Abstract
In a recent landmark paper, Khoa Le (2020) established a stochastic sewing lemma which since has found many applications in stochastic analysis. He further conjectured that a similar result may hold in the context of the reconstruction theorem within Hairer’s regularity structures. The purpose of this article is to provide such a stochastic reconstruction theorem. Our formulation makes use of the distributional viewpoint of Caravenna–Zambotti (2021).

1 Introduction

1.1 Stochastic reconstruction in a nutshell
In recent years, the reconstruction theorem from Martin Hairer’s regularity structure theory [Hai14] has gained popularity in the mathematical community, not just within the said theory, but also as a
Remark 1.2. They also showed that it is possible to find such a distribution \( f \), which around any point \( x \in \mathbb{R}^d \) locally looks like \( F \), as follows: If \( \alpha \) and \( \beta \) are Hölder continuous with \( \alpha + \beta > 0 \), how can we define the product \( g \cdot h \), if \( g \) is not smooth? [RS96] and [BCD11] have used paraproducts to show that a natural choice called the Young product does exist for \( \alpha + \beta > 0 \).

As it turns out, it is easy to find a local approximation for this product: Around any point \( x \in \mathbb{R} \), \( g(y) \) looks like its Taylor approximation \( g(y) \approx T_g x (y) := \sum_{k=0}^{n} \frac{g^{(k)}(x)}{k!}(y - x)^k \) and the distribution \( (T_g x \cdot h)(\psi) := h(T_g x \cdot \psi) \) is well defined since \( T_g x \cdot \psi \) is a smooth test function. This allows us to locally approximate our product as \( g \cdot h \approx T_g x \cdot h \) around \( x \). The only ingredient missing to find \( g \cdot h \) is a way to reconstruct the distribution from its local approximations.

To return to the general setting, let us consider a family of distributions \( (F_x)_{x \in \mathbb{R}^d} \) and let us formalize what it means to “locally look like \( F_x \)” around \( x \): Given a smooth, compactly supported mollifier \( \psi \), one can use the rescaled function \( \psi_x \), which approaches the Dirac distribution \( \delta_x \) as \( \epsilon \to 0 \). (One can think of \( \psi_x \) as a mollified Dirac delta.) Since \( \psi_x \) is highly concentrated around \( x \), we can analyze the local behaviour around an \( x \in \mathbb{R}^d \) of a distribution by analysing \( f(\psi_x) \). To be precise, the rigorous condition to “locally look like \( F_x \)” is given by

\[
\|(f - F_x)(\psi_x)\| \lesssim \epsilon^\lambda
\]

for some \( \lambda > 0 \). It especially holds that \( |(f - F_x)(\psi_x)| \to 0 \) for \( \epsilon \to 0 \) at rate \( \lambda \), which justifies the expression “\( f(x) \approx F_x(x) \)”.

Caravenna and Zambotti found a condition called coherence in [CZ20], which ensures (1) and is given as follows: \( (F_x)_{x \in \mathbb{R}^d} \) is called coherent, if

\[
|(F_x - F_y)(\psi_x^\gamma)| \lesssim \epsilon^\alpha (|x - y| + \epsilon)^{-\gamma \alpha}
\]

for some \( \alpha \in \mathbb{R} \) (typically negative) and a \( \gamma > 0 \). This quite technical condition can be interpreted as follows: If \( F_x, F_y \) are distributions of negative regularity, we expect \( (F_x - F_y)(\psi_x^\gamma) \) to explode for \( \epsilon \to 0 \), which it indeed does at rate \( -\alpha \). However, if we link \( |x - y| \) with \( \epsilon \), i.e. take \( |x - y| \approx \epsilon \), we get the convergence \( |(F_x - F_y)(\psi_x^\gamma)| \lesssim \epsilon^\gamma \to 0 \) as \( \epsilon \to 0 \). This indicates a form of continuity, i.e. \( F_x \) and \( F_y \) look very similar as \( x \) tends to \( y \), which can be used to construct some form of limit distribution “\( f(x) \approx F_x(x) \)”.

Under this assumption, Caravenna and Zambotti proved the following theorem:

**Theorem 1.1** ([CZ20]). Let \( (F_x)_{x \in \mathbb{R}^d} \) be a coherent germ for some \( \gamma > 0 \). Then there exists a unique distribution \( f \) with

\[
|(f - F_x)(\psi_x^\gamma)| \lesssim \epsilon^\gamma.
\]

**Remark 1.2.** They also showed that it is possible to find such a distribution \( f \) for \( \gamma < 0 \). However, this distribution is no longer unique. Also, note that for \( \gamma < 0 \), the bound \( \epsilon^\gamma \) does explode, so the condition is much weaker. Thus, we will concentrate on the \( \gamma > 0 \) case.

At this point, the reconstruction theorem is a purely analytic tool. This is surprising, as it is often applied in SPDEs, see for example [CFG17], [Hai14], [Bay+20],[Bra19] and many more. In all those examples, the reconstruction theorem only uses the analytic properties of the stochastic processes, neglecting their stochastic properties.

This naturally leads to the question, if there exists a stochastic version of the reconstruction theorem, especially if one considers its close connection to the sewing lemma [Gub04], [FL06]: In rough paths
theory, rough integrals can be constructed with the sewing lemma (see [Lyo98], [FH14]), whereas in regularity structure theory the reconstruction theorem is used to construct the corresponding products. And in [Le20], Khoa Lê showed the existence of a stochastic version of the sewing lemma.

In this paper, we show that Lê’s approach can be generalized to the multidimensional setting of the reconstruction theorem: Consider a family of random distributions \((F_x)_{x \in \mathbb{R}^d}\), i.e. \(F_x\) maps test functions \(\psi\) onto random variables in some \(L^p\) space, \(2 \leq p < \infty\), which is somehow adapted to a filtration \((\mathcal{F}_y)_{y \in \mathbb{R}}\) (this will be made rigorous in Section 3). We can enrich the coherence property by a condition on the conditional expectation of \(F_x\) as follows:

\[
\|(F_x - F_y)(\psi_x)\|_{L^p} \lesssim \epsilon^{\alpha}(|x - y| + \epsilon)^{\tilde{\gamma} - \alpha}
\]

\[
\|E^{\mathcal{F}_y} (F_x - F_y)(\psi_x)\|_{L^p} \lesssim \epsilon^{\alpha}(|x - y| + \epsilon)^{\tilde{\gamma} - \alpha},
\]

where \(y = (y_1, \ldots)\) and for some \(\tilde{\gamma} > \gamma\), so the conditional expectation is better behaved than the germ itself. We then hope, that \((F_x)_{x \in \mathbb{R}^d}\) can “borrow regularity” from its conditional expectation.

Khoa Lê showed in [Le20] a technique, based on the Doob-Meyer decomposition, which allows precisely that: He managed to borrow up to \(\frac{1}{2}\) regularity from the conditional expectations of stochastic processes, under suitable adaptedness assumptions. This indicates that we should assume \(\tilde{\gamma} = \gamma + \frac{1}{2}\).

The main technique he used in his paper is the following: Consider a sequence of random variables \((Z_n)_{n \in \mathbb{N}} \subset L^p\) for some \(2 \leq p < \infty\), which is adapted to some filtration \((\mathcal{F}_{n+1})_{n \in \mathbb{N}}\) (i.e. \(Z_n\) is \(\mathcal{F}_{n+1}\)-measurable), then one can use the Doob-Meyer [Doo+53] decomposition and the Burkholder-Davis-Gundy inequality [BDG72] to show

\[
\left\langle \sum_{i=1}^N Z_i \right\rangle_{L^p} \lesssim \sum_{i=1}^N \|E^{\mathcal{F}_y} Z_i\|_{L^p} + \left(\sum_{i=1}^N \|Z_i - E^{\mathcal{F}_y} Z_i\|_{L^p}^2\right)^{\frac{1}{2}}.
\]

Under the assumption that the conditional expectations \(E^{\mathcal{F}_y} Z_i\) are somehow better behaved than \(Z_i\) itself, this is a strictly better bound than the naive bound \(\sum_{i=1}^N \|Z_i\|_{L^p}\). For all details, see [Le20].

However, the higher dimension of our germ enables us to repetitively use this technique: That is, if we have suitable filtrations \(\mathcal{F}_{y_i}\) for \(i = 1, \ldots, e \leq d\) and

\[
\|E^{\mathcal{F}_{y_i}} (F_x - F_y)(\psi_x)\|_{L^p} \lesssim \epsilon^{\alpha}(|x - y| + \epsilon)^{\tilde{\gamma} - \alpha},
\]

holds for all directions \(i = 1, \ldots, e\), we can borrow \(\frac{1}{2}\) regularity from all of those direction, resulting in \(\gamma = \tilde{\gamma} - \frac{1}{2}\). We call \(e\) the stochastic dimension of \((F_x)\). We say that \((F_x)\) is stochastically \(\gamma\)-coherent, if it fulfills certain adaptedness properties (see Definition 3.3 for details), and for \(i = 1, \ldots, e \leq d\)
\[(F_x - F_y)(\psi_x)\] \[\lesssim \epsilon^\alpha (|x - y| + \epsilon)^{\gamma - \frac{d}{2} - \alpha} \]

Under this condition, we can formulate our main result:

**Theorem 1.3 (Stochastic reconstruction).** Assume the adaptedness condition of Definition 3.3 and that \((F_x)_{x \in \mathbb{R}^d}\) is stochastically \(\gamma\)-coherent for some \(\gamma > 0\) with stochastic dimension \(e \leq d\). Then, there exists a unique random distribution \(f\), which fulfills

\[\|(f - F_x)(\psi_x^i)\|_{L_p} \lesssim \epsilon^{\gamma - \frac{d}{2}}\]

\[\left\| E^{\mathcal{F}_i} (f - F_x)(\psi_x^i) \right\|_{L_p} \lesssim \epsilon^\gamma\]

for \(i = 1, \ldots, e\).

### 1.2 The structure of this paper

This paper is structured as follows: In Section 2, we will formally introduce distribution and scalings, as well as the wavelet techniques needed for the proofs. This section mainly follows [Hai14] and [Mey93].

Section 3 will then talk about the main result and prove the stochastic reconstruction theorem. It should be noted that while our setting closely resembles the setting of Caravenna and Zambotti [CZ20], our proofs are closer to Hairer’s original proof, as his wavelet techniques are better suited to apply Lê’s stochastic techniques.

In Section 4, we show that in one dimension the stochastic reconstruction theorem becomes the stochastic sewing lemma under weak additional assumptions needed for the distributional framework.

The last three sections of this paper are dedicated to showing simple examples, of how the stochastic reconstruction theorem could be applied. In Section 5, we consider a Gaussian martingale measure \(W_t(A)\) and a stochastic process \(X(t, x)\), and show how the Walsh type integral [Wal86]

\[\int_0^\infty \int_{\mathbb{R}^d} X(s, x) W(ds, dx)\]

can be reconstructed as a product between the process \(X\) and the distribution \(W(ds, dx)\). This closely resembles the case of the Young product in the deterministic case, which was described at the very start of this paper. Thus, this highlights how the integral can be seen as a stochastic version of the Young product of a function \(f\) of some Hölder regularity \(\alpha > 0\) and a distribution \(g\) of Hölder regularity \(\beta < 0\).

Since the above integral only assumes martingale properties in one dimension, this case only yields stochastic dimension \(e = 1\). To give an example with \(e > 1\), we show a similar reconstruction for integration against white noise in Section 6 and reconstruct the integral

\[\int_{\mathbb{R}^d} X(z) \xi(dz),\]

which can be found in [Qua12].

Finally, in Section 7, we discuss our results and where the stochastic reconstruction theorem might lead to in the future.
2 Preliminaries

2.1 Distributions and Hölder continuity

A property which is typical for the theory of SPDEs is that most solutions are too irregular to be viewed as functions and need to be seen as distributions. Let us quickly introduce those: Let $C^\infty_c$ be the space of smooth, compactly supported test functions, and let $C^r_c$ be the space of compactly supported, $r$ times continuously differentiable functions. We equip those spaces with the following $C^r_c$ norms: For any multiindex $k = (k_1, \ldots, k_n)$ and $k_1 + \cdots + k_n$ times continuously differentiable function $\psi$, let $\psi^{(k)} := \frac{\partial^{k_1 + \cdots + k_n}}{\partial x_1^{k_1} \cdots \partial x_n^{k_n}} \psi$ be a partial derivative of $\psi$. Then, for some $r \in \mathbb{N}$, we set

$$||\psi||_{C^r_c} = \sum_{k_1 + \cdots + k_n \leq r} ||\psi^{(k)}||_\infty.$$  

This allows us to define the space of distributions as follows:

**Definition 2.1.** For any $r \in \mathbb{N}$, a distribution is a linear map $f : C^r_c \to \mathbb{R}$, such that for any compact set $K$ there is a constant $C(K)$, such that for any $\psi \in C^r_c$ with support in $K$, it holds that

$$|f(\psi)| \leq C(K)||\psi||_{C^r_c}.$$  

Further, for any $p < \infty$, we call a linear map $f : C^r_c \to L^p(\Omega)$ a random distribution, if it fulfills

$$||f(\psi)||_{L^p} \leq C(K)||\psi||_{C^r_c}.$$  

We use the notation $|f(\psi)| \lesssim ||\psi||_{C^r_c}$, where we allow constants hidden in $\lesssim$ to depend on underlying compact sets.

We need to extend the notion of Hölder continuity to distributions. This requires us to measure the local behavior of distributions, which can be achieved with the help localizations of test functions. To this end, we call the family of maps $(S^\lambda)_{\lambda \geq 0}$ a scaling associated to the vector $s \in \mathbb{R}^d$ with $s_i > 0$ for all $i = 1, \ldots, d$, if it is given by

$$S^\lambda : \mathbb{R}^d \to \mathbb{R}^d$$

$$(x_1, \ldots, x_d) \mapsto (\lambda^{s_1}x_1, \ldots, \lambda^{s_d}x_d).$$

The rank of $S$ is given by $|S| = |s| := s_1 + \cdots + s_d$. If $\mathbb{R}^d$ has a scaling $S$ assigned to it, we also equip the space with the seminorm

$$|x| = |x_1|^{s_1} + \cdots + |x_d|^{s_d},$$

which is often referred to as a homogeneous norm, although not being a norm in the strict sense. Note that it has the property, that $|S^\lambda x| = \lambda |x|$.

To give two short examples, the canonical scaling $x \mapsto \lambda x$ is simply given by the $S$ associated to $s = (1, \ldots, 1)$, while the parabolic scaling is associated to $s = (2, 1, \ldots, 1)$.

With this in mind, we can now take a look at the localization of a test function: Let $\psi \in C^r_c$ be a test function, $x \in \mathbb{R}^d$ and $\lambda \in (0, 1)$. Then, the localized test function $\psi^\lambda_2$ (under the scaling $S$) is given by

$$\psi^\lambda_2 := \frac{1}{\lambda |S|} \psi \left( S_2^\lambda (x - y) \right).$$

In the case that $S$ is the canonical scaling associated to $(1, \ldots, 1)$, this is simply given by the classical notion of localized test functions:
As mentioned above, for \( \alpha < \) Hölder continuous. In consistence with the \( \approx \), these properties justify thinking of \( \psi \) speed of divergence of \( f \) is taken over all compact sets \( x \) around \( f \), and we call \( \psi \) of divergence is going to give us a way to define the regularity of \( R \) or random processes, we define the space of \( \alpha \) for an \( F \) or true distribution \( \lambda \) is positive regularities: \( F \) or a true distribution \( \delta \). Indeed, as \( \lambda \to 0 \), this converges to the Dirac measure \( \delta \). For all continuous functions \( f : \mathbb{R}^d \to \mathbb{R} \)

\[
\langle f, \psi^\lambda_R \rangle \xrightarrow{\lambda \to 0} f(x),
\]

(3)

where \( \langle f, g \rangle = \int_{\mathbb{R}^d} f(x)g(x)dx \) is simply the \( L_2(\mathbb{R}^d) \) scalar product.

