The $v$-function in the wild McKay correspondence is not determined by the ramification filtration

Takahiro Yamamoto

Abstract

The $v$-function appears in the wild McKay correspondence and it is an invariant of a Galois extension over a local field which measures about the ramification of extension. The ramification filtration is also such invariant. Yasuda presented the problem whether the $v$-function is determined by ramification filtration. In this paper, we give a formula for the $v$-function for 2-dimensional representations of the bicyclic group of order $p^2$ with $p$ the characteristic of our base field. Using this formula, we construct an example of $v$-function not determined by the ramification filtration.

1 Introduction

The $v$-function appears in the wild McKay correspondence for quotient varieties $\mathbb{A}^d/G$ associated to linear action as a weighting function (see [5], [6]). This is a function on the moduli space of $G$-étale $K$-algebras for some local field $K$ and it is an invariant to study ramification of the algebras. The value of $v$-function

*Affiliation: Osaka City University Advanced Mathematical Institute (3-3-138, Sugimoto, Sumiyoshi-Ku, Osaka city, Osaka-fu), email:mass.11235813@gmail.com
coincides with the valuation of generator of the module resolvent defined by Fröhlich \[1\] (see also \[2\], Rem 9.4).

As another invariant to study ramification of extensions of local fields, there is the ramification filtration, which is a sequence \((G_i)_{i \geq -1}\) of subgroups of Galois group. Yasuda presented the problem whether the \(v\)-function is determined by the ramification filtration or not in \[8\], Problem 5.1. The \(v\)-function has been computed in some cases. For the representation of \(p\)-cyclic group over the Laurent power series field \(k((t)))\) of characteristic \(p\), a formula of the \(v\)-function computed from the ramification jump, that is the index satisfying \(G_i \neq G_{i+1}\), in \[7\]. Similarly, for the representation of \(p^n\)-cyclic group, a formula of the \(v\)-function is determined by the ramification jumps in \[4\], Theorem 3.11. For any permutation action, the \(v\)-function is the same as the Artin conductor, which is determined by the ramification filtration \[5\], Theorem 4.8.

In this paper, we give a formula of the \(v\)-function for subgroup \(G \subset \text{SL}_2(k)\) isomorphic to \((\mathbb{Z}/p\mathbb{Z})^2\).

### Theorem 1.1 (Main theorem, Theorem 5.3)

Let \(k\) be an algebraically closed field of characteristic \(p > 0\). Let \(K\) be the Laurent power series field \(k((t)))\) and let \(\mathcal{O}_K\) be the valuation ring of \(K\). Let \(v_K\) be the valuation of \(K\).

For a subgroup \(G \subset \text{SL}_2(k)\) generated by

\[
\sigma = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad \tau = \begin{bmatrix} 1 & a \\ 0 & 1 \end{bmatrix} \quad (a \in k \setminus \mathbb{F}_p),
\]

we consider the induced \(G\)-representation \(V = \mathbb{F}_k^2 \otimes \mathcal{O}_K\). For a \(G\)-Galois extension \(L/K\), let \(g_1, g_2\) be the corresponding elements of \(L^\sigma, L^\tau\) by the Artin-Schreier theory. Then

\[
v_V(g_1, g_2) = \left\lceil -\min\{v_K(g_1), pv_K(a^p g_1 + g_2)\} \right\rceil p^2.
\]

We prove this theorem by direct computation. The \(v\)-function for linear action is computed from the tuning module, which is the set of \(G\)-equivariant \(\mathcal{O}_K\)-linear homomorphisms from the linear part of the coordinate ring of \(V\) to \(\mathcal{O}_L\). First, we choose a \(K\)-basis of \(L\). In this situation, homomorphisms in the tuning module is characterized by the value of \(x_2\), which is second coordinate of \(V\). We determine the sets of the value of \(x_2\) with respect to elements of the tuning module. From this computation, we get an \(\mathcal{O}_K\)-basis of the tuning module. By the defining formula of \(v\)-function using determinant, we get the formula in the above theorem.

From this formula, we get a counterexample for Yasuda’s problem.

### Corollary 1.2 (Corollary 5.4)

We keep the notation of the main theorem. Then the value of \(v_V\) at a \(G\)-extension \(L/K\) is not determined by the ramification filtration of \(G\) associated to \(L/K\).

