Multiscale genesis of a tiny giant for percolation on scale-free random graphs

July 12, 2021

Abstract

We study the critical behavior for percolation on inhomogeneous random networks on \(n\) vertices, where the weights of the vertices follow a power-law distribution with exponent \(\tau \in (2, 3)\). Such networks, often referred to as scale-free networks, exhibit critical behavior when the percolation probability tends to zero at an appropriate rate, as \(n \to \infty\). We identify the critical window for a host of scale-free random graph models such as the Norros-Reittu model, Chung-Lu model and generalized random graphs. Surprisingly, there exists a finite time inside the critical window, after which, we see a sudden emergence of a tiny giant component. This is a novel behavior which is in contrast with the critical behavior in other known universality classes with \(\tau \in (3, 4)\) and \(\tau > 4\).

Precisely, for edge-retention probabilities \(\pi_n = \lambda n^{-(\beta - \tau)/2}\), there is an explicitly computable \(\lambda_c > 0\) such that the critical window is of the form \(\lambda \in (0, \lambda_c)\), where the largest clusters have size of order \(n^\beta\) with \(\beta = (\tau^2 - 4\tau + 5)/(2(\tau - 1)) \in [\sqrt{2} - 1, \frac{1}{2}]\) and have non-degenerate scaling limits, while in the supercritical regime \(\lambda > \lambda_c\), a unique ‘tiny giant’ component of size \(\sqrt{n}\) emerges. For \(\lambda \in (0, \lambda_c)\), the scaling limit of the maximum component sizes can be described in terms of components of a one-dimensional inhomogeneous percolation model on \(\mathbb{Z}_+\) studied in a seminal work by Durrett and Kesten [27]. For \(\lambda > \lambda_c\), we prove that the sudden emergence of the tiny giant is caused by a phase transition inside a smaller core of vertices of weight \(\Omega(\sqrt{n})\).

1 Introduction

1.1 Background

Percolation phase transitions are one of the foundational tenets in the application of probabilistic combinatorics to areas ranging from statistical physics to social dynamics [29]. At the simplest level, one starts with a base (potentially random) graph. For a parameter \(\pi\), each edge in the graph is retained with probability \(\pi\) and deleted with probability \(1 - \pi\), independently across edges. The first questions of interest is understanding the emergence of a giant connected component as one increases the value of \(\pi\), and identifying critical values of this parameter where abrupt changes in the connectivity occurs. These question arise as building blocks for more complex interacting particle systems e.g. in the study of epidemics, condensed
matter theory, robustness of networks such as the Internet when the edges of the underlying network experience random failure [6, 26, 37].

Unlike phase transition on infinite graphs such as lattices, there is typically no unique value for phase transition in large but finite graphs. Instead, there is an interval of $\pi$-values, often referred to as the critical window, where this structural transition in the component sizes takes place. To fix ideas, let us recall classical results for percolation on complete graphs with $n$ vertices and $\pi = c/n$ or Erdős-Rényi random graphs ER($n, c/n$). It is well known that the critical window is given by a bounded interval $[\lambda_{c}, \lambda_{c}]$, i.e., $\pi_{c} = c/n_{c}$ for some explicitly computable model dependent critical time $n_{c}$. We show that the critical window for percolation on scale-free random graphs models can all be proven to have the same asymptotic behavior in the critical regime, see e.g. [8, 9, 10, 11]. We show that the critical window for percolation on scale-free random graphs out to be central in understanding universality phenomenon for critical random graphs in the sense that, once these models have been understood, a host of other canonical random graph models experience random failure [6, 26, 37].

New universality class: This paper considers a number of major families of scale-free random graph models with degree exponent $\tau \in (2, 3)$ related to Aldous’s multiplicative coalescent [2]; these include models such as the Norros-Reittu model, the Chung-Lu model, and the generalized random graph (see Section 2.2 for more details). This class of models has turned out to be central in understanding universality phenomenon for critical random graphs in the sense that, once these models have been understood, a host of other canonical random graph models can all be proven to have the same asymptotic behavior in the critical regime, see e.g. [8, 9, 10, 11]. We show that the critical window for percolation on scale-free random graphs will be given by

$$\pi_{c}(\lambda) = \frac{\lambda n^{-(3-\tau)/2}}{2\lambda_{c}n^{2/3}\log|\lambda_{c}|}, \quad \lambda \in (0, \lambda_{c}),$$

for some explicitly computable model dependent critical time $\lambda_{c}$. Thus, surprisingly, the critical window is given by a bounded interval $\lambda \in (0, \lambda_{c})$. In other words, if we look at the
coalescence of the critical components as the percolation parameter transitions through the critical window, the components evolve in a non-trivial manner only up to a finite time \( \lambda_c \), after which all of the critical components suddenly coalesce with each other. This is in contrast with Aldous’ multiplicative coalescent, where the coalescence happens over an infinite length window. This phenomenon had not been predicted by the extensive investigation via numerical approaches on these models carried out in areas such as statistical physics and condensed matter theory.

Multiscale emergence of connectivity and technical novelty: Analyzing the critical regime of models in this class present significant technical challenges as standard techniques based on exploration processes or differential equations cannot be implemented; rather one needs to carefully understand the contribution of extremal degree vertices or hubs of different scales contributing to connectivity at each value of \( \pi_c(\cdot) \). More precisely:

(a) Critical scaling window: For \( \lambda \in (0, \lambda_c) \), we show that the maximal component sizes scale like \( n^\beta \) with \( \beta = \frac{1}{\tau - 1} - \frac{3 + \tau}{2} \in [\sqrt{2} - 1, \frac{1}{2}) \), and the rescaled vector of ordered component sizes converges to a non-degenerate random vector in \( \ell^2 \)-topology. The distributional asymptotics can be derived in terms of an inhomogeneous percolation model on \( \mathbb{Z}_+ \), which represents the core connectivity structure between the hubs. In this regime, connectivity emerges owing to interconnections between macro-hubs, namely maximal degree vertices (with weights \( n^{1/(\tau - 1)} \)). However note that with \( \pi_c(\lambda) \to 0 \), these macro-hubs cannot be directly connected; rather (with positive probability) they are connected via two step paths thorough intermediete scale meso-hubs of weight \( n^{(\tau - 2)/(\tau - 1)} \). This interconnected structure forms the core of the critical components, and we use path-counting techniques to show that the 1-neighborhood of the core spans the critical components (see Figure 1). The core can be coupled with a one-dimensional inhomogeneous percolation model on \( \mathbb{Z}_+ \), which was studied in a seminal work of Durrett and Kesten [27] and in follow-up work by Zhang [40].

(b) Supercritical regime: For \( \lambda > \lambda_c \), instead, we show that there is a unique giant component of size \( \sqrt{n} \gg n^\beta \), and the size of the rescaled giant component concentrates. In this case we show that the graph restricted to a special set of vertices of weight at least \( \sqrt{n} \) can be approximated by a well-behaved inhomogeneous random graph in the spirit of Bollobás, Janson and Riordan [14]. A small giant component (of size \( \sqrt{n} \)) appears inside this restricted set precisely when \( \lambda > \lambda_c \). This forms the core of the giant component in the whole graph, and again the 1-neighborhood of the core spans the giant component (and, in fact, the core itself is, in size, negligible to this 1-neighborhood). Analyzing the resulting random structure requires several delicate estimates of multi-type branching process as well as a careful topological analysis of paths exiting and returning to these special class of vertices.

2 Main results

2.1 Preliminaries: notation, convergence and topologies

To describe the main results of this paper, we need some definitions and notations. We use \( \xrightarrow{p} \) and \( \xrightarrow{d} \) to denote convergence in probability and in distribution respectively. The topology needed for convergence in distribution will be specified unless clear from the context. We use the Bachmann-Landau notation \( O(\cdot) \), \( o(\cdot) \), \( \Theta(\cdot) \) for large \( n \) asymptotics of real numbers. For two real sequences \( (a_n)_{n \geq 1}, (b_n)_{n \geq 1} \), write \( a_n \asymp b_n \) for \( a_n/b_n = (1 + o(1)) \). A sequence of events \( (\mathcal{E}_n)_{n \geq 1} \) is said to occur with high probability (whp) with respect to the associated sequence of probability measures \( (\mathbb{P}_n)_{n \geq 1} \) if \( \mathbb{P}_n(\mathcal{E}_n) \to 1 \). For two sequences of real-valued random
variables \((X_n)_{n \geq 1}\) and \((Y_n)_{n \geq 1}\), write \(X_n = O_p(Y_n)\) if \((|X_n|/|Y_n|)_{n \geq 1}\) is a tight sequence; \(X_n = o_p(Y_n)\) when \(X_n/Y_n \xrightarrow{p} 0\); \(X_n = \Theta_p(Y_n)\) if both \(X_n = O_p(Y_n)\) and \(Y_n = O_p(X_n)\). We use \(C, C', C_1, C_2\) etc as generic notation for positive constants whose value can change from line to line. Fix \(\tau \in (2,3)\). Throughout this paper, we denote

\[
\alpha = 1/(\tau - 1), \quad \rho = (\tau - 2)/(\tau - 1), \quad \eta = (3 - \tau)/(\tau - 1), \quad \eta_n = (3 - \tau)/2. \quad (2.1)
\]

For \(p > 0\), let \(\ell^p\) denote the collection of sequences \(x = (x_1, x_2, x_3, \ldots)\) with \(\sum_{i=1}^{\infty} |x_i|^p < \infty\). Equip this space with the \(p\)-norm metric \(d(x,y) = \left( \sum_{i=1}^{\infty} |x_i - y_i|^p \right)^{1/p}\). Let \(\ell^p_n \subset \ell^p\) be the collection of sequences \(x\) with \(x_i \geq 0\) for all \(i\) and the elements of the sequence arranged in non-increasing order.

### 2.2 Scale-free random graph models

We now describe the main models studied in this paper. Given a set of weights \(w = (w_i)_{i \in [n]}\) on the vertex set \([n]\), the Poissonian random graph or Norros-Reittu model \([38]\), denoted by \(\text{NR}_n(w)\), is generated by creating an edge between vertex \(i\) and \(j\) independently with probability

\[
p_{ij} = p_{ij}^{\text{NR}} := 1 - e^{-w_iw_j/\ell_n}, \quad (2.2)
\]

where \(\ell_n = \sum_{i \in [n]} w_i\) denotes the total weight. Our results for the critical window hold more generally, for example, for the Chung-Lu Model \([17,18]\) (denoted by \(\text{CL}_n(w)\)) with

\[
p_{ij}^{\text{CL}} := \min\{w_iw_j/\ell_n, 1\}, \quad (2.3)
\]

and the generalized random graph model \([15]\) (denoted by \(\text{GRG}_n(w)\)) with

\[
p_{ij}^{\text{GRG}} := \frac{w_iw_j}{\ell_n + w_iw_j}. \quad (2.4)
\]

The final model has the property that, conditionally on the degree sequence \(d = (d_i)_{i \in [n]}\), the law of the obtained random graph is the same as that of a uniformly chosen graph from the space of all simple graphs with degree distribution \(d\) (cf. [30, Theorem 6.15]).