For a true distribution \( g \) (i.e. there is no function \( \tilde{g} \), such that \( g(\psi) = \langle \tilde{g}, \psi \rangle \) for all \( \psi \in C^\infty_c \)), \( g(\psi^\lambda) \) is bound to diverge as \( \lambda \to 0 \). (If it were to converge, we could set \( \tilde{g}(x) = g(\delta_x) = \lim_{\lambda \to 0} g(\psi^\lambda(x)) \)). The speed of divergence is going to give us a way to define the regularity of \( g \), which will help us to define Hölder spaces of negative regularity.

Let us first introduce Hölder continuity for positive regularities: For an \( \alpha \in (0,1] \), and a compact set \( K \subset \mathbb{R}^d \), let

\[
C^\alpha(K) := \{ f \in C^\alpha(\mathbb{R}^d) \mid \exists C > 0 \forall x, y \in K : |f(x) - f(y)| \leq C |x - y|^\alpha \},
\]

and we call \( C^\alpha := \bigcap_{K \subset \mathbb{R}^d} C^\alpha(K) \) the set of (locally) \( \alpha \)-Hölder continuous functions, where the intersection is taken over all compact sets \( K \) in \( \mathbb{R}^d \). We also refer to this space simply as the space of Hölder-continuous functions (and drop the “locally”), as every function and distribution in this paper will be only locally Hölder continuous. In consistence with the \( \lesssim \) notation, we write \( |f(x) - f(y)| \lesssim |x - y|^\alpha \) for \( f \in C^\alpha \).

For random processes, we define the space of \( \alpha \)-Hölder continuous processes by

\[
C^\alpha(L^p(\Omega)) := \{ X : \mathbb{R}^d \to L^p(\Omega) \mid \|X(x) - X(y)\|_{L^p} \lesssim |x - y|^\alpha \}.
\]

As mentioned above, for \( \alpha < 0 \), we measure the Hölder regularity of a distribution \( f \) by measuring the speed of divergence of \( f(\psi^\lambda) \) for \( \lambda \to 0 \). More specifically, we define the space \( C^\alpha \) for negative \( \alpha \) as follows:

**Definition 2.2.** Let \( \alpha < 0 \), and \( r \in \mathbb{N} \) with \( r > |\alpha| \). A distribution \( f : C^\infty_\mathbb{C} \to \mathbb{R} \) is in the space \( C^\alpha \), if for every distribution \( \psi \) with \( \|\psi\|_{C^\infty_\mathbb{C}} = 1 \) and compact support in \([-1,1]^d\), and for each compact set \( K \subset \mathbb{R}^d \), there is some constant \( C(K) \), such that for \( x \in K \) the following holds:

\[
|f(\psi^\lambda)| \leq C(K)\lambda^\alpha.
\]

For a random distribution, we say that \( f \in C^\alpha(L^p(\Omega)) \), if it holds that

\[
||f(\psi^\lambda)||_{L^p} \leq C(K)\lambda^\alpha.
\]
2.2 Wavelet Basis

One of the most powerful tools we will use is the wavelet basis. We introduce this tool, following section 3.1 of [Hai14]. If one is interested in a more detailed discussion of the topic, it can be found in [Mey93].

Intuitively, a wavelet basis is given by a smooth, compactly supported function $\phi$, such that any test function $\psi$ can be decomposed in the form

$$
\psi = \lim_{n \to \infty} \sum_{k \in \Delta_n} b_{n,k} \phi^n_k,
$$

where the limit holds in $L_2(\mathbb{R}^d)$ and $\phi^n_k$ is a certain localized version of $\phi$ around $k$ and $\Delta_n$ is a mesh, which gets increasingly fine as $n \to \infty$. This allows us to analyze arbitrary test functions $\psi$, using only the local properties of $\phi^n_k$. Such a wavelet can be constructed using the following theorem of Daubechies, which can be found in [Dau88]:

**Theorem 2.3 (Daubechies).** For any $r \in \mathbb{N}$, there exists a function $\phi \in C^r_c(\mathbb{R})$, such that

1. For all $z \in \mathbb{Z}$, it holds that
   $$
   \langle \phi, \phi(\cdot - z) \rangle = \delta_{0,z}.
   $$
2. $\phi$ is self-replicable, i.e. there exist constants $(a_k)_{k \in \mathbb{Z}}$, such that
   $$
   \frac{1}{2} \phi(x/2) = \sum_{k \in \mathbb{Z}} a_k \phi(x - k).
   $$

Due to the compact support of $\phi$, it holds that $a_k = 0$ for all but finitely many $k$. In Daubechies’ setting, it does not matter where the support of $\phi$ lies, as long as it is compact. However, the stochastic theory requires us to separate the number line $\mathbb{R}$ into the “future” $[0, \infty)$ and the “past” $(-\infty, 0]$. In particular, we will only be interested in functions $\phi$ with compact support in the future, i.e. $\text{supp}(\phi) \subset [0, R]$ for some $R > 0$. Such a wavelet can be easily constructed by replacing $\phi$ with $\phi(\cdot - x)$ for a large enough $x > 0$. Further observe that, by choosing $x$ large enough, we can also assure that $a_k = 0$ for all $k < 0$ in property ii).

Property i) ensures that the recentered wavelets $\phi_z$, $z \in \mathbb{Z}$ form an orthonormal system in $L_2(\mathbb{R})$. Since this theory works in $L_2$, our usual $L_1$ localization is less useful than the following $L_2$ localization: Let $\Delta_n := 2^{-n} \mathbb{Z}$. Then, for all $k \in \Delta_n$, we define

$$
\phi^n_k(x) := 2^{-n} \phi(2^n(x - k)) = 2^{-n} \phi^{2^{-n}}(x).
$$

With this notation, it is indeed well understood that we get a representation in the form of (4): For any $\psi \in L_2(\mathbb{R})$, it holds that

$$
\lim_{n \to \infty} \sum_{k \in \Delta_n} \langle \psi, \phi^n_k \rangle \phi^n_k = \psi,
$$

where the limit holds in $L_2(\mathbb{R}^d)$.

Let $V_n := \text{span}\{\phi^n_k \mid k \in \Delta_n\}$. It follows from the self-replication-property of $\phi$, that $V_{n-1} \subset V_n$. Equation (5) gives us that $L_2(\mathbb{R}^d) = \bigcup_{n \in \mathbb{N}} V_n$, so we can really think of $(\phi^n_k)_{k \in \Delta_n}$ as “almost an orthonormal basis” of $L_2$ for sufficiently high $n$.

One of the strongest properties of this wavelet basis is, that we also have a precise description of the “missing part” $\psi - \sum_{k \in \Delta_n} \langle \psi, \phi^n_k \rangle \phi^n_k$, given through the following theorem from [Mey93].
Theorem 2.4 (Meyer). There is a function $\hat{\phi} \in C^\infty_c$, such that

i) $\hat{V}_n := \text{span}\{\hat{\phi}_k^n \mid k \in \Delta_n\}$ is the orthogonal complement of $V_n$ in $V_{n+1}$, i.e. $\hat{V}_n = V_n^\perp$. 

ii) Let $\hat{\phi}_k^n := 2^{-n/2} \hat{\phi}_{|k|}$. Then, $(\hat{\phi}_k^n)_{n \in \mathbb{N}, k \in \Delta_n}$ is a family of orthonormal functions:

$$\langle \hat{\phi}_k^n, \hat{\phi}_{l}^m \rangle = \delta_{n,m} \delta_{k,l}.$$ 

iii) $\hat{\phi}$ eliminates all polynomials of degree less than $r$: For any monomial $x^m$, $m \leq r$, it holds that

$$\langle x^m, \hat{\phi} \rangle = 0.$$ 

Remark 2.5. Property i) and ii) give us, that for all $n \in \mathbb{N}$,

$$\{\phi_k^n \mid k \in \Delta_n\} \cup \{\hat{\phi}_l^n \mid m \geq n, l \in \Delta_m\}$$
forms an orthonormal basis of $L_2$. It especially holds that each $\psi \in L_2$ can be represented via

$$\psi = \sum_{k \in \Delta_n} \langle \psi, \phi_k^n \rangle \phi_k^n + \sum_{m=n}^{\infty} \sum_{l \in \Delta_m} \langle \psi, \hat{\phi}_l^m \rangle \hat{\phi}_{l}^m,$$

where the right-hand side should be seen as an $L_2$ limit. This representation should be interpreted as $\hat{\phi}$ approximating $\psi$, and $\phi$ "filling in the details".

How do we extend this wavelet basis to $\mathbb{R}^d$ equipped with a scaling $S$? The trick is to use $d$ copies of $\phi$ or $\hat{\phi}$, respectively, and multiplying them to get a multidimensional wavelet. To get started, let $S$ be associated to $s \in \mathbb{R}^d_+$, and let $\Delta_n^S \subset \mathbb{R}^d$ be the rescaled mesh defined by

$$\Delta_n^S = \left\{ \sum_{i=1}^d 2^{-ns_i} l_i \tilde{e}_i \mid l_i \in \mathbb{Z} \right\},$$

where $\tilde{e}_i = (0, \ldots, 0, 1, 0, \ldots, 0)$ is the $i$-th unit vector of $\mathbb{R}^d$. We usually drop the index $S$ on $\Delta_n^S$, since the scaling will be fixed in the later sections of this paper. We can define $\phi$ as a map on $\mathbb{R}^d$ as

$$\phi(y) = \prod_{i=1}^d \phi(y_i)$$
to get a wavelet on $\mathbb{R}^d$. Its $L_2$-localizations

$$\phi_k^n = 2^{-n |l|} \hat{\phi}_k^n,$$

where $k \in \Delta_n$, form a wavelet basis for $L_2(\mathbb{R}^d)$, which respects $S$.

We need to find a description of $V_n^\perp V_{n+1}$, similar to before. While this is no longer possible with a single function $\hat{\phi}$ and its rescaled versions, it is possible to find a finite set $\Phi$, such that

$$V_n^\perp V_{n+1} = \text{span}\{\hat{\phi}_k^n \mid k \in \Delta_n, \hat{\phi} \in \Phi\}.$$ 

In fact, $\Phi$ is given by all possible functions of the form $\hat{\phi}(x_1, \ldots, x_n) = \prod_{i=1}^n \hat{\phi}_i(x_i)$, where all $\hat{\phi}_i(x_i)$ are either $\phi(x_i)$ or $\hat{\phi}(x_i)$ and at least one $\hat{\phi}_i(x_i)$ is given by $\hat{\phi}(x_i)$ (for reference, see [Mey93]). Since
\( \hat{\phi} \) eliminates polynomials of degree less or equal to \( r \), this implies that for all \( \hat{\phi} \in \Phi \), \( \langle \hat{\phi}, p \rangle = 0 \) for all multivariate polynomials \( p \) of degree less or equal to \( r \).

Having to deal with a set \( \Phi \) instead of a single function \( \hat{\phi} \) is usually just a technical detail. As it turns out, the summation over \( \Phi \) only adds a constant to the estimates in Section 3. At no point does it help or obstruct our arguments in a meaningful way.

One can show, that \( \phi \) and all \( \hat{\phi} \in \Phi \) fulfill the properties of Theorem 2.3 and 2.4, which will be stated in detail in the Summary 2.7.

One of the most practical properties, which we are going to use extensively, is that both \( \langle \hat{\phi}^n, \psi \rangle \) and \( \langle \hat{\phi}^n, \psi \rangle \) go to 0 as \( n \to \infty \) at well known rates. This should not be surprising, as (3) implies that \( 2^{-n} \langle \hat{\phi}^n, \psi \rangle \to 0 \) for \( n \to \infty \). Thus, \( \hat{\phi}^n \) should go to 0 at rate \( 2^{-n} \). What is surprising, is that \( \hat{\phi} \) converges at a faster rate, thanks to property iii) of Theorem 2.4:

**Lemma 2.6.** Let \( \psi \in C^r_c \). Then, for all \( \hat{\phi} \in \Phi \), \( n \in \mathbb{N}, y \in \Delta_n, z \in \mathbb{R}^d \) and \( 2^{-n} \leq \lambda \leq 1 \), it holds that

\[
\begin{align*}
|\langle \hat{\phi}^n, \psi \rangle| \lesssim & \ 2^{-n} \left| \langle \hat{\phi}^n, \psi \rangle \right| \lesssim 2^{-n} \lambda^{-|S|} \lVert \psi \rVert_{C^r_c} \\
|\langle \hat{\phi}^n, \psi \rangle| \lesssim & \ 2^{-n} \lambda^{-|S|} \lVert \psi \rVert_{C^r_c},
\end{align*}
\]

where \( \tilde{r} = r \cdot \min_{i=1,...,d} (s_i) \).

**Proof.** To show (6), observe that

\[
|\langle \hat{\phi}^n, \psi \rangle| \leq 2^n \lambda^{-|S|} \left| \int \langle \hat{\phi}^n, \psi \rangle \left( S^n (x - y) \right) \right| dx
\]

\[
= 2^{-n} \lambda^{-|S|} \left| \int \langle \hat{\phi}^n, \psi \rangle \left( S^n (x - z) \right) \right| du
\]

\[
\leq 2^{-n} \lambda^{-|S|} \sup_u \lVert \psi (u) \rVert L_1
\]

\[
\lesssim 2^{-n} \lambda^{-|S|} \lVert \psi \rVert_{C^r_c}.
\]

To see (7), let \( T_{x_0}^r \) be the \( r \)-th Taylor approximation of \( \psi \) at the point \( x_0 \). Recall that

\[
\lVert \psi (x_0 + u) - T_{x_0}^r (x_0 + u) \rVert \lesssim \left| \lVert u \rVert_1 \right| \left| \psi^{(r)} \right| \infty,
\]

where \( \lVert u \rVert_1 = |u_1| + \cdots + |u_d| \) is the 1-norm of the vector \( u \). Let \( s = \min_{i=1,...,d} (s_i) \) and observe that \( \frac{1}{2^{s}} \leq 1 \) implies

\[
\left| \int S^{\frac{1}{2^n} u} \right|_1 = \left| \frac{1}{2^{n s_1} \lambda s_1} u_1 \right| + \cdots + \left| \frac{1}{2^{n s_d} \lambda s_d} u_d \right|
\]

\[
= \left( \frac{1}{2^n} \right)^s \left| \frac{1}{2^{n s_1 - s} \lambda s_1} u_1 \right| + \cdots + \left| \frac{1}{2^{n s_d - s} \lambda s_d - s} u_d \right|
\]

\[
\leq \left( \frac{1}{2^n} \right)^s \left| \lVert u \rVert_1 \right|.
\]

With this in mind, we can use \( \int \hat{\phi} (u) T_{x_0}^r (u) du = 0 \) to get

9
\[
\left| \langle \hat{\phi}_y, \psi \rangle \right| \leq 2^{-n|\mathbf{l}|} \lambda^{-|\mathbf{l}|} \int \left| \hat{\phi}(u - S^{\mathbf{y}}) \right| \left| \psi \left( S^{\mathbf{z}} u - S^{\mathbf{z}} \right) - T^r \left( S^{\mathbf{z}} u - S^{\mathbf{z}} \right) \right| du
\]
\[
\lesssim \|S^{\mathbf{z}} u\|_1 \|\psi^{(r)}\|_\infty \lesssim 2^{-n\lambda - r} \|u\|_1 \|\psi^{(r)}\|_\infty
\]
\[
\lesssim 2^{-n|\mathbf{l}|} \lambda^{-|\mathbf{l}|} \int \left| \hat{\phi}(u - S^{\mathbf{y}}) \right| |u^r| \|\psi^{(r)}\|_\infty du
\]
\[
\lesssim 2^{-n|\mathbf{l}|} \lambda^{-|\mathbf{l}|} \|\psi\|_{C^r}.
\]

For the reader's convenience, we summarize the conditions that our constructed wavelets \( \phi, \hat{\phi} \) fulfill:

**Summary 2.7.** \( \Delta_n \subset \mathbb{R}^d \) denotes the scaled mesh, given by

\[
\Delta_n = \left\{ \sum_{i=1}^d 2^{-n_i} l_i e_i \mid l_i \in \mathbb{Z} \right\}.
\]

For any \( r \in \mathbb{N} \), there exists a wavelet basis defined by a function \( \phi \in C^r_c(\mathbb{R}^d) \) and a finite set \( \Phi \subset C^r_c(\mathbb{R}^d) \), such that the following properties hold:

i) There is an \( R > 0 \), such that \( \text{supp}(\phi), \text{supp}(\hat{\phi}) \subset [0, R]^d \) for all \( \hat{\phi} \in \Phi \).

ii) There exist coefficients \( (a_k)_{k \in \mathbb{Z}^d} \) with \( a_k = 0 \) if any entry of the vector \( k \) is negative, such that

\[
2^{-|\mathbf{k}|} \phi(S^{1/2} x) = \sum_{k \in \Delta_1} a_k \phi_k(x)
\]  

Note that the compact support of \( \phi \) immediately implies that only finitely many \( a_k \) are non-zero.

iii) For all \( \hat{\phi} \in \Phi \), denote

\[
\phi_y^n := 2^{-n|\mathbf{l}|} \phi_y^{\mathbf{z} - \mathbf{n}}
\]
\[
\hat{\phi}_y^n := 2^{-n|\mathbf{l}|} \hat{\phi}_y^{\mathbf{z} - \mathbf{n}}.
\]

We further denote the spaces spanned by these localized functions by

\[
V_n := \text{span}\{\phi_y^n | y \in \Delta_n\}
\]
\[
\hat{V}_n := \text{span}\{\hat{\phi}_y^n | y \in \Delta_n, \hat{\phi} \in \Phi\}
\]

and the projections onto these spaces by

\[
P_n f := \sum_{y \in \Delta_n} \langle f, \phi_y^n \rangle \phi_y^n
\]
\[
\hat{P}_n f := \sum_{y \in \Delta_n} \sum_{\hat{\phi} \in \Phi} \langle f, \hat{\phi}_y^n \rangle \hat{\phi}_y^n.
\]
iv) \( \hat{V}_n \) is the orthogonal complement of \( V_n \) in the space \( V_{n+1} \):

\[
\hat{V}_n = V_n^\perp V_{n+1}.
\]

v) For all \( n \in \mathbb{N} \),

\[
\{ \phi^n_y \mid y \in \Delta_n \} \cup \{ \hat{\phi}^m_y \mid \hat{\phi} \in \Phi, y \in \Delta_m, m \geq n \}
\]

is an orthonormal basis of \( L_2(\mathbb{R}^d) \). In particular, \( L_2(\mathbb{R}^d) = V_n \oplus_{m \geq n} \hat{V}_m \) and it holds that

\[
\psi = P_n \psi + \sum_{m=n}^{\infty} \hat{P}_m \psi
\]

for any \( \psi \in L_2(\mathbb{R}^d) \).

vi) The first part of the above decomposition converges to \( \psi \) in \( L_2(\mathbb{R}^d) \), i.e.

\[
\psi = \lim_{n \to \infty} \sum_{k \in \Delta_n} \langle \psi, \phi^n_k \rangle \phi^n_k.
\]

vii) For all \( \hat{\phi} \in \Phi, n \in \mathbb{N}, y \in \Delta_n, z \in \mathbb{R}^d \) and \( 2^{-n} \leq \lambda \leq 1 \), the following inequalities hold:

\[
\left| \langle \phi^n_y, \psi^{\lambda}_z \rangle \right| \lesssim 2^{-n} |\lambda|^{-|S|} \| \psi \|_{C^r_{\mathbb{R}^d}}
\]

\[
\left| \langle \hat{\phi}^m_y, \psi^{\lambda}_z \rangle \right| \lesssim 2^{-n} |\lambda|^{-|S|} \| \psi \|_{C^r_{\mathbb{R}^d}},
\]

where \( r = r \cdot \min_{i=1,\ldots,d}(s_i) \).

3 Stochastic Reconstruction

The goal of this section is to show and prove our main result, the stochastic reconstruction theorem. Let \( (F_z)_{z \in \mathbb{R}^d} \) be a family of distributions, which we call a germ. Recall that Martin Hairer showed in [Hai14] that the reconstructing sequence

\[
f_n(\psi) := \sum_{y \in \Delta_n} F_y(\phi^n_y)(\phi^n_y, \psi) \tag{9}
\]

converges to a limiting distribution, whenever the germ \( (F_z)_{z \in \mathbb{R}^d} \) fulfills a property called \( \gamma \)-coherence for a \( \gamma > 0 \). (Note that Hairer did not namely mention the coherence property. It was introduced by Caravenna and Zambotti in [CZ20]. However, Hairer’s proof works for (9) under the coherence assumption of Caravenna-Zambotti.)

Our analysis of the stochastic case led us to the introduction of a new concept, which we call stochastic dimension. To motivate this, consider space time white noise \( \xi(t,x) \) in \( 1+1 \) dimension and an \( \alpha \)-Hölder
continous (for now deterministic) function \( X \in C^\alpha(\mathbb{R}^2) \) for some \( \alpha > 0 \). We show in Section 6 that, for the germ \((F_{t,x})_{(t,x)\in\mathbb{R}^2}\) defined by

\[
F_{t,x}(\psi) := X(t,x)\xi(\psi) = X(t,x)\iint \psi(s,y)\xi(s,y)dsdy,
\]
the reconstructing sequence \( f_n(\psi) \) converges in \( L_p(\Omega) \) for \( p < \infty \) to

\[
f_n(\psi) \xrightarrow{n\to\infty} \iint X(s,y)\psi(s,y)\xi(s,y)dsdy,
\]
where the right-hand side is a Walsh-type integral against white noise, see [Wal86] for reference. It is also not hard to see, that \( F_{t,x} \) is only \((-1+\alpha)^-\)-coherent (which reflects \( \xi \) having regularity \((-1)^-\), if we use the canonical scaling \( s = (1,1) \), and \( X \) having regularity \( \alpha \)). This indicates that it is indeed possible to use stochastic machinery to improve the reconstructing theorem. Furthermore, there is a neat interpretation of the \( \gamma \) being slightly bigger than \(-1\): Stochastic sewing allowed martingale properties to improve the required regularity by \( \frac{1}{\gamma} \). The white noise from the example, however, has martingale properties in both directions: time and space. It is thus possible to apply the technique from the stochastic sewing lemma twice, improving the required regularity two times by \( \frac{1}{2} \). This allows the reconstruction up to \( \gamma > -1 \).

Before we continue, let us make two quick remarks:

**Remark 3.1.** This also works for a stochastic process \( X(t,x) \), which is adapted to the natural \( \sigma \)-algebra of white noise in time and space, which is \( \alpha \)-Hölder continuous in the following sense:

\[
\|X(t,x) - X(s,y)\|_{L_p} \leq |(t,x) - (s,y)|^{\alpha}.
\]

**Remark 3.2.** It should be noted that for the above germ, Caravenna-Zambotti reconstructing sequence given by

\[
f_n(\psi) = \int_{\mathbb{R}^d} F_z(\rho_z^x)\psi(z)dz
\]
converges against the same limit. We suspect that the main result of this paper can also be achieved using their mollification techniques.

This motivates us to split the dimensions \( 1, \ldots, d \) into two types of directions: Those, in which we have certain stochastic properties, and those, which lack such properties. We call the number of directions, which have such properties the **stochastic dimension** of the germ.

What is the correct stochastic setting for this process? Let us again take a look at the Example (10): \( (F_{t,x})_{(t,x)\in\mathbb{R}^2} \) is a random germ over the probability space \((\Omega,\mathcal{F},P)\), where \( \mathcal{F} = \sigma(\xi(\psi)|\psi \in L_2(\mathbb{R}^2)) \) is the sigma algebra generated by white noise. This sigma algebra comes with a natural filtration, which one can write informally as \( \mathcal{F}_t = \{\xi(s,x)|s \leq t\} \). The formal definition for this is of course given by

\[
\mathcal{F}_t = \sigma(\xi(\psi)|\text{supp}(\psi) \subset (-\infty,t]\times\mathbb{R}).
\]

Let now \( t \in \mathbb{R} \) and \( \psi \) with a support in \((-\infty,s]\times\mathbb{R}\) be fixed. It then holds that \( \xi(\psi) \) is \( \mathcal{F}_s \)-measurable and we assume that \( X(\cdot,x) \) is adapted to \((\mathcal{F}_t)_{t\in\mathbb{R}}\), i.e. \( X(t,x) \) is \( \mathcal{F}_t \)-measurable for all \( x \in \mathbb{R} \). It immediately follows, that \( F_{t,x}(\psi) = X(t,x)\xi(\psi) \) is \( \mathcal{F}_{\max(s,t)} \)-measurable.

Of course, a similar construction can be made in the spatial direction \( x \) with respect to the filtration \( \mathcal{F}_{x}^{\text{spatial}} := \sigma(\xi(\psi)|\text{supp}(\psi) \subset \mathbb{R}\times(-\infty,x]) \). This gives us two different filtrations, and our germ is adapted to both in the sense that for \( t, x \in \mathbb{R} \) and \( \psi \) with support in \((-\infty,s]\times(-\infty,y]\), \( F_{t,x}(\psi) \) is \( \mathcal{F}_{\max(s,t)} \) and \( \mathcal{F}_{\max(x,y)}^{\text{spatial}} \)-measurable.
We want to generalise this adaptedness property: Let \((\Omega, \mathcal{F}, P)\) be a complete probability space, and let \((F_t)_{t \in \mathbb{R}^d}\) be a random germ over that space, i.e. for \(z \in \mathbb{R}^d\), let \(F_z : C^r_c \to L_p(\Omega)\) be a continuous, linear map for some \(p < \infty\). As in the example above, consider \(e\) many filtrations \((F_t^{(i)})_{t \in \mathbb{R}}, i = 1, \ldots, e\).

We make the following assumptions on these filtrations:

- **Completeness:** We assume, that each \(F_t^{(i)}\) is complete. This guarantees, that for an \(F_t^{(i)}\)-measurable \(X\), any modification of this \(X\) is still \(F_t^{(i)}\)-measurable.

- **Right-continuity:** We assume, that for \(i = 1, \ldots, e\), \((F_t^{(i)})_{t \in \mathbb{R}}\) is a right continuous filtration. This will allow the limits in the proofs to come to have the right adaptedness properties.

- **Orthogonality:** In the proof of Theorem 3.8, we will iteratively condition our germs onto \(\sigma\)-algebras \(F_t^{(i)}\) with different \(i\). For this to make sense, we need to assume that conditioning in one direction does not change measurability along the other directions. To be precise, we assume, that if a random variable \(X\) is \(F_t^{(i)}\)-measurable for some \(1 \leq i \leq e\) and \(z_i \in \mathbb{R}\), then \(E^{F_t^{(i)}} X\) is still \(F_t^{(j)}\)-measurable for all \(1 \leq j \leq e, j \neq i\) and all \(z_j \in \mathbb{R}\).

We denote by \(\pi_i\) the projection onto the \(i\)-th coordinate. With this notation, we can now define the term stochastic dimension:

**Definition 3.3.** Let \((F_t)_{t \in \mathbb{R}^d}\) be a random germ (i.e. a family of random distributions) in \(d\) dimensions, and let \(e \leq d\). Let \((F_t^{(i)})_{i \in \mathbb{R}}, i = 1, \ldots, e\) be filtrations of some \(\sigma\)-Algebra \(\mathcal{F}\), which fulfill the above three properties of completeness, right-continuity and orthogonality.

We say that \((F_t)\) is of stochastic dimension \(e\), if for \(i = 1, \ldots, e\):

For any test function \(\psi\) with support \(\text{supp}(\psi) \subset \mathbb{R}^{d-1} \times (-\infty, y] \times \mathbb{R}^{d-i}\), it holds that

\[
F_t(\psi) \text{ is } F_{\max(\pi_i(x), y)}^{(i)}\text{-measurable. (11)}
\]

We further say that a random distribution \(f\) has stochastic dimension \(e\), if for any test function \(\psi\) with support \(\text{supp}(\psi) \subset \mathbb{R}^{d-1} \times (-\infty, y] \times \mathbb{R}^{d-i}\)

\[
f(\psi) \text{ is } F_y^{(i)}\text{-measurable.}
\]

**Remark 3.4.** As most readers have undoubtedly noticed, we use a two-directional setting in the sense that we always use \(t \in \mathbb{R}\) instead of \(t \in [0, \infty)\). In one dimension, our example (10) becomes a two-sided Brownian motion, not a classical one.

Since this whole theory highly depends on recentering and scaling operations, the origin point does not have any special role, which makes this two-directional setting more natural. However, one can use the locality of this theory to achieve a one-sided setting, by restricting oneself to compact sets \(K \subset [0, \infty) \times \mathbb{R}^{d-1}\) in Definition 3.5 and Theorem 3.8.

Since we work with a scaling \(S\) associated to some \(s \in \mathbb{R}^d_+\), we do not consider \(e\) to be the number of stochastic dimensions, but rather consider

\[
E := \sum_{i=1}^e s_i \leq |S|.
\]

With the definition of the stochastic dimension in mind, we can now formulate a stochastic version of the coherence property. Since we aim to get \(L_p\)-convergence, let us fix now some \(2 \leq p < \infty\) and define stochastic coherence as follows:
Definition 3.5. Let \((F_x)_{x \in \mathbb{R}^d}\) be a stochastic germ with stochastic dimension \(e \leq d\) and let \(E\) be as above. We call \((F_x)\) stochastically \(\gamma\)-coherent, if there is an \(\alpha \in \mathbb{R}\), such that the following holds for all test functions \(\psi \in C^\infty_c((\mathbb{R}^d)^\varepsilon)\) with \(||\psi||_{C^\infty_c} = 1\) and \(\text{supp}(\psi) \subset [0, \tilde{R}]^e \times [-\tilde{R}, \tilde{R}]^{d-e}\) for some \(\tilde{R} > 0\), for the stochastic directions \(i = 1, \ldots, e\), for any compact set \(K \subset \mathbb{R}^d\) and for any \(x, y \in K\) with \(\pi_i(x) \leq \pi_i(y)\):

\[
\left| \mathbb{E}^{F_x(x)}(F_x - F_y)(\psi_y) \right|_{L_p} \lesssim \epsilon^\alpha (|x - y| + \epsilon)^{\gamma - \alpha},
\]

where the constant appearing in \(\lesssim\) is allowed to depend on the compact set \(K\) and the radius \(\tilde{R}\).

Remark 3.6. In the usual construction of stochastic integrals, it is far more natural to use left-side approximations than two-sided ones. Thus, (10) is only a useful approximation, if the support of \(\psi\) is in \([t, \infty) \times [x, \infty)\). We therefore only consider test functions with positive support in the stochastic directions in the definition above and in Theorem 3.8. It is however possible to get a two-sided stochastic reconstruction, which will be discussed in Section 3.1.

Remark 3.7. It is possible to allow \(\alpha = \alpha(K)\) to depend on the compact set \(K\). In this case, one simply has to replace \(\alpha\) with \(\alpha(K)\) in the proofs, for some fattening \(\tilde{K}\) of \(K\) which depends on the support of the wavelet.

Note that each stochastic dimension reduces the coherence required by \((F_x)\) in (12) by \(\frac{1}{2}\), resulting in a total reduction of \(\frac{e}{2}\), under the corresponding scaling. In particular, if the scaling is just the canonical scaling \(s = (1, \ldots, 1)\), we get a reduction by \(\frac{e}{2}\). Further note that the support of \(\psi_y\) lies completely on the right-hand side of the time we condition on, \(\pi_i(x)\), with respect to the direction \(i\).

