof. Equation (56), after some cleaning, reads

$$
\begin{equation*}
\gamma_{n+1}=\eta \frac{\eta+(b-n) n+\left(2 n-b-\beta_{n}\right) \beta_{n}-\gamma_{n}}{\eta-\gamma_{n}} \tag{60}
\end{equation*}
$$

which is [28, Equation (16)]. In the one hand, from (60) and the Toda equation (35a) we find (59a). That is Equation (18) in [28]. On the other hand, from (47a) and the Toda equation (35b] we get (59b).

Remark 11. Differential system (59) was used in [28] to get a second order nonlinear ODE for $\beta_{n}$ and then showed [28, Theorem 2.1] that an auxiliary function y, see [28, Equation (20)], satisfies an instance of the $P_{V}$ related to the $P_{\text {III. }}$. Notice that y is a solution to a Ricatti equation in where $\beta_{n}$ appears in the coefficients.
Theorem 5 (Second order ODE for generalized Charlier). The recursion coefficient $\gamma_{n}$ satisfies the second order nonlinear ODE

$$
\begin{align*}
\left(1-\frac{\gamma_{n}}{\eta}\right)\left(\vartheta _ { \eta } \left(\frac{\vartheta_{\eta} \gamma_{n}}{\gamma_{n}}\right.\right. & \left.\left.+\frac{n \eta}{\gamma_{n}}\right)+2 \gamma_{n}\right)+2\left(\gamma_{n}-\eta+(n-b) n\right)  \tag{61}\\
& =-\frac{1}{2}\left(\frac{\vartheta_{\eta} \gamma_{n}}{\gamma_{n}}+\frac{n \eta}{\gamma_{n}}\right)^{2}+(n+1)\left(\frac{\vartheta_{\eta} \gamma_{n}}{\gamma_{n}}+\frac{n \eta}{\gamma_{n}}\right)+(-b+n-1)(-b+3 n+1)
\end{align*}
$$

Proof. Observe that Equation (59b) leads to

$$
\begin{equation*}
\beta_{n}=\frac{1}{2}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}-b+n-1\right), \tag{62}
\end{equation*}
$$

so that

$$
\begin{equation*}
\vartheta_{\eta} \beta_{n}=\frac{1}{2} \vartheta_{\eta}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right) . \tag{63}
\end{equation*}
$$

From (59a) and (63) we get

$$
\left(1-\frac{\gamma_{n}}{\eta}\right)\left(\frac{1}{2} \vartheta_{\eta}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right)+\gamma_{n}\right)+\gamma_{n}-\eta+(n-b) n=(2 n-b) \beta_{n}-\beta_{n}^{2}
$$

and replacing $\beta_{n}$ by the expression provided in (62) we get (61). To check it let us elaborate on the RHS of the equation

$$
\begin{aligned}
(2 n-b) \beta_{n}-\beta_{n}^{2}= & \frac{2 n-b}{2}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}-b+n-1\right)-\frac{1}{4}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}-b+n-1\right)^{2} \\
= & \frac{2 n-b}{2}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}-b+n-1\right)-\frac{1}{4}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right)^{2} \\
& \quad-\frac{(b-n+1)^{2}}{4}+\frac{b-n+1}{2}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right) \\
= & -\frac{1}{4}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right)^{2}+\frac{n+1}{2}\left(\vartheta_{\eta} \log \gamma_{n}+\frac{n \eta}{\gamma_{n}}\right)+\frac{(-b+n-1)(-b+3 n+1)}{2},
\end{aligned}
$$

and the statement is proven.
Some additional properties of this generalized Charlier case follow.
Proposition 14. For the generalized Charlier case, $\sigma=\eta$ and $\theta=z(z+b)$, the following holds:
i) The dressed Pascal matrix is

$$
\Pi=I+\Lambda^{\top} D+\eta^{-1}\left(\Lambda^{\top}\right)^{2}\left(T_{-} \gamma\right) \gamma=\left[\begin{array}{cccccc}
1 & & 0 & & 0 & \cdots \tag{64}
\end{array}\right] \cdot \ldots \text {. }
$$

Moreover, the Jacobi and dressed Pascal matrices are linked by

$$
\begin{equation*}
J^{2}+b J=\eta \Pi H \Pi^{\top} H^{-1} . \tag{65}
\end{equation*}
$$

ii) The corresponding orthogonal polynomials satisfy

$$
\eta^{-1}=\frac{P_{n+1}(0) P_{n}(-b)-P_{n+1}(-b) P_{n}(0)}{P_{n+2}(0) P_{n+1}(-b)-P_{n+2}(b) P_{n+1}(0)}, \quad \frac{n+1}{\gamma_{n+1}}=\frac{P_{n+2}(0) P_{n}(-b)-P_{n+2}(-b) P_{n}(0)}{P_{n+2}(0) P_{n+1}(-b)-P_{n+2}(-b) P_{n+1}(0)} .
$$

ii) We apply the ideas that leads to Christoffel formula for a Christoffel perturbation. From (28) we get $\theta(z) P(z-1)=\Psi H^{-1} P(z)=\eta H \Pi^{\top} H^{-1} P(z)$, where the last equation holds due the generalized Charlier restrictions to the weight. Therefore,

$$
\theta(z) H^{-1} P(z-1)=\Pi^{\top} H^{-1} P(z) .
$$

As $\theta(0)=\theta(-b)=0$ we have

$$
\Pi^{\top} H^{-1} P(0)=0, \quad \quad \Pi^{\top} H^{-1} P(-b)=0 .
$$

Both equations can be simplified to

$$
\left[\left[\begin{array}{ll}
\eta^{-1} \gamma_{n+2} \gamma_{n+1} & n+1
\end{array}\right]=-\left[\begin{array}{ll}
H_{n}^{-1} P_{n}(0) & H_{n}^{-1} P_{n}(-b)
\end{array}\right]\left[\begin{array}{ll}
H_{n+2}^{-1} P_{n+2}(0) & H_{n+2}^{-1} P_{n+2}(-b) \\
H_{n+1}^{-1} P_{n+1}(0) & H_{n+1}^{-1} P_{n+1}(-b)
\end{array}\right]^{-1}\right.
$$

from where the result follows.

## 3. Generalized Meixner weights

Another interesting case appears when one takes $\sigma=z+a$, that we call extended Meixner type. The generalized Meixner, which is the main example of these extended Meixner weights, corresponds to the choice $\sigma(z)=\eta(z+a)$ and $\theta(z)=z(z+b)$. A weight that satisfies the Pearson equation

$$
(k+1)(k+1+b) w(k+1)=\eta(k+a) w(k)
$$

is proportional to the generalized Meixner weight

$$
w(z)=\frac{\Gamma(b+1) \Gamma(z+a) \eta^{z}}{\Gamma(a) \Gamma(z+b+1) \Gamma(z+1)}=\frac{(a)_{z}}{(b+1)_{z}} \frac{\eta^{z}}{z!} .
$$

The finiteness of the moments requires $a(b+1)>0$ and $\eta>0$ [24]. In this case the moments are expressed in terms of $\rho_{0}={ }_{1} F_{1}(a ; b+1 ; \eta)=M(a, b+1, \eta)$, also known as the confluent hypergeometric function or Kummer function.