The percolated graph \(\text{NR}_n(w, \pi)\) is obtained by keeping each edge of the graph independently with probability \(\pi\). This deletion process is also independent of the randomization of the graph. Naturally, the behavior of \(\text{NR}_n(w)\), and thus of \(\text{NR}_n(w, \pi)\) depends sensitively on the choice of vertex weights. The following choice of vertex weights will give rise to scale-free random graphs:

**Assumption 2.1** (Scale-free weight structure). For some \(\tau \in (2,3)\), consider the distribution function \(F\) satisfying \([1 - F](w) = Cw^{-(\tau-1)}\) for some \(C > 0\), and let \(w_i = [1 - F]^{-1}(i/n)\).

In this setting, if \(W_n\) denotes the weight of a vertex chosen uniformly at random, then \(W_n\) will satisfy an asymptotic power-law in the sense that for any \(w > 0\), \(\mathbb{P}(W_n > w) \to Cw^{-(\tau-1)}\), and, as a result, the asymptotic weight distribution will have the same exponent \(\tau\) (see [31, Chapter 6]) resulting in a scale-free random graph. Further,

\[
\mathbb{E}[W_n] = \frac{1}{n} \sum_{i \in [n]} w_i \to \mu = \mathbb{E}[W], \quad (2.5)
\]

and, for all \(i \in [n]\),

\[
n^{-\alpha}w_i = c_F i^{-\alpha}, \quad (2.6)
\]

for some constant \(c_F > 0\). Throughout \(c_F\) will denote the special constant appearing above.
2.3 Results

We start by describing our results for the barely subcritical regime, then the critical window, and end with the super-critical regime. To explicitly describe limit constants, we will phrase the results with respect to the Norros-Reittu model deferring statements to other models to Theorem 2.7. The phase transition is described in terms of functionals of the relevant components. Let \((\mathcal{C}_i(\pi))_{i \geq 1}\) be the component sizes of \(NR_n(w, \pi)\), arranged in non-increasing order (breaking ties arbitrarily). Further, let \((W_i(\pi))_{i \geq 1}\) denote the corresponding weight of these clusters, i.e.,

\[
W_i(\pi) = \sum_{j \in C_i(\pi)} w_j.
\]  

(2.7)

The phase transitions will be described in terms of these two functionals.

2.3.1 Behavior in the barely sub-critical regime

Recall the constants related to the degree exponent in (2.1).

**Theorem 2.2** (Subcritical regime for \(NR_n(w, \pi_n)\)). Suppose that \(w\) satisfies Assumption 2.1, and consider \(NR_n(w, \pi)\) with \(\pi_n = \lambda_n n^{-\eta_n}\) with \(\lambda_n = o(1)\), and \(\pi_n \gg n^{-\alpha}\). Then, for any fixed \(i \geq 1\), as \(n \rightarrow \infty\),

\[
\frac{|\mathcal{C}_i(\pi_n)|}{n^\alpha \pi_n} \xrightarrow{P} c_\pi^{-1}\alpha, \quad \text{and} \quad \frac{W_i(\pi_n)}{n^\alpha} \xrightarrow{P} c_\pi^{-1}\alpha.
\]  

(2.8)

Theorem 2.2 implies that the largest percolation clusters with \(\pi_n \ll n^{-\eta_n}\) are the clusters of the hubs, i.e., the vertices with the largest weights (\(w_i = \Theta(n^\alpha)\)). Further, the hubs with high probability lie in disjoint components. Since, after percolation, the number of neighbors of hub \(i\) is close to \(\pi_n w_i \approx n^\alpha \pi_n c_\pi^{-1}\alpha\), these largest clusters consist mostly of the hubs with their immediate neighbors. In particular, since the largest cluster sizes concentrate, we are not in the critical window when \(\pi_n \ll n^{-\eta_n}\).

2.3.2 Behavior in the critical window

As discussed in the introduction, this critical window consists of \(\pi_n = \lambda n^{-\eta_n}\) for some explicit bounded interval of \(\lambda\). In particular, such values of \(\pi_n\) are much larger than the values considered in the previous section. We will see that there is a surprising phase transition in \(\lambda\), occurring at a finite positive value \(\lambda_c\). Below \(\lambda_c\), the scaling limits of the largest connected components have non-degenerate scaling limits, and any two hubs are in the same component with asymptotic probabilities strictly bounded between 0 and 1. Recall (2.1), and define

\[
\pi_c = \pi_c(\lambda) := \lambda n^{-\eta_n}, \quad \text{for} \ \lambda \in (0, \lambda_c),
\]  

(2.9)

where \(\lambda_c\) is given by

\[
\lambda_c := \sqrt{\frac{\eta}{4B_\alpha}} = \frac{c_\pi^{-1/\alpha}}{2} \sqrt{\frac{(3 - \tau)\mu^{1/\alpha}}{A_\alpha}},
\]  

(2.10)

\[
A_\alpha := \int_0^\infty \frac{1 - e^{-z}}{z^{1/\alpha}} dz, \quad B_\alpha := \frac{c_\pi^{2/\alpha}}{\alpha^{1/\alpha}}.
\]  

(2.11)

**Theorem 2.3** (Critical regime for \(NR_n(w, \pi_n)\)). Suppose that \(w\) satisfies Assumption 2.1, and consider \(NR_n(w, \pi_n)\) with \(\pi_n = \pi_c(\lambda)\) for \(\lambda \in (0, \lambda_c)\), with \(\lambda_c\) as in (2.10). Then, as \(n \rightarrow \infty\),

\[
(n^\alpha \pi_c)^{-1}|\mathcal{C}_i(\pi_c(\lambda))|_{i \geq 1} \xrightarrow{d} (W_i(\pi_c(\lambda)))_{i \geq 1} \quad \text{and} \quad n^{-\alpha}(W_i(\pi_c(\lambda)))_{i \geq 1} \xrightarrow{d} (W_i(\pi_c(\lambda)))_{i \geq 1}
\]  

(2.12)

with respect to the \(\ell^\alpha_{\pi}\)-topology and \(\ell^2\)-topology respectively. The limiting random variables \((W_i(\pi_c(\lambda)))_{i \geq 1}\) are non-degenerate and described in Definition 2.4 below.
The non-degenerate scaling limit of the component sizes, as well as their weights is the hallmark of critical behavior. To define the limiting variables in Theorem 2.2, we need the following infinite weighted random graph which belongs to a general class of models studied by Durrett and Kesten in [27].

**Definition 2.4 (Limiting variables).** Fix vertex set $\mathbb{Z}_+$ and let vertex $i \in \mathbb{Z}_+$ have weight $\theta_i := c_F i^{-\alpha} \mu^{-1}$. Consider the random multi-graph $\mathcal{G}_n(\lambda)$ on $\mathbb{Z}_+$ where vertices $i$ and $j$ are joined independently by Poisson($\lambda_{ij}$) many edges with $\lambda_{ij}$ given by

$$
\lambda_{ij} := \lambda^2 \int_0^\infty \Theta_i(x) \Theta_j(x) dx, \quad \text{where} \quad \Theta_i(x) := 1 - e^{-c_F \theta_i x^{-\alpha}}.
$$

(2.13)

For $i \geq 1$, let $\mathcal{W}_{(i)}(\lambda)$ denote the $i$-th largest element of the set

$$
\left\{ \sum_{i \in \mathcal{C}} \theta_i : \mathcal{C} \text{ is a connected component} \right\},
$$

which is well-defined when $\langle \mathcal{W}_{(i)}(\lambda) \rangle_{i \geq 1} \in \ell_+^2$ almost surely.

We will see that asymptotically there are Poisson($\lambda_{ij}$) many two-step paths between macro-hubs $i$ and $j$ via intermediate meso-scale hubs of size $\Theta(n^\alpha)$ in $\mathcal{N}_n(w, \pi_n(\lambda))$, for $i, j$ fixed as $n \to \infty$. These two-step paths between hubs form the backbone of the largest connected components. The connectivity structure of these two-step connections undergoes a phase transition, as we next explain. The following result implies that the limiting object is well-defined for $\lambda \in (0, \lambda_c]$, and undergoes a phase transition at $\lambda = \lambda_c$.

**Proposition 2.5 (Phase transition for the limiting model).** (a) For $\lambda \leq \lambda_c$, $\mathcal{G}_\infty(\lambda)$ is connected almost surely, in particular $\mathcal{W}_{(1)}(\lambda) = \infty$ and $\mathcal{W}_{(2)}(\lambda) = 0$ almost surely.

(b) For $\lambda > \lambda_c$, $\mathcal{G}_\infty(\lambda)$ is connected almost surely, in particular $\mathcal{W}_{(1)}(\lambda) = \infty$ and $\mathcal{W}_{(2)}(\lambda) = 0$ almost surely.

### 2.3.3 Behavior in the supercritical regime

Let us now consider percolation with probability $\pi_n = \lambda n^{-\eta}$ for $\lambda > \lambda_c$. Since $\mathcal{G}_\infty(\lambda)$ represents the connectivity structure between the hubs, Proposition 2.5 (b) suggests that (1) the hubs are in the same component whp, (2) the largest connected component after $\lambda_c$ is much larger than the components before $\lambda_c$. Our result next result shows that in fact a unique giant component of size $\sqrt{n}$ appears in the graph, and the size of this giant component concentrates. Moreover, the giant component is unique in the sense that the second largest component is of a smaller order. To describe the limiting size of the giant component, fix $a > 0$, and define

$$
\zeta^\lambda_a := \lambda \int_0^\infty c_F u^{-\alpha} \rho^\lambda_a(u) du,
$$

(2.14)

where $\rho^\lambda_a : (0, a] \to [0, 1]$ is the maximum solution to the fixed point equation

$$
\rho^\lambda_a(u) = 1 - e^{-\lambda \int_a^\infty \kappa(u, v) \rho^\lambda_a(v) dv}, \quad \text{with} \quad \kappa(u, v) := 1 - e^{-c_F \frac{(uv)^{-\alpha}}{\mu}}.
$$

(2.15)

In Proposition 4.5, we will see that $\zeta^\lambda_a = \lim_{a \to \infty} \zeta^\lambda_a$ exists and $\zeta^\lambda \in (0, \infty)$, whenever $\lambda > \lambda_c$. We now state our result for the emergence of the giant component for $\lambda > \lambda_c$.

**Theorem 2.6 ($\sqrt{n}$-asymptotics of size and uniqueness giant).** Suppose that $w$ satisfies Assumption 2.1, and consider $\mathcal{N}_n(w, \pi_n)$ with $\pi_n = \lambda n^{-\eta}$ for some $\lambda > \lambda_c$. Then, as $n \to \infty$,

$$
\begin{align*}
n^{-1/2} |\mathcal{C}_{(1)}(\pi_n)| & \xrightarrow{P} \zeta^\lambda, \quad \text{and} \quad n^{-1/2} |\mathcal{C}_{(2)}(\pi_n)| \xrightarrow{P} 0,
\end{align*}
$$

(2.16)

where $\zeta^\lambda = \lim_{a \to \infty} \zeta^\lambda_a$ with $\zeta^\lambda_a$ given by (2.14). Further, $\{v : w_v \geq n^{1/2+\delta}\} \subseteq \mathcal{C}_{(1)}(\pi_n)$ whp for every $\delta > 0$. 

6
2.4 Discussion

In this section, we discuss some insights to our results, extensions and open problems.