We say that a random distribution \(\tilde{f}\) is a modification of \(f\), if for all test functions \(\psi \in C^\infty_c\), \(f(\psi) = \tilde{f}(\psi)\) almost surely. With this in mind, we can formulate our main result:

Theorem 3.8 (Stochastic Reconstruction). Let \((F_x)\) be a random germ with stochastic dimension \(e \leq d\), which is stochastically \(\gamma\)-coherent for some \(\gamma > 0\). Then, where is a unique random distribution \(f\) (up to modifications) with stochastic dimension \(e\) with regard to the same filtrations \(\mathcal{F}_{[t]}\) as our germ, such that the following holds for any test function \(\psi \in C^\infty_c\) with \(||\psi||_{C^\infty_c} = 1\) and which support is in \(\text{supp}(\psi) \subset [2R, 2R + \tilde{R}]^e \times [-\tilde{R}, \tilde{R}]^{d-e}\) for some \(\tilde{R} > 0\):

\[
\left| (f - F_x)(\psi) \right|_{L_p} \lesssim \lambda^{\gamma - \frac{e}{2}},
\]

\[
\left| \mathbb{E}^{F_x(x)}(f - F_y)(\psi_y) \right|_{L_p} \lesssim \lambda^\gamma,
\]

where the constant in \(\lesssim\) again depends on the constant set \(K \subset \mathbb{R}^d\) with \(x \in K\) and \(\tilde{R}\).

Note that the support \(\psi\) does not just have to be positive, but it has to be far enough away from zero, to “fit in” the wavelet \(\phi\) between zero and the support of \(\psi\) twice. (Recall, that the support of the wavelet is in \([0, \tilde{R}]^d\).)

Remark 3.9. The restrictions to \(\psi\) might seem strange to the reader. Indeed, it seems that this theorem only makes a statement about test functions with (strictly) positive supports in the stochastic directions. However, this is not true, since the localizations \(\psi_y\) can have negative supports in all directions depending on \(y\). The support does only serve to separate the point of localization of \(\psi\) and the index of the germ.
Another way to formulate the result, is to use \( \psi \) with any compact support, and take a look at \( F(y \ast \varphi (\psi_y^L)) \) for a certain vector \( C \) depending on the support of \( \psi \), and which directions are supposed to be stochastic.

The proof will be split into three parts, which we show in separate lemmas:

i) Lemma 3.10 will show the \( L_p \) convergence of the reconstructing sequence: For
\[
 f^{(\alpha)} := \sum_{x \in \Delta_n} F_x(\phi^n_x)\phi^n_x,
\]
it holds that
\[
f_n(\psi) \xrightarrow{L_p} f(\psi).
\]

ii) Lemma 3.13 will show, that the limit \( f \) fulfills (13) and (14).

iii) Lemma 3.14 will show that there is at most one distribution (up to modifications) fulfilling (13) and (14), and thus the lemma shows the uniqueness of the reconstruction.

**Lemma 3.10.** Let \( (F_x) \) be as in Theorem 3.8. Further, define the reconstructing sequence by
\[
f^{(\alpha)}(y) := \sum_{n \in \Delta_n} F_x(\phi^n_x)\phi^n_x(y).
\]
Then, for any test function \( \psi \in C^e_0 \) the sequence \( f^{(\alpha)}(\psi) = \langle f^{(\alpha)}, \psi \rangle \) converges in \( L_p(\Omega) \). We denote the limit by \( f(\psi) \) and it holds that \( f \) is a random distribution with stochastic dimension \( e \) with regards to the filtrations \( F^{(i)}, i = 1, \ldots, e \).

**Proof.** Our strategy for this proof is to write \( f^{(n)} \) as the telescopic sum \( f^{(n)} = f^{(0)} + \sum_{m=0}^{n-1} (f^{(m+1)} - f^{(m)}) \) and show the convergence of this series by finding a \( c > 0 \) such that \( \| f^{(n+1)} - f^{(n)}(\psi) \| \lesssim 2^{-nc} \) for any test function \( \psi \in C^e_0 \). This implies, that \( f^{(n)}(\psi) \) is Cauchy, and thus convergent in \( L_p(\Omega) \).

We first analyze the behavior of \( f^{(n)} \) tested against wavelets \( \psi = \phi^n_x \) with \( x \in \Delta_n \). Using the definition of \( f^{(n)} \) and (8), we get
\[
(f^{(n+1)} - f^{(n)})(\phi^n_x) = \sum_{z \in \Delta_{n+1}} F_z(\phi^{n+1}_z, \phi^n_x) - \sum_{y \in \Delta_n} F_y(\phi^n_y, \phi^n_x).
\]
\[
= \sum_{z \in \Delta_{n+1}} \sum_{k \in \Delta_{n+1}} F_z(\phi^{n+1}_z, \phi^{n+1}_x, \phi^n_x) - \sum_{y \in \Delta_n} F_y(\phi^n_y, \phi^n_x)
\]
\[
= \sum_{k \in \Delta_{n+1}} a_k^{n+1} R_{x+k} - \sum_{k \in \Delta_{n+1}} a_k^{n+1} R_{x+k} - \sum_{k \in \Delta_{n+1}} a_k^{n+1} R_{x+k}.
\]

Note that \( a_k^{n+1} \neq 0 \) only for \( |k| \leq dR2^{-n} \). This also implies, that the sum is finite. Thus,
\[
\| f^{(n+1)} - f^{(n)}(\phi^n_x) \|_{L_p} \leq \sum_{k \in \Delta_{n+1}} a_k^{n+1} \| R_{x+k} \|_{L_p}
\]
\[
\lesssim 2^{-n(1+\gamma)} (1 + 2^{-n(1+\gamma)+E/2}) \lesssim 2^{-n(1+\gamma)+E/2},
\]
(15)
where we used in the last line that $a_k^{(n+1)} \neq 0$ implies $|k| \leq dR2^{-n}$. Also note in the first line that $\pi_i(k) \geq 0$ for all non-zero terms and that the support of $\phi$ is positive, which justifies using the coherence property. Analogously, for $i = 1, \ldots, e$, it follows that

$$
\left\| E^{F_{\tau,1}^{(i)}} (f^{(n+1)} - f^{(n)}) (\phi^a_k) \right\|_{L^p} \lesssim 2^{-n \gamma - n \frac{|a|}{n}}. \quad (16)
$$

Observe that $(f^{(n+1)} - f^{(n)}) (\phi^a_k)$ is $F_{\hat{S}(\tau,1)}^{(i)}$-measurable for $\hat{S}(\tau,1) := \pi_i(x) + (2^{-n \gamma} + 2^{-(n+1) \nu}) R$.

We want to bound $\left\| (f^{(n+1)} - f^{(n)}) (\psi) \right\|$ for an arbitrary test function $\psi$ with compact support. To do so, we split $\psi$ into

$$
\psi = P_n \psi + \sum_{m \geq n} \hat{P}_m \psi,
$$

and bound both terms individually. Since finding a bound for $(f^{(n+1)} - f^{(n)}) (P_n \psi)$ is quite lengthy, let us formulate this step as a separate lemma:

**Lemma 3.11.** Under the assumptions of Lemma 3.10, it holds that for any $x_0$ in some compact set $K \subset \mathbb{R}^d$, and $1 \geq \lambda \geq 2^{-n}$:

$$
\left\| (f^{(n+1)} - f^{(n)}) (P_n \psi^\lambda_{x_0}) \right\|_{L^p} \lesssim 2^{-n \gamma} \lambda - \frac{\psi}{C^*}.
$$

There the constant in $\lesssim$ is allowed to depend on $K$. In particular,

$$
\left\| (f^{(n+1)} - f^{(n)}) (P_n \psi) \right\|_{L^p} \lesssim 2^{-n \gamma} \| \psi \|_{C^*}.
$$

**Proof.** Recall that

$$(f^{(n+1)} - f^{(n)}) (P_n \psi^\lambda_{x_0}) = \sum_{x \in \Delta_n} \frac{(f^{(n+1)} - f^{(n)}) (\phi^a_k)}{\phi^a_k} \phi^a_k (\phi_{x_0}^\lambda) = \sum_{x \in \Delta_n} \frac{(f^{(n+1)} - f^{(n)}) (\phi^a_k)}{\phi^a_k} \phi^a_k (\phi_{x_0}^\lambda).
$$

Our strategy will be to use (2) on the outermost sum and then iterate this step over all stochastic directions. To this end, we specify the definition

$$
\Delta_{n}^{a,b} := \left\{ \sum_{i=a}^{b} 2^{-n \lambda} l_i e_i \mid l_i \in \mathbb{Z} \right\}
$$

to be the rescaled mesh in the variables $a$ to $b$. Unfortunately, naively applying (2) does not work for our sum: If we set $Z_y := \sum_{x \in \Delta_n} g(x, y)$ so that $(f^{(n+1)} - f^{(n)}) (P_n \psi^\lambda_{x_0}) = \sum_{y \in \Delta_n} Z_y$, we note that $Z_y$ is $F_{\hat{S}(\tau,1)}^{(i)}$-measurable. (2) would now allow us to condition $Z_y$ onto $F_{\hat{S}(\tau,1)}^{(i),2^{-n \gamma}}$, which results in a random variable which we do not control.

Instead, we are going to split the sum into $[C]^c$ many sums for $C = (1 + 2^{-n}) R$ in which the nets have a bigger mesh, to get the right conditioning. To this end, let $0 \leq r_i \leq [C] - 1, i = 1, \ldots, e$ be natural numbers and set

$$
r_n^{(k)} := S^{2^{-n}} (r_{k+1}, \ldots, r_e, 0, \ldots, 0) \in \Delta_n^{k+1,d}
$$

for $k = 0, \ldots, e$. We define the rescaled and shifted net for each such $r_n^{(k)}$ by

$$
\Delta_n^{k+1,d}(r_n^{(k)}) = \left\{ \sum_{i=k+1}^{d} [C] \cdot 2^{-n \lambda} l_i e_i + r_n^{(k)} \mid l_i \in \mathbb{Z} \right\}
$$

16
and split
\[(f^{(n+1)} - f^n)(P_n \psi^\lambda_{x_0}) = \sum_{r_n^{(0)}} \sum_{x \in \Delta_n^{1,d}(r_n^{(0)})} g_x\]

into \([C]^\epsilon\) many sums, where the first sum runs over all possible \(r_n^{(0)}\). It suffices to find a bound for the sum over \(x\) as the sum over \(r_n^{(0)}\) will merely add the constant factor \([C]^\epsilon\). Using (2), we now do indeed get
\[
\left\| \sum_{x \in \Delta_n^{1,d}(r_n^{(0)})} g_x \right\|_{L_p} \lesssim \sum_{y \in \Delta_n^{2,d}(r_n^{(1)})} \left\| \sum_{x \in \Delta_n^{2,d}(r_n^{(1)})} E_{x,y}^{(1)} g_{(y,x)} \right\|_{L_p} + \left( \sum_{y \in \Delta_n^{1,d}(r_n^{(1)})} \left\| \sum_{x \in \Delta_n^{2,d}(r_n^{(1)})} g_{(y,x)} - E_{x,y}^{(1)} g_{(y,x)} \right\|_{L_p} \right)^{\frac{1}{2}}, \tag{17}
\]

We want to iterate this step over all stochastic directions. To this end, we introduce the notation
\[
\begin{align*}
g_x &:= (f^{(n+1)} - f^{(n)})(\phi^\alpha_x)(\phi^\alpha_{x_0}) & x &\in \Delta_n^{1,d} \\
g_{y,x} &:= g_{(y,x)} - E_{x,y}^{(1)} g_{(y,x)} & x &\in \Delta_n^{2,d}, y \in \Delta_n^{1,1} \\
g_{y_1,y_2,x} &:= g_{y_1,(y_2,x)} - E_{x,y_2}^{(2)} g_{y_1,(y_2,x)} & x &\in \Delta_n^{3,d}, y_1 \in \Delta_n^{1,1}, y_2 \in \Delta_n^{2,2} \\
\vdots \\
g_{y_1,\ldots,y_e,x} &:= g_{y_1,\ldots,y_{e-1}(y_e,x)} - E_{y_e,x}^{(e)} g_{y_1,\ldots,y_{e-1}(y_e,x)} & x &\in \Delta_n^{e+1,d}, y_1 \in \Delta_n^{1,1}, \ldots, y_e \in \Delta_n^{e,e},
\end{align*}
\]

And find bounds for \(\left\| \sum_{x \in \Delta_n^{1,d}(r_n^{(i)})} g_{y_1,\ldots,y_i,x} \right\|_{L_p}\) using a backwards induction over \(i = 0, \ldots, e\). Recall, that (6) gives us
\[
\left| \langle \phi^\alpha_{x_0}, \psi^\lambda \rangle \right| \lesssim 2^{-n\gamma - n\frac{d}{2} - n\frac{d}{2} - n\frac{d}{2}} \lambda^{-|S|} \|\psi\|_{C^\epsilon_x}. \tag{18}
\]
Together with (15), this implies
\[
\left\| g_x \right\|_{L_p} \leq \left\| (f^{(n+1)} - f^{(n)})(\phi^\alpha_x) \right\|_{L_p} \left| \langle \phi^\alpha_{x_0}, \psi^\lambda \rangle \right| \lesssim 2^{-n\gamma - n\frac{d}{2} - n\frac{d}{2} - n\frac{d}{2}} \lambda^{-|S|} \|\psi\|_{C^\epsilon_x} = 2^{-n\gamma - n|S| + n\frac{d}{2} - n\frac{d}{2}} \lambda^{-|S|} \|\psi\|_{C^\epsilon_x}, \tag{19}
\]
and analogously, using (16)
\[
\left\| E_{x,y}^{(1)} g_{(y,x)} \right\|_{L_p} \lesssim 2^{-n\gamma - n|S|} \lambda^{-|S|} \|\psi\|_{C^\epsilon_x}. \tag{20}
\]
Observe that for any \(i = 1, \ldots, e\), \(g_{y_1,\ldots,y_i,x}\) is just a finite linear combination of \(g_{y_1,\ldots,y_i,x}\) conditioned on different sigma algebras. By the contraction properties of the conditional expectation, (19) and (20) thus hold for any \(g_{y_1,\ldots,y_i,x}, i = 0, \ldots, e\).

We claim, that the following holds for \(i = 0, \ldots, e\):
\[
\left\| \sum_{x \in \Delta_n^{i+1,d}(r_n^{(i)})} g_{y_1,\ldots,y_i,x} \right\|_{L_p} \lesssim 2^{-n \gamma - n \frac{E}{2}} \lambda^{-\frac{E}{2}} ||\psi||_{C^r},
\]

where \( E_i := \sum_{j=1}^i s_j \). As said above, we show this claim by backwards induction. For \( i = e \), note that the \( g_x \neq 0 \) implies \( \langle \phi_n^n, \psi \rangle \neq 0 \), which is only true for \( \geq 2^{n} \lambda^e \) many \( x \) for every coordinate \( i = 1, \ldots, d \).