Remark 12. From previous comments and (24) we get that in terms of the following $\delta$-Wronskian of the Kummer function

$$
\tau_{n}:=\mathscr{W}_{n}(M(a, b+1, \eta)),
$$

we get explicit expressions for the recursion coefficients

$$
\beta_{n}=\vartheta_{\eta} \log \frac{\tau_{n+1}}{\tau_{n}}, \quad \quad \gamma_{n+1}=\frac{\tau_{n+1} \tau_{n-1}}{\tau_{n}^{2}}, \quad n \in \mathbb{N}_{0}
$$

Remark 13. Meixner introduced the non generalized version with $w=(a)_{z} \frac{\eta^{z}}{z!}$ in [45].
Remark 14. For an extended Meixner type weight, as $M=\operatorname{deg} \sigma=1$ we have that the Laguerre-Freud matrix $\Psi=\Pi^{-1} H \theta\left(J^{\top}\right)=\eta(J+a) H \Pi^{\top}$ is a banded matrix with only one subdiagonal and $N$ superdiagonals. Now we do not have, as in the extended Charlier case that $\Psi=H \Pi^{\top}$, which implied that the dressed Pascal matrix $\Pi$ had only three nonzero subdiagonals. In the extended Meixner case the dressed Pascal matrix will possibly have an infinite number of nonzero subdiagonals.

Theorem 6 (The generalized Meixner Laguerre-Freud structure matrix). For a generalized Meixner weight; i.e. $\sigma=\eta(z+a)$ and $\theta=z(z+b)$, the structure matrix is

Proof. The structure matrix has a diagonal structure, see [27, $\Psi=\Lambda^{\top} \psi^{(-1)}+\psi^{(0)}+\psi^{(1)} \Lambda+\psi^{(2)} \Lambda^{2}$. As $\Psi=\eta(J+a I) H \Pi^{\top}$ we find

$$
\begin{align*}
\Psi=\eta\left(\Lambda^{\top} \gamma+\beta+a I+\Lambda\right) H\left(I+D \Lambda+\pi^{[2]} \Lambda^{2}\right. & \left.+\pi^{[3]} \Lambda^{3}+\cdots\right)  \tag{67}\\
=\underbrace{\eta \Lambda^{\top} \gamma H}_{\text {first subdiagonal }}+\underbrace{\eta\left(\Lambda^{\top} \gamma H D \Lambda+(\beta+a I) H\right)}_{\text {main diagonal }} & +\underbrace{\eta\left(\Lambda^{\top} \gamma H \pi^{[2]} \Lambda^{2}+(\beta+a I) H D \Lambda+\Lambda H\right)}_{\text {first superdiagonal }} \\
& +\underbrace{\eta\left(\Lambda^{\top} \gamma H \pi^{[3]} \Lambda^{3}+(\beta+a I) H \pi^{[2]} \Lambda^{2}+\Lambda H D \Lambda\right)}_{\text {second superdiagonal }}+\cdots
\end{align*}
$$

we get $\psi^{(0)}=\eta T_{+}(\gamma H D)+\eta(\beta+a I) H$. Now, as

$$
J^{2}+b J=\left(\Lambda^{\top}\right)^{2}\left(T_{-} \gamma\right) \gamma+\Lambda^{\top}\left(\beta+T_{-} \beta+b I\right) \gamma+\gamma+T_{+} \gamma+\beta^{2}+b \beta+\left(\beta+T_{-} \beta+b I\right) \Lambda+\Lambda^{2}
$$

from the alternative expression $\Psi=\Pi^{-1} H\left(\left(J^{\top}\right)^{2}+b J^{\top}\right)$, we find

$$
\left.\begin{array}{rl}
\Psi= & \left(I-\Lambda^{\top} D+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]}-\left(\Lambda^{\top}\right)^{3} \pi^{[-3]}+\cdots\right) H  \tag{68}\\
& \times\left(\left(\Lambda^{\top}\right)^{2}+\Lambda^{\top}\left(\beta+T_{-} \beta+b I\right)+\gamma+T_{+} \gamma+\beta^{2}+b \beta+\left(\beta+T_{-} \beta+b I\right) \gamma \Lambda+\left(T_{-} \gamma\right) \gamma \Lambda^{2}\right)
\end{array} \begin{array}{rl}
\text { second superdiagonal }
\end{array} \begin{array}{rl}
H\left(T_{-} \gamma\right) \gamma \Lambda^{2} \\
& +\underbrace{-\Lambda^{\top} D H\left(T_{-} \gamma\right) \gamma \Lambda^{2}+H\left(\beta+T_{-} \beta+b I\right) \gamma \Lambda}_{\text {frrst superdiagonal }}
\end{array}\right)
$$

Thus, $\psi^{(1)}=-T_{+}\left(D H\left(T_{-} \gamma\right) \gamma\right)+H\left(\beta+T_{-} \beta+b I\right) \gamma$. Finally, the Laguerre-Freud matrix has the form

$$
\Psi=\eta \Lambda^{\top} T_{-} H+\eta\left(\beta+a I+T_{+} D\right) H+\left(\beta+T_{-} \beta+b I-T_{+} D\right) T_{-} H \Lambda+T_{-}^{2} H \Lambda^{2} .
$$

When expressed component wise we get the given form in 66).
Proposition 15 (Compatibility). For the generalized Meixner case the recursion coefficients fulfill

$$
\begin{align*}
\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right) \gamma_{n+1}-\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n} & =\eta\left(\beta_{n}+a+n\right),  \tag{69a}\\
\gamma_{n+2}-\gamma_{n}-2 \eta+\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right)\left(\beta_{n+1}-\beta_{n}-1\right) & =0 . \tag{69b}
\end{align*}
$$

Proof. The matrix
satisfies the compatibility condition 29a. As we have

we get for the first row

$$
\gamma_{1}=\frac{\eta\left(\beta_{0}+a\right)}{\beta_{0}+\beta_{1}+b-\eta}, \quad \quad \gamma_{2}=\beta_{0}+\beta_{1}+b-\left(\beta_{0}+\beta_{1}+b-\eta\right)\left(\beta_{1}-\beta_{0}\right)+\eta
$$

while for the next rows we obtain

$$
\begin{aligned}
\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right) \gamma_{n+1}-\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n} & =\eta\left(\beta_{n}+a+n\right) \\
\gamma_{n+2}-\gamma_{n}-\eta+\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right)\left(\beta_{n+1}-\beta_{n}\right) & =\beta_{n}+\beta_{n+1}+b-n .
\end{aligned}
$$

Which are 69a) and 69b (in disguise the last one, some clearing is required).
An alternative manner to get (69a) follows. The matrix $\Psi H^{-1}$ fulfills 38 b , where $\Phi=-J_{-}$, and we have $\vartheta_{\eta}\left(\Psi H^{-1}\right)=\left[\Psi H^{-1}, J_{-}\right]$. The explicit expression of the above commutator is:
and, consequently, we find the following equations

$$
\begin{align*}
\vartheta_{\eta}\left(\eta \gamma_{n}\right) & =\eta \gamma_{n}\left(\beta_{n}-\beta_{n-1}+1\right),  \tag{70}\\
\vartheta_{\eta}\left(\beta_{n}+\beta_{n+1}+b-n\right) & =\gamma_{n+2}-\gamma_{n},  \tag{71}\\
\vartheta_{\eta}\left(\eta\left(\beta_{n}+a+n\right)\right) & =\gamma_{n+1}\left(\beta_{n}+\beta_{n+1}+b-n\right)-\gamma_{n}\left(\beta_{n-1}+\beta_{n}+b-(n-1)\right) . \tag{72}
\end{align*}
$$