Critical window for other rank-1 models. Our results for the subcritical regime, and the critical window hold more generally for the Chung-Lu Model $CL_n(w)$ and the generalized random graph model $GRG_n(w)$ described in (2.3) and (2.4). To state this formally, define

$$A^{\text{CL}}_\alpha = \int_0^\infty \min\{1, z\} z^{-1/\alpha} dz, \quad A^{\text{GRG}}_\alpha = \int_0^\infty z^{1-1/\alpha} \frac{1}{1+z} dz,$$

and define $B^{\text{CL}}_\alpha, B^{\text{GRG}}_\alpha$, and the critical values $\lambda^{\text{CL}}_c$ and $\lambda^{\text{GRG}}_c$ identically as in (2.10) and (2.11) with the above choices of $A^{\text{CL}}_\alpha$ and $A^{\text{GRG}}_\alpha$ respectively. To define the limiting object, let

$$\Theta_i^{\text{CL}}(x) = \min \left\{ \frac{c^2_i x^{-\alpha}}{\mu} - x^{-\alpha}, 1 \right\}, \quad \Theta_i^{\text{GRG}}(x) = \frac{c^2_i x^{-\alpha} - x^{-\alpha}}{\mu + c^2_i x^{-\alpha}}.$$  

Denote the graph $CL_n(w, p)$, $GRG_n(w, p)$ obtained by independently keeping each edge of the graph $CL_n(w)$ and $GRG_n(w)$ respectively.

**Theorem 2.7 (Extensions to other rank-1 models).** Under Assumption 2.1, Theorems 2.2, 2.3 hold for $CL_n(w, \pi_c(\lambda))$ and $GRG_n(w, \pi_c(\lambda))$ with $\lambda_c$ replaced by $\lambda^{\text{CL}}_c$ and $\lambda^{\text{GRG}}_c$ defined below (2.17) respectively, and the scaling limits given by Definition 2.4 with $\Theta_i(x)$ replaced by $\Theta_i^{\text{CL}}(x)$ and $\Theta_i^{\text{GRG}}(x)$ defined in (2.18), respectively.

The proof of Theorem 2.7 only requires minor adaptations on the proofs of Theorems 2.2, 2.3. We point out the key modifications in Remarks 3.5, 3.9 and skip redoing the whole proof for Theorem 2.7. We also believe that a result analogous to Theorem 2.6 holds for the giant component in $CL_n(w, \pi_n)$ and $GRG_n(w, \pi_n)$ with

$$\kappa^{\text{CL}}(u,v) := \min \left\{ \frac{c^2(u,v)^{-\alpha}}{\mu} - (u,v)^{-\alpha}, 1 \right\}, \quad \kappa^{\text{GRG}}(u,v) := \frac{c^2(u,v)^{-\alpha} - (u,v)^{-\alpha}}{\mu + c^2(u,v)^{-\alpha}}.$$  

However, since the proof of Theorem 2.6 is extremely delicate, we leave this as an open question.

When does the single-edge constraint matter? In concurrent works [23, 24], we study percolation on scale-free networks around criticality for models that allow for multi-edges such as the configuration model [24] and the Norros-Reittu model [23], where in the latter model, the number of edges between vertices $i$ and $j$ is Poisson($w_i w_j / \ell_n$). It turns out that a giant emerges in these multi-edge models when

$$\pi_n = \lambda_n n^{-(3-\tau)/(\tau-1)}, \quad \text{where } \lambda_n \to \infty.$$  

Thus, the emergence of giant happens in multi-edge models for much smaller $\pi_n$ values. Interestingly, when $\pi_n = \lambda n^{-\eta}$ and $\lambda > \lambda_c$, both the single-edge and multi-edge version of the Norros-Reittu model contain a giant component of size $\sqrt{n}$, but the description of their asymptotic sizes are vastly different. In fact, we believe that the asymptotic proportions are strictly different although we do not prove it in this article. On the other hand, if $\pi_n = \lambda_n n^{-\eta}$ with $\lambda_n \to \infty$, then the giants in both the single and multi-edge Norros-Reittu model turn out to have the same size [23]. Such differences in multi-edge versus single-edge settings are absent in the $\tau > 3$ settings.
Critical windows: emergence of hub connectivity. The critical window changes due to the single-edge constraint as noted in the previous paragraph. However, there are some common features. First, the component sizes are of the order $n^c\pi_c(\lambda)$ in both the regimes. This is due to the fact that the main contribution to the component sizes comes from hubs and their direct neighbors. Second, in both cases, the critical window is the regime in which hubs start getting connected. More precisely, the critical window is given by those values of $\pi$ such that, for any fixed $i, j \geq 1$,

$$\liminf_{n \to \infty} P(i, j \text{ are in the same component in the } \pi\text{-percolated graph}) \in (0, 1). \quad (2.21)$$

For multi-edge models, hubs are connected directly with strictly positive probability, while under the single-edge constraint, hubs are connected with positive probability via intermediate vertices of degree $\Theta(n^\rho)$. In the barely subcritical regime, instead, all the hubs are in different components. Hubs start forming the critical components as connection probability $\pi$ varies over the critical window. Finally in the barely super-critical regime the giant component is formed, and this giant contains all the hubs. This feature is also observed in the $\tau \in (3, 4)$ case [13]. However, the distinction between $\tau \in (3, 4)$ and $\tau \in (2, 3)$ is that, for $\tau \in (3, 4)$, the paths between the hubs have lengths that grow with $n$, namely as $n^{(\tau-3)/(\tau-1)}$.

Open problems. We believe that the results proved in this paper are universal for percolation problems on a host of scale-free random graph models. For example, we believe that our results carry over to the setting of uniform random graphs with a given degree distribution, for which the probability that hubs $i$ and $j$ are connected is close to $d_id_j/(\ell_n + d_id_j)$ (see, e.g., [28]). Further, we believe that similar results apply to site percolation on scale-free random graphs, irrespective of whether the model has a single-edge constraint or not. In fact, for site percolation, the clusters for the erased and normal configuration models are identical, so that also their scaling behavior is expected to be identical.

The previous discussion suggests that the typical distances in large critical components are quite small, and it would be of interest to describe their distributions in more detail. Further, it would be of interest to derive the scaling limit of the diameter of the large critical components. Finally, we show that the critical window in the single-edge case is $\pi_n = \lambda n^{(3-\tau)/2}$ for $\lambda \in (0, \lambda_c)$, which does not include the critical point $\lambda_c$. However, $\lambda_c$ is included in the critical case for the limiting graph in Proposition 2.5. This raises the question what happens for $\pi_n = n^{-(3-\tau)/2}\lambda_c(1 + \varepsilon_n)$ for $\varepsilon_n = o(1)$. Is barely supercritical behavior then observed, or does a second type of critical behavior emerge? We leave this as an interesting open question.

2.5 Proof outline

The critical window (Section 3). The key idea is that the largest critical components correspond to connected components containing macro-hubs (maximal weight vertices). However since $\pi_n \to 0$ any two macro-hubs cannot be directly connected in the large network limit, rather these have non-trivial probability of being connected via a two-step path passing through meso-scale intermediate hubs of weight $w_i = \Theta(n^\rho)$. In fact, we can couple the hubs and these two-step connections to the infinite graph $\mathcal{G}_\infty(\lambda)$ as in Definition 2.4 in total variation distance (see Proposition 3.6 below). Next, we show that the primary contribution to the component sizes come from the one-neighborhood of the subgraph consisting of hubs and their two-step connections. This is reflected in the fact that, when we explore the graph starting from hubs in a breadth-first manner, we see an alternating structure with the hubs appearing in the even generations, and the odd generations consisting of vertices having weight $\Theta(n^\rho)$, see Figure 1 and Proposition 3.11 below. The main technique here is to use appropriate path-counting techniques (see Proposition 3.10 below). Finally, we conclude the proof of Theorem 2.3 by showing that the vector of component sizes is tight in $\ell_1^2$ when $\lambda < \lambda_c$ (see
Figure 1: Visualization of the core structure of components and the exploration of the neighborhood. Red vertices indicate hubs with \(w_i = \Theta(n^\alpha)\), and blue vertices having \(w_i = \Theta(n^\rho)\) are intermediate vertices that connect hubs via two-step paths (indicated by green edges).

Proposition 3.16). The phase transition at \(\lambda = \lambda_c\) is exemplified in Proposition 2.5, as \(G_\infty(\lambda)\) becomes connected for \(\lambda > \lambda_c\).

Supercritical regime (Sections 4 and 5). The key observation is that the core of the giant component can be identified by looking at a special set of vertices \(V\) consisting of vertices with \(w_i = \Omega(\sqrt{n})\). Note that these vertices are present only in the \(\tau \in (2, 3)\) regime (for \(\tau > 3\), the maximum weight is \(o(\sqrt{n})\)). Now, the subgraph restricted to \(V\) is an inhomogeneous random graph with kernel approximately equal to \(\kappa\) given by (2.15). Using general results from inhomogeneous random graphs [14], this allows us to conclude that the graph restricted to \(V\) exhibits a phase transition, and a unique giant component of approximate size \(|V|\zeta^\lambda\) appears for some \(\lambda > \lambda_1\), where \(\lambda_1\) is given by the inverse of norm of a suitable integral operator. Thus, a giant component appears inside \(V\) precisely after \(\lambda_1\). This constitutes the core of vertices, and the 1-neighborhood of this tiny giant spans almost the entire giant component. The quantity \(\zeta^\lambda\) in (2.14) should be interpreted as the size of the 1-neighborhood of the small giant. Thus, we see two structural transitions occurring at \(\lambda = \lambda_c\) and at \(\lambda = \lambda_1\). These values have rather different origins, namely \(\lambda_c\) arises as the connectivity threshold for an inhomogeneous percolation on the integers in Proposition 2.5, and \(\lambda_1\) as the critical value of an appropriate inhomogeneous random graph, described in terms of an operator of some branching process. However, an explicit computation shows that, in fact, \(\lambda_c = \lambda_1\), see Lemma 4.4 below.

3 Proofs for subcritical and critical regimes

We begin with the proof of the critical regime, starting in Section 3.1 by proving Proposition 2.5 and in particular showing that the asserted limiting object is finite. In Section 3.2, we set up technical ingredients to study the connectivity structure between macro-hubs. In Section 3.3, we derive path-counting estimates, which are used in Section 3.4 to show that if we start exploring the components containing hubs, then the total number of vertices at even distances is negligible, and the total number of vertices at large and odd distances is also negligible (the same estimates will be useful in the sub-critical regime, which explains why we start with the critical regime first). This allows us to compute the size of the components containing hubs in Section 3.5. We conclude the proof of Theorem 2.3 in Section 3.6 by showing that the vector of component sizes is tight in \(l^2\). The subcritical regime is analyzed in Section 3.7 where using path counting techniques we show that the largest components are essentially stars with hubs as centers.
3.1 Finiteness of the limiting object for \( \lambda \leq \lambda_c \): proof of Proposition 2.5

Recall \( \lambda_c \) from (2.10), and the constants \( A_\alpha, B_\alpha \) from (2.11). Define the symmetric function \( h : (0, \infty)^2 \to (0, \infty) \) by

\[
h(x, y) := B_\alpha(x \land y)^{-1}(1-\alpha)(x \lor y)^{-\alpha}. \tag{3.1}
\]

Note that \( h(i, j) \) is perfectly homogeneous of exponent \(-1\), i.e., \( h(tx, ty) = t^{-1}h(x, y) \) for all \( x, y, t > 0 \). Analogous to \( G_\infty(\lambda) \) in Definition 2.4, consider the following random graph which belongs to a general class of models studied by Durrett and Kesten [27]:

**Definition 3.1** (Inhomogeneous percolation model). Consider the random graph \( G_{\text{DR}}(\lambda) \) on \( \mathbb{Z}_+ \) where vertices \( i \) and \( j \) are joined with probability \( \min\{\lambda^2 h(i, j), 1\} \), independently across edges.