Thus, using (19), we conclude that

\[
\sum_{x \in \Delta_n^{i+1,d}(r_n^{(i)})} ||g_{y_1,\ldots,y_i,x}||_{L_p} \lesssim 2^{-n \gamma - n |S| + n \frac{E}{2}} \lambda^{-|S|} \cdot 2^{n(|S|-E)} \lambda^{|S|-E} ||\psi||_{C^r} = 2^{-n \gamma - n \frac{E}{2}} \lambda^{-E} ||\psi||_{C^r}.
\]

(21)

For the induction step, observe that

\[
\sum_{x \in \Delta_n^{i+1,d}(r_n^{(i)})} \left\| E^{(i)}_{x_{i+1}} g_{y_1,\ldots,y_{i-1},(y_i,x)} \right\|_{L_p} \lesssim 2^{-n \gamma - n |S| \lambda^{-|S|} \cdot 2^{n(|S|-E_i)} \lambda^{|S|-E_i} ||\psi||_{C^r}}
\]

holds, and that summing over the squares and taking the square root has the effect of multiplying a factor of \( 2^{-n \frac{E}{2}} \lambda^E \):

\[
\left( \sum_{k=1}^{\left\lfloor \frac{2^{n \lambda^k}}{a} \right\rfloor} a^2 \right)^{\frac{1}{2}} \leq 2^{\frac{n \lambda}{2}} \lambda^E a.
\]

Now, using (17), we get

\[
\left\| \sum_{x \in \Delta_n^{i+1,d}(r_n^{(i)})} g_{y_1,\ldots,y_i,x} \right\|_{L_p} \lesssim \sum_{y_{i+1} \in \Delta_n^{i+1,d}(r_n^{(i+1)})} \sum_{x \in \Delta_n^{i+1,d}(r_n^{(i+1)})} \left\| E^{(i+1)}_{y_{i+1}} g_{y_1,\ldots,y_i,(y_{i+1},x)} \right\|_{L_p} \lesssim 2^{-n \gamma - n E_i} \lambda^{-E_i} ||\psi||_{C^r}
\]

\[
+ \left( \sum_{y_{i+1} \in \Delta_n^{i+1+1}(r_n)} \sum_{x \in \Delta_n^{i+2,d}(r_n^{i+1})} \left\| g_{y_1,\ldots,y_{i+1},x} \right\|_{L_p} \right)^{\frac{1}{2}} \lesssim 2^{-n \gamma - n E \frac{E_i}{2}} \lambda^{-E \frac{E_i}{2}} ||\psi||_{C^r}.
\]

This shows the claim. Therefore, \( i = 0 \) implies

\[
\left\| \sum_{x \in \Delta_n} g_x \right\|_{L_p} \lesssim \sum_{r_n} \sum_{x \in \Delta_n^{1,d}(r_n)} ||g_x||_{L_p} \lesssim 2^{-n \gamma \lambda^{-E} ||\psi||_{C^r}},
\]

which finishes the proof of the lemma.
It remains to bound the norm of \((f^{(n+1)} - f^{(n)}) \left( \sum_{m \geq n} \hat{P}_m \psi \right)\). Since \(f^{(n+1)} - f^{(n)} \in V_{n+1} \perp \hat{V}_n\) for any \(m \geq n + 1\), it follows that
\[
(f^{(n+1)} - f^{(n)}) \left( \sum_{m \geq n} \hat{P}_m \psi \right) = (f^{(n+1)} - f^{(n)}) (\hat{P}_n \psi),
\]
so it suffices to bound this term. To do so, let us formulate a slight variation of Lemma 4.12 from [CZ20]:

**Lemma 3.12.** Let \((F_x)_{x \in \mathbb{R}^d}\) be a stochastic \(\gamma\)-coherent germ. Then, for any compact subset \(K \subset \mathbb{R}\), there is a \(\beta = \beta(K) \in \mathbb{R}^d\) such that \((F_x)_{x \in \mathbb{R}^d}\) fulfills the homogeneity bound
\[
||F_x(\psi^n)||_{L_p} \lesssim \lambda^\beta
\]
for all \(x \in K\).

**Proof.** Observe that any stochastic \(\gamma\)-coherent germ is \(\gamma - \frac{\beta}{\gamma}\) coherent (if one replaces the absolute value with the \(L_p\)-norm). Thus, we can apply Lemma 4.12 from [CZ20] to get the result. \(\square\)

Using this lemma together with the fact, that for any \(\phi \in \Phi\)
\[
\sum_{y \in \Delta_{n+1}} |\langle \phi_{y}^{n+1}, \hat{\phi}_{x}^{n} \rangle| \leq \sum_{y \in \Delta_{n+1}} 2^{(n+1)/2} |S| \int |\phi(S^{2^n+1} (z - y)) \hat{\phi}^n(S^{2^n} (z - x))| \, dz
\]
\[
= \sum_{k \in \mathbb{Z}^d} 2^{d/2} \int |\phi(u - k) \hat{\phi}(S^{2^n} u - S^{2^n} x)| \, du
\]
is bound by a constant independent of \(n\), it follows, that
\[
\left\| f^{(n+1)}(\hat{\phi}_{x}^{n}) \right\|_{L_p} \leq \sum_{y \in \Delta_{n+1}} \left\| F_y(\phi_{y}^{n+1}) \right\|_{L_p} \left| \langle \phi_{y}^{n+1}, \hat{\phi}_{x}^{n} \rangle \right|
\]
\[
\lesssim \sum_{y \in \Delta_{n+1}} \left| \langle \phi_{y}^{n+1}, \hat{\phi}_{x}^{n} \rangle \right| \lesssim 2^{-n^{\frac{d}{2}} - n^\beta}
\]
Thus, using \(f^{(n)} \in V_n \perp \hat{V}_n\), we see that
\[
\left\| (f^{(n+1)} - f^{(n)})(\hat{P}_n \psi) \right\|_{L_p} \leq \sum_{x \in \Delta_n} \sum_{\phi \in \Phi} \left\| (f^{(n+1)} - f^{(n)})(\hat{\phi}_{x}^{n}) \right\|_{L_p} \left| \langle \hat{\phi}_{x}^{n}, \psi \rangle \right|
\]
\[
= \sum_{x \in \Delta_n} \sum_{\phi \in \Phi} \left\| (f^{(n+1)}(\hat{\phi}_{x}^{n}) \right\|_{L_p} \left| \langle \hat{\phi}_{x}^{n}, \psi \rangle \right|
\]
\[
\lesssim 2^{-n^{\beta} - n^\beta} ||\psi||_{C^\gamma},
\]
where we used \(\sum_{x \in \Delta_n} \left| \langle \hat{\phi}_{x}^{n}, \psi \rangle \right| \lesssim 2^{n^{\frac{d}{2}} - n^\beta} ||\psi||_{C^\gamma}\), which follows from (7) together with the fact, that the number of non-zero summands is of order \(2^{n |S|}\). We can now conclude that
Lemma 3.13. We can now continue with the second step of the proof: Using the fact that

\[ \lim_{n \to \infty} P_n(f^{(n+1)} - f^{(n)})(\psi) \]

where

\[ f^{(n)}(\psi) = \sum_{x} F_x(\phi_{x}^{n,}\psi) \]

and let \( \psi \) be the limit achieved in Lemma 3.10. Let \( \psi \) be a smooth test function with compact support in \([2R, R]^c \times [-R, R]^{d-c} \). Then, (13) and (14) hold, i.e. for \( i = 1, \ldots, c \):

\[ \left\| (f - F_x)(\psi_x^n) \right\|_{L_p} \lesssim \lambda^{-\frac{2}{q}} \]

\[ \left\| E^{^{F_x}}(f - F_x)(\psi_x^n) \right\|_{L_p} \lesssim \lambda^{2}. \]

Proof. Using the fact that \( P_n + \sum_{m=n}^{\infty} \hat{P}_m = id \), as well as \( f^{(n+1)} - f^{(n)} \in V_{n+1} = V_n \oplus \hat{V}_n \), it follows, that

\[
f - F_x = f^{(n)} + \sum_{m=n}^{\infty} (f^{(m+1)} - f^{(m)}) - F_x = f^{(n)} + \sum_{m=n}^{\infty} (P_m + \hat{P}_m)(f^{(m+1)} - f^{(m)}) + \left( P_n + \sum_{m=n}^{\infty} \hat{P}_m \right) F_x
\]

\[
= f^{(n)} + \sum_{m=n}^{\infty} \hat{P}_m(f^{(m+1)} - f^{(m)}) + \sum_{m=n}^{\infty} P_m(f^{(m+1)} - f^{(m)}),
\]

where \( n \) is chosen in such a way, that \( 2^{-n} \leq \lambda \leq 2^{-n+1} \). We will find bounds for these three terms individually.

Regarding (I), observe that

\[ (I)(\psi_x^n) = \sum_{y \in \Delta_n} (F_y - F_x)(\phi_{y}^{n,}\psi_{x}^{\lambda}). \]

We use (6) to see \( \left| \langle \phi_{y}^{n,}\psi_{x}^{\lambda} \rangle \right| \lesssim 2^{-n|\Sigma|} \lambda^{-|S|} \lesssim 2^n|\Sigma| \), since \( \lambda \geq 2^{-n} \). Also, \( \langle \phi_{y}^{n,}\psi_{x}^{\lambda} \rangle \) is only non-zero for finitely many (independent of \( n \)) \( y \). This implies

\[
\sum_{y} \left| \langle \phi_{y}^{n,}\psi_{x}^{\lambda} \rangle \right| \lesssim 2^n|\Sigma|.
\]
Further note that $\langle \phi^m_y, \psi^n_y \rangle \neq 0$ implies, that the supports of $\phi^m_y$ and $\psi^n_y$ overlap. Thus, for $i = 1, \ldots, e$, we get $\pi_i(y) \geq \pi_i(x) + \lambda^n 2R - 2^{-m_i} R \geq \pi_i(x)$. This allows us to use stochastic coherence, and we get:

$$\| (I)(\psi^2_y) \|_{L_p} \leq \sum_{y \in \Delta_n} \| (F_y - F_x)(\phi^m_y) \|_{L_p} \| \langle \phi^m_y, \psi^2_y \rangle \|
\lesssim \lambda^{-\frac{3}{4}} 2^{-n \frac{\lambda_i}{2}} \sum_{y} \| \langle \phi^m_y, \psi^2_y \rangle \|
\lesssim \lambda^{-\frac{3}{4}}$$

$$\| E^{F}_{\pi_i(x)} (I)(\psi^2_y) \|_{L_p} \leq \sum_{y \in \Delta_n} \| E^{F}_{\pi_i(x)} (F_y - F_x)(\phi^m_y) \|_{L_p} \| \langle \phi^m_y, \psi^2_y \rangle \|
\lesssim \lambda^{-\frac{3}{4}} 2^{-n \frac{\lambda_i}{2}} \sum_{y} \| \langle \phi^m_y, \psi^2_y \rangle \|
\lesssim \lambda^\gamma.$$  

To analyze (II), we take a look at how $\hat{P}_m$ acts on all terms involved:

$$\hat{P}_m f^{(m)} = \sum_{y \in \Delta_m} \sum_{z \in \Delta_m} \sum_{\phi \in \Phi} F_z(\phi^m_y) \langle \phi^m_y, \hat{\phi}_y \rangle \hat{\phi}_y = 0$$

$$\hat{P}_m f^{(m+1)} = \sum_{y \in \Delta_m} \sum_{z \in \Delta_m+1} \sum_{\phi \in \Phi} F_z(\phi^{m+1}_y) \langle \phi^{m+1}_y, \hat{\phi}_y \rangle \hat{\phi}_y$$

$$\hat{P}_m F_x = \sum_{y \in \Delta_m} \sum_{z \in \Delta_m+1} \sum_{\phi \in \Phi} F_x(\phi^{m+1}_y) \langle \phi^{m+1}_y, \hat{\phi}_y \rangle \hat{\phi}_y,$$

where the equation for $\hat{P}_m F_x$ is of course only rigorous as

$$\hat{P}_m F_x(\psi) = \sum_{y \in \Delta_m} \sum_{z \in \Delta_m+1} \sum_{\phi \in \Phi} F_x(\phi^{m+1}_y) \langle \phi^{m+1}_y, \hat{\phi}_y \rangle \hat{\phi}_y \langle \hat{\phi}_y, \psi \rangle.$$

Using these and the notation $\hat{P}_m F^{(m)}(\psi) = \langle \hat{P}_m f^{(m)}, \psi \rangle$, we get

$$\hat{P}_m (f^{(m+1)} - f^{(m)} - F_x)(\psi) = \sum_{y \in \Delta_m} \sum_{z \in \Delta_m+1} \sum_{\phi \in \Phi} (F_x - F)_z(\phi^{m+1}_y) \langle \phi^{m+1}_y, \hat{\phi}_y \rangle \hat{\phi}_y \langle \hat{\phi}_y, \psi \rangle.$$

Observe that the only non-zero terms fulfill for $i = 1, \ldots, e$, that $\pi_i(z) \geq \pi_i(y) - 2^{-m_i} R \geq \pi_i(x) + \lambda^n 2R - 2 \cdot 2^{-m_i} R \geq \pi_i(x)$, so we can use stochastic coherence. Note that the number of $z$, such that $\langle \phi^{m+1}_z, \phi^m_y \rangle \neq 0$ for any fixed $y$ is of order 1, and the number of $y$, such that $\langle \phi^m_y, \psi^n_y \rangle \neq 0$ is of order $2^{m|S|\lambda |S|}$. Using (7), $\| \langle \phi^{m+1}_z, \phi^m_y \rangle \| \lesssim 1$ as well as stochastic coherence, we get:
\[ \left\| \hat{P}_m (f^{(m+1)} - f^{(m)} - F_x (\psi^\lambda_x)) \right\|_{L_p} \leq \sum_{y \in \Delta_m} \sum_{z \in \Delta_{m+1}} \sum_{\phi \in \Phi} \left\| (F_z - F_x) (\phi^{m+1}) \right\|_{L_p} \]
\[ \leq 2^{-m \frac{|z-y|}{2} - ma \lambda \gamma + \frac{\delta}{2} - \alpha} \times \left\| \langle \phi_{\psi}^{m+1}, \psi_y \rangle \right\| \]
\[ \leq 2^{-m \frac{|z-y|}{2} - ma \lambda \gamma + \frac{\delta}{2} - \alpha} 2^{-m \frac{|z-y|}{2} - m \lambda \gamma - |S| - r} \]
\[ \approx 2^{-m \gamma \lambda - \frac{\delta}{2} - \alpha - r}. \]

This allows us to find the following bound for (II):
\[ \left\| (II) (\psi_x^\lambda) \right\|_{L_p} \lesssim \sum_{m=n}^{\infty} 2^{-ma - m \lambda \gamma - \frac{\delta}{2} - \alpha - r} \approx \lambda^{-\frac{\delta}{2}}, \]
where we used \( 2^{-n} \approx \lambda \). Analogously, it further holds that
\[ \left\| E^{\mathcal{F}_{\pi_x}(\cdot)} \hat{P} (f^{(m+1)} - f^{(m)} - F_x (\psi^\lambda_x)) \right\|_{L_p} \lesssim \lambda^\gamma. \]

It remains to bound (III). By Lemma 3.11, it follows that
\[ \left\| (\text{III}) (\psi_x^\lambda) \right\|_{L_p} \leq \sum_{m=n}^{\infty} \left\| P_m (f^{(m+1)} - f^{(m)}) (\psi^\lambda_x) \right\|_{L_p} \]
\[ \lesssim \sum_{m=n}^{\infty} 2^{-m \gamma \lambda - \frac{\delta}{2}} \approx \lambda^{-\frac{\delta}{2}}. \]

For the conditional expectation of (III), we use (16) and (6) and see
\[ \left\| E^{\mathcal{F}_{\pi_x}(\cdot)} (\text{III}) (\psi_x^\lambda) \right\|_{L_p} = \left\| \sum_{m=n}^{\infty} E^{\mathcal{F}_{\pi_x}(\cdot)} P_m (f^{(m+1)} - f^{(m)}) (\psi^\lambda_x) \right\| \]
\[ \lesssim \sum_{m=n}^{\infty} 2^{-m \gamma - m \frac{\gamma |S|}{2}} \sum_{y \in \Delta_m} \left| \langle \phi_y^m, \psi_x^\lambda \rangle \right| \]
\[ \lesssim \sum_{m=n}^{\infty} 2^{-m \gamma - m \frac{\gamma |S|}{2} - m \frac{\gamma |S|}{2} - |S| 2m |S| \lambda |S|} \]
\[ \lesssim \sum_{m=n}^{\infty} 2^{-m \gamma} \approx \lambda^\gamma, \]
where we used in the third line, that the number of \( y \) with \( \langle \phi_y^m, \psi_x^\lambda \rangle \neq 0 \) is of order \( 2^m |S| \lambda |S| \).

As all three terms fulfill the necessary bounds, the lemma is proven. \( \square \)

22
It remains to show that (13) and (14) uniquely characterize the reconstructed distribution \( f \). We show this in the following lemma, and thus finish the proof of Theorem 3.8:

**Lemma 3.14.** There is at most one random distribution \( f \) (up to modifications) with stochastic dimension \( e \), which fulfills (13) and (14).