Notice that (70) and (71) follow from the Toda equations for the recursion coefficients (35). The Toda equation (35a) allows to write (72) as follows

$$
\eta\left(\beta_{n}+a+n\right)+\eta \gamma_{n+1}-\eta \gamma_{n}=\gamma_{n+1}\left(\beta_{n}+\beta_{n+1}+b-n\right)-\gamma_{n}\left(\beta_{n-1}+\beta_{n}+b-(n-1)\right),
$$

and we get 69a).
Proposition 16 (Laguerre-Freud relations). For $n \in \mathbb{N}$, we find the following Laguerre-Freud equations
(73)

$$
\gamma_{n+1}=-\gamma_{n}-\left(\beta_{n}+b-n\right) \beta_{n}+n(b-a-n+1)+\eta\left(\beta_{n}+a+n\right)+\eta^{-1}\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n},
$$

$$
\begin{align*}
0= & (n+3)(n+2)(n+1)\left(\beta_{n}-\beta_{n+2}+1\right)-\left(\eta^{-1} \gamma_{n+3}-n-3\right) \gamma_{n+2}  \tag{74}\\
& +(n+3)(n+2)\left(\eta^{-1}\left(\beta_{n+1}+\beta_{n+2}+b-n-1-\eta\right) \gamma_{n+2}-(n+2)\left(\beta_{n+1}+a\right)\right) \\
& -(n+2)(n+1)\left(\eta^{-1}\left(\beta_{n+3}+\beta_{n+4}+b-n-3-\eta\right) \gamma_{n+4}-(n+4)\left(\beta_{n+3}+a\right)\right) \\
& +\left(-\beta_{n+2}+a-b\right)\left(\eta^{-1}\left(\beta_{n+2}+\beta_{n+3}+b-n-2-\eta\right) \gamma_{n+3}-(n+3)\left(\beta_{n+2}+a\right)\right) \\
& +\left(\beta_{n+2}+\beta_{n+3}+b-n-3-\eta\right) \gamma_{n+3}-(n+3)\left(\gamma_{n+2}+\beta_{n+2}^{2}+b \beta_{n+2}\right) \\
& +(n+3)(n+2)\left(\beta_{n+1}+\beta_{n+2}+b\right) .
\end{align*}
$$

## We also find

$$
\begin{equation*}
p_{n+1}^{1}=-\eta^{-1}\left(\beta_{n+1}+\beta_{n+2}+b-n-1-\eta\right) \gamma_{n+2}+\beta_{n+1}+a(n+2)+\frac{(n+2)(n+1)}{2} \tag{75}
\end{equation*}
$$

Proof. Comparing (67) with (68) and recalling (11) we obtain

$$
\begin{align*}
& \eta T_{-} H=\left(\beta+T_{-} \beta+b I\right) T_{-} H- D H\left(\gamma+T_{+} \gamma+\beta^{2}+b \beta\right)  \tag{76}\\
& \quad+T_{+}\left(\pi^{[-2]}\left(\beta+T_{-} \beta+b I\right) H \gamma\right)+T_{+}^{2}\left(\pi^{[-3]} H\left(T_{-} \gamma\right) \gamma\right) \\
& \eta\left(T_{+}(\gamma H D)+(\beta+a I) H\right)= H\left(\gamma+T_{+} \gamma+\beta^{2}+b \beta\right)  \tag{77}\\
& \quad-T_{+}\left(D H\left(\beta+T_{-} \beta+b I\right) \gamma\right)+T_{+}^{2}\left(\pi^{[-2]} H\left(T_{-} \gamma\right) \gamma\right) \\
& \eta\left(T_{+}\left(\gamma H \pi^{[2]}\right)+(\beta+a I) H D+\right.\left.T_{-} H\right)=-T_{+}\left(D H\left(T_{-} \gamma\right) \gamma\right)+H\left(\beta+T_{-} \beta+b I\right) \gamma  \tag{78}\\
& \eta\left(T_{+}\left(\gamma H \pi^{[3]}\right)+(\beta+a I) H \pi^{[2]}+T_{-}(H D)\right)=H\left(T_{-} \gamma\right) \gamma \tag{79}
\end{align*}
$$

Let us study relations 77 ) and 78 . In the one hand, if we choose to solve $\sqrt[78]{6}$ for $\pi^{[2]}$, we get (recall that $\left.T_{-} T_{+}=\mathrm{id}\right)$

$$
\begin{align*}
\pi^{[2]} & =-H^{-1} \gamma^{-1} T_{-}\left((\beta+a I) H D+T_{-} H\right)-\eta^{-1} D T_{-} \gamma+\eta^{-1} H^{-1} \gamma^{-1} T_{-}\left(H \gamma\left(\beta+T_{-} \beta+b I\right)\right) \\
& =\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma-\left(T_{-} D\right)\left(T_{-} \beta+a I\right) \tag{80}
\end{align*}
$$

so that

$$
\pi_{n}^{[2]}=\eta^{-1}\left(\beta_{n+1}+\beta_{n+2}+b-n-1-\eta\right) \gamma_{n+2}-(n+2)\left(\beta_{n+1}+a\right)
$$

Moreover, from $\beta=T_{+} S^{[1]}-S^{[1]}$ and $\pi^{[2]}=D^{[2]}+\left(T_{-} S^{[1]}-S^{[1]}\right) D-S^{[1]}$ we get

$$
\begin{equation*}
S^{[1]}=-\pi^{[2]}+D^{[2]}-D T_{-} \beta \tag{81}
\end{equation*}
$$

that, component wise, is (75). Now, recalling (15), we write (77) as follows

$$
\begin{equation*}
\eta\left(\beta+a I+T_{+} D\right)=\gamma+T_{+} \gamma+\beta^{2}+b \beta-T_{+}\left(D\left(\beta+T_{-} \beta+b I\right)\right)+T_{+}^{2}\left(-\pi^{[2]}+2 D^{[2]}\right) \tag{82}
\end{equation*}
$$

that is, using 12 ,

$$
\begin{aligned}
\eta\left(T_{-}^{2} \beta+a I+T_{-} D\right)= & T_{-}^{2} \gamma+T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta-\left(T_{-} D\right)\left(T_{-} \beta+T_{-}^{2} \beta+b I-D\right)-\pi^{[2]} \\
= & T_{-}^{2} \gamma+T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta-\left(T_{-} D\right)\left(T_{-} \beta+T_{-}^{2} \beta+b I-D\right) \\
& \quad-\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma+\left(T_{-} D\right)\left(T_{-} \beta+a I\right) \\
= & T_{-}^{2} \gamma+T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta-\left(T_{-} D\right)\left(T_{-}^{2} \beta+(b-a) I-D\right) \\
& \quad-\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma
\end{aligned}
$$

that component wise reads

$$
\begin{aligned}
\eta\left(\beta_{n+2}+a+n+2\right)=\gamma_{n+3}+\gamma_{n+2}+\beta_{n+2}^{2}+b \beta_{n+2}-(n+2) & \left(\beta_{n+2}+b-a-n-1\right) \\
& -\eta^{-1}\left(\beta_{n+1}+\beta_{n+2}+b-n-1-\eta\right) \gamma_{n+2}
\end{aligned}
$$

