SMOOTH FANO 4-FOLDS IN GORENSTEIN FORMATS

MUHAMMAD IMRAN QURESHI

Abstract. We construct some new deformation families of four dimensional Fano manifolds of index 1 in some known classes of Gorenstein formats. These families have explicit descriptions in terms of equations, defining their image under the anti-canonical embedding in some weighted projective space. The constructed families have relatively smaller anti-canonical degree than most other known families of smooth Fano 4-folds.

1. Introduction

A projective algebraic variety $X$ with an ample anti-canonical divisor class $-K_X$ is called a Fano variety. The Fano index $i$ is the largest integer such that $-K_X = iD$, for some ample divisor $D$ on $X$. Fano varieties are one of the central topics of research in algebraic geometry in general and in classification problems in particular. It is well known that there are only finitely many deformation families of smooth Fano varieties in each dimension [20]. In dimension less than or equal to three the classification has been completed [15, 16, 17, 24, 25]. There are 1, 10 and 105 deformation families of smooth Fano varieties in dimension 1, 2 and 3 respectively.

In dimension greater than or equal to 4 the full classification is still to be completed. The complete classification of smooth Fano 4-folds of index greater than or equal to 2 is known and there are 35 deformation families of such Fano 4-folds [9, 10, 11, 12, 15, 17, 19, 33, 34], listed in [5]. The index 1 case is still not complete, although there are a number of partial classification results. The toric Fano 4-folds have been classified by Batyrev [1] and found 123 deformation families. One of the larger set of examples was constructed by Coates, Kasprzyk and Prince: in [4] they constructed 527 new deformation families of Fano 4-folds as complete intersections in toric varieties and one more in [6] by using the Laurent inversion. Another collection of 141 deformation families have been given by Coates, Kasprzyk and Kalashnikov [18] as quiver flag zero loci in quiver flag varieties. The smooth Fano 4-folds of Picard rank 2 with hypersurface Cox ring have been classified by Hausen, Laface and Mauz [13]: finding 17 new deformation families of smooth Fano 4-folds of index 1. Some of the earlier index 1 examples have been constructed by K"uchle [21, 22] as sections of homogeneous vector bundles over Grassmannians and complete intersections in weighted projective spaces.

In this article, we aim to contribute to the classification of smooth Fano 4-folds of index 1, which can be thought of as an extension of K"uchle’s lists as some of his examples

2010 Mathematics Subject Classification. 14J45 (Primary); 14J35, 14Q15, 14M07 (Secondary).

Key words and phrases. Fano varieties, Gorenstein formats, 4-folds.
also appear in our list. We construct some new deformation families of smooth Fano 4-folds of index 1 as weighted complete intersections of some known classes of Gorenstein formats (Definition 2.1). As a starting point, we use a computer algebra system to search for candidate families of smooth Fano 4-folds by using the algorithmic approach [29, 3]. Then we prove the existence of these 4-folds by analysing the explicit equations of these candidate varieties.

**Summary of results.** In total, we obtained 25 candidate families of smooth Fano 4-folds by using the computer search routine [29, 3]. Four as hypersurfaces, 8 as codimension 2 complete intersections, one each complete intersection in codimension 3 and 4, four in \(\text{Gr}(2,5)\) format, four in \(\mathbb{P}^2 \times \mathbb{P}^2\) format and three in codimension 4 \(\text{Gr}(2,5) \cap \mathcal{H}\) format. Among these one candidate codimension 2 complete intersection and one candidate examples in \(\text{Gr}(2,5) \cap \mathcal{H}\) format failed to be smooth. All the hypersurfaces and complete intersection examples already appeared in [22], so new deformation families appear as non-complete intersection Fano 4-folds.

**Theorem 1.1.** There exist at least ten families of smooth Fano 4-folds of index 1 such that their images under the anti-canonical embedded in a weighted projective space can be described as non-complete intersection varieties, given in Table 1. In four of these cases they can be be described in \(\mathbb{P}^7(w_1)\) by using \(\text{Gr}(2,5)\) format, in two cases by \(\text{Gr}(2,5) \cap \mathcal{H}\) format in \(\mathbb{P}^8(w_1)\) and in four cases by using \(\mathbb{P}^2 \times \mathbb{P}^2\) format in \(\mathbb{P}^8(w_1)\). The families 1–6 have Picard rank 1 and 7–10 have Picard rank 2.