**Proof.** Let \( f, g \) fulfill (13) and (14), and let \( \mu \) be any distribution with support in \( \text{supp}(\mu) \subset [0, R]^d \). Let \( r = (2R, \ldots, 2R, 0, \ldots, 0) \), such that \( \mu_r = \mu(\cdot - r) \) has the right support to apply (13) and (14). It then follows that

\[
\| (f-g)(\mu_E^r) \|_{L_p} = \| (f-g)((\mu_r)_{x-S^r_y}) \|_{L_p} \\
\leq \| (f-F_{x-S^r_y})(\mu_r)_{x-S^r_y} \|_{L_p} + \| (g-F_{x-S^r_y})(\mu_r)_{x-S^r_y} \|_{L_p} \\
\lesssim \lambda^{\gamma - \frac{d}{2}},
\]

and analogously, for \( i = 1, \ldots, e \):

\[
\| E_{\lambda^i,\mu^r}^{\mathcal{F}^{(i)}}(f-g)(\mu_E^r) \|_{L_p} \lesssim \lambda^\gamma.
\]

This especially holds for our wavelets \( \phi, \tilde{\phi} \). Now, let \( \psi \) be any smooth test function with bounded support. It then follows that for any \( n \in \mathbb{N} \):

\[
(f-g)(\psi) = \sum_{y \in \Delta_n} (f-g)(\phi^n_y, \phi^n_y, \psi) \\
\hspace{1cm} + \sum_{m=n}^{\infty} \sum_{y \in \Delta_m} \sum_{\phi \in \Phi} (f-g)(\hat{\phi}^m_y, \hat{\phi}^m_y, \psi).
\]

Observe that only \( \simeq 2^{n|S|} \) many summands of (I) are non-zero, while the second (inner sum) has \( \simeq 2^{m|S|} \) many summands not equal to zero. Let us first analyse (II):

\[
\left\| \sum_{y \in \Delta_m} \sum_{\phi \in \Phi} (f-g)(\hat{\phi}^m_y, \hat{\phi}^m_y, \psi) \right\|_{L_p} \leq \sum_{y \in \Delta_m} \sum_{\phi \in \Phi} \left\| (f-g)(\hat{\phi}^m_y, \hat{\phi}^m_y, \psi) \right\|_{L_p} \\
\lesssim \sum_{m=n}^{\infty} \sum_{y \in \Delta_m} \sum_{\phi \in \Phi} \left\| (f-g)(\hat{\phi}^m_y, \hat{\phi}^m_y, \psi) \right\|_{L_p} \lesssim 2^{-m}(\gamma - \frac{d}{2} + \tilde{r}) \lesssim 2^{-m(\gamma - \frac{d}{2} + \tilde{r})}.
\]

Since \( \tilde{r} \) can be chosen to be big enough, such that \( \gamma - \frac{d}{2} + \tilde{r} > 0 \), we conclude

\[
\left\| \sum_{m=n}^{\infty} \sum_{y \in \Delta_m} \sum_{\phi \in \Phi} (f-g)(\hat{\phi}^m_y, \hat{\phi}^m_y, \psi) \right\|_{L_p} \lesssim \sum_{m=n}^{\infty} 2^{-m(\gamma - \frac{d}{2} + \tilde{r})} \\
\lesssim 2^{-n(\gamma - \frac{d}{2} + \tilde{r})} \xrightarrow{n \to \infty} 0.
\]
For (I), we will use the same technique as in the proof of the existence of the limit. This will require us to split \( \Delta_n \) into \( ([3R])^e \) many nets \( \Delta_n^{d+1, d}(r^{(i)}_n) \), similar to before. Of course, this only adds a factor \( ([3R])^e \) to the inequality and does not change the underlying argument. We thus suppress this notation.

Iteratively define

\[
g_y := (f - g)(\phi_y^n, \psi^n)
g_{y_1, y} := g(y_1, y) - E_{S_1}^{(t)} \Delta_n g(y_1, y)
\vdots
\]

\[
g_{y_1, \ldots, y_n, y} := g_{y_1, \ldots, y_{n-1}, y_{n-1}, y_{n-1}, \ldots, y_{n-1}, y_{n-1}, y_{n-1}, y_{n-1}, (y, y)}
\]

where \( S_i(y_i) := y_i - 2^{-n_s} \cdot 2R \). Observe, that

\[
||g_y||_{L_p} = \left\langle \langle f - g \rangle (\phi_y^n), \psi^n \rangle \right\rangle_{L_p} \lesssim 2^{-n \gamma_n - n|S| + \frac{d}{2}}.
\]

and analogously

\[
\left\| E_{S_1}^{(t)} g_{y_1, y} \right\|_{L_p} \lesssim 2^{-n \gamma_n - n|S|}.
\]

Of course, the same bounds apply to all \( g_{y_1, \ldots, y, y} \). We claim, that for \( i = 0, \ldots, e \), it holds that

\[
\left\| \sum_{y \in \Delta_n^{d+1, d}} g_{y_1, \ldots, y, y} \right\|_{L_p} \lesssim 2^{-n \gamma_n - n \frac{d}{2}}.
\]

This especially implies, that

\[
\left\| \sum_{y \in \Delta_n} (f - g)(\phi_y^n, \psi_y^n) \right\|_{L_p} = \left\| \sum_{y \in \Delta_n} g_y \right\|_{L_p} \lesssim 2^{-n \gamma \to \infty} 0.
\]

We show the claim inductively: for \( i = e \), it holds that only \( \lesssim 2^n (|S| - E) \) many terms of the following sum are non-zero, which implies

\[
\left\| \sum_{y \in \Delta_n^{d+1, d}} g_{y_1, \ldots, y, y} \right\|_{L_p} \lesssim 2^n (|S| - E), 2^{-n \gamma_n - n|S| + n \frac{d}{2}} = 2^{-n \gamma_n - n \frac{d}{2}}.
\]

If we assume that the claim holds for \( i + 1 \), the stochastic machinery gives us
Thus, we have shown the claim, and conclude \((f - g)(\psi) = 0\), since \(n\) can be chosen arbitrarily large. \(\square\)

### 3.1 Two-sided Reconstruction

The theorem we showed so far is modeled after left-sided approximations of stochastic integrals. However, it is also possible (and closer to the original reconstruction Theorem) to have a two-sided reconstruction, i.e., to use test functions \(\psi\) with support in \([-R, R]^d\) for some \(R > 0\). In this setting, it no longer makes sense to condition \(F_x(\psi_x^n)\) onto \(\mathcal{F}^{(i)}_{\pi_i(x)}\), since the conditioning would not have any effect on test functions with purely negative support. Instead, we are going to condition it on the left boundary of the support of \(\psi_x^n\), i.e., onto \(\mathcal{F}^{(i)}_{\pi_i(x) - \gamma_x, R}\).

**Definition 3.15** (two-sided stochastic coherence). Let \((F_x)_{x \in \mathbb{R}^d}\) be a stochastic germ with stochastic dimension \(e \leq d\). We call \((F_x)\) two-sided stochastically \(\gamma\)-coherent, if there is an \(\alpha \in \mathbb{R}\), such that the following holds for all \(\psi \in C_C^\gamma\) with \(\|\psi\|_{C_C^\gamma} = 1\) and support in \([-R, R]\) for some \(R > 0\), for the stochastic directions \(i = 1, \ldots, e\), for any compact set \(K \subset \mathbb{R}^d\) and for any \(x, y \in K\):

\[
\left\| E^{\mathcal{F}^{(i)}_{\pi_i(x) - \gamma_x, R}} (F_x - F_y)(\psi_x^n) \right\|_{L^2_x} \lesssim \lambda^\alpha (|x - y| + \lambda)^{\gamma - \alpha}
\]

\[
\left\| (F_x - F_y)(\psi_y^n) \right\|_{L^2_x} \lesssim \lambda^\alpha (|x - y| + \lambda)^{\gamma - \alpha'},
\]

where the constant in \(\lesssim\) is allowed to depend on the compact set \(K\) and \(R\).

Note that this definition also does not have the condition, that \(\pi_i(x) \leq \pi_i(y)\), but rather uses arbitrary \(x, y\). Further note that there is no cheap way to get from the one-sided coherence property to the two-sided, or vice versa: If one replaces \(\psi\) with a shifted function \(\psi_{\tilde{y}}\) to get a test function with a purely positive support, and substitute \(y\) with \(\tilde{y} = y - S^\gamma \tilde{y}\), such that \(\psi_{\tilde{y}}^\lambda = (\psi_{\tilde{y}})^\lambda\), one gets \(F_{\tilde{y} + S^\gamma \tilde{y}}\) instead of \(F_{\tilde{y}}\).

This highlights the main difference between the two versions: In the one-sided reconstruction, \(F\) only gets tested against the future, while in the two-sided version, \(F\) sits “in the middle” of the support of the test function. This makes the two-sided version closely connected to Stratonovich integration. Since we are interested in the martingale properties, the one-sided version (which is closely connected to Itô integration) is more natural.

Using this property, one can show the following theorem:

**Theorem 3.16** (two-sided stochastic reconstruction). Let \((F_x)\) be a random germ with stochastic dimension \(e \leq d\), which is two-sided stochastically \(\gamma\)-coherent for some \(\gamma > 0\). Then, where is a unique (up to modifications) random distribution \(f\) with stochastic dimension \(e\) with respect to the same filtrations.
as the germ \((F_x)\), such that the following holds for a test function \(\psi\) with support in \([-\tilde{R}, \tilde{R}]^d\) for some \(\tilde{R} > 0\):

\[
\left\| f - F_x (\psi^\lambda_x) \right\|_{L^2} \lesssim \lambda^{3-\frac{d}{2}}
\]

\[
\left\| E^{T_{x}^{(i)}} (f - F_x (\psi^\lambda_x)) \right\|_{L^2} \lesssim \lambda^\gamma,
\]

where \(\tilde{S}_i(x) := \pi_i(x) - \lambda^s (\tilde{R} + 4R)\), and the constant in \(\lesssim\) is allowed to depend on the compact set \(K \subset \mathbb{R}^d\) with \(x \in K\).

**Proof.** The proof is essentially the same as for the one-sided version. However, one can use the more usual wavelets with supports fulfilling \(\text{supp} (\phi), \text{supp} (\hat{\phi}) \subset [-R, R]^d\).

**Remark 3.17.** Note that this theorem has a similar fattening happening in the uniqueness-property: We do not condition on the left boundary \(\pi_i(x) - \lambda^s \tilde{R}\), but we leave a “gap”, in which enough wavelets fit.

## 4 Stochastic reconstruction is stochastic sewing in 1 dimension

As we discussed in the introduction, sewing and reconstruction are closely related to one another. It is well known (although we are not aware of a reference, which has written this down in a concise way), that for a two-parameter process \((A(s, t))_{s, t \in [0, T]}\) which fulfills the conditions of the classical sewing lemma, the germ given by

\[
F_x(t) = \frac{\partial}{\partial t} A(s, t)
\]

fulfills the conditions of the reconstruction theorem (as formulated in [CZ20]). Here, \(\frac{\partial}{\partial t}\) should be seen as a distributional derivative, so the rigorous way to write it should be

\[
F_x(\psi) = - \int_{-\infty}^{\infty} A(s, t) \psi'(t) dt
\]

for any \(\psi \in C_c^\infty\). It further holds, that the following diagram commutes:

\[
\begin{array}{ccc}
A(s, t) & \xrightarrow{\frac{\partial}{\partial t}} & F_x(t) = \frac{\partial}{\partial t} A(s, t) \\
\xrightarrow{\text{sewing}} & & \xrightarrow{\text{reconstruction}} \\
\int(t) & \xrightarrow{\hat{\cdot}} & f = \hat{I}
\end{array}
\]

Thus, sewing can indeed be seen as the one-dimensional case of reconstruction. By a result of [Bra19], Lemma 3.10, we can reverse the time derivative and regain \(I(t)\) as \("f(1_{[0, t]}\)”, which is of course only rigorous as the function \(z\) from Brault’s Lemma, so the arrows in the middle can be reversed.

Given all this, it should come as little surprise, that the statement stays true in the stochastic case: indeed, the stochastic reconstruction theorem is nothing else than the distributional version of Khoa Le’s stochastic sewing Lemma in one dimension. We recall said stochastic sewing lemma [Le20]:

**Theorem 4.1** (stochastic sewing lemma). Let \(2 \leq p \leq \infty\), and let \((A(s, t))_{s, t \in [0, T]}\) be a two parameter process in \(L_p(\Omega)\), which is adapted to some complete, right-continuous filtration \(\mathcal{F}_t\) in the sense, that
$A(s,t) \in \mathcal{F}_t$ for all $0 \leq s \leq t \leq T$. Suppose that there is a $\gamma > 0$, such that for all $0 \leq s \leq u \leq t \leq T$, it holds that

$$
||A(s,t) - A(s,u) - A(u,t)||_{L_p} \lesssim |t - s|^{\frac{1}{2} + \gamma},
$$

$$
||E^{\mathcal{F}_s}(A(s,t) - A(s,u) - A(u,t))||_{L_p} \lesssim |t - s|^{1 + \gamma}.
$$

Then, there is a unique (up to modifications) process $(I(t))_{t \in [0,T]}$ in $L_p(\Omega)$, which is adapted to $\mathcal{F}_t$, has $I(0) = 0$ and fulfills for all $0 \leq s \leq t \leq T$

$$
||I(t) - I(s) - A(s,t)||_{L_p} \lesssim |t - s|^{\frac{1}{2} + \gamma},
$$

$$
||E^{\mathcal{F}_s}(I(t) - I(s) - A(s,t))||_{L_p} \lesssim |t - s|^{1 + \gamma}.
$$

Note that we can easily extend $A(s,t)$ to be a process over $\mathbb{R}^2$, by setting $A(s,t) = A(0,t)$ for $s \leq 0, t \in [0,T]$ and $A(s,t) = A(s,T)$ for $t \geq T, s \in [0,T]$. Should both parameter $s,t \notin [0,T]$, we simply set $A(s,t) = A(0,T)$ if $s \leq 0$ and $t \geq T$ and $A(s,t) = 0$, if both are less than 0 or greater than $T$. This leads to a process $I(t)$, which is the same for $t \in [0,T]$ and constant outside of this interval.

We want to set $F_s(t) = \frac{d}{dt}A(s,t)$, as above. To do so, we need to assume that almost surely $A(s,\cdot)$ is locally integrable. In practice, most candidates for $A$ are almost surely continuous or at least piecewise continuous, so this additional assumption is reasonable to make. Under this assumption, we define the germ

$$
F_s(\psi) = -\int_{-\infty}^{\infty} A(s,t)\psi'(t)dt
$$

as before. Then, one can show the following:

**Theorem 4.2.** Let $A(s,t)$ fulfill the assumptions of the stochastic sewing lemma, and assume $A(s,\cdot)$ is in $L_{loc}^1(\mathbb{R})$ almost surely. Then, $(F_s)_{s \in \mathbb{R}}$ is stochastic $\gamma$-coherent with stochastic dimension $1$. Let $I(t)$ be the process we get from the sewing lemma from $A(s,t)$, and let $f$ be the distribution gained from Theorem 3.8 applied to $(F_s)$. It holds that

$$
f(\psi) = -\int_{-\infty}^{\infty} I(t)\psi'(t)dt,
$$

for all $\psi \in C_c^\infty$.