**Theorem 3.2** (Previous results for \( G_{\text{DR}}(\lambda) \), [27, 40]). (a) By [27], the random graph \( G_{\text{DR}}(\lambda) \) is connected almost surely for \( \lambda > \lambda_c \).

(b) For \( i, j \in \mathbb{Z}_+ \), write \( \mathbb{P}_{\lambda, \text{DR}}(i \leftrightarrow j) \) for the probability that \( i, j \) are connected by some path in \( G_{\text{DR}}(\lambda) \). By [40], there exists \( c_1 < \infty \) such that for \( \lambda = \lambda_c \), and for any \( 1 \leq i < j \),

\[
\mathbb{P}_{\lambda_c, \text{DR}}(i \leftrightarrow j) \leq c_1 \log(i \lor 2)/\sqrt{ij}.
\]

To see that the \( \lambda_c \) in (2.10) gives the same critical value as [27, (1.5)], we compute

\[
\left[ \int_0^\infty \frac{h(1,y)}{\sqrt{y}} dy \right]^{-1} = \frac{1}{B_\alpha} \left[ \int_0^1 \frac{dy}{y^{1+1-\alpha}} + \int_1^\infty \frac{dy}{y^{1+\alpha}} \right]^{-1} = \frac{2\alpha - 1}{4B_\alpha} = \frac{2}{4B_\alpha}, \tag{3.2}
\]

where we have used that \( \alpha \in (1/2, 1) \). The square root in (2.10) is due to the fact that we have used \( \lambda^2 \) in Definition 3.1 instead of \( \lambda \) as in [27]. The factor \( \lambda^2 \) arises for us, since we deal with two-step paths. We next discuss an extension where the connection probabilities are asymptotically equal to \( h(i, j) \) also proven in [27, Extension (a)].

**Corollary 3.3** (Extension to asymptotic edge probabilities). Consider the graph \( G'_{\text{DR}}(\lambda) \) constructed by keeping an edge between \( i \) and \( j \) independently with probability \( r(i, j) \), and let

\[
\lim_{i \to \infty} \lim_{j \to \infty} r(i, j)/\lambda^2 h(i, j) = 1. \tag{3.3}
\]

Then, \( G'_{\text{DR}}(\lambda) \) is connected almost surely if \( \lambda > \lambda_c \).

We next state the following lemma which allows us to compare the connection probabilities in Definitions 2.4 and 3.1. Let \( p_\infty(i, j) := 1 - e^{-\lambda_{ij}} \), with \( \lambda_{ij} \) as in (2.13), be the probability that there is an edge between \( i, j \) in \( G_\infty(\lambda) \) in Definition 2.4.

**Lemma 3.4** (Asymptotics of two-step probabilities). For all \( i, j \in \mathbb{Z}_+ \), \( p_\infty(i, j) \leq \lambda^2 h(i, j) \). Further,

\[
\lim_{i \to \infty} \lim_{j \to \infty} p_\infty(i, j)/\lambda^2 h(i, j) = 1. \tag{3.4}
\]

Consequently, \( G_\infty(\lambda) \) is almost surely connected for \( \lambda > \lambda_c \).

**Proof.** Without loss of generality, let \( i < j \). We first show the first assertion on domination. Using \( 1 - e^{-x} \leq x \) for all \( x > 0 \) twice, as well as (2.13), we note that

\[
p_\infty(i, j) \leq \lambda_{ij} = \lambda^2 \int_0^\infty \Theta_i(x) \Theta_j(x) dx \leq \frac{\lambda^2 c_{ij}^\alpha}{\mu} \int_0^\infty \left( 1 - e^{-\frac{c_{ij}^\alpha}{\mu^2} i x^{-\alpha}} \right) x^{-\alpha} dx. \tag{3.5}
\]
Substituting \( z = (i^{-\alpha}x^{-\alpha})c_{x}^{2}/\mu \) with \( x = c_{x}^{2/\alpha}\mu^{-1/\alpha}z^{-1/\alpha}i^{-1} \) and \( \mu = -\alpha c_{x}^{2/\alpha}\mu^{-1/\alpha}z^{-1/\alpha} \), we have

\[
p_{\infty}(i, j) \leq \frac{\lambda^{2}}{\alpha} \int_{0}^{\infty} (1 - e^{-z}) \frac{c_{x}^{2/\alpha}}{\mu^{1/\alpha}z^{1/\alpha}} dz = \frac{\lambda^{2} c_{x}^{2/\alpha}}{\alpha \mu^{1/\alpha}z^{1/\alpha}} \int_{0}^{\infty} 1 - e^{-z} dz,
\]

and thus using (2.11), it follows that \( p_{\infty}(i, j) \leq \lambda^{2} h(i, j) \). For the second assertion, note that
\[
\lim_{x \to 0}[1 - e^{-x}] / x = 1 \text{ to conclude (3.4).} \]

**Remark 3.5** (Related rank-one models). If we replace \( \Theta_{l}(x) \) by \( \Theta^{cl}_{l}(x) \) and \( \Theta^{GRG}_{l}(x) \) from (2.18) respectively, then Lemma 3.4 holds with \( h(i, j) \) replaced by \( h^{cl}(i, j) = (B^{cl}_{\alpha} / B_{\alpha}) h(x, y) \) and
\[
h^{GRG}(i, j) = (B^{GRG}_{\alpha} / B_{\alpha}) \text{ respectively from (2.18).}
\]

**Proof of Proposition 2.5.** Recall that \( \theta_{l} = c_{x}i^{-\alpha} \mu^{-1} \). Using Corollary 3.3, together with Theorem 3.2 and Lemma 3.4, the graph \( G_{\infty}(\lambda) \) is almost surely connected for \( \lambda > \lambda_{c} \). Thus, Proposition 2.5 (b) follows from Theorem 3.2 (a) and the fact that \( \sum_{i=1}^{\infty} \theta_{i} = \infty \). Next, by the upper bound in Lemma 3.4 and monotonicity in \( \lambda \) for the connection probabilities, it is enough to show Proposition 2.5 (a) for \( G_{\infty}(\lambda) \). To this end, let \( C(j) \) denote the component of vertex \( j \) in \( G_{\infty}(\lambda) \). Define

\[
C_{\leq}(j) = \begin{cases} C(j) & \text{if } j = \min\{i: i \in C(j)\}, \\ \emptyset & \text{otherwise.} \end{cases}
\]

Then it is enough to show that

\[
L := \mathbb{E}\left( \sum_{j=1}^{\infty} \left( \sum_{i \in C_{\leq}(j)} \theta_{i} \right)^{2} \right) < \infty.
\]

Expanding the above, we obtain

\[
L \leq \sum_{j=1}^{\infty} \theta_{j}^{2} + 2 \sum_{i_{1} > i_{2} \geq j} \theta_{i_{1}} \theta_{i_{2}} \mathbb{P}_{\lambda_{c}, \infty} \left( i_{1} \leftrightarrow i_{2} \text{ in } [j, \infty), i_{1}, i_{2} \in C(j) \right) := \|\theta\|_{2}^{2} + 2L_{1}.
\]

Here the event \( \{i_{1} \leftrightarrow i_{2} \text{ in } [j, \infty)\} \) is the event that there exists a path in \( G_{\infty}(\lambda_{c}) \) from \( i_{1} \) and \( i_{2} \) with intermediate vertices in \( [j, \infty) \). Since \( \theta \in \ell_{2}^{2} \), it is enough to show that \( L_{1} < \infty \). Splitting into cases depending on whether \( i_{2} = j \) or \( i_{2} > j \), we get \( L_{1} = L_{2} + L_{3} \), where

\[
L_{2} := \sum_{j=1}^{\infty} \sum_{i_{1} > i_{2} \geq j} \theta_{i_{1}} \theta_{i_{2}} \mathbb{P}_{\lambda_{c}, \infty} \left( i_{1} \leftrightarrow j \text{ in } [j, \infty) \right) \leq \sum_{j=1}^{\infty} \frac{1}{\mu^{1/\alpha}} \sum_{i_{1} > j} \frac{c_{1} \log j}{\sqrt{i_{1}}} < \infty,
\]

where the second inequality follows from Theorem 3.2 (b) and the last inequality uses \( \alpha > 1/2 \). The final term to bound is \( L_{3} \). For any \( i_{1}, i_{2} > j \) write \( \{i_{1} \leftrightarrow i_{2}\} \) for the event \( \{i_{1} \leftrightarrow i_{2} \text{ in } [j, \infty)\} \) in \( G_{\infty}(\lambda_{c}) \). Next note that

\[
\{i_{1} \leftrightarrow i_{2} \text{ in } [j, \infty), i_{1}, i_{2} \in C(j) \} \subseteq \bigcup_{z \geq j} \left[ \{z \leftrightarrow j\} \cup \{i_{1} \leftrightarrow z\} \cup \{i_{2} \leftrightarrow z\} \right],
\]

where \( \{z \leftrightarrow j\} \cup \{i_{1} \leftrightarrow z\} \cup \{i_{2} \leftrightarrow z\} \) denotes the event that the implied connections are realized using disjoint sets of edges. The union bound combined with the BK-inequality [7, Theorem 3.3] implies that, for fixed \( i_{1} > i_{2} > j \),

\[
\mathbb{P}_{\lambda_{c}, \infty}(i_{1} \leftrightarrow i_{2} \text{ in } [j, \infty), i_{1}, i_{2} \in C(j)) \leq \sum_{z \geq j} \mathbb{P}_{\lambda_{c}, \infty}(z \leftrightarrow j) \mathbb{P}_{\lambda_{c}, \infty}(z \leftrightarrow i_{1}) \mathbb{P}_{\lambda_{c}, \infty}(z \leftrightarrow i_{2}) \leq \sum_{z \geq j} c_{1}^{2} \log(j + 2) \log(i_{1} \vee z) \log(i_{2} \vee z) \leq C \left( \log(j + 2) \log(i_{1} \vee 2) \log(i_{2} \vee 2) \right),
\]

where
Lemma 3.7 (Moment estimates) and Proposition 3.6 (Hub connectivity) complete the proof of (3.8) and hence Proposition 2.5 (a).