We prove this by applying the main theorem to a special sequence of pairs \(g_1, g_2\) parameterized by \(c \in k \setminus \mathbb{F}_p\) such that every \(L_{g_1, g_2}\) has the same ramification filtration. We can see that if \(c = -a^2\) then the value of \(v\)-function at \(L_{g_1, g_2}\) is different from the one of the other case.
This paper is organized as follows. In section three, we recall the lower and upper ramification filtrations and basic facts about them. In section four, we give the definition of the \( v \)-function. In section five, we show the main theorem and its corollary.

Acknowledgements

I am grateful to Takehiko Yasuda for teaching me and for his valuable comments. Without his help, this paper would not have been possible. This work was partially supported by JSPS KAKENHI Grant Number JP18H01112.

2 Notation and Convention

Throughout the paper, \( k \) denotes an algebraically closed field of characteristic \( p > 0 \) and \( K \) denotes the Laurent power series field \( k((t)) \) and \( \mathcal{O}_K \) denotes the valuation ring of \( K \) with respect to the normalized valuation \( v_K \). For a finite group \( G \), a \( G \)-étale \( K \)-algebra \( A \) means an étale \( K \)-algebra endowed with \( G \)-action satisfying \( A^G \cong K \) and \( \dim_K A = \#G \).

3 Ramification filtration

The ramification filtration is an invariant used to study the ramification of Galois extension of local field. For details, see [3]. Let \( L/K \) be a Galois extension. We denote the Galois group of \( L/K \) by \( G \). Then \( G \) acts on the integral closure \( \mathcal{O}_L \) of \( \mathcal{O}_K \) in \( L \).

The \( i \)-th lower ramification group \( G_i \) of \( G \) is defined by

\[
G_i = \{ \sigma \in G \mid v_L(\pi\sigma - \pi) \geq i + 1 \}
\]

for \( i \geq -1 \) where \( \pi \) is an uniformizer of \( \mathcal{O}_L \). The lower ramification groups give a descending sequence of subgroups of \( G \):

\[
G = G_0 \supset G_1 \supset G_2 \supset \cdots \supset G_i \supset G_{i+1} \supset \cdots
\]

The sequence is called the lower ramification filtration.

In general, the lower ramification filtration is not compatible with quotient of group. To fix this problem, we consider the upper ramification group which is defined as follows. For a real number \( t \geq -1 \), we define \( G_t = G_{\lceil t \rceil} \). We define a function \( \varphi \) by

\[
\varphi(x) = \int_0^x \frac{dt}{(G_0 : G_t)}
\]

where \( (G_0 : G_t) \) is index of \( G_0/G_t \). Note that \( (G_0 : G_t) \) means the inverse of the index of \( G_0/G_{-1} \) for \( -1 \leq t < 0 \) as convention. Then \( \varphi \) has its inverse function \( \psi \). We define

\[
G^\psi = G_{\psi(\varphi)}
\]
which called the \( v \)-th upper ramification group. As \( \varphi \) is monotonically increasing, the upper ramification groups also gives a descending sequence of subgroups of \( G \):

\[
G = G^0 \supset G^1 \supset G^2 \supset \cdots \supset G^i \supset G^{i+1} \supset \cdots
\]

This sequence is called the upper ramification filtration.

**Proposition 3.1** (Proposition 14, page 74, [3]). The upper ramification filtration is compatible with quotients of the group. Namely, for a normal subgroup \( H \subset G \), we get

\[
(G/H)^v = G^v H/H
\]

for all \( v \geq -1 \).

### 4 The \( v \)-function

In this paper, we define the \( v \)-function associated to a linear action. For more detail, see [5] or [9]. The \( v \)-function is a function from the set of \( G \)-étale \( K \)-algebras to \( \frac{1}{2\pi} \mathbb{Z} \). A \( G \)-étale \( K \)-algebra is a \( K \)-algebra endowed with \( G \)-action satisfying the stable subalgebra of \( G \) is isomorphic to \( K \).