which is 73.
Now, $\sqrt{79}$ can be written as follows
$\pi^{[3]}=-\left(T_{-} \beta+a I\right) T_{-} \pi^{[2]}+\left(\eta^{-1} T_{-}^{2} \gamma-T_{-}^{2} D\right) T_{-} \gamma$
$=-\left(T_{-} \beta+a I\right)\left(\eta^{-1}\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-} D-\eta\right) T_{-}^{2} \gamma-\left(T_{-}^{2} D\right)\left(T_{-}^{2} \beta+a I\right)\right)+\left(\eta^{-1} T_{-}^{2} \gamma-T_{-}^{2} D\right) T_{-} \gamma$,
where (80) has been used. From (15), $\pi^{[3]}+\pi^{[-3]}=2\left(\left(T_{-}{ }^{2} S^{[1]}\right) D^{[2]}-\left(T_{-} D^{[2]}\right) S^{[1]}\right)$, and (81) (noticing that $\left.3 D^{[3]}=2 D^{[2]}\left(T_{-}^{2} D^{[2]}-T_{-} D^{[2]}\right)\right)$ we get

$$
\begin{aligned}
\pi^{[-3]}= & 2 D^{[2]}\left(-T_{-}^{2} \pi^{[2]}+T_{-}^{2} D^{[2]}-\left(T_{-}^{2} D\right) T_{-}^{3} \beta\right)-2\left(T_{-} D^{[2]}\right)\left(-\pi^{[2]}+D^{[2]}-D T_{-} \beta\right)-\pi^{[3]} \\
= & 3 D^{[3]}+2\left(T_{-} D^{[2]}\right)\left(\pi^{[2]}+D T_{-} \beta\right)-2 D^{[2]}\left(T_{-}^{2} \pi^{[2]}+\left(T_{-}^{2} D\right) T_{-}^{3} \beta\right)-\pi^{[3]} \\
= & 3 D^{[3]} T_{-}\left(\beta-T_{-}^{2} \beta+I\right)+2\left(T_{-} D^{[2]}\right) \pi^{[2]}-2 D^{[2]} T_{-}^{2} \pi^{[2]}-\pi^{[3]} \\
= & 3 D^{[3]} T_{-}\left(\beta-T_{-}^{2} \beta+I\right)-\left(\eta^{-1} T_{-}^{2} \gamma-T_{-}^{2} D\right) T_{-} \gamma \\
& +2\left(T_{-} D^{[2]}\right)\left(\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma-\left(T_{-} D\right)\left(T_{-} \beta+a I\right)\right) \\
& -2 D^{[2]}\left(\eta^{-1}\left(T_{-}^{3} \beta+T_{-}^{4} \beta+b I-T_{-}^{2} D-\eta\right) T_{-}^{3} \gamma-\left(T_{-}^{3} D\right)\left(T_{-}^{3} \beta+a I\right)\right) \\
& +\left(T_{-} \beta+a I\right)\left(\eta^{-1}\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-} D-\eta\right) T_{-}^{2} \gamma-\left(T_{-}^{2} D\right)\left(T_{-}^{2} \beta+a I\right)\right) .
\end{aligned}
$$

We now write 76) as follows

$$
\begin{aligned}
\pi^{[-3]}= & -\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-}^{2} D-\eta\right) T_{-}^{2} \gamma+\left(T_{-}^{2} D\right)\left(T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta\right)-\left(T_{-} \beta+T_{-}^{2} \beta+b I\right) T_{-}\left(2 D^{[2]}-\pi^{[2]}\right) \\
= & -\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-}^{2} D-\eta\right) T_{-}^{2} \gamma+\left(T_{-}^{2} D\right)\left(T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta\right) \\
& \quad-\left(T_{-} \beta+T_{-}^{2} \beta+b I\right) T_{-}\left(2 D^{[2]}-\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma+\left(T_{-} D\right)\left(T_{-} \beta+a I\right)\right) .
\end{aligned}
$$

Thus, we get the following equation

$$
\begin{aligned}
0= & 3 D^{[3]}\left(T_{-} \beta-T_{-}^{3} \beta+I\right)-\left(\eta^{-1} T_{-}^{2} \gamma-T_{-}^{2} D\right) T_{-} \gamma \\
& +2\left(T_{-} D^{[2]}\right)\left(\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma-\left(T_{-} D\right)\left(T_{-} \beta+a I\right)\right) \\
& -2 D^{[2]}\left(\eta^{-1}\left(T_{-}^{3} \beta+T_{-}^{4} \beta+b I-T_{-}^{2} D-\eta\right) T_{-}^{3} \gamma-\left(T_{-}^{3} D\right)\left(T_{-}^{3} \beta+a I\right)\right) \\
& +\left(T_{-} \beta+a I\right)\left(\eta^{-1}\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-} D-\eta\right) T_{-}^{2} \gamma-\left(T_{-}^{2} D\right)\left(T_{-}^{2} \beta+a I\right)\right) \\
& +\left(T_{-}^{2} \beta+T_{-}^{3} \beta+b I-T_{-}^{2} D-\eta\right) T_{-}^{2} \gamma-\left(T_{-}^{2} D\right)\left(T_{-} \gamma+T_{-}^{2} \beta^{2}+b T_{-}^{2} \beta\right) \\
& +\left(T_{-} \beta+T_{-}^{2} \beta+b I\right) T_{-}\left(2 D^{[2]}-\eta^{-1}\left(T_{-} \beta+T_{-}^{2} \beta+b I-D-\eta\right) T_{-} \gamma+\left(T_{-} D\right)\left(T_{-} \beta+a I\right)\right) .
\end{aligned}
$$

Hence, component wise we get 74).
Remark 15. Notice that the long and cumbersome expression in (74) is a ligature for the recursion coefficients

$$
\left(\beta_{n+4}, \beta_{n+2}, \beta_{n+1}, \beta_{n}, \gamma_{n+4}, \gamma_{n+3}, \gamma_{n+2}\right)
$$

We just wanted to show that the method gives these equations. Indeed, (73) is a better Laguerre-Freud equation for the $\beta$ 's. However, notice that (73) implies an expression of $\beta_{n+1}$ in terms $\left(\beta_{n-1}, \beta_{n}, \gamma_{n+1}, \gamma_{n}\right)$ while (69a) involves and expression for $\beta_{n}$ in terms of $\left(\beta_{n}, \beta_{n-1}, \gamma_{n}, \gamma_{n+1}\right)$. In both cases we need to go two steps down, and we say that we have length two relations. However, we can mix both Laguerre-Freud equations to find an improved expression for $\beta_{n+1}$ involving only one step down, i.e. $\left(\beta_{n}, \gamma_{n}, \gamma_{n+1}\right)$, a length one relation. A similar reasoning holds for 69b).