3.2 Connectivity structure between hubs

In this section, we estimate the connection probabilities between macro-hubs. Recall $p_{ij}$ from (2.2). Henceforth, in this section we simply write $\pi_c$ for $\pi_c(\lambda)$. For any $i \neq j$, let $X_{ij}$ denote the number of paths of length 2 from $i$ to $j$. For $v \notin \{i, j\}$, let $\xi_{ij}(v)$ denote the indicator that $\{i, v\}$ and $\{v, j\}$ create edges in $\text{NR}(w, \pi_c)$. Thus,

$$X_{ij} = \sum_{v \neq i, j} \xi_{ij}(v), \quad \text{with } \xi_{ij}(v) \sim \text{Bernoulli}(\pi_c^2 p_{iv} p_{ij}), \text{ independently.}$$

Proposition 3.6 (Hub connectivity). For each fixed $i, j \geq 1$

$$\lim_{n \to \infty} d_{TV}(X_{ij}, P_{ij}) = 0, \quad \text{where } P_{ij} \sim \text{Poisson}(\lambda_{ij}),$$

and $d_{TV}(\cdot, \cdot)$ denotes the total variation distance. Moreover, for any fixed $K \geq 1$, $(X_{ij})_{1 \leq i < j \leq K}$ are asymptotically independent.

Before embarking on the proof of Proposition 3.6, we describe moment estimates on the weights $w$. Recall that $\ell_n = \sum_{i\in[n]} w_i$, and $a_n \asymp b_n$ denotes that $a_n = b_n(1 + o(1))$.

Lemma 3.7 (Moment estimates). Under Assumption 2.1, for any fixed $a > 0$,

$$\#\{k : w_k \geq \alpha \ell_n/w_i\} \asymp n\left(\frac{c_F w_i}{\alpha \ell_n}\right)^{\tau-1}, \quad \sum_{w_k > \alpha \ell_n/w_i} w_k \asymp \frac{c_F^{-1} n}{1-\alpha} \left(\frac{w_i}{\alpha \ell_n}\right)^{\tau-2},$$

$$\sum_{k : w_k \leq \alpha \ell_n/w_i} w_k^2 \asymp \frac{c_F^{-1} n}{2\alpha - 1} \left(\frac{\alpha \ell_n}{w_i}\right)^{3-\tau},$$

where the approximations are uniform over $i \in [n]$.

Proof. The first approximation follows from (2.6) by noting that

$$w_k \geq \frac{\alpha \ell_n}{w_i} \iff c_F \left(\frac{n}{K}\right)^\alpha \geq \frac{\alpha \ell_n}{w_i} \iff k \leq n\left(\frac{c_F w_i}{\alpha \ell_n}\right)^{\tau-1}. \quad (3.17)$$

Moreover,

$$\sum_{k : w_k > \alpha \ell_n/w_i} w_k = c_F n^\alpha \sum_{k < n(c_F w_i/\alpha \ell_n)^{\tau-1}} k^{-\alpha} \quad \times \frac{c_F n^\alpha}{1-\alpha} \left(n \left(\frac{c_F w_i}{\alpha \ell_n}\right)^{\tau-1}\right)^{1-\alpha} \times \frac{c_F^{-1} n}{1-\alpha} \left(\frac{w_i}{\alpha \ell_n}\right)^{\tau-2}, \quad (3.18)$$

and

$$\sum_{k : w_k \leq \alpha \ell_n/w_i} w_k^2 = \frac{c_F n^{-\alpha}}{2\alpha - 1} \sum_{k \geq n(c_F w_i/\alpha \ell_n)^{-1}} k^{-2\alpha} \quad \times \frac{c_F n^{-\alpha}}{2\alpha - 1} \left(\frac{\alpha \ell_n}{c_F w_i}\right)^{3-\tau} n^{1-2\alpha} \times \frac{c_F^{-1} n}{2\alpha - 1} \left(\frac{\alpha \ell_n}{w_i}\right)^{3-\tau}, \quad (3.19)$$

where the approximations are uniform over $i \in [n]$. Thus, the proof follows.
Proof of Poisson approximation in Proposition 3.6. We first prove the Poisson approximation in (3.15), followed by the asserted asymptotic independence. Fix $\delta > 0$. Recall $\rho = 1 - \alpha$. We start by splitting the sum in (3.14) over three sets $\{v : w_v < \delta n^\rho\}$, $\{v : \delta n^\rho \leq w_v \leq \delta^{-1} n^\rho\}$ and $\{v : w_v > \delta^{-1} n^\rho\}$. Let us denote these three partial sums by $X_{ij}^{(I)}(\delta)$, $X_{ij}^{(II)}(\delta)$ and $X_{ij}^{(III)}(\delta)$ respectively. Now, using Lemma 3.7,

$$
\mathbb{E}[X_{ij}^{(I)}(\delta)] \leq \frac{w_i w_j \pi_c}{\ell_2^2} \sum_{v : w_v < \delta n^\rho} w_v^2 \leq C \delta^{3-\tau} n^{2\alpha-2+1+(3-\tau)\rho} \pi_c^2 \leq C \delta^{3-\tau},
$$

(3.20)

$$
\mathbb{E}[X_{ij}^{(II)}(\delta)] \leq \pi_c^2 \times \#\{v : w_v > \delta^{-1} n^\rho\} = C \delta^{-1}.
$$

For non-negative integer-valued random variables $X, Y, Z$, with $X, Y$ being independent, by the triangle inequality,

$$
d_{TV}(X + Y, Z) = \sum_{k=0}^{\infty} |\mathbb{P}(X + Y = k) - \mathbb{P}(Z = k)|
\leq \sum_{k=0}^{\infty} |\mathbb{P}(X = k) - \mathbb{P}(Z = k)| + \sum_{k=0}^{\infty} |\mathbb{P}(X = k) - \mathbb{P}(X = k, Y = 0)| + \sum_{k=0}^{\infty} \mathbb{P}(X = k, Y \geq 1)
\leq d_{TV}(X, Z) + 2\mathbb{P}(Y \geq 1) \leq d_{TV}(X, Z) + 2\mathbb{E}[Y],
$$

(3.21)

where the last step uses Markov’s inequality. Using (3.20) and (3.21), in order to prove (3.15), it suffices to show that

$$
\lim_{\delta \to 0} \lim_{n \to \infty} d_{TV}(X_{ij}^{(I)}(\delta), P_{ij}) = 0, \quad \text{where } P_{ij} \sim \text{Poisson}(\lambda_{ij}).
$$

(3.22)

Define

$$
P_{ij}^{(n)}(\delta) \sim \text{Poisson}(\lambda_{ij}^{(n)}(\delta)), \quad \text{where } \lambda_{ij}^{(n)}(\delta) = \sum_{v : w_v \in [\delta n^\rho, \delta^{-1} n^\rho]} \pi_c^2 p_{iv} p_{vj}.
$$

(3.23)

Using standard inequalities from Stein’s method [30, Theorem 2.10], it follows that, as $n \to \infty$,

$$
d_{TV}(X_{ij}^{(II)}(\delta), P_{ij}^{(n)}(\delta)) \leq \sum_{v : w_v \in [\delta n^\rho, \delta^{-1} n^\rho]} \left( \pi_c^2 p_{iv} p_{vj} \right)^2 \leq C n^{4\alpha-4} \pi_c^4 \sum_{v : w_v \in [\delta n^\rho, \delta^{-1} n^\rho]} w_v^4
\leq \frac{C}{\delta^2} n^{2\alpha-2-4} \pi_c^4 \sum_{v : w_v \in [\delta n^\rho, \delta^{-1} n^\rho]} w_v^2 = \frac{C}{\delta^2} n^{2\alpha-2-4} n^{-2(3-\tau)} n^1(3-\tau)\rho = \frac{C n^{-3(3-\tau)} \delta^2}{\delta^2} \to 0.
$$

(3.24)

Further,

$$
\lambda_{ij}^{(n)}(\delta) \asymp \pi_c^2 \sum_{k=\delta^{-1} n^3-\tau}^{\delta n^3-\tau} \left( 1 - e^{-\frac{\delta^2}{\rho n} \frac{\delta^2}{\rho n} i - \alpha k - \alpha} \right) \left( - e^{-\frac{\delta^2}{\rho n} \frac{\delta^2}{\rho n} j - \alpha} \right)
\leq \pi_c^2 \int_{\delta^{-1} n^3-\tau}^{\delta n^3-\tau} \left( 1 - e^{-\frac{\delta^2}{\rho n} \frac{\delta^2}{\rho n} y - \alpha} \right) dy
\leq \lambda^2 \int_{\delta^{-1} n^3-\tau}^{\delta n^3-\tau} \left( 1 - e^{-\frac{\delta^2}{\rho n} j - \alpha} \right) dx := \lambda_{ij}(\delta).
$$

(3.25)

As $\delta \to 0$, we have $\lambda_{ij}(\delta) \to \lambda_{ij}$. Since the total variation distance between two Poisson distributions is at most the difference of their means, we conclude (3.22), and hence the proof of (3.15) also follows. 

\[\square\]
Remark 3.8 (No hubs connected via two hop paths in subcritical regime). When \( \pi_n = \lambda_n n^{-\nu} \) with \( \lambda_n = o(1) \), we can use identical argument as above to show that for any \( K \geq 1 \),

\[
\lim_{n \to \infty} \mathbb{P}(X_{ij} \geq 1 \text{ for some } 1 \leq i < j \leq K) = 0.
\]

(3.26)

Indeed, the bounds in (3.20), (3.24) and (3.25) would all tend to zero as \( n \to \infty \).

Proof of asymptotic independence in Proposition 3.6. Fix \( K \geq 1 \). Note that for pairs \((i, j)\), and \((k, l)\) with \( \{i, j\} \cap \{k, l\} = \emptyset \), \( X_{ij} \) and \( X_{kl} \) are independent due to the independence of the occupancy of edges in \( \mathcal{N}_n(w, \pi_c) \). The only dependence between \( X_{ij} \) and \( X_{ik} \) arises due to potential connections \((i, v), (v, j)\) and \((v, k)\). To simplify notation we give a full proof for the asymptotic independence of \((X_{12}, X_{13})\), and a minor adaptation of this proof holds for any general \( K \geq 1 \). Fix \( \delta > 0 \) and let \( V_n(\delta) = \{v: \delta n^\rho \leq w_v \leq \delta^{-1} n^\rho\} \). Let \( X^{(12)}_n(\delta) \), \( X^{(13)}_n(\delta) \) be the random variables as in (3.22). Recall the definition of the constant \( \lambda_{ij}(\delta) \) from (3.25). Arguing as in the convergence of the marginals, it is enough to prove that as \( n \to \infty \)

\[
d_{TV}[(X^{(12)}_n(\delta), X^{(13)}_n(\delta)), (P_{12}(\delta), P_{13}(\delta))] \to 0,
\]

(3.27)

where \( P_{12}(\delta), P_{13}(\delta) \) are independent Poisson random variables with means \( \lambda_{12}(\delta), \lambda_{13}(\delta) \) respectively.