This list of examples in not a formal complete classification of Fano 4-folds in these Gorenstein formats but it is very unlikely that we get any further such examples. In fact, we searched for about half a million candidate embeddings of Fano 4-folds by using computer algebra, combining all cases. The examples 1 and 5 also appeared in [22] and the rest of the examples are new deformation families of smooth Fano 4-folds.

It is well known that the plurigenera of the Hilbert series $P_X(t) = \sum h^0(-nK_X)t^n$ are deformation invariant [32]. In particular, by using Reimann-Roch formula for smooth 4-folds one can establish that knowing the first plurigenus $h^0(-K)$ and the anti-canonical degree $(-K_X)^4$ is sufficient to distinguish between non deformation equivalent families, see Proposition 4.1. For the known families of smooth Fano 4-folds the list of these invariants can be found in [21, 22, 5, 4, 6, 18, 13]. We obtain at least 6 new deformation families of smooth Fano 4-folds of index 1. The lists we obtain are conjecturally complete classifications of such varieties in these formats.

A linear section $Y$ of each of the Fano 4-folds in Table I is a smooth Calabi–Yau 3-fold. Therefore by Lefschetz’s hyperplane theorem, the Picard rank of a Fano 4-fold $X$ will be equal to that of its Calabi–Yau 3-fold section $Y$. The Picard rank for the corresponding $Y$ have been calculated by using [8, Theorem 2.5] and computer algebra package [14] in Macaulay2.

**Remark 1.2.** A pair of examples #2 and #9 and another pair of examples #4 and #10 have same numerical invariants $h^0(-K_X)$ and $(-K_X)^4$ but they lie in different codimension. We expect them to lie in different deformation families; a similar phenomenon was observed for some terminal Fano 3-folds in [2]. The corresponding Calabi–Yau 3-folds sections of pairs #2, #9 and #4, #10 have distinct Hodge numbers [23] and lie in different deformation families, which provide an evidence that the corresponding Fano 4-folds also belong to distinct deformation families.

Remark 1.3. Our computer search routine also recovered the 13 examples of smooth Fano 4-folds of index 1 which are hypersurfaces or complete intersections in weighted projective spaces. However, we do not list them as part of a theorem since they are very well known examples that appeared in [22] and further studied in [26]. We list them for the reader in Table 2.

Remark 1.4. We did search for examples of smooth Fano 4-folds in some other well known classes of Gorenstein formats, namely in Grassmannians $\text{Gr}(2, 6)$ [28], Lagrangian Grassmannians $\text{LGr}(3, 6)$ [27], a two step flag variety in $\mathbb{C}^4$ [27], Orthogonal Grassmannians $\text{OGr}(5, 10)$ [7] and weighted homogeneous $F_4$ variety [30] but no new candidate examples of smooth Fano 4-folds were found.

2. Definitions and notations

A weighted projective variety $X \hookrightarrow \mathbb{P}^N(w_i)$ of codimension $c$ is called wellformed if it does not contain a singular stratum of codimension $c + 1$. A format is roughly a way of representing the equations of varieties. For example, the Segre embedding of $\mathbb{P}^2 \times \mathbb{P}^2$ can be described as $2 \times 2$ minors of the size 3 matrix. A more formal definition of Gorenstein format is given below.

Definition 2.1. [3] A codimension $c$ Gorenstein format $F$ is a triple $(\widetilde{V}, R, \mu)$ which consists of a codimension $c$ affine Gorenstein variety $\widetilde{V} \subset \mathbb{A}^n$, a minimal graded free
resolution $\mathcal{R}$ of $\mathcal{O}_{\tilde{V}}$ as a graded $\mathcal{O}_A$-module, and a $\mathbb{C}^*$-action $\mu$ of strictly positive weights on $\tilde{V}$.

We only consider those Gorenstein formats where the action $\mu$ leaves the variety $\tilde{V}$ invariant and the free resolution $\mathcal{R}$ is equivariant for the action. The varieties defined below as 2.2 and 2.3 are examples of such Gorenstein formats.