Proposition 17. The generalized Meixner recursion coefficients are subject to the following length one LaguerreFreud equation

$$
\begin{equation*}
\beta_{n+1}=\frac{1}{\gamma_{n+1}}\left(\eta\left(\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right)+\eta(\eta+1)\left(\beta_{n}+a+n\right)\right)-\beta_{n}-b+n+1+2 \eta . \tag{84}
\end{equation*}
$$

Proof. We write (73) as follows

$$
\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n}=\eta\left(\gamma_{n+1}+\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right)+\eta^{2}\left(\beta_{n}+a+n\right)
$$

that, when introduced in (69a), delivers

$$
\begin{aligned}
\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right) \gamma_{n+1} & =\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n}+\eta\left(\beta_{n}+a+n\right) \\
& =\eta\left(\gamma_{n+1}+\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right)+\eta(\eta+1)\left(\beta_{n}+a+n\right),
\end{aligned}
$$

and we obtain the Laguerre-Freud equation (84).
Let us shift by $n \rightarrow n+1$ the relation (73)

$$
\begin{aligned}
\gamma_{n+2}=-\gamma_{n+1}-\left(\beta_{n+1}+b-n-1\right) \beta_{n+1} & +n(b-a-n) \\
& +\eta\left(\beta_{n+1}+a+n+1\right)+\eta^{-1}\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right) \gamma_{n+1},
\end{aligned}
$$

and introduce the expression for $\gamma_{n+2}$ into 69b). In doing so we obtain

$$
\begin{aligned}
\gamma_{n}+2 \eta-\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right)\left(\beta_{n+1}\right. & \left.-\beta_{n}-1\right)=-\left(\beta_{n+1}+b-n-1\right) \beta_{n+1}+n(b-a-n) \\
& +\eta\left(\beta_{n+1}+a+n+1\right)+\eta^{-1}\left(\beta_{n}+\beta_{n+1}+b-n-2 \eta\right) \gamma_{n+1}
\end{aligned}
$$

but (84) can be written

$$
\gamma_{n+1}\left(\beta_{n+1}+\beta_{n}+b-n-2 \eta\right)=\eta\left(\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right)+\eta(\eta+1)\left(\beta_{n}+a+n\right)+\gamma_{n+1},
$$

so that

$$
\begin{aligned}
& \gamma_{n}+2 \eta-\left(\beta_{n}+\beta_{n+1}+b-n-\eta\right)\left(\beta_{n+1}-\beta_{n}-1\right)=-\left(\beta_{n+1}+b-n-1\right) \beta_{n+1}+n(b-a-n) \\
&+\eta\left(\beta_{n+1}+a+n+1\right)+\left(\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right) \\
&+(\eta+1)\left(\beta_{n}+a+n\right)+\eta^{-1} \gamma_{n+1} .
\end{aligned}
$$

Our best Laguerre-Freud equations are (84) and (73), having lengths one and two, respectively. For the reader convenience we reproduce them again as a Theorem
Theorem 7 (Laguerre-Freud equations for generalized Meixner). The generalized Meixner recursion coefficients satisfy the following Laguerre-Freud relations
$\beta_{n+1}=\frac{1}{\gamma_{n+1}}\left(\eta\left(\gamma_{n}+\left(\beta_{n}+b-n\right) \beta_{n}-n(b-a-n+1)\right)+\eta(\eta+1)\left(\beta_{n}+a+n\right)\right)-\beta_{n}-b+n+1+2 \eta$, $\gamma_{n+1}=-\gamma_{n}-\left(\beta_{n}+b-n\right) \beta_{n}+n(b-a-n+1)+\eta\left(\beta_{n}+a+n\right)+\eta^{-1}\left(\beta_{n-1}+\beta_{n}+b-n+1-\eta\right) \gamma_{n}$.
Remark 16. In [50] a system of Laguerre-Freud equations was presented. There are two functions $u_{n}, v_{n}$ that are linked with $\beta_{n}, \gamma_{n}$ by

$$
\gamma_{n}=n \eta-(a-1) u_{n}, \quad \quad \beta_{n}=n+a-b-1+\eta-\frac{(a-1) v_{n}}{\eta},
$$

and the nonlinear system, see equations (3.2) and (3.3) in [50], is

$$
\begin{aligned}
& \left(u_{n}+v_{n}\right)\left(u_{n+1}+v_{n}\right)=\frac{a-1}{\eta^{2}} v_{n}\left(v_{n}-\eta\right)\left(v_{n}-\eta \frac{a-b-1}{a-1}\right), \\
& \left(u_{n}+v_{n}\right)\left(u_{n}+v_{n-1}\right)=\frac{u_{n}}{u_{n}-\frac{\eta n}{a-1}}\left(u_{n}+\eta\right)\left(u_{n}+\eta \frac{a-b-1}{a-1}\right) .
\end{aligned}
$$

Observe that the first relation, (3.2) in [50], gives $\gamma_{n+1}$ as a rational function of $\left(\gamma_{n}, \beta_{n}\right)$, a length one relation. The rational function is a cubic polynomial divided by a linear function on the recursion coefficients. Instead, our (73) is a length two relation, but is quadratic polynomial in the recursion coefficients, not rational and involving cubic polynomials as does (3.1). The second relation (3.3) in [50] gives $\beta_{n+1}$ in terms of rational function of $\left(\gamma_{n+1}, \beta_{n}\right)$ a length one relation. Now the rational function is a cubic polynomial divided by a quadratic one. Relation (84) is length one as well, but our rational function is quadratic polynomial divided by a linear one.

Remark 17. A nice feature of the Smet-Van Assche system is that for the particular value a $=1$ provides the explicit expression $\beta_{n}=n-b+\eta$ and $\gamma_{n}=n \eta$. Indeed, we check using SageMath 9.0 that (69a), (69b), (73) and (74) are satisfied. For $a=1$, the weight is $w(z)=\frac{\eta^{z}}{(b+1)_{z}}$ and the 0 -th moment is given by the Kummer function $\rho_{0}=M(1, b+1, \eta)=\frac{b}{\eta^{b}} \mathrm{e}^{\eta}(\Gamma(b)-\Gamma(b, \eta))$, where $\Gamma(b, \eta)=\int_{\eta}^{\infty} t^{b-1} \mathrm{e}^{-t} \mathrm{~d} t$ is the incomplete Gamma function. According to [29], it corresponds to the Charlier case on the shifted lattice $\mathbb{N}-b$.

## 4. Gauss hypergeometric weights

The choice $\sigma(z)=\eta(z+a)(z+b)$ and $\theta(z)=z(z+c)$ leads to the following Pearson equation

$$
(k+1)(k+1+c) w(k+1)=\eta(k+a)(k+b) w(k)
$$

whose solutions are proportional to $w(z)=\frac{(a)_{z}(b)_{z}}{(c+1)_{z}} \frac{\eta^{z}}{z!}$. According to [22, 24] this is the generalized Hahn weight of type I. The first moment is $\rho_{0}={ }_{2} F_{1}\left[\begin{array}{c}a, b \\ c+1\end{array} ; \eta\right]$, i.e., the Gauss hypergeometric function. For $\eta=1$, Hahn introduced these discrete orthogonal polynomials in [32]. The standard Hahn polynomials considered in the literature take $a=\alpha+1, b=-N$ and $c=-N-1-\beta$, with $N$ a positive integer.