We need some additional notation to prove this proposition. For \( v \in V_n(\delta) \) and for \( i \in \{1, 2, 3\} \), let \( I_{iv} \) be the indicator representing presence of edge \( \{i, v\} \) in \( \mathcal{N}_n(w, \pi_c) \), so that the two hop indicator equals \( \xi_{ij}(v) = I_{iv} I_{jv} \). Fix two constants \( p, q \in [0, 1] \) and for each \( v \in V_n(\delta) \), let \( J_{2v}, J_{3v} \) be Bernoulli \( p, q \) random variables, respectively independent of each other and all the other indicator random variables. Here the constants depend on \( p, q \). Write

\[
R_n := \sum_{v \in V_n(\delta)} [J_{2v} I_{1v} I_{2v} + J_{3v} I_{1v} I_{3v}] = \sum_{\beta \in I} \mathbb{1}_\beta,
\]

(3.28)

where the index set \( I \) is given by \( I = \cup_{v \in V_n(\delta)} \{(v, 1, 2), (v, 1, 3)\} \) and \( \mathbb{1}_\beta = J_{kv} I_{1v} I_{kv} \) for \( \beta = (v, 1, k) \). Our main tool is the Poisson Cramér-Wold device in [5, Corollary 2.2], which implies that in order to prove (3.27), it is enough to show that, for every \( p, q \in [0, 1] \), as \( n \to \infty \),

\[
d_{TV}(R_n, P) \to 0, \quad P \sim \text{Poisson}(p \lambda_{12}(\delta) + q \lambda_{13}(\delta)).
\]

(3.29)

Letting \( P^{(n)} \) be a Poisson random variable with mean \( p \lambda_{12}^{(n)}(\delta) + q \lambda_{13}^{(n)}(\delta) \) with \( \lambda_{12}^{(n)}(\delta) \) as in (3.25), it is enough to show that \( d_{TV}(R_n, P^{(n)}) \to 0 \). We aim to apply Poisson approximation via Stein’s method [33, Theorem 6.23]. For any \( \beta_1 = (v_1, 1, k_1) \in I \) and \( \beta_2 = (v_2, 1, k_2) \in I \), \( I_{\beta_1} \) and \( I_{\beta_2} \) are not independent only if \( v_1 = v_2 \). Thus, [33, Theorem 6.23] implies

\[
d_{TV}(W, P^{(n)}) \leq \sum_{\beta_1 \in I} (\mathbb{E}[\mathbb{1}_{\beta_1}])^2 + \sum_{\beta_1, \beta_2 \in I, v_1 = v_2, \beta_1 \neq \beta_2} \mathbb{E}[\mathbb{1}_{\beta_1} \mathbb{1}_{\beta_2}] := 2(b_1 + b_2).
\]

(3.30)

Thus it is enough to show \( b_1, b_2 \to 0 \) as \( n \to \infty \). Indeed, using \( p_{ij} \leq \pi_n w_i w_j / \ell_n \),

\[
b_1 \leq C \sum_{v_1 \in V_n(\delta), k_1 = 2, 3} \left( \frac{\pi_n^\alpha w_i w_j w_k}{\ell_n^2} \right)^2 \leq C n^{4\alpha - 4} \pi_n^4 \sum_{v_1 \in \mathcal{N}_n(\delta)} w_i^4 \to 0,
\]

(3.31)

where the last step uses (3.24). Similarly,

\[
b_2 \leq C \sum_{v_1 \in V_n(\delta), k_1, k_2 = 2, 3} \pi_n^\alpha w_i w_j w_k w_{k_2} \leq C \pi_n^3 w_i^3 \ell_n^3 \sum_{v_1: w_{v_1} \leq \delta^{-1} n^\rho} w_{v_1}^3 \leq C \pi_n^3 n^{3\alpha - 3 + \rho + 1 + (3 - \tau)\rho} = O(\pi_n).
\]

(3.32)
This completes the proof of (3.30) and thus we have proven the asymptotic independence stated in Proposition 3.6 for \( K = 2 \). The proof of the asymptotic independence in Proposition 3.6 for general \( K \) follows the same line of argument, now using a \( K(K-1)/2 \)-dimensional version of the Poisson Cramér-Wold device in [5, Corollary 2.2]. We omit further details. ■

**Remark 3.9** (Related rank-one models). The proof of Proposition 3.6 extends verbatim for the Chung-Lu model and generalized random graph with \( \lambda \) replaced by \( \lambda_{ij}^{CL}(x) \) and \( \lambda_{ij}^{GRG}(x) \), respectively, where

\[
\lambda_{ij}^{CL}(x) = \lambda^2 \int_0^\infty \Theta_{ij}^{CL}(x) \Theta_{ij}(x) dx, \quad \lambda_{ij}^{GRG}(x) = \lambda^2 \int_0^\infty \Theta_{ij}^{GRG}(x) \Theta_{ij}^{GRG}(x) dx,
\]

where \( \Theta_{ij}^{CL}(x) \) and \( \Theta_{ij}^{GRG}(x) \) are defined in (2.18). Indeed, all the asymptotic bounds only use the fact that \( p_{uw} \leq \{w_u w_v / \ell_n, 1 \} \). The mean of the Poisson approximation changes depending on the model due to the computations in (3.25).

### 3.3 Path-counting estimates

In this section, we prove path-counting estimates for \( NR_n(w, \pi_c) \) for \( \lambda < \lambda_c \). Such estimates will play a pivotal role in showing that, when we start exploring from a hub, most vertices are found within a finite distance (see Proposition 3.11 in the next Section). Similar estimates arise also in the context of preferential attachment model for example [25, Lemma 2.4]. For two distinct vertices \( i \neq j \in [n] \), let \( f_{2k}(i, j) \) denote the probability that there exists a path of length \( 2k \) from \( i \) to \( j \) in \( NR_n(w, \pi_c) \).

**Proposition 3.10** (Connection probabilities at even distance). Fix \( \varepsilon > 0 \) and \( \lambda < \lambda_c \). There exists \( n_0 = n_0(\varepsilon) \geq 1 \) and \( b = b(\varepsilon) \in (\frac{1}{2}, \alpha) \) such that for all \( n \geq n_0, k \geq 1, i \neq j \in [n] \),

\[
f_{2k}(i, j) \leq (1 + \varepsilon)^{2k} \left( \frac{\lambda}{\lambda_c} \right)^{2k} \frac{1}{(i \land j)^{1-b(i \lor j)^b}},
\]

where \( \lambda_c \) is defined by (2.10).

**Proof.** Fix \( \varepsilon > 0 \). Without loss of generality, let \( i < j \) so that \( w_i > w_j \). Let us first relate the expected number of two-step connections to \( h \) given in (3.1). We achieve this by showing that there exists \( n_0 = n_0(\varepsilon) \geq 1 \) such that for all \( n \geq n_0 \) and \( i \neq j, i, j \in [n] \),

\[
p_n(i, j) := \sum_{v \in [n]\setminus\{i, j\}} \pi_c^2 p_{iv} p_{vj} \leq (1 + \varepsilon)^2 h(i, j).
\]

Using that \( 1 - e^{-x} \leq x \) for all \( x > 0 \) and \( \ell_n = (1 + o(1))n \mu_{ij} \), we can bound

\[
p_n(i, j) \leq (1 + \varepsilon) \lambda^2 n^{-(3-r)} \frac{c_n^2 n^{2\alpha-1}}{\mu_j^\alpha} \sum_{v \in [n]} \left( 1 - e^{-c_n^{2} n^{3(r-\alpha)} v^{-\alpha}} \right) v^{-\alpha}
\]

\[
\leq (1 + \varepsilon) \lambda^2 \frac{c_n^2}{\mu_j^\alpha} \int_0^\infty \left( 1 - e^{-c_n^{2} z^{-\alpha} / \mu} \right) z^{-\alpha} dz.
\]

The final term is identical to the right hand side of (3.5), and using the exact same argument following (3.5), the proof of (3.35) follows.

We next investigate more general even-length paths. For any \( k \geq 1 \), define \( I_k = I_k(i, j) := \{ v = (v_j)_{j=0}^k : v_0 = i, v_k = j, \text{ and } v_j \text{’s are distinct} \} \), i.e., the set of possible self-avoiding paths of length \( k \) started at \( i \) and ending at \( j \). Using (3.35),

\[
f_{2k}(i, j) \leq ((1 + \varepsilon)^2)^k \sum_{v \in I_k} h(v_{r-1}, v_r).
\]
Using $\lambda_c = \sqrt{\eta/4B_\alpha}$ from (2.10), it is enough to show that, for any $k \geq 1$,

$$
\gamma_k(i, j) := \sum_{v \in 2^{v+1}} \prod_{r=1}^{k} \frac{1}{(v_{r-1} \land v_{r})^{1-\alpha}(v_{r-1} \lor v_{r})^\alpha} \leq (1 + \varepsilon)^k \left(\frac{4}{\eta}\right)^k \frac{1}{(i \lor j)^{1-b(i \land j)^b}}.
$$

(3.38)

We use induction on $k$. For $k = 1$,

$$
\gamma_1(i, j) = \frac{1}{i^{1-\alpha}j^\alpha} = \frac{1}{i} \left(\frac{i}{j}\right)^{\alpha} \leq \frac{1}{i} \left(\frac{i}{j}\right)^{b} < (1 + \varepsilon) \frac{4}{\eta} \frac{1}{(i \lor j)^{1-b(i \land j)^b}},
$$

(3.39)

where the third step follows using $i < j$ and $b < \alpha$, and the final step follows using $\eta < 4$.

Next, let us indicate the choice of $b$ that works. For $b \in (1 - \alpha, \alpha)$, let

$$
f(b) = \frac{1}{\alpha + b - 1} + \frac{1}{\alpha - b},
$$

which has a unique minimum at $b = \frac{1}{2}$ and $f(\frac{1}{2}) = \frac{2}{\eta}$. Since $f$ is continuous, we can choose $b = b(\varepsilon) > \frac{1}{2}$ such that $f(b) < (1 + \varepsilon) \frac{4}{\eta}$. This will be the $b$ that we work with from now on.

The induction step for proving (3.38) is given by

$$
\gamma_{k+1}(i, j) \leq \sum_{v < i} \frac{1}{i^{a-1}j^\alpha} \gamma_k(v, j) + \sum_{v > i} \frac{1}{i^{1-\alpha}v^\alpha} \gamma_k(v, j)
$$

\leq (1 + \varepsilon)^k \left(\frac{4}{\eta}\right)^k \left[ \frac{1}{i^{a-j}b} \sum_{v < i} \frac{1}{v^{2-\alpha-b}} + \frac{1}{i^{1-\alpha}j^b} \sum_{v < i} \frac{1}{v^{1-b+\alpha}} + \frac{1}{i^{1-\alpha}j^b} \sum_{v > j} \frac{1}{v^{1-b+\alpha}} \right]
$$

\leq (1 + \varepsilon)^k \left(\frac{4}{\eta}\right)^k \left[ \frac{1}{i^{a-j}b} \int_{0}^{i} \frac{dv}{v^{2-\alpha-b}} + \frac{1}{i^{1-\alpha}j^b} \int_{i}^{j} \frac{dv}{v^{1-b+\alpha}} + \frac{1}{i^{1-\alpha}j^b} \int_{j}^{\infty} \frac{dv}{v^{1-b+\alpha}} \right]
$$

\leq (1 + \varepsilon)^k \left(\frac{4}{\eta}\right)^k \left[ \frac{1}{i^{a-j}b} \alpha + b - 1 + \frac{1}{i^{1-\alpha}j^b} \left( \frac{b-\alpha}{b} - \frac{b-\alpha}{b} \right) + \frac{1}{i^{1-\alpha}j^b} \left( \frac{1}{\alpha + b - 1} - \frac{1}{\alpha - b} \right) \right]
$$

\leq (1 + \varepsilon)^{k+1} \left(\frac{4}{\eta}\right)^{k+1} \frac{1}{i^{1-bj^b}},
$$

where in the last step we have bounded the first term using our choice of $b$, and the second term is negative since $\alpha + b - 1 > \alpha - b$ for $b > \frac{1}{2}$. Thus, the proof follows.