Let \( V \) be an \( n \)-dimensional representation of a finite group \( G \subset \text{GL}_n(k) \) over \( \mathcal{O}_K \). Note that the following definition can be applied for representations of subsets of \( \text{GL}_n(k) \). We denote the coordinate ring of \( V \) by \( \mathcal{O}_K[\{x_1, \ldots, x_n\}] \). Then the linear part \( M = \sum_{i=1}^n \mathcal{O}_K x_i \) of \( \mathcal{O}_K[x_1, \ldots, x_n] \) is the free \( \mathcal{O}_K \)-module of degree \( n \). For a \( G \)-étal \( K \)-algebra \( A \), we define its tuning module \( \mathcal{V}^V_{A/K} \) by the set of all \( G \)-equivariant \( \mathcal{O}_K \)-linear homomorphisms from \( M \) to \( \mathcal{O}_A \) where \( \mathcal{O}_A \) is the integral closure of \( \mathcal{O}_K \) in \( A \):

\[
\mathcal{V}^V_{A/K} = \text{Hom}_{\mathcal{O}_K}(M, \mathcal{O}_A)
\]

Note that \( \mathcal{V}^V_{A/K} \) is also a free \( \mathcal{O}_K \)-module of degree \( n \). The \( G \)-étale \( K \)-algebra \( A \) is written as

\[
A = L_1 \oplus L_2 \oplus \cdots \oplus L_m
\]

where \( L_i \) are copies of a Galois extension \( L/K \). The \( v \)-function \( v_V \) is defined by

\[
v_V(A) = \frac{1}{2G} \text{length}_{\mathcal{O}_K} \frac{\text{Hom}_{\mathcal{O}_K}(M, \mathcal{O}_A)}{\mathcal{O}_A \cdot \mathcal{V}^V_{A/K}}
\]

in [9, Definition 5.4]. Let \( (\varphi_i)_{i=1}^n \subset \mathcal{V}^V_{A/K} \) be a \( \mathcal{O}_K \)-basis of \( \mathcal{V}^V_{A/K} \). Then the \( v_V \) is computed by

\[
v_V(A) = \frac{1}{2G} v_L(\det(\varphi_i(x_j))). \quad (1)
\]
5 Computation of $v$-function

We consider a subgroup $G$ of $\text{SL}_2(k)$ generated by
\[
\sigma = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad \tau = \begin{bmatrix} 1 & a \\ 0 & 1 \end{bmatrix},
\]
where $a \in k \setminus \mathbb{F}_p$.

We denote the subset
\[\bigoplus_{p^j \cdot j > 0} k t^{-j} \subset K\]
by $J$. Note that $J$ is a set of representatives of $K/P(K)$. We put
\[J^{(2)} = \{(g_1, g_2) \in J^2 \mid g_1 \neq 0, g_2 \notin \mathbb{F}_p g_1\}.
\]

Let $L/K$ be a $G$-extension. Since the fixed fields $L^\sigma$, $L^\tau$ are $p$-cyclic extensions, there exist uniquely $\alpha$, $\beta \in L$ such that the following conditions holds.

- $L^\sigma = K[\alpha]$ and $L^\tau = K[\beta]$.
- $\alpha^p - \alpha$, $\beta^p - \beta \in J$.
- $\alpha \cdot \tau = \alpha + 1$, $\beta \cdot \sigma = \beta + 1$.

We denote $\alpha^p - \alpha$, $\beta^p - \beta$ by $g_1$, $g_2$, respectively. Then $(g_1, g_2) \in J^2$. In this case, we denote $L$ by $L_{g_1, g_2}$.

**Proposition 5.1.** We have the one-to-one correspondence:
\[
\{\text{G-extensions } L/K\} \leftrightarrow J^{(2)} \quad L_{g_1, g_2} \mapsto (g_1, g_2).
\]

**Proof.** We show that $(g_1, g_2) \in J^{(2)}$, which equivalent to that $g_1 \neq 0$, $g_2 \notin \mathbb{F}_p g_1$, for a $G$-extension $L_{g_1, g_2}$. If $g_1 = 0$, then $L^\sigma = K$, that contradicts the fact that $L/K$ is $G$-extension. Thus we get $g_1 \neq 0$. If $g_2 \in \mathbb{F}_p g_1$, then there exists $0 \neq s \in \mathbb{F}_p$ such that $g_2 = sg_1$. Since $s \in \mathbb{F}_p$, we have $s^p = s$. Hence
\[
(s\alpha)^p - s\alpha = s(\alpha^p - \alpha) = sg_1 = g_2.
\]
Therefore, $s\alpha$ and $\beta$ are solutions of the equation $x^p - x = g_2$. Thus $s = \alpha t$ for some $t \in \mathbb{F}_p$, and hence $\beta \in L^\tau$. That contradicts to that $L/K$ is $G$-extension. Therefore, we have $g_2 \notin \mathbb{F}_p g_1$.