**Proof.** Let us check the coherence property: Observe that

$$(F_s - F_u)(\psi) = \int_{-\infty}^{\infty} (A(s,t) - A(s,u) - A(u,t))\psi'(t)dt,$$

where we used that $A(s,u)\int_{-\infty}^{\infty}\psi'(t) = 0$ since $\psi$ is only compactly supported. It follows that for all $s \leq u$ and $\psi$ with compact, positive support

$$
\left|\left|(F_s - F_u)(\psi_u^\lambda)\right|\right|_{L_2} \leq \sup_{t \in \text{supp}(\psi_u^\lambda)} ||A(s,t) - A(s,u) - A(u,t)||_{L_2} \int_{-\infty}^{\infty} (\psi_u^\lambda)'(t)dt
$$

$$
\lesssim (|u - s| + \lambda)^{\frac{1}{2} + \gamma} \lambda^{-1},
$$

27
and analogously
\[ \| E^{F_s}(F_s - F_u)(\psi^s_u) \|_{L^2} \leq (|u - s| + \lambda)^{1+\gamma} \lambda^{-1}. \]

Thus, \((F_s)_{s \in \mathbb{R}}\) is indeed stochastic \(\gamma\)-coherent and there exists a reconstruction \(f\). It remains to show that \(f = \dot{I}\). To this end, we calculate
\[ (F_s - \dot{I})(\psi) = -\int_{-\infty}^{\infty} (A(s, t) - (I(t) - I(s)))\psi'(t)dt, \]
where we again used that \(I(s)\int \psi'(t)dt = 0\). It follows that for all test functions with strictly positive support
\[ \left\| (F_s - \dot{I})(\psi^s_u) \right\|_{L^2} \leq \sup_{t \in \text{supp}(\psi^s_u)} \| A(s, t) - (I(t) - I(s)) \|_{L^2} \int_{-\infty}^{\infty} (\psi^s_u)'(t)dt \lesssim \lambda^{-\frac{1}{2} + \gamma}, \]
and analogously,
\[ \left\| E^{F_s}(F_s - \dot{I})(\psi^s_u) \right\|_{L^2} \lesssim \lambda^\gamma. \]

By the uniqueness of the reconstruction, this concludes the proof. \(\square\)

5 Gaussian Martingale Measure

As an application of stochastic reconstruction, we show that integration against Gaussian martingale measures can be seen as a product of a process in \(C^\alpha\) and a distribution in \(C^\beta\), similar to the young product between distributions presented in the introduction. The martingale properties of the measure will allow us to do this reconstruction up to \(\alpha + \beta > -\frac{1}{2}\), in comparison to the classical assumption \(\alpha + \beta > 0\).

We begin by introducing the notation of martingale measures, which can be found in [Wal86] or [Dal+09].

5.1 Gaussian martingale measures and Walsh-type Integration

Loosely speaking, a Gaussian martingale measure is a Gaussian family \((W_t(A))_{t \geq 0, A \in A_K}\) for some subset \(A_K \subset B(\mathbb{R}^d)\), such that

- \(W_t(A)\) is a martingale in \(t\), and
- \(W_t(A)\) is a Gaussian measure in \(A\).

To get a Gaussian measure (or a Gaussian family in general), we need to clarify what its covariance is. This is given through the notion of a covariance measure:

\[ \text{Definition 5.1. Let } K \text{ be a symmetric, positive definite and } \sigma \text{-finite signed measure on } (\mathbb{R}^d \times \mathbb{R}^d, B(\mathbb{R}^d) \otimes B(\mathbb{R}^d)). \text{ Then, } K \text{ is called a covariance measure, if there is a symmetric, positive definite, and } \sigma \text{-finite measure } |K|, \text{ such that for all } A, B \in B(\mathbb{R}^d): \]
\[ |K(A \times B)| \leq |K|(A \times B). \]
We set
\[ ||f||_K^2 := \int_{\mathbb{R}^d \times \mathbb{R}^d} f(x)f(y)K(dx, dy), \]
and define \( ||f||_{|K|} \) analogously. We further set \( A_K := \{ A \in B(\mathbb{R}^d) \mid K(A \times A) < \infty \} \). This allows us to formally define the Gaussian martingale measure \( W \) as follows:

**Definition 5.2.** Let \( K \) be a covariance measure. A Gaussian martingale measure is a family of centered Gaussian variables
\[ (W_t(A) \mid t \geq 0, A \in \mathcal{A}_K), \]
such that

i) \( W_0(A) = 0 \).

ii) For all \( A \in \mathcal{A}_K \), \((W_t(A))_{t \geq 0}\) is a continuous martingale with respect to the filtration \( \sigma(W_s(A) \mid 0 \leq s \leq t, A \in \mathcal{A}_K) \).

iii) Its covariance is given by
\[ E(W_s(A)W_t(B)) = (s \land t)K(A \times B). \]

We also denote the closure of the above filtration as
\[ F_t := \sigma(W_s(A) \mid 0 \leq s \leq t, A \in \mathcal{A}_K). \]

The construction of the integral over such martingale measure is rather straightforward: We call processes of the form
\[ H(s, x) = \sum_{k=1}^{n-1} \sum_{l=1}^{L_k} h_{k,l}1_{(t_k, t_{k+1})}(s)1_{A_{k,l}}(x) \]
with \( h_{k,l} \in L^\infty(F_{t_k}) \) and \( A_{k,l} \in \mathcal{A}_K \) elementary processes, and define the integral over such processes by
\[ \int_0^{\infty} \int_{\mathbb{R}^d} H(s, x)W(ds, dx) := \sum_{k=1}^{n-1} \sum_{l=1}^{L_k} h_{k,l}(W_{t_{k+1}}(A_{k,l}) - W_{t_k}(A_{k,l})). \]

We want to extend this definition to a certain \( L^2 \) space. To do this, let \( \mathcal{P} \) be the predictable \( \sigma \)-algebra, which is generated by the elementary processes. We set
\[ L^2(W) := \left\{ H \text{ predictable}, E\left( \int_0^{\infty} ||H(s, \cdot)||_{|K|}^2 ds \right) < \infty \right\}. \]

The following result can be found in [Wal86]:

**Lemma 5.3.** The set of elementary processes is dense in \( L^2(W) \).

Our notion of an integral extends to the space \( L^2(W) \), as the following theorem states:
Theorem 5.4 (Walsh Integral). The above given integral can be extended uniquely to a continuous, linear map

\[ L_2(\mathcal{W}) \to M_0^2 \]
\[ H \mapsto \int_0^t \int_{\mathbb{R}^d} H(s,x)W(ds, dx), \]

where \( M_0^2 \) is the set of square-integrable martingales starting in 0.

The proof can be found in [Wal86].

By a simple approximation argument, one can show that the Itô-isometry holds for all \( H \in L_2(\mathcal{W}) \) and \( t \geq 0 \):

\[ E\left( \left( \int_0^t \int_{\mathbb{R}^d} H(s,x)W(ds, dx) \right)^2 \right) = E\left( \int_0^t \|H(s, \cdot)\|_{L_2}^2 \, ds \right). \]

With this, we can tackle the main result of this section:

5.2 Reconstruction of the Walsh-type Integral

Let \( W \) be a Gaussian martingale measure, and let \( X(t,x) \) be a predictable process. We want to show, that the distribution associated with the Walsh-type integral

\[ \psi \mapsto \int_0^\infty \int_{\mathbb{R}^d} \psi(s,x)X(s,x)W(ds, dx). \]

Can be constructed with the stochastic reconstruction theorem. Note that the integral is a martingale in the time \( t \), making our stochastic dimension \( e = 1 \).

We need a local approximation for the integral, which we get by the constant approximating \( X(s,x) \approx X(t,y) \) for \( (s,x) \) close to \( (t,y) \). This motivates using the germ \( F_{t,y} = X(t,y)W \), i.e.

\[ F_{t,y}(\psi) := X(t,y) \int_0^\infty \int_{\mathbb{R}^d} \psi(s,x)W(ds, dx). \]

Remark 5.5. While this allows us to formally define the germ on any test function, it is only really useful on test functions with a support on the right-hand-side of \( t \), so that \( X(t,y) \int_0^t \int_{\mathbb{R}^d} \psi(s,x)W(ds, dx) \) is a martingale. Our left-sided version of the reconstruction theorem mirrors this property.

For simplicity, we restrict ourselves to \( L_2(\Omega) \), but one can always use Gaussianity to extend our result into \( L_p \) spaces for more general \( p \). The regularity of \( X \) is governed by its Hölder-continuity, i.e. we assume \( X \in C^\alpha(L_2(\Omega)) \) for some \( \alpha > 0 \), where we use the classical scaling \( s = (1,1,\ldots,1) \). It is however not clear a priori how to measure the regularity of \( W \). To this end, let \( K \) be the covariance measure of \( W \). We say that \( K \) has a scaling \( \delta > 0 \) if it holds that

\[ K(\lambda dx, \lambda dy) = \lambda^\delta K(dx, dy). \]

The following lemma shows, that \( W \) as a distribution is \(-d + \frac{1}{2} + \frac{\delta}{2}\)-Hölder continuous, if its covariance measure has the scaling \( \delta \):
Lemma 5.6. Let $K$ have scaling $\delta$, as above. It holds that:
\[
\int_0^\infty ||\phi_{t,y}^\lambda(s,\cdot)||^2_K ds \lesssim \lambda^{2\alpha}
\]
for $\alpha = -d + \frac{1}{2} + \frac{\delta}{2}$. We say that $K$ is of homogeneity $\alpha$.

Proof. A straightforward calculation shows:
\[
\int_0^\infty \int_{\mathbb{R}^d \times \mathbb{R}^d} \phi_{t,y}^\lambda(s, x_1) \phi_{t,y}^\lambda(s, x_2) K(dx_1, dx_2) ds
= \lambda^{-2d} \int_0^\infty \int_{\mathbb{R}^d \times \mathbb{R}^d} \phi_{t,y}(s/\lambda, x_1/\lambda) \phi_{t,y}(s/\lambda, x_2/\lambda) K(dx_1, dx_2) ds
= \lambda^{-2d} \int_0^\infty \int_{\mathbb{R}^d \times \mathbb{R}^d} \phi_{t,y}(r, v_1) \phi_{t,y}(r, v_2) K(\lambda dv_1, \lambda dv_2) ds
= \lambda^{-2d+1+\delta} \int_0^\infty \int_{\mathbb{R}^d \times \mathbb{R}^d} ||\phi_{t,y}(s,\cdot)||^2_K ds
= \lambda^{-2d+1+\delta} \int_0^\infty ||\phi_{t,y}(s,\cdot)||^2_K ds.
\]

Remark 5.7. Using the Itô-isometry, this implies that
\[
\left\| \int_{\mathbb{R}^d \times \mathbb{R}^d} \psi(s, x) W(ds, dx) \right\|_{L^2} = \left( \int_0^\infty ||\phi_{t,y}^\lambda(s,\cdot)||^2_K ds \right)^{\frac{1}{2}} \lesssim \lambda^\alpha.
\]
Thus, the distribution $\psi \mapsto \int_{\mathbb{R}^d \times \mathbb{R}^d} \psi(s, x) W(ds, dx)$ is indeed in $C^\alpha$.

With this result, we can reconstruct the Walsh integral:

Theorem 5.8. Let $K$ be of homogeneity $\alpha$, and let $X \in C^\beta(L^2(\Omega))$ for some $\beta \in (0, 1)$. Let $(F_{t,y})$ be as above. If $\alpha + \beta > -\frac{1}{2}$, then $(F_{t,y})$ fulfills the assumption of Theorem 3.8, and thus there exists a distribution $f$ fulfilling (13) and (14). It further holds, that $f$ is given by the Walsh-type integral, i.e.
\[
f(\psi) = \int_0^\infty \int_{\mathbb{R}^d} X(s, x) \psi(s, x) W(ds, dx),
\]
for all $\psi \in C^r_\omega$, $r = \max([-\alpha] + 1, 1)$.

Remark 5.9. Observe that by Lemma 5.6, Theorem 5.8 automatically applies to all $K$ with a scaling $\delta$, such that
\[
\beta + \frac{\delta}{2} > d - 1.
\]

Proof. We first show that the assumptions of Theorem 3.8 are fulfilled: Let $t \leq s$, and let $\psi$ be a test function with support in $[0, 1] \times [-1, 1]^d$. It holds that:
\[ E^{F_z} (F_{t,y} - F_{s,x})(\psi^\lambda_{s,x}) \]
\[
= E^{F_z} \left( (X(t,y) - X(s,x))E^{F_z} \int_0^\infty \int_{\mathbb{R}^2} \psi^\lambda_{s,x}(u,v)W(du, dv) \right) = 0,
\]
since \( \int_0^\tau \int_{\mathbb{R}^2} \psi^\lambda_{s,x}(u,v)W(du, dv) \) is a martingale in \( \tau \) and \( s \) is on the edge of the support of \( \psi^\lambda_{s,x} \). It remains to show, that
\[
\| (F_{t,y} - F_{s,x})(\psi^\lambda_{s,x}) \|_{L^2} \lesssim \lambda^{\tilde{\alpha}} \| (t,y) - (s,x) \|^{\alpha + \beta - \tilde{\alpha}}
\]
for some \( \tilde{\alpha} \in \mathbb{R}, \gamma > 0 \). We chose \( \gamma = \alpha + \beta + \frac{1}{2} \) and observe the following:
\[
\| (F_{t,y} - F_{s,x})(\psi^\lambda_{s,x}) \|_{L^2}^2 = \| (X(t,y) - X(s,x)) \int_0^\infty \int_{\mathbb{R}^2} \psi^\lambda_{s,x}(u,v)W(du, dv) \|_{L^2}^2
\]
\[
\leq \int_0^\infty \int_{\mathbb{R}^2} \| (X(t,y) - X(s,x)) \|_{L^2}^2 \psi^\lambda_{s,x}(u,v) \psi^\lambda_{s,x}(u,w) K(du, dv) du
\]
\[
\lesssim \| (t,y) - (s,x) \|^{2\beta} \int_0^\infty \| \psi^\lambda_{s,x} \|_K^2 ds
\]
\[
\lesssim \| (t,y) - (s,x) \|^{2\beta} \lambda^{\alpha + \beta - \gamma}.
\]
Thus, using \( \tilde{\alpha} = \alpha \), it follows that
\[
\| (F_{t,y} - F_{s,x})(\psi^\lambda_{s,x}) \|_{L^2} \lesssim \lambda^{\alpha} \| (t,y) - (s,x) \| + \lambda \| (t,y) - (s,x) \|^{\gamma - \frac{1}{2} - \tilde{\alpha}}.
\]
This shows that there is a unique reconstruction \( f \). To find \( r \), note that the proof of Theorem 3.8 requires \( \tilde{r} = r \) to be strictly greater to the absolute value of the homogeneity of the germ, which is \( \alpha \) according to Remark 5.7, and \( r \geq \gamma - \frac{1}{2} > -\frac{1}{2} \). It follows that \( r = \max([-\alpha, 1, 1]) \).