3.4 Negligible contributions to the total weight

Let $C(i)$ denote the component in $\text{NR}_n(w, \pi_c)$ containing vertex $i$ and $W_k(i) = \sum_{v \in C(i), d(v,i)=k} w_{v,i}$ where $d(\cdot, \cdot)$ is used in the rest of the paper for graph distance. We will later see that $C(i)$, appropriately normalized, is close to $W(i) = \sum_{k=1}^{\infty} W_k(i)$. In this section, we identify the terms that provide negligible contributions to $W(i)$. The next proposition states that the contribution to the total weight arising from vertices in odd neighborhoods is small. Moreover, the total weight outside a large, but finite, neighborhood of $i$ is also negligible. Intuitively, this is due to the hubs appearing only in finite even distances, and these hubs are unlikely to be at very large distance.

**Proposition 3.11.** Suppose that $\lambda \in (0, \lambda_c)$. For any fixed $i \geq 1$ and $\varepsilon' > 0$,

$$
\lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P} \left( \sum_{k>0} W_{2k}(i) > \varepsilon' n^\alpha \right) = 0 \quad \text{and} \quad \lim_{n \to \infty} \mathbb{P} \left( \sum_{k=0}^{\infty} W_{2k+1}(i) > \varepsilon' n^\alpha \right) = 0.
$$

(3.41)
Proof. We start by proving the result on even distances. Recall the definition of \( f_k(i,j) \) from Proposition 3.10. Since \( \lambda < \lambda_c \), we can choose \( \varepsilon > 0 \) sufficiently small such that \( \Lambda = (1 + \varepsilon)^2(\lambda/\lambda_c)^2 < 1 \). Therefore, using Proposition 3.10,

\[
n^{-\alpha} \mathbb{E}[W_{2k}(i)] \leq n^{-\alpha} \sum_{j \in [n]} w_j f_{2k}(i,j) \leq c_F \Lambda^k \left( \sum_{j \leq i} \frac{1}{\ell_j^{1-b+\alpha}} + \sum_{j > i} \frac{1}{\ell_j^{1-b+\alpha}} \right) \leq \frac{C\Lambda^k}{i^b}, \tag{3.42}
\]

for some constant \( C > 0 \), where in the last step we have used that \( b \in (\frac{1}{2}, \alpha) \). Since \( \Lambda < 1 \), an application of Markov’s inequality proves the first part of (3.41).

Next, we compute \( \mathbb{E}[W_{2k+1}(i)] \). Using (3.42),

\[
n^{-\alpha} \mathbb{E}[W_{2k+1}(i)] \leq n^{-\alpha} \sum_{v \in [n]} \mathbb{P}\{\{i,v\} \text{ is an edge}\} \mathbb{E}[W_{2k}(v)] \leq n^{-\alpha} \sum_{v \in [n]} \tau_v \mathbb{P}[v \in v_i, v \in v_j, v] \frac{C\Lambda^k n^\alpha}{v^{1-b}}, \tag{3.43}
\]

Let us split the above sum in two terms by taking partial sums over \( \{v : w_v \leq \ell_n\} \) and \( \{v : w_v > \ell_n\} \), respectively. Denote the two terms by (I) and (II) respectively. Then, by Lemma 3.7,

\[
(1) \leq C\pi_c \Lambda^k \sum_{v > Cn(w_v/\ell_n)^{\tau-1}} \frac{1}{\ell_v^{\alpha+b}} \leq C\pi_c \Lambda^k \sum_{v > Cn(w_v/\ell_n)^{\tau-1}} \left( \frac{w_i}{\ell_n} \right)^{\tau-1} \leq \frac{C\Lambda^k n^{\alpha}}{i^{1-b}}, \tag{3.44}
\]

where \( \varepsilon_0 = (3-\tau)(b-\frac{1}{2}) > 0 \). Similarly,

\[
(II) \leq C\pi_c \Lambda^k \sum_{v \leq Cn(w_v/\ell_n)^{\tau-1}} \frac{1}{\ell_v^{\alpha+b}} \leq C\pi_c \Lambda^k \left( \frac{w_i}{\ell_n} \right)^{\tau-1} \leq \frac{C\Lambda^k n^{\alpha}}{i^{1-b}}, \tag{3.45}
\]

and thus we conclude that,

\[
\mathbb{E}[W_{2k+1}(i)] \leq \frac{C\Lambda^k n^{\alpha}}{i^{1-b}}. \tag{3.46}
\]

The second assertion of (3.41) again follows using Markov’s inequality.

The next proposition states that for each fixed \( k \geq 1 \), the primary contribution to \( W_{2k}(i) \) arises only due to the hubs. In its statement, we let \( W_{2k}^R(i) := \sum_{v \in [R], d(v,i) = k} w_v \).

**Proposition 3.12** (Weight of non-hubs at even distances). Suppose that \( \lambda \in (0, \lambda_c) \). For any fixed \( i \geq 1 \), and \( \varepsilon' > 0 \),

\[
\lim_{R \to \infty} \lim_{n \to \infty} \sup_{i} \mathbb{P}\left( \sum_{k=1}^{\infty} W_{2k}^R(i) > \varepsilon' n^\alpha \right) = 0. \tag{3.47}
\]

**Proof.** As before, in Proposition 3.10 choose \( \varepsilon > 0 \) sufficiently small such that \( \Lambda = (1 + \varepsilon)^2(\lambda/\lambda_c)^2 < 1 \). Choose \( R \) large so that \( i \in [R] \). Using Proposition 3.10,

\[
\mathbb{E}[W_{2k}^R(i)] \leq C \sum_{v > R} \frac{n^\alpha}{\ell_v^{\alpha+b}} \Lambda^k \sum_{v > R} \frac{1}{\ell_v^{\alpha+b}} \leq \frac{C\Lambda^k n^\alpha}{R^{\alpha+b-1}}, \tag{3.48}
\]

where we have used that \( \alpha + b > 1 \). Therefore,

\[
n^{-\alpha} \mathbb{E}\left[ \sum_{k=1}^{\infty} W_{2k}^R(i) \right] \leq \frac{C}{(1-\Lambda)i^{1-b}R^{\alpha+b-1}}, \tag{3.49}
\]

Once again an application of Markov’s inequality completes the proof. 

\[\]
3.5 Sizes of components containing hubs

In this section, we consider the asymptotic size of \( C(i) \), the component containing vertex \( i \). Recall the asserted limit object \( G_\infty(\lambda) \) from Section 2.3.2. In \( G_\infty(\lambda) \), let \( \mathcal{W}(i) = \sum_j d(i,j) = k \theta_j \). Thus the total weight of the component containing \( i \) in \( G_\infty(\lambda) \) is \( W(i) = \sum_{k=0}^\infty \mathcal{W}(i) \). We start by relating the asymptotics of the total weight \( W(i) = \sum_{k=1}^\infty W_k(i) \) in \( NR_n(w, \pi_c) \), defined in the previous Section to \( \mathcal{W}(i) \).

**Theorem 3.13** (Total weight containing hub). Suppose that \( \lambda \in (0, \lambda_c) \). For each fixed \( i \geq 1 \), as \( n \to \infty \), \( n^{-\alpha} W(i) \to \mathcal{W}(i) \).

**Proof.** Let \( W_k^{\leq R}(i) := \sum_{j \in [R]} d(i,j) = k \ w_j \) and \( W_k^{\geq R}(i) := \sum_{j \in [R]} d(i,j) = k \ \theta_j \). Proposition 3.6 implies that, for any \( K, R \geq 1 \),

\[
\lim_{n \to \infty} \sum_{k=1}^K n^{-\alpha} W_k^{\leq R}(i) \to \sum_{k=1}^K \mathcal{W}_k(i).
\]  

(3.50)

Now, \( \sum_{k=1}^K \mathcal{W}_k(i) \to \mathcal{W}(i) \) almost surely, as \( R \to \infty \). Thus, an application of Proposition 3.12 yields

\[
\lim_{n \to \infty} \sum_{k=1}^K n^{-\alpha} W_k(i) \to \sum_{k=1}^K \mathcal{W}_k(i).
\]  

(3.51)

Finally, \( \sum_{k=1}^K \mathcal{W}_k(i) \to \mathcal{W}(i) \) almost surely, as \( K \to \infty \), and thus we conclude the proof using Proposition 3.11.

**Theorem 3.14** (Component sizes of hubs). Suppose that \( \lambda \in (0, \lambda_c) \). For each fixed \( i \geq 1 \), as \( n \to \infty \), \( (n^a \pi_c)^{-1} |C(i)| \to \mathcal{W}(i) \).

We start by identifying the main contributions on the component sizes by proving analogues of Propositions 3.11–3.12 for cluster sizes instead of cluster weights. Define \( C_k(i) := \{ v \in C(i) : d(v, i) = k \} \). Thus \( C_k(i) \) denotes the set of vertices at distance exactly \( k \) from vertex \( i \). Also, let \( C_k^R(i) \subset C_k(i) \) denote the vertices of \( C_k(i) \) that are neighbors of some vertex in \( C_{k-1}(i) \cap [R] \).

**Lemma 3.15** (Main contributions to cluster sizes). Suppose that \( \lambda \in (0, \lambda_c) \). For any fixed \( i \geq 1 \), and \( \varepsilon > 0 \),

\[
\lim_{n \to \infty} \mathbb{P}\left( \sum_{k=0}^\infty |C_{2k}(i)| > \varepsilon n^a \pi_c \right) = 0, \quad \lim_{K \to \infty} \lim_{n \to \infty} \mathbb{P}\left( \sum_{k=K}^\infty |C_{2k+1}(i)| > \varepsilon n^a \pi_c \right) = 0,
\]  

(3.52)

and

\[
\lim_{R \to \infty} \lim_{n \to \infty} \mathbb{P}\left( \sum_{k=0}^\infty |C_{2k+1}(i) \setminus C_{2k+1}^R(i)| > \varepsilon n^a \pi_c \right) = 0.
\]  

(3.53)

**Proof.** Note that

\[
\mathbb{E}\left[ |C_{k+1}(i)| \right] \leq \sum_{r=1}^k \sum_{v_1 \in C_r(i)} \sum_{v_2 \in [n]} \pi_c \mathbb{P}(v_1v_2) \leq \pi_c W_k(i),
\]  

(3.54)

and therefore \( \mathbb{E}[|C_{k+1}(i)|] \leq \pi_c \mathbb{E}[W_k(i)] \). Now the estimates in Proposition 3.11 prove (3.52). Using an identical argument as in (3.54) yields

\[
\mathbb{E}[|C_{2k+1}(i) \setminus C_{2k+1}^R(i)|] \leq \pi_c \mathbb{E}[W_{2k}(i)],
\]  

and (3.53) follows from Proposition 3.12.
Proof of Theorem 3.14. Let us consider the breadth-first exploration of $\mathcal{G}(i)$ starting from vertex $i$. Let $F_k$ denote the sigma-algebra that contains information about the exploration when all vertices at depth $k$ have been explored. Thus, $\cup_{k=1}^\infty \mathcal{G}_k(i)$ is measurable with respect to $F_k$. Using Lemma 3.15, and (3.51), it is now enough to show that, for each fixed $i \geq 1$ and $k, R \geq 1$,

$$|\mathcal{G}_2^n(i)\mathcal{G}(i)\mathcal{G}(i)| = \pi_c W^{\leq R}_{2k}(i) + o_p(n^\alpha \pi_c).$$