We denote the $G$-extension field $L$ of $K$ corresponding $(g_1, g_2) \in J^{(2)}$ by $L_{g_1, g_2}$.

Let $V$ be the natural representation of $G$ of rank two over $\mathcal{O}_K$. We denote $v_V(L_{g_1, g_2})$ by $v_V(g_1, g_2)$. Let $\mathcal{O}_K[x_1, x_2]$ be the coordinate ring of $V$. 

---

5
Proposition 5.2. The tuning module $\Xi_{L/K}^V$ for a $G$-extension field $L$ of $K$ is isomorphic to

$$\Theta_L := \{ m \in \mathcal{O}_L \mid m(\sigma - 1)^2 = 0, \ m(\tau - 1) = am(\sigma - 1) \}$$

as an $\mathcal{O}_K$-module by the following maps:

$$\Xi_{L/K}^V \ni \varphi \mapsto \varphi(x_2) \in \Theta_L$$

$$\Theta_L \ni m \mapsto (m(\sigma - 1))\varphi_1 + m\varphi_2 \in \Xi_{L/K}^V$$

where $\varphi_1, \varphi_2$ are $\mathcal{O}_K$-linear homomorphisms from the linear part of $\mathcal{O}_K[x_1, x_2]$ to $\mathcal{O}_L$ defined by

$$\varphi_i(x_j) = \begin{cases} 1 & (i = j) \\ 0 & (i \neq j) \end{cases}$$

Proof. Let $\varphi \in \Xi_{L/K}^V$ and let $m = \varphi(x_2)$. Since $\varphi$ is $G$-equivariant, we get

$$m(\sigma - 1) = \varphi(x_2(\sigma - 1))$$

$$= \varphi(x_1),$$

$$m(\sigma - 1)^2 = \varphi(x_1(\sigma - 1))$$

$$= \varphi(0) = 0,$$

and

$$m(\tau - 1) = \varphi(x_2(\tau - 1))$$

$$= \varphi(ax_1)$$

$$= am(\sigma - 1).$$

Thus $m \in \Theta_L$.

On the other hand, for $m \in \Theta_L$, we define $\varphi = (m(\sigma - 1))\varphi_1 + m\varphi_2$. Since $m(\sigma - 1)^2 = 0$, we have

$$\varphi(x_1)\sigma = m(\sigma - 1)\sigma$$

$$= m((\sigma - 1)^2 + (\sigma - 1))$$

$$= m(\sigma - 1)$$

$$= \varphi(x_1) = \varphi(x_1\sigma)$$

and

$$\varphi(x_2)\sigma = m\sigma$$

$$= m(\sigma - 1) + m$$

$$= \varphi(x_1 + x_2) = \varphi(x_2\sigma).$$
Since \( m(\tau - 1) = am(\sigma - 1) \), we have

\[
\varphi(x_1)\tau = m(\sigma - 1)\tau \\
= m((\sigma - 1)(\tau - 1) + (\sigma - 1)) \\
= am(\sigma - 1)^2 + m(\sigma - 1) \\
= m(\sigma - 1) \\
= \varphi(x_1) = \varphi(x_1\sigma)
\]

and

\[
\varphi(x_2)\tau = m\tau \\
= m(\tau - 1) + m \\
= am(\sigma - 1) + m \\
= \varphi(ax_1 + x_2) = \varphi(x_2\tau).
\]

These equations show that \( \varphi \) is \( G \)-equivariant because \( G \) is generated by \( \sigma, \tau \) and \( x_1, x_2 \) forms \( \mathcal{O}_K \)-basis of the linear part of \( \mathcal{O}_K[x_1, x_2] \). Therefore, \( \varphi \in \Xi^V_{L/K} \).