**Definition 2.2.** [7] Consider the Plücker embedding $\text{Gr}(2,5) \hookrightarrow \mathbb{P}^9 \left( \bigwedge^2 \mathbb{C}^5 \right)$ of Grassmannians of 2-planes in $\mathbb{C}^5$. For a choice of vector of $w := (a_1, \cdots, a_5)$ where all $a_i \in \frac{1}{2}\mathbb{Z}$ satisfying

$$a_i + a_j > 0, \ 1 \leq i < j \leq 5,$$

one can define the weighted Grassmannian $w\text{Gr}(2,5)$ as quotient of affine cone minus the vertex $\tilde{\text{Gr}}(2,5) \setminus \{0\}$ by $\mathbb{C}^\times$ action given by:

$$\mu : x_{ij} \mapsto \mu^{a_i+a_j} x_{ij}.$$

Therefore we get the embedding

$$w\text{Gr}(2,5) \hookrightarrow \mathbb{P}(\{w_{ij} : 1 \leq i < j \leq 5, w_{ij} = a_i + a_j\}).$$

We will use $w\mathcal{G}$ to denote the $w\text{Gr}(2,5)$. The image of $w\mathcal{G}$ under the embedding (1) can be defined by five maximal Pfaffians of $5 \times 5$ skew symmetric matrix

$$\begin{pmatrix} x_{12} & x_{13} & x_{14} & x_{15} \\ x_{23} & x_{24} & x_{25} \\ x_{34} & x_{35} \\ x_{45} \end{pmatrix},$$

where we omit writing down the diagonal of zeros and lower triangular part of the skew symmetric matrix. If $w\mathcal{G}$ does not contain a 5 dimensional singular locus of $\mathbb{P}(w_i)$ then the canonical divisor class is given by

$$K_{w\mathcal{G}} = \left( -\frac{1}{2} \sum_{1 \leq i < j \leq 5} w_{ij} \right) H,$$

for an ample divisor $H$. Another variant of this format is the $\text{Gr}(2,5) \cap \mathcal{H}$ format which is a non-quasilinear hypersurface section of $\text{Gr}(2,5)$ format.

**Definition 2.3.** [2, 31] Let $\Sigma$ be the Segre embedding of

$$\mathbb{P}^2 \times \mathbb{P}^2 \hookrightarrow \mathbb{P}^8(x_{ij}), \ 1 \leq i, j \leq 3$$

and consider a pair of half integer vectors $b = (b_1, b_2, b_3)$ and $c = (c_1, c_2, c_3)$

$$b_i + c_j > 0, b_i \leq b_j \text{ and } c_i \leq c_j \text{ for } 1 \leq i \leq j \leq 3.$$

Then quotient of the punctured affine cone $\tilde{\Sigma} \setminus \{0\}$ by $\mathbb{C}^\times$:

$$\mu : x_{ij} \mapsto \mu^{b_i+c_j} x_{ij}, \ 1 \leq i, j \leq 3,$$
is called a weighted $\mathbb{P}^2 \times \mathbb{P}^2$ variety, which we will denote by $w\mathcal{P}$. Thus for a parameter 
$p = (b, c) = (b_1, b_2, b_3; c_1, c_2, c_3)$, we get the embedding 

$$w\mathcal{P} \hookrightarrow \mathbb{P}^8 (w_{ij} : w_{ij} = b_i + c_j; 1 \leq i, j \leq 3).$$

The equations of image are well known $2 \times 2$ minors of the $3 \times 3$ matrix, which we usually refer to as weight matrix and write it as

$$\begin{pmatrix}
    w_{11} & w_{12} & w_{13} \\
    w_{21} & w_{22} & w_{23} \\
    w_{31} & w_{32} & w_{33}
\end{pmatrix}$$

where $w_{ij} = b_i + c_j; 1 \leq i, j \leq 3$. \hspace{1cm} (4)

If $w\mathcal{P}$ is wellformed then the canonical divisor class is given by

$$K_{w\mathcal{P}} = \left(-\sum_{i=1}^{3} w_{ii}\right) H,$$

for an ample divisor $H$.

3. Families of Fano smooth 4-folds

In this section we provide a proof of the theorem 1.1 by providing details of the calculations in three cases. The rest of the cases can be computed by performing similar calculations.