Remark 18. From previous comments and (24) we get that in terms of the following $\delta$-Wronskian of the Gauss hypergeometric function

$$
\tau_{n}:=\mathscr{W}_{n}\left({ }_{2} F_{1}\left[\begin{array}{c}
a, b \\
c+1
\end{array} ; \eta\right]\right)
$$

we get explicit expressions for the recursion coefficients

$$
\beta_{n}=\vartheta_{\eta} \log \frac{\tau_{n+1}}{\tau_{n}}
$$

$$
\gamma_{n+1}=\frac{\tau_{n+1} \tau_{n-1}}{\tau_{n}^{2}}
$$

$$
n \in \mathbb{N}_{0}
$$

Theorem 8 (The Gauss hypergeometric Laguerre-Freud structure matrix). For a Gauss hypergeometric weight; i.e. $\sigma=\eta(z+a)(z+b)$ and $\theta=z(z+c)$, we find

$$
\begin{align*}
& p_{n+1}^{1}=(n+2) \beta_{n+2}+\beta_{n+1}+\frac{\eta-1}{\eta+1}( \left.\gamma_{n+3}+\gamma_{n+2}+\beta_{n+2}^{2}+\frac{(n+2)(n+1)}{2}\right)  \tag{85}\\
&+\frac{1}{\eta+1}\left(\eta a b+(\eta(a+b)-c) \beta_{n+2}+(\eta(a+b)+c)(n+2)\right) \\
& \pi_{n}^{[2]}=\frac{1}{1+\eta}\left((n+2)(n+1)-\eta a b-(\eta(a+b)-c) \beta_{n+2}-(\eta(a+b)+c)(n+2)\right)  \tag{86}\\
&+\frac{1-\eta}{1+\eta}\left(\gamma_{n+3}+\gamma_{n+2}+\beta_{n+2}^{2}\right)-(n+2)\left(\beta_{n+2}+\beta_{n+1}\right)
\end{align*}
$$

The Laguerre-Freud structure matrix is
(87)

Proof. In this case, since the polynomials $\sigma$ y $\theta$, the Freud-Laguerre matrix has the following diagonal structure $\Psi=\left(\Lambda^{\top}\right)^{2} \psi^{(-2)}+\Lambda^{\top} \psi^{(-1)}+\psi^{(0)}+\psi^{(1)} \Lambda+\psi^{(2)} \Lambda^{2}$. That is, it has two subdiagonals, two superdiagonals and the main diagonal.

In the one hand, from $\Psi=\sigma(J) H \Pi^{\top}$, we get for the Laguerre-Freud structure matrix

$$
\text { 8) } \begin{align*}
& \Psi=\underbrace{\eta \Lambda^{\top} \gamma \Lambda^{\top} \gamma H}_{\text {second subdiagonal }}+\underbrace{\eta\left(\Lambda^{\top} \gamma \Lambda^{\top} \gamma H D \Lambda+\Lambda^{\top} \gamma(\beta+b) H+(\beta+a) \Lambda^{\top} \gamma H\right)}_{\text {first subdiagonal }}  \tag{88}\\
&+\underbrace{\eta\left(\Lambda^{\top} \gamma \Lambda H+\Lambda \Lambda^{\top} \gamma H+(\beta+a)(\beta+b) H+\left(\Lambda^{\top} \gamma(\beta+b)+(\beta+a) \Lambda^{\top} \gamma\right) H D \Lambda+\Lambda^{\top} \gamma \Lambda^{\top} \gamma H \pi^{[2]} \Lambda^{2}\right)}_{\text {main diagonal }} \\
&+\underbrace{\eta\left(\left((\beta+a)(\beta+b)+\Lambda^{\top} \gamma \Lambda+\Lambda \Lambda^{\top} \gamma\right) H D \Lambda+(\beta+a) \Lambda H+\Lambda(\beta+b) H\right.}
\end{align*}
$$

first superdiagonal

$$
\underbrace{\left.+\Lambda^{\top}(\beta+b) H \pi^{[2]} \Lambda^{2}+(\beta+a) \Lambda^{\top} H \pi^{[2]} \Lambda^{2}+\Lambda^{\top} \gamma \Lambda^{\top} \gamma H \pi^{[3]} \Lambda^{3}\right)}
$$

first superdiagonal

$$
+\underbrace{\eta\left(\Lambda^{\top} \gamma \Lambda^{\top} \gamma H \pi^{[4]} \Lambda^{4}+\left(\Lambda^{\top} \gamma(\beta+b)+(\beta+a) \Lambda^{\top} \gamma\right) H \pi^{[3]} \Lambda^{3}\right.}_{\text {second superdiagonal }}
$$

$$
\underbrace{\left.+\left(\Lambda^{\top} \gamma \Lambda+\Lambda \Lambda^{\top} \gamma+(\beta+a)(\beta+b)\right) H \pi^{[2]} \Lambda^{2}+(\Lambda(\beta+b)+(\beta+a) \Lambda) H D \Lambda+\Lambda^{2} H\right)}_{\text {second superdiagonal }} .
$$

In the other hand, from $\Psi=\Pi^{-1} H \theta\left(J^{\top}\right)$ we deduce

$$
\begin{array}{l}
\text { (89) } \Psi=\underbrace{H\left(\Lambda^{\top}\right)^{2}+\Lambda^{\top} D H \Lambda^{\top}\left(\beta+T_{-} \beta+c\right)+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]} H\left(\gamma+T_{+} \gamma+\beta^{2}+c \beta\right)}_{\text {second subdiagonal }}  \tag{89}\\
\underbrace{-\left(\Lambda^{\top}\right)^{3} \pi^{[-3]} H\left(\beta+T_{-} \beta+c\right) \gamma \Lambda+\left(\Lambda^{\top}\right)^{4} \pi^{[-4]} H\left(T_{-} \gamma\right) \gamma \Lambda^{2}}_{\text {second subdiagonal }}
\end{array}+\underbrace{H \Lambda^{\top}\left(\beta+T_{-} \beta+c\right)-\Lambda^{\top} D H\left(\gamma+T_{+} \gamma+\beta^{2}+c \beta\right)+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]} H\left(\beta+T_{-} \beta+c\right) \gamma \Lambda-\left(\Lambda^{\top}\right)^{3} \pi^{[-3]} H\left(T_{-} \gamma\right) \gamma \Lambda^{2}}_{\text {first subdiagonal }}), \underbrace{H\left(\gamma+T_{+} \gamma+\beta^{2}+c \beta\right)-\Lambda^{\top} D H\left(\beta+T_{-} \beta+c\right) \gamma \Lambda+\left(\Lambda^{\top}\right)^{2} \pi^{[-2]} H\left(T_{-} \gamma\right) \gamma \Lambda^{2}}_{\text {main diagonal })})
$$

From (88) we get the first two subdiagonals of $\Psi$, namely

$$
\psi^{(-2)}=\eta H \gamma T_{-} \gamma, \quad \psi^{(-1)}=\eta \gamma T_{+} \gamma T_{+} H+\gamma(\beta+b) H+\left(T_{-} \beta+a\right) \gamma H,
$$

and from (89) we get the first two superdiagonals of $\Psi$, namely

$$
\psi^{(1)}=\left(\beta+T_{-} \beta+c\right) \gamma-\left(T_{+} D\right)\left(T_{+} H\right) \gamma T_{+} \gamma, \quad \quad \psi^{(2)}=H\left(T_{-} \gamma\right) \gamma
$$