As above, we have two \( \mathcal{O}_K \)-linear homomorphisms

\[
\Xi^V_{L/K} \ni \varphi \mapsto \varphi(x_2) \in \Theta_L, \\
\Theta_L \ni m \mapsto (m(\sigma - 1))\varphi_1 + m\varphi_2 \in \Xi^V_{L/K}.
\]

These maps are inverse of each other. \( \Box \)

**Theorem 5.3.** For a subgroup \( G \subset \text{SL}_2(k) \) generated by

\[
\sigma = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad \tau = \begin{bmatrix} 1 & a \\ 0 & 1 \end{bmatrix} \quad (a \in k \setminus \mathbb{F}_p),
\]

we consider the \( G \)-representation \( V = \mathcal{A}_G^2 \). For \((g_1, g_2) \in J^{(2)}\), we get

\[
v_V(g_1, g_2) = \left[ \frac{\min\{v_K(g_1), pv_K(f)\}}{p^2} \right]
\]

where \( f = ap g_1 + g_2 \).

**Proof.** We put \( L = L_{g_1, g_2} \) for \((g_1, g_2) \in J^{(2)}\). Let \( \alpha, \beta \in L \) be generators of \( L^\sigma, L^\tau \) over \( K \) satisfying \( \alpha\tau = \alpha + 1, \beta\sigma = \beta + 1, \alpha^p - \alpha = g_1, \) and \( \beta^p - \beta = g_2 \). The fixed field \( L^\sigma \) is naturally regarded as a cyclic representation of \( \langle \tau \rangle \) over \( K \).

Since

\[
\alpha^i(\tau - 1) = (\alpha + 1)^i - \alpha^i = i\alpha^{i-1} + \sum_{l=0}^{i-2} \binom{i}{l} \alpha^l
\]

for \( i \geq 1 \), \( \alpha^i(\tau - 1)^j \) is a polynomial of \( \alpha \) degree \( i - j \). In particular, \( \alpha^{p-1}(\tau - 1)^{p-1} \neq 0 \). Hence the representation matrix of \( \tau \) on \( L^\sigma \) has only one Jordan block. Hence, we can choose \( K \)-basis \( (A_i)_{i=0}^{p-1} \) of \( L^\sigma \) which satisfies

\[
A_i(\tau - 1) = A_{i-1} \quad (1 \leq i \leq p - 1)
\]

7
and \( A_1 = \alpha \). Similarly, we can choose \( K \)-basis \( (B_i)_{i=0}^{p-1} \) of \( L^7 \) which satisfies

\[
B_i(\sigma - 1) = B_{i-1} \quad (1 \leq i \leq p-1)
\]

and \( B_1 = \beta \). Then \( (A_i B_j)_{i,j=0}^{p-1} \) is a \( K \)-basis of \( L \).

We compute a \( \mathcal{O}_K \)-basis of \( \Theta_L \), which defined in Proposition 5.2. Let \( m \in \Theta_L \). We can write \( m = \sum_{i=0}^{p-1} \sum_{j=0}^{p-1} c_{ij} A_i B_j \) with \( c_{ij} \in K \). Since \( A_i \in L^\sigma \), we have

\[
(A_i B_j)(\sigma - 1) = (A_i \sigma)(B_j \sigma) - A_i B_j = A_i(B_j(\sigma - 1)) = A_i B_{j-1}.
\]

Similarly, we have

\[
(A_i B_j)(\tau - 1) = A_{i-1} B_j.
\]

Then we get

\[
m(\sigma - 1)^2 = \sum_{i=0}^{p-1} \sum_{j=2}^{p-1} c_{ij} A_i B_{j-2}
\]

\[
= \sum_{i=0}^{p-1} \sum_{j=0}^{p-3} c_{i+2,j} A_i B_j
\]

Since \( m \in \Theta_L \), \( m \) satisfies \( m(\sigma - 1)^2 = 0 \). Hence we get

\[
m = \sum_{i=0}^{p-1} (c_{i0} A_i + c_{i1} A_i B_1).
\]

Moreover \( m \) satisfies \( m(\tau - 1) = am(\sigma - 1) \). We have

\[
m(\tau - 1) = \sum_{i=0}^{p-1} (c_{i0} (A_i(\tau - 1)) + c_{i1} (A_i B_1(\tau - 1)))
\]

\[
= \sum_{i=1}^{p-1} (c_{i0} A_{i-1} + c_{i1} A_{i-1} B_1)
\]

\[
= \sum_{i=0}^{p-2} (c_{i+1,0} A_i + c_{i+1,1} A_i B_1),
\]

\[
am(\sigma - 1) = a \sum_{i=0}^{p-1} (c_{i0} (A_i(\sigma - 1)) + c_{i1} (A_i B_1(\sigma - 1)))
\]

\[
= \sum_{i=0}^{p-1} ac_{i1} A_i B_0.
\]