3.1. Example #3. For $w = \frac{1}{3}(1, 1, 1, 3, 3)$ we get the embedding $w\mathcal{G} \hookrightarrow \mathbb{P} \left(1^3, 2^6, 3\right)$. Let $x_1, x_2, x_3$ be weight one variables, $y_1, \cdots, y_6$ be weight 2 variables and $z$ be the weight 3 variable. Now it is evident that $w\mathcal{G}$ does not contain any 5-dimensional singular locus of the ambient $\mathbb{P}^9(w_i)$: the weight 3 locus is just an orbifold point and weight 2 locus describes a cubic 3-fold in $\mathbb{P}^5$, so it is wellformed. Thus by using formula (3) we have $K_{w\mathcal{G}} = \mathcal{O}(-9)$. Let $Y_1 \subset \mathbb{P} \left(1^6, 2^6, 3\right)$ be a projective cone over $w\mathcal{G}$ with vertex $\mathbb{P}^2$, i.e. we add three variables of weight 1 to the ambient $\mathbb{P}^9(w_i)$ which are not involved in any defining equations of $w\mathcal{G}$. $Y_1$ is a 9-dimensional variety with $K_{Y_1} = \mathcal{O}(-12)$.

We take a complete intersection of $Y_1$ with 4 general quadrics to get a Fano 5-fold

$$Y_2 \subset \mathbb{P} \left(1^6, 2^2, 3\right)$$

with $K_{Y_2} = \mathcal{O}(-12 + 2 \times 4) = \mathcal{O}(-4)$, by using adjunction formula. Now the base locus of the linear system of quadrics $|\mathcal{O}(2)|$ contain a single point which is a coordinate point of the variable $z$. Moreover $Y_2 \cap \mathbb{P} \left(2, 2\right)$ is empty locus and only singular point on $Y_2$ is $\frac{1}{3}(1, 1, 1, 2, 2)$ quotient singularity. As a last step we take an intersection of $Y_2$ with a general cubic to get a Fano 4-fold

$$X \subset \mathbb{P}(1^6, 2^2)$$

with $K_X = \mathcal{O}(-1)$. By using the Hilbert series one can easily show that $(-K_X)^4 = 7$, and $h^0(-K_X) = 6$ is evident from the embedding.
3.2. **Example #6.** The Grassmannian \( \text{Gr}(2, 5) \) has the embedding in \( \mathbb{P}^9(x_1, \cdots, x_{10}) \). It is a 6-fold with \( K_X = \mathcal{O}(-5) \). Let \( Y_1 \) be variety obtained by taking a cone of weight 2 over it, i.e. we have the embedding

\[
Y_1 = C^2 \text{Gr}(2, 5) \hookrightarrow \mathbb{P}^{10}(1^9, 2)
\]

where the new variable \( y \) of weight 2 is not involved in any defining equations. \( Y_1 \) is a singular 7-fold with \( K_{Y_1} = \mathcal{O}(-7) \). Now we take a general quartic section

\[
Q_4 = y^2 + f_4(x_i, y), 1 \leq i \leq 10
\]

to get a 6-fold \( Y_2 \subset \mathbb{P}^{10}(1^9, 2) \) with \( K_{Y_2} = \mathcal{O}(-3) \).

The linear system \( |\mathcal{O}(4)| \) has empty base locus. The 6-fold \( Y_2 \) is a codimension 4 smooth variety; since the weight 2 points have been removed by the quartic section. Now we take two hyperplane sections of \( Y_2 \) to get a smooth Fano 4-fold \( X \subset \mathbb{P}^{10}(1^8, 2) \) of index 1 with \( h^0(-K_X) = 8 \) and \( -K_X^4 = 10 \).