We can obtain an expression for the main diagonal that does not depend on $\pi^{[+2]}$ o de $\pi^{[-2]}$ by equating the terms corresponding to the main diagonal in both previous expressions 88) and 89), and we obtain

$$
\begin{aligned}
(\eta-1)\left(T_{+} \gamma+\gamma+\beta^{2}\right)+\beta[\eta(a+b)-c]+\eta a b+(\eta+1)\left(T_{+} D\right)\left[T_{+} \beta+\beta\right]+\left(T_{+} D\right) & {[\eta(a+b)+c] } \\
& =T_{+}^{2}\left(\pi^{[-2]}-\eta \pi^{[2]}\right) .
\end{aligned}
$$

Recalling (13), i.e. $\pi_{n}^{[ \pm 2]}=\frac{(n+2)(n+1)}{2} \mp(n+1) \beta_{n+1} \mp p_{n+1}^{1}$, and substituting in the previous expression we can clear $p_{n+1}^{1}$, and subsequently replaced it in the expression of $\pi^{[2]}$ so that the main diagonal no longer depends on it. Reading element by element the first equality and clearing for $p_{n+1}^{1}$, we obtain

$$
\begin{aligned}
p_{n+1}^{1}=(n+2) \beta_{n+2}+\beta_{n+1}+\frac{\eta-1}{\eta+1}\left(\gamma_{n+3}\right. & \left.+\gamma_{n+2}+\beta_{n+2}^{2}+\frac{(n+2)(n+1)}{2}\right) \\
& +\frac{1}{\eta+1}\left(\eta a b+(\eta(a+b)-c) \beta_{n+2}+(\eta(a+b)+c)(n+2)\right),
\end{aligned}
$$

and the entries of the diagonal matrix $\pi^{[2]}$ are

$$
\begin{aligned}
\pi_{n}^{[2]}=\frac{1}{1+\eta}((n+2)(n+1)-\eta a b-(\eta(a+b) & \left.-c) \beta_{n+2}-(\eta(a+b)+c)(n+2)\right) \\
& +\frac{1-\eta}{1+\eta}\left(\gamma_{n+3}+\gamma_{n+2}+\beta_{n+2}^{2}\right)-(n+2)\left(\beta_{n+2}+\beta_{n+1}\right) .
\end{aligned}
$$

Simplifying, the Laguerre-Freud matrix is gotten

$$
\begin{aligned}
\Psi=\eta\left(\Lambda^{\top}\right)^{2} T_{-}^{2} H & +\eta \Lambda^{\top}\left(a+b+T_{+} D+\beta+T_{-} \beta\right) T_{-} H
\end{aligned} \quad \begin{aligned}
& \\
& \left.\quad \eta\left(T_{+} \gamma+\gamma+(\beta+a)(\beta+b)+T_{+}(D)\left(a+b+T_{+} \beta+\beta\right)+T_{+}^{2} \pi^{[2]}\right)\right) H \\
& +\left(c-T_{+} D+\beta+T_{-} \beta\right) T_{-} H \Lambda+T_{-}^{2} H \Lambda^{2} .
\end{aligned}
$$

Let us analyze the compatibility $\left[\Psi H^{-1}, J\right]=\Psi H^{-1}$,
Theorem 9 (Laguerre-Freud equations for Gauss hypergeometric ). The Gauss hypergeometric recursion coefficients satisfy the following Laguerre-Freud relations

$$
\begin{align*}
& \left(\eta^{2}-1\right)\left(\left(\beta_{n+1}+\beta_{n}\right) \gamma_{n+1}-\left(\beta_{n-1}+\beta_{n}\right) \gamma_{n}\right)  \tag{90a}\\
& +\eta\left(\beta_{n}\left(2 \beta_{n}+a+b+c\right)+2\left(\gamma_{n+1}+\gamma_{n}\right)+n(a+b-c+n-1)+a b\right) \\
& +(\eta+1)\left((\eta(a+b)-c-(\eta+1) n)\left(\gamma_{n+1}-\gamma_{n}\right)+(\eta+1) \gamma_{n}\right)=0, \\
& (\eta+1)\left((n-1) \beta_{n}+(n+1) \beta_{n+1}\right)+(\eta-1)\left(\gamma_{n+2}-\gamma_{n}+\beta_{n+1}^{2}-\beta_{n}^{2}+n\right)  \tag{90b}\\
& +(\eta(a+b)-c)\left(\beta_{n+1}-\beta_{n}\right)+\eta(a+b)+c=0 .
\end{align*}
$$

Proof. We analyze the compatibility $\left[\Psi H^{-1}, J\right]=\Psi H^{-1}$ by diagonals. In both sides of the equation we find matrices whose only non-zero diagonals are the main diagonal, the first and second subdiagonals and the first and second superdiagonals. Equating the non-zero diagonals of both matrices, two identities for the second superdiagonal and subdiagonal are obtained. From the remaining diagonals we obtain the two LaguerreFreud equations (we obtain the same equality from the first subdiagonal and from the first superdiagonal). Firstly, by simplifying we obtain that:

$$
\begin{aligned}
\Psi H^{-1}= & \eta\left(\Lambda^{\top}\right)^{2}\left(T_{-} \gamma\right) \gamma+\eta \Lambda^{\top} \gamma\left(T_{+}(D)+(\beta+b)+T_{-}(\beta+a)\right) \\
& \quad+\frac{\eta}{\eta+1}\left(2\left(T_{+} \gamma+\gamma+\beta^{2}\right)+(a+b+c) \beta+a b+T_{+} D(a+b-c)+T_{+} D T_{+}^{2} D\right) \\
& +\left(\beta+T_{-} \beta+c-T_{+}(D)\right) \Lambda+\Lambda^{2} .
\end{aligned}
$$

From the main diagonal, clearing, we obtain:

$$
(1-\eta) \beta_{n-1} \gamma_{n}+(\eta-1) \beta_{n+1} \gamma_{n+1}+\beta_{n}\left(\frac{\eta}{\eta+1}\left(2 \beta_{n}+a+b+c\right)+(\eta-1)\left(\gamma_{n+1}-\gamma_{n}\right)\right)+
$$

$\left(\frac{\eta}{\eta+1}\left(2\left(\gamma_{n+1}+\gamma_{n}\right)-n c+n(a+b+n-1)+a b\right)-(\eta+1)\left(n\left(\gamma_{n}-\gamma_{n+1}\right)-\gamma_{n}\right)+(\eta(a+b)-c)\left(\gamma_{n+1}-\gamma_{n}\right)\right)=0$
and we get Equation (90a).
From the first superdiagonal and from the first subdiagonal we get

$$
\begin{aligned}
\left((\eta+1)\left(\beta_{n}+\beta_{n+1}+n\left(\beta_{n+1}-\beta_{n}\right)\right)+(\eta-1)\left(\gamma_{n+2}-\gamma_{n}+\beta_{n+1}^{2}-\beta_{n}^{2}\right.\right. & +n)+c\left(1+\beta_{n}-\beta_{n+1}\right) \\
& +\eta(a+b)\left(1+\beta_{n+1}-\beta_{n}\right)=0
\end{aligned}
$$

that leads to 90b.
We now proceed with the compatibility $\left[\Psi H^{-1}, J_{-}\right]=\vartheta_{\eta}\left(\Psi H^{-1}\right)$, recall that $J_{-}:=\Lambda^{\top} \gamma$ and $\vartheta_{\eta}=\eta \frac{d}{d \eta}$. As we will see we get no further equations than those already obtained in Theorem 9 .
Proposition 18. The recursion coefficients for the Gauss hypergeometric discrete orthogonal polynomials satisfy