Combining these, we get

\[
ac_{i1} = c_{i+1,0}
\]
for $0 \leq i \leq p - 2$ and

$$c_{i1} = 0$$

for $1 \leq i \leq p - 1$. These implies that

$$m = c_{00} + c_{11}(a\alpha + \beta).$$

We put $\gamma = a\alpha + \beta$ and $s = v_L(\gamma)$. We have

$$N_{L/L^s}(\gamma) = \prod_{i=0}^{p-1} \gamma^s_i = \prod_{i=0}^{p-1} (\gamma + i)$$

$$= \gamma^p - \gamma = (a^p\alpha^p + \beta^p) - (a\alpha + \beta)$$

$$= a^p(\alpha + g_1) - a\alpha + (\beta^p - \beta)$$

$$= (a^p - a)\alpha + a^pg_1 + g_2 = (a^p - a)\alpha + f.$$

Thus

$$s = -v_{L^s}((a^p - a)\alpha + f).$$

Now

$$v_{L^s}(\alpha) = v_K(N_{L^s/K}(\alpha)) = v_K(g_1),$$

which is not divided by $p$. Since

$$v_{L^s}(f) = pv_K(f) \in p\mathbb{Z},$$

we get $v_{L^s}((a^p - a)\alpha) \neq v_{L^s}(f)$. Hence

$$s = -v_{L^s}((a^p - a)\alpha + f)$$

$$= -\min\{v_{L^s}((a^p - a)\alpha), v_{L^s}(f)\}$$

$$= -\min\{v_K(g_1), pv_K(f)\}.$$

Note that $s \notin p^2\mathbb{Z}$. Therefore,

$$m \in \mathcal{O}_L \iff c_{00} \in \mathcal{O}_K \text{ and } c_{11} \in t\left[\frac{s}{p^2}\right]\mathcal{O}_K.$$

Thus $1, t\left[\frac{s}{p^2}\right]$ is an $\mathcal{O}_K$-basis of $\Theta_L$. This corresponds to an $\mathcal{O}_K$-basis

$$\varphi_2, t\left[\frac{s}{p^2}\right] \gamma \varphi_1 + t\left[\frac{s}{p^2}\right] \varphi_2$$

of the tuning module $\Xi_{L/K}^V$.

By formula 1, we get

$$v_{V}(L) = \frac{1}{p^2}v_L\left(\det \left[ \begin{array}{cc} 0 & 1 \\ \left[\frac{s}{p^2}\right] & \left[\frac{s}{p^2}\right] \gamma \end{array} \right] \right) = \left[\frac{s}{p^2}\right].$$

As $s = -\min\{v_K(g_1), pv_K(f)\}$, we get

$$v_{V}(g_1, g_2) = \left[\frac{-\min\{v_K(g_1), pv_K(f)\}}{p^2}\right].$$

□
Corollary 5.4. We keep the notation of this section. Then the value of $v_V$ at a $G$-extension $L/K$ is not determined by the ramification filtration of $G$ associated to $L/K$.

Proof. In the situation of Theorem 5.3, we set $g_1 = t^{-(p^2-1)}$ and $g_2 = ct^{-(p^2-1)} + t^{-1}$ where $c \in k - \mathbb{F}_p$. By Theorem 5.3, we get

$$v_V(g_1, g_2) = \begin{cases} p & (c \neq -a^2) \\ 1 & (c = -a^2) \end{cases}$$

In particular, $v_V(g_1, g_2)$ depends on the value of $c$.

On the other hand, the upper ramification filtration is compatible with passing to a quotient group. Hence the upper ramification filtration is determined from the ones of all the intermediate fields of $L/K$ by Proposition 5.1. Any intermediate field is determined from a subgroup of $\mathbb{F}_p g_1 + \mathbb{F}_p g_2$ by Artin-Schreier theory. An upper ramification filtration of an intermediate field is determined from the valuations of all elements of the corresponding subgroup of $\mathbb{F}_p g_1 + \mathbb{F}_p g_2$. As $c \not\in \mathbb{F}_p$, each nonzero element of $\mathbb{F}_p g_1 + \mathbb{F}_p g_2$ has valuation $-(p^2 - 1)$. Therefore, the ramification filtration of $L_{g_1, g_2}$ does not depend on $c$.