3.3. **Example #10.** For a choice of parameter \( w = (1, 1, 1; 1, 1, 1) \) we have \( wP \hookrightarrow \mathbb{P}(2^9) \) which is a priori a non well-formed 4-fold. Consider a projective cone \( Y_1 \) over \( wP \) with vertex \( P \) then we have a 9-fold

\[
Y_1 \subset \mathbb{P}(1^5, 2^9) \quad \text{with} \quad K_{Y_1} = \mathcal{O}(-11).
\]

The 9-fold \( Y_1 \) is wellformed, though it contains the orbifold locus of dimension 4 defined by weight 2 variables and further \( \mathbb{P}^4 \) given by cone variables. Then the quasilinear section of \( Y_1 \) with 5 general quadrics is a Fano 4-fold

\[
X = Y_1 \cap \{ \cap_{i=1}^5 Q_i \} \subset \mathbb{P}(1^5, 2^4) \quad \text{with} \quad K_X = \mathcal{O}(-11 + 10) = \mathcal{O}_X(-1).
\]

i.e. \( X \) is a Fano 4-fold of index 1. The intersection \( X \cap \mathbb{P}(1^5, 2^4) \) is empty and also the base locus of the linear system \( |\mathcal{O}(2)| \) of quadrics is empty; \( X \) is a smooth Fano 4-fold.

4. **Geography of smooth Fano 4-folds**

The deformation type of a smooth Fano variety \( X \) depends on the plurigenera \( h^0(-nK_X) \) of the Hilbert series \( \sum_{n \geq 0} h^0(-nK_X)t^n \) of \( X \), as they are invariant under smooth projective deformations [32]. Therefore if two varieties have different plurigenera then they represent two distinct different deformation families of Fano 4-folds. Now by using various vanishing theorems one can get the following form of the Riemann–Roch formula for smooth Fano 4-folds of index 1 [22, p.48].

\[
\chi(-nK_X) = h^0(-nK_X) = 1 + \frac{n(n+1)}{24}(-K_X)^2c_2(X) + \frac{n^2(n+1)^2}{24}(-K_X)^4 \quad (6)
\]

In particular,

\[
h^0(-K_X) = 1 + \frac{(-K_X)^2c_2(X)}{24} + \frac{(-K_X)^4}{6}. \quad (7)
\]

Thus the intersection number \( (-K_X)^2c_2(X) \) is determined easily from the first term if we can compute \( h^0(-K_X) \) and \( (-K_X)^4 \). In our case, these two invariants can be readily computed from the Hilbert series of \( X \). Therefore we have the following result.
**Proposition 4.1.** Let $X$ and $Y$ be two smooth Fano 4-folds of index 1 such that $h^0(-K_X) \neq h^0(-K_Y)$ and $(-K_X)^4 \neq (-K_Y)^4$ then $X$ and $Y$ belong to two distinct deformation families of smooth Fano 4-folds.

4.1. **Geography with respect to $h^0(-K_X)$ and $(-K_X)^4$.** In total there are at least 987 known deformation families of smooth Fano 4-folds with distinct anti-canonical degree $(-K_X)^4$ and $h^0(-K_X)$. They can be found in [21, 22, 4, 6, 13]. Among these, there are 13 examples of Fano 4-folds of index 1 which are hypersurfaces or complete intersections in weighted projective spaces [22]. For all these examples, the first plurigenus $h^0(-K_X)$ and the anti-canonical degree $(-K_X)^4$ satisfy,

$$1 \leq (-K_X)^4 \leq 17 \quad \text{and} \quad 3 \leq h^0(-K_X) \leq 9. \quad (8)$$

In what follows, we call a smooth Fano 4-fold to have small invariants if its invariants satisfy (8). There are very few families of smooth Fano 4-folds with such small invariants, other than hypersurfaces and complete intersections in weighted projective spaces. In total, excluding the hypersurfaces or complete intersections, only 7 out of the rest of about 970 known examples have small invariants. Among these, 3 of them appeared in [21, 22], 3 are listed in [5] and 3 in [13] but 2 of them have same invariants as those in [22]. All our new families of Fano 4-folds have small invariants and thus they lie in the left-down corner of the graph of geography of smooth Fano 4-folds if we draw a graph in positive quadrant with $(-K_X)^4$ on x-axis and $h^0(-K_X)$ on y-axis. In figure 1, we list those smooth families of Fano 4-folds with known small invariants.

**Figure 1.** Fano 4-folds with small invariants satisfying (8). The red circles represent new examples constructed in this paper, blue squares represent the examples already appeared in [21, 22, 13], and the filled red dots represents those examples which appeared in this paper and in [22].