$$
\begin{gather*}
\vartheta_{\eta}\left(\beta_{n}+\beta_{n+1}+c-n\right)=\gamma_{n+2}-\gamma_{n}  \tag{91a}\\
\vartheta_{\eta}\left(\frac{\eta}{\eta+1}\left(2\left(\gamma_{n+1}+\gamma_{n}+\beta_{n}^{2}\right)+c\left(\beta_{n}-n\right)+n(n-1)+(a+b)\left(\beta_{n}+n\right)+a b\right)\right)=  \tag{91b}\\
\gamma_{n+1}\left(\beta_{n}+\beta_{n+1}+c-n\right)-\gamma_{n}\left(\beta_{n-1}+\beta_{n}+c-(n-1)\right), \\
\vartheta_{\eta}\left(\eta \gamma_{n+1}\left(n+a+b+\beta_{n}+\beta_{n+1}\right)\right)=  \tag{91c}\\
\frac{\eta}{\eta+1} \gamma_{n+1}\left(2\left(\gamma_{n+2}-\gamma_{n}+\beta_{n+1}^{2}-\beta_{n}^{2}\right)+(a+b+c)\left(\beta_{n+1}-\beta_{n}\right)+2 n+(a+b-c)\right) \\
\vartheta_{\eta}\left(\eta \gamma_{n+1} \gamma_{n+2}\right)=\eta \gamma_{n+1} \gamma_{n+2}\left(\beta_{n+2}-\beta_{n}+1\right) . \tag{91d}
\end{gather*}
$$

Proof. From the diagonals of $\left[\Psi H^{-1}, J_{-}\right]=\vartheta_{\eta}\left(\Psi H^{-1}\right)$ we get
i) From the first superdiagonal we obtain (91a)
ii) From the main diagonal cleaning up we get 91 b ).
iii) From the first subdiagonal we get, symplifying (91c).
iv) Finally, from the second subdiagonal we get (91d).

Remark 19. We see that (91a) follow from the Toda equation (35a and (91d) follow from Toda equation (35b). Moreover the two remaining equations (from the main diagonal and the first subdiagonal) are those of Theorem 9

Remark 20. Dominici in [22, Theorem 4] found the following Laguerre-Freud equations

$$
\begin{aligned}
(1-\eta) \nabla\left(\gamma_{n+1}+\gamma_{n}\right) & =\eta v_{n} \nabla\left(\beta_{n}+n\right)-u_{n} \nabla\left(\beta_{n}-n\right), \\
\Delta \nabla\left(u_{n}-\eta v_{n}\right) \gamma_{n} & =u_{n} \nabla\left(\beta_{n}-n\right)+\nabla\left(\gamma_{n+1}+\gamma_{n}\right),
\end{aligned}
$$

with $u_{n}:=\beta_{n}+\beta_{n+1}-n+c+1$ and $v_{n}:=\beta_{n}+\beta_{n-1}+n-1+a+b$. Therefore, the first one is of type $\gamma_{n+1}=$ $F_{1}\left(n, \gamma_{n}, \gamma_{n-1}, \beta_{n}, \beta_{n-1}\right)$, of length two, and the second of the form $\beta_{n+1}=F_{2}\left(n, \gamma_{n+1}, \gamma_{n}, \gamma_{n-1}, \beta_{n}, \beta_{n-1}, \beta_{n-2}\right)$, is of length three. .
Remark 21. Filipuk and Van Assche in [30, Equations (3.6) and (3.9)] introduce new non local variables ( $x, y_{n}$ ),

$$
\begin{aligned}
\beta_{n} & =x_{n}+\frac{n+(n+a+b) \eta-c-1}{1-\eta}, \\
\frac{1-\eta}{\eta} \gamma_{n} & =y_{n}+\sum_{k=0}^{n-1} x_{k}+\frac{n(n+a+b-c-2)}{1-\eta} .
\end{aligned}
$$

Then, in [30, Theorem 3.1] Equations (3.13) and (3.14) for $\left(x_{n}, y_{n}\right)$ are found, of length 0 and 1 respectively, in the new variables. Recall, that these new variables are non-local and involve all the previous recursion coefficients. In this respect, is it not so clear the meaning of length. The nice feature in this case, is that [30, Equations (3.13) and
(3.14)] is a discrete Painlevé equation, that combined with the Toda equations lead to a differential system for the new variables $x_{n}$ and $y_{n}$ that after suitable transformation can be reduced to Painlevé VI $\sigma$-equation. Very recently, [27] it has been shown that this system is equivalent to $d P\left(D_{4}^{(1)} / D_{4}^{(1)}\right)$, known as the difference Painlevé $V$.

## Conclusions and outlook

In their studies of integrable systems and orthogonal polynomials, Adler and van Moerbeke have thoroughly used the Gauss-Borel factorization of the moment matrix (see [1, 2, 3]). This strategy has been extended and applied by us in different contexts, such as CMV orthogonal polynomials, matrix orthogonal polynomials, multiple orthogonal polynomials, and multivariate orthogonal polynomials (see [5, 4, 6, 7, 8, 9, 11, 12]). For a general overview, see [41].

Recently, we extended those ideas to the discrete world (see [44]). In particular, we applied that approach to the study of the consequences of the Pearson equation on the moment matrix and Jacobi matrices. For that description, a new banded matrix is required, the Laguerre-Freud structure matrix, which encodes the Laguerre-Freud relations for the recurrence coefficients. We have also found that the contiguous relations fulfilled by generalized hypergeometric functions, which determine the moments of the weight, describe a discrete Toda hierarchy known as the Nijhoff-Capel equation (see [46]). In [42], we study the role of Christoffel and Geronimus transformations in the description of the mentioned contiguous relations, as well as the use of Geronimus-Christoffel transformations to characterize the shifts in the spectral independent variable of the orthogonal polynomials.

In this paper, we delve deeper into that program and further explore the discrete semiclassical cases. We find Laguerre-Freud relations for the recursion coefficients of three types of discrete orthogonal polynomials: generalized Charlier, generalized Meixner, and Gauss hypergeometric cases. We observe that for all cases -generalized Charlier, generalized Meixner, or Gauss hypergeometric- a solution to each system of nonlinear equations of Laguerre-Freud type for the recursion coefficients is provided by the $\tau$-function, which is defined as a Wronskian of the modified Bessel, Kummer, and Gauss hypergeometric functions, respectively. Notice that in [26] we presented a similar study as the one in this paper for the hypergeometric cases ${ }_{1} F_{2},{ }_{2} F_{2}$ and ${ }_{3} F_{2}$.

For the future, we will extend these techniques to multiple discrete orthogonal polynomials [13] and their relations with the transformations presented in [17], as well as quadrilateral lattices [21, 43].

## Acknowledgments

This work has its roots in several inspiring conversations with Diego Dominici during a research stay at Johannes Kepler University in Linz.

## Declarations

i) Conflict of interest: The authors declare no conflict of interest.
ii) Ethical approval: Not applicable.
iii) Contributions: All the authors have contribute equally.
iv) Data availability: This paper has no associated data.