It remains to show (25). To this end, assume that the support of \( \psi \) is in \( [C, C+1] \times [-1, 1]^d \) for some \( C > 0 \). We need to show that
\[
\tilde{f}(\psi) := \int_0^\infty \int_{\mathbb{R}^2} X(s,x)\phi(s,x)W(ds,dx)
\]
fulfills (13) and (14). Note that (14) is again obvious due to the martingale properties of \( \int_0^\tau \int_{\mathbb{R}^2} X(s,x)(\psi(s,x)W(ds, dx) \), so it remains to show (13). Using the same calculation as in (26), we see that
\[
\| (\tilde{f} - F_{t,y})(\psi^\lambda_{t,y}) \|_{L^2} = \| \int_0^\infty \int_{\mathbb{R}^2} (X(s,x) - X(t,y))\psi^\lambda_{t,y}(s,x)W(ds,dx) \|_{L^2}
\]
\[
\lesssim \sup_{(s,x) \in \text{supp}(\psi^\lambda_{t,y})} \| X(s,x) - X(t,y) \|_{L^2} \int_0^\infty \| \psi^\lambda_{s,x} \|_K^2 ds
\]
\[
\lesssim \lambda^{\alpha + \beta} = \lambda^{\gamma - \frac{1}{2}}.
\]
Thus, \( \tilde{f} = f \) up to modifications, which finishes the proof. □
6 Integration against white noise

We would like to present an example with a non-trivial stochastic dimension. To do so, let \( \xi \) be white noise over \( \mathbb{R}^d \): Consider the Gaussian family \( (\xi(\psi))_{\psi \in L_2(\mathbb{R}^d)} \), where each \( \xi(\psi) \) is a centered, Gaussian random variable with covariance

\[
E(\xi(\psi)\xi(\phi)) = \int_{\mathbb{R}^d} \psi(z)\phi(z)dz, \tag{27}
\]

which is also referred to as \( E(\xi(x)\xi(y)) = \delta(x-y) \) and we define the integral of a deterministic function against white noise through

\[
\int \psi(z)\xi(dz) := \xi(\psi).
\]

Note that \( \xi \) as a map from \( L_2(\mathbb{R}^d) \rightarrow L_2(\Omega) \) is continuous thanks to (27), so \( \xi \) is an \( L_2(\Omega) \)-valued distribution. Our goal is to construct the iterated integrals

\[
\int_{z_1 \leq \ldots \leq z_n \in \mathbb{R}^d} \psi(z_1, \ldots, z_n)\xi(dz_1) \ldots \xi(dz_n), \tag{28}
\]

from the Wiener chaos ([Nua06], [Jan97]), where we use the notation \( z_1 \leq z_2, \) if for all \( i = 1, \ldots, d \) it holds that \( z_{1,i} \leq z_{2,i} \). Ordering the variables \( z_i \) like this will guarantee that we have the right adaptedness properties in each step of the integration. To get more specific on this, let us fix our filtrations: The natural choice for a \( \sigma \)-algebra on our space is given by \( \mathcal{F} = \sigma(\xi(\psi)|\psi \in L_2(\mathbb{R}^d)) \) and for each direction \( i = 1, \ldots, d \), we get a natural filtration which can be sloppily written as \( \mathcal{F}^{(i)} = \sigma(\xi(z)|\pi_i(z) \leq t) \). For a more rigorous definition, we set

\[
\mathcal{F}^{(i)}_t = \sigma(\xi(\psi)|\text{supp}(\psi) \subset \mathbb{R}^{d-1} \times (-\infty, t] \times \mathbb{R}^{d-i}).
\]

With these in mind, our approach to define the integral (28) will be to set \( X_0 = \psi \) and recursively define

\[
X_{k+1}(z_1, \ldots, z_{n-k-1}) = \int_{z_{n-k} \leq z_{n-k-1}} X_k(z_1, \ldots, z_{n-k})\xi(dz_{n-k}).
\]

It follows, that \( X_k(z_1, \ldots, z_{n-k}) \in \mathcal{F}^{(i)}_{\pi_i(z_{n-k})} \) for all \( i = 1, \ldots, d \), so the problem reduces to reconstructing the integral

\[
\int_{z \in \mathbb{R}^d} X(z)\xi(dz) \tag{29}
\]

for a stochastic process \( X \), which is adapted in all directions \( i = 1, \ldots, d \), i.e. \( X(z) \in \mathcal{F}^{(i)}_{\pi_i(z)} \). Let us quickly think about the amount of regularity, \( X \) will need to have: \( \xi \) as a distribution fulfills

\[
||\xi(\psi_x)\|_{L_2(\Omega)} = ||\psi_x^\lambda\|_{L_2(\mathbb{R}^d)} \lesssim \lambda^{-\frac{d}{2}},
\]

and is thus of regularity \(-d/2\). Since white noise has martingale properties in all of its directions, we expect it to have the stochastic dimension \( e = d \). Thus, we get an increase in regularity of \( d/2 \), and it should suffice for \( X \) to have any regularity \( \alpha > 0 \). This also holds up to our intuition, that (29) should make sense for any continuous process \( X \) as an Ito integral over some compact interval.

To reconstruct the integral, we use the same germ as in Section 5, given by

\[
F_x(\psi) := X(z)\xi(\psi).
\]
Thanks to the adaptedness of $X$, it follows that $(F_z)_{z \in \mathbb{R}^d}$ has stochastic dimension $d$ with respect to the filtrations $\mathcal{F}^{(i)}$. The following result shows, that $(F_z)_{z \in \mathbb{R}^d}$ can indeed be reconstructed:

**Theorem 6.1.** Let $X$ be an adapted process in the above sense $(X(z) \in \mathcal{F}^{(i)}_{\pi_i(z)}$ for all $i = 1, \ldots, d)$, with $X \in C^0(L_2(\Omega))$ for some $\alpha > 0$. Then $(F_z)_{z \in \mathbb{R}^d}$ is a stochastic $\alpha$-coherent germ with stochastic dimension $e = d$. It follows that there is a unique distribution $f$, fulfilling (13) and (14).

**Proof.** It is clear, that $(F_z)_{z \in \mathbb{R}^d}$ is of stochastic dimension $d$, so we only need to check (12). Let $\psi \in C^r_c$ be a test function with compact support in $[0, \infty)^d$, and let $z, y \in \mathbb{R}^d$ with $\pi_i(z) \leq \pi_i(y)$ for some $i \in \{1, \ldots, d\}$. Since $\text{supp}(\psi^\lambda_y) \in \mathbb{R}^{i-1} \times (\pi_i(y), \infty) \times \mathbb{R}^{d-i}$, it follows that $X(z) - X(y) \in \mathcal{F}^{(i)}_{\pi_i(y)}$ is independent of $\xi(\psi^\lambda_y)$. Thus,

$$||(F_z - F_y)(\psi^\lambda_y)||_{L_2} = ||X(z) - X(y)||_{L_2} \leq |z - y|^\alpha \lambda^{-\frac{d}{2}}.$$  

Further observe that the martingale properties of $\xi$ imply

$$E^{\mathcal{F}^{(i)}_{\pi_i(z)}}(F_z - F_y)(\psi^\lambda_y) = E^{\mathcal{F}^{(i)}_{\pi_i(z)}}(X(z) - X(y)) E^{\mathcal{F}^{(i)}_{\pi_i(y)}}(\xi(\psi^\lambda_y)) = 0.$$

Thus, the germ fulfills (12) and can be reconstructed. \qed

The distribution $f$ can be seen as the product between $X$ and $\xi$, so we write it as $f = X \cdot \xi$. As one would suspect, it gets locally approximated by $(X \cdot \xi)(\psi) \approx X(z) \int_{\mathbb{R}^d} \psi(y) \xi(dy)$. We want to show that $(X \cdot \xi)(\psi)$ coincides with the classical definition of the integral $\int_{\mathbb{R}^d} X(z) \psi(z) \xi(dz)$, so let us quickly recall this definition, following [Qua12]. For a more detailed construction, one can look up [Nua06] or [Jan97].

We call processes of the form

$$X(t,x) = \sum_{i=1}^{m} X_i 1_{[a_i,b_i]}(t) \psi_i(x)$$

**simple processes**, where for $i = 1, \ldots, m$ it holds that $a_i < b_i$, $\psi_i \in C^\infty_c$ and $X_i$ is a bounded, $\mathcal{F}^{(i)}_{a_i}$-measurable random variable. For simple processes, it is straightforward to define the integral against white noise as

$$\int X(z) \xi(dz) := \sum_{i=1}^{m} X_i \int_{(t,x) \in \mathbb{R}^d} 1_{[a_i,b_i]}(t) \psi_i(x) \xi(dt,dx),$$

where the integral $\int_{(t,x) \in \mathbb{R}^d} 1_{(a_i,b_i]}(t) \psi_i(x) \xi(dt,dx)$ is well defined, since $1_{(a_i,b_i]}(t) \psi_i(x)$ is non-random. Let us denote the set of simple processes by $\mathcal{S}$ and the $\sigma$-field generated by $\mathcal{S}$ with $\mathcal{P}$ and let $L_2(\mathbb{R}^d \times \Omega, \mathcal{P})$ be the set of square-integrable, predictable processes. It is well known (if not, see [Qua12], Lemma 2.1) that the set of simple processes is dense in the set of predictable, square integral processes and that the map

$$\int \cdot \xi(dz) : \mathcal{S} \rightarrow L_2(\Omega)$$

$$X \mapsto \int X(z) \xi(dz)$$

34
is continuous, so it can be extended by a simple approximation argument to $L_2(\mathbb{R}^d \times \Omega, \mathcal{F})$.

We want to show that our reconstructed product $X \cdot \xi$ is equivalent to the integral described above, i.e. for all $\psi \in C_c^\infty$:

$$(X \cdot \xi)(\psi) = \int_{z \in \mathbb{R}^d} X(z)\psi(z)\xi(dz).$$

To show this, we make the following observations: For a $\mathcal{F}_t^{(1)}$-measurable random variable $X \in L_2(\Omega)$ and a test function $\psi$ with support in $[t, \infty) \times \mathbb{R}^{d-1}$, it holds that

$$\int_{z \in \mathbb{R}^d} X\psi(z)\xi(dz) = X \int_{z \in \mathbb{R}^d} \psi(z)\xi(dz) = F_y(\psi), \quad (30)$$

if $X(y) = X$. This simply follows from approximating $\psi$ with piecewise constant functions, and applying the definition of our integral. We also recall the Itô-isometry: For all $X \in L_2(\mathbb{R}^d \times \Omega, \mathcal{F})$,

$$\left\| \int_{z \in \mathbb{R}^d} X(z)\xi(dz) \right\|_{L_2(\Omega)}^2 = \int_{\mathbb{R}^d} \|X(z)\|_{L_2(\Omega)}^2 \, dz, \quad (31)$$

which can be found as equation (126) in [Qua12]. With this in mind, we can show:

**Theorem 6.2.** Let $X$ be as in Theorem 6.1. Then, for any $\psi \in C_c^\infty$, it holds that almost surely

$$(X \cdot \xi)(\psi) = \int_{z \in \mathbb{R}^d} X(z)\psi(z)\xi(dz).$$

**Proof.** Since $X$ is adapted and continuous, it follows that it is predictable and due to $\psi$ being compactly supported, $X\psi$ is square-integrable. Thus, $\int_{z \in \mathbb{R}^d} X(z)\psi(z)\xi(dz)$ is well defined. We show that $\int_{z \in \mathbb{R}^d} X(z)\psi(z)\xi(dz)$ fulfills (13) and (14), the equality then follows from the uniqueness of the reconstruction. To do this, let $\psi$ have a strictly positive support. Then (30) implies, that $F_z(\psi^\lambda_2) = \int_{y \in \mathbb{R}^d} X(z)\psi^\lambda_2(y)\xi(dy)$, and we can use (31) to calculate

$$\begin{align*}
\left\| \int_{y \in \mathbb{R}^d} X(y)\psi^\lambda_2(y)\xi(dy) - F_z(\psi^\lambda_2) \right\|_{L_2} &= \left\| \int_{y \in \mathbb{R}^d} (X(y) - X(z))\psi^\lambda_2(y)\xi(dy) \right\|_{L_2} \\
&= \left( \int_{\mathbb{R}^d} \|X(y) - X(z)\|_{L_2(\Omega)}^2 \|\psi^\lambda_2(y)\|^2 \, dy \right)^{\frac{1}{2}} \\
&\leq \sup_{y \in \text{supp} (\psi^\lambda_2)} \|X(y) - X(z)\|_{L_2(\Omega)} \|\psi^\lambda_2\|_{L_2(\mathbb{R}^d)} \\
&\leq \lambda^\alpha \lambda^{-\frac{d}{2}}.
\end{align*}$$

It further holds that

$$E^{\mathcal{F}_{\tau_i}(z)} \left( \int_{y \in \mathbb{R}^d} X(y)\psi^\lambda_2(y)\xi(dy) - F_z(\psi^\lambda_2) \right) = E^{\mathcal{F}_{\tau_i}(z)} \int_{y \in \mathbb{R}^d} (X(y) - X(z))\psi^\lambda_2(y)\xi(dy) = 0,$$

since $\int_{-\infty}^{\tau} \int_{z \in \mathbb{R}^d} X(t, z)\xi(dt, dz)$ is a martingale in $\tau$ for all predictable processes $X$, and we can use any direction $i = 1, \ldots, d$ to construct $\int_{z \in \mathbb{R}^d} X(z)\xi(dz)$. Thus, $\psi \mapsto \int_{z \in \mathbb{R}^d} X(z)\psi(z)\xi(dz)$ fulfills (13) and (14), which shows the claim. 

35
7 Discussion and outlook

So far, we have demonstrated that a stochastic reconstruction theorem is possible and indeed a generalization of the stochastic sewing lemma. The theorem also offers us a new perspective on well-known constructions like the integrals against martingale measures.

However, all those applications are merely reconstructing already well-known concepts, and we would like to outline a genuinely new application that we have in mind: In the new paper [FHL21], Peter Friz, Antoine Hocquet and Khoa Lê use the stochastic sewing lemma to built a “hybrid” theory, allowing them to analyze several applications rough stochastic PDE, which combine rough and stochastic analysis. We conjecture that the stochastic reconstruction theorem might allow a similar theory for SPDEs.

To get more specific, consider a gPAM equation, which gets perturbed by a white noise in time:

\[ du - \Delta u dt = f(u) dB + g(u) dW, \]  

(32)

where \( dW \) is a space white noise, and \( B_t \) is a Brownian motion in time. Since \( W \) depends on space and \( B \) depends on time, it is not possible to combine them into a single higher dimensional Brownian motion, so (32) lies outside the scope of the classical approach.

The most natural way to approach such an equation would most certainly be a regularity structure approach, similar to the one in [CFG17], as it offers a natural way to treat both noises at the same time. However, this approach requires a rather high regularity of the coefficients \( f, g \) since it is based on a renormalization approach. For coefficients of lower regularity, one might still be able to abuse the stochastic properties of \( B \) and \( W \) to formulate a weak solution theory, but this would lie outside the scope of renormalization methods.

In this case, the stochastic reconstruction theorem might allow us to get the best of both worlds: It could allow one to use regularity structure techniques in situations, which there previously only reached by weak solution theories. To illustrate our point, consider the simplified system of equations

\[
\begin{align*}
\mu - \Delta u dt &= f_0 dB + g_0 dW \\
\mu - \Delta u dt &= f(v) dB + g(v) dW
\end{align*}
\]

(33)

in 1 + 2 dimensions. This system can trivially be solved through convolution with the heat kernel \( K \):

\[
\begin{align*}
v(t, x) &= f_0 B_t + g_0 (K * dW)(t, x) \\
u(t, x) &= (K * (f(v) dB))(t, x) + (K * (g(v) dW))(t, x).
\end{align*}
\]

As long as \( f, g \in C^\epsilon \) for any \( \epsilon > 0 \), this is perfectly well defined in a weak sense. However, \( \epsilon \leq 1 \) do not allow one to use renormalization methods. The regularity of \( dB \) and \( dW \) is \(-1\) in parabolic scaling, and the regularity of \( f(v), g(v) \) is most definitely smaller than 1, with the exact regularities depending on the Hölder-continuity of \( f \) and \( g \). Thus, both products \( f(v) dB \) and \( g(v) dW \) are ill-defined, and require us to subtract constants of the form \( f'(v^\epsilon) C_\epsilon, g'(v^\epsilon) C_\epsilon \). Thus, we need at least \( f, g \in C^{1+\epsilon} \) to achieve a solution in the renormalized sense.

We believe that the stochastic reconstruction theorem may combine the advantages of both approaches. Indeed, if one looks at the simplified system (33), one can model \( dB \) and \( dW \) as abstract symbols \( \Xi_1, \Xi_2 \) and get an abstract solution for \( u \) given by \( u = f(v) \Xi_1 + g(v) \Xi_2 \). In the last step, the symbols \( f(v) \Xi_1 \) and \( g(v) \Xi_2 \) can then easily be reconstructed with the technique given in section 6 which coincide with the Ito and Walsh integral needed for the weak solution, respectively. The regularity needed for this is only \(-1+\epsilon \), since \( dB \) and \( dW \) both have rescaled stochastic dimensions of \( E = 2 \), so \( f, g \in C^\epsilon \) suffices for this approach.
Acknowledgments

I want to thank Peter Friz for suggesting this topic to me, and for many helpful discussions throughout the process of writing this paper. I further want to thank Khoa Lê and Philipp Forstner for their helpful remarks, and Carlo Bellingeri for our mathematical discussions.

This project was funded by the DFG international research training group 2544.