This follows from Chebyshev’s inequality if we can show that for any fixed $k, R \geq 1$,

$$\mathbb{E}[|\mathcal{G}_2^n(i)\mathcal{G}(i)\mathcal{G}(i)| | F_{2k}] = \pi_c W^{\leq R}_{2k}(i) + o_p(n^\alpha \pi_c), \quad \text{Var}(|\mathcal{G}_2^n(i)\mathcal{G}(i)\mathcal{G}(i)| | F_{2k}) \leq E_n,$$  

(3.55)

where $\mathbb{E}[E_n] = o(n^{2\alpha} \pi_c^2)$. To this end, we first note that

$$\mathbb{E}[|\mathcal{G}_2^n(i)\mathcal{G}(i)\mathcal{G}(i)| | F_{2k}] \leq \sum_{v \not\in \cup_{r \leq 2k} \mathcal{G}_r(i)} \sum_{u \in \mathcal{G}_2(i) \cap [R]} \pi_c p_{uv} \leq \sum_{u \in \mathcal{G}_2(i) \cap [R]} \sum_v \pi_c p_{uv}. \quad \text{(3.56)}$$

Further, using inclusion-exclusion with respect to the union of $u \in \mathcal{G}_2(i) \cap [R]$ (for each $v \notin \mathcal{G}_2(i)$), it follows that

$$\mathbb{E}[|\mathcal{G}_2^n(i)| | F_{2k}] \geq \sum_{v \not\in \cup_{r \leq 2k} \mathcal{G}_r(i)} \sum_{u \in \mathcal{G}_2(i) \cap [R]} \pi_c p_{uv} - \sum_{v \not\in \cup_{r \leq 2k} \mathcal{G}_r(i)} \sum_{u_1, u_2 \in \mathcal{G}_2(i) \cap [R]} \pi_c^2 p_{u_1v} p_{u_2v}. \quad \text{(3.57)}$$

Let us denote the first and second term in (3.57) by (I) and (II), respectively. Note that

$$(\text{II}) \leq \sum_{u_1, u_2 \in [R]} \sum_{v \in [n]} \pi_c^2 p_{u_1 v} p_{u_2 v} = O(1) = o(n^\alpha \pi_c), \quad \text{(3.58)}$$

almost surely, where the second step follows using (3.20) and (3.22). Further, we observe that

$$\frac{1}{n^\alpha \pi_c} \sum_{u \in \mathcal{G}_2(i) \cap [R]} \sum_v \pi_c (1 - e^{-w_u w_v / \ell_n}) \leq \frac{1}{n^\alpha \ell_n} \left( \sum_{r \leq 2k} W_r(i) \right)^2 = O_p(n^{\alpha - 1}) = o_p(1), \quad \text{(3.59)}$$

where in the second step, we have used Theorem 3.13. It thus follows that

$$\mathbb{E}[|\mathcal{G}_2^n(i)| | F_{2k}] \geq \sum_{u \in \mathcal{G}_2(i) \cap [R]} \sum_v \pi_c p_{uv} + o_p(n^\alpha \pi_c). \quad \text{(3.60)}$$

We now simplify the right hand side of (3.60). Fix $\varepsilon \in (0, \rho^2)$, and let us split the sum in two parts with $\{v : w_v \leq n^{\rho^2 - \varepsilon}\}, \{v : w_v > n^{\rho^2 - \varepsilon}\}$, and denote them by (Ia) and (Ib) respectively. Using Lemma 3.37, and the fact that $-\rho(r - 2) + \varepsilon(r - 1) < 0$ since $\varepsilon < \rho^2$,

$$\frac{(\text{Ib})}{n^\alpha \pi_c} \leq CR \frac{n^{1-(r-1)\rho+\varepsilon(r-1)}}{n^\alpha} \leq CR n^{-\rho(r-2)+\varepsilon(r-1)} = o(1), \quad \text{almost surely}, \quad \text{(3.61)}$$

while

$$\frac{(\text{Ia})}{n^\alpha \pi_c} = \sum_{w_u \leq n^{\rho^2 - \varepsilon}} \frac{w_u w_v}{\ell_n(1 + o(1))} = \pi_c W^{\leq R}_{2k}(i)(1 + o(1)). \quad \text{(3.62)}$$

The estimate for the expectation term in (3.55) now follows.

For $u \in \mathcal{G}_2(i)$, let $N_u$ denote the number of neighbors of $u$ in $\mathcal{G}_2(i)$. For the variance term, it follows using the independence of edge occupancies that

$$\text{Var}(|\mathcal{G}_2^n(i)| | F_{2k}) = \sum_{u \in \mathcal{G}_2(i) \cap [R]} \text{Var}(N_u) \leq \sum_{u \in \mathcal{G}_2(i) \cap [R]} \sum_v \pi_c p_{uv} \leq \pi_c W^{\leq R}_{2k}(i) =: E_n. \quad \text{(3.63)}$$

Using (3.50) and the fact that $n^{-\alpha} W^{\leq R}_{2k}(i)$ is bounded, we see that $\mathbb{E}[E_n] = O(n^\alpha \pi_c) = o(n^{2\alpha} \pi_c^2)$, which proves the required estimate in (3.55). Hence, the proof of Theorem 3.14 is complete. ■
3.6 Tightness of component sizes and weights: Proof of Theorem 2.3

The goal of this section is to show that the vector of component sizes and their weights (appropriately normalized) is tight in $\ell^2$. The proof will also show that the largest connected components correspond to those containing hubs. Then the proof of Theorem 2.3 will follow using Theorems 3.13–3.14. To this end, define

$$C_\leq(j) = \begin{cases} C(j) & \text{if } j = \min \{ v : v \in C(j) \}, \\ \emptyset & \text{otherwise}, \end{cases}$$

and let $W_\leq(j) := \sum_{k \in C_\leq(j)} w_k$. The main ingredient is the following proposition:

**Proposition 3.16 (Tightness in $\ell^2$).** Suppose that $\lambda \in (0, \lambda_c)$. For any $\varepsilon > 0$,

$$\lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P} \left( \sum_{j > K} \left| C_\leq(j) \right|^2 > \varepsilon \pi_c^2 n^{2\alpha} \right) = 0, \quad \lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P} \left( \sum_{j > K} \left| W_\leq(j) \right|^2 > \varepsilon \pi_c^2 n^{2\alpha} \right) = 0. \quad (3.65)$$

**Proof.** Recall that $C(i)$ is the $i$-th largest component of $\text{NR}_n(w, \pi_c)$, $W(i) = \sum_{v \in C(i)} w_v$ (we have suppressed the dependence of $\pi_c = \pi_c(\lambda)$ in the notation). For a fixed $K \geq 1$, consider the graph $\text{NR}_n(w, \pi_c) \setminus [K]$. We augment a previously defined notation with a superscript $> K$ to denote the corresponding quantity for $\text{NR}_n(w, \pi_c) \setminus [K]$. Since the components $\{C(j) : j > K\}$ do not contain any vertices in $[K]$, $\sum_{j > K} |C(j)|^2 \leq \sum_{i \geq 1} |C(i)|^2$. Therefore, it is enough to show that for any $\varepsilon > 0$,

$$\lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P} \left( \sum_{i \geq 1} \left| C(i)^e \right|^2 > \varepsilon \pi_c^2 n^{2\alpha} \right) = 0, \quad \lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P} \left( \sum_{i \geq 1} \left| W(i)^e \right|^2 > \varepsilon \pi_c^2 n^{2\alpha} \right) = 0. \quad (3.66)$$

Using the weight sequence $(w_i)_{i \geq K}$, let $V_{n,K}^* \subset [n \setminus [K]]$ denote a vertex chosen in a size-biased manner from $[n \setminus [K]]$ chosen independently from $\text{NR}_n(w, \pi_c)$ (i.e., for any $i > K$, $\mathbb{P}(V_{n,K}^* = i) \propto w_i$). Let $L_{n,K} := \sum_{i > K} w_i$. Then, $L_{n,K} \leq L_n$ for all $K \geq 1$. Note that (3.54) yields

$$\mathbb{E} \left[ \sum_{i \geq 1} \left| C(i)^e \right|^2 \right] = \mathbb{E} \left[ \sum_{v \in [n] \setminus [K]} \left| C^e(v) \right| \right] \leq \pi_c \mathbb{E} \left[ \sum_{v \in [n] \setminus [K]} W^e(v) \right] \leq \pi_c \mathbb{E} \left[ \sum_{i \geq 1} \left| C(i)^e \right| \times W^e(i) \right] = \pi_c \mathbb{E} \left[ \max_{i \geq 1} \left| C(i)^e \right| \times W^e(i) \right] \leq \pi_c \mathbb{E} \left[ \max_{i \geq 1} \left| C(i)^e \right| \right] \cdot \mathbb{E} \left[ W^e(V_{n,K}^*) \right]. \quad (3.67)$$

Further,

$$\mathbb{E} \left[ \sum_{i \geq 1} \left| W^e(i) \right|^2 \right] = \mathbb{E} \left[ \sum_{i \geq 1} \left| W(i)^e \right|^2 \right] = \mathbb{E} \left[ W^e(V_{n,K}^*) \right]. \quad (3.68)$$

Now, by (3.42) and (3.46), for any fixed $v \in [n]$, $\mathbb{E}[W^e(v)] \leq Cn^t(v-b + n^{-\varepsilon}\alpha v^{-1+b})$, where $C > 0$ is independent of $K$, and hence,

$$\mathbb{E}[W^e(V_{n,K}^*)] \leq Cn^t(b + n^{1-b} + n^{2\alpha-\varepsilon}). \quad (3.69)$$

Since $b \in (\frac{1}{2}, \alpha)$, both $\sum_{v > K} \frac{1}{v^{1+b}}$ and $\sum_{v > K} \frac{1}{v^{1-b}}$ go to zero as $K \to \infty$. Therefore,

$$\lim_{K \to \infty} \limsup_{n \to \infty} \sum_{i \geq 1} \left| C(i)^e \right|^2 = 0, \quad \lim_{K \to \infty} \limsup_{n \to \infty} \sum_{i \geq 1} \left| W(i)^e \right|^2 = 0. \quad (3.70)$$

Thus, (3.67) follows using Markov’s inequality completing the proof of Proposition 3.16. ■
Proof of Theorem 2.3. We give the proof for the component sizes. The proof for the weight follows similarly. Let $\mathcal{C}_{(i),K}$ be the $r$-th largest component among $\{\mathcal{C}_{(i),j} : j \leq K\}$. For $K = \infty$, $\mathcal{C}_{(i),K} = \mathcal{C}_{(i)}$. We first show that for each fixed $i \geq 1$, $\mathcal{C}_{(i)} \approx \mathcal{C}_{(i),K}$ if $K$ is large. More precisely, for any fixed $r \geq 1$ and $\varepsilon > 0$,

$$
\lim_{K \to \infty} \limsup_{n \to \infty} \mathbb{P}(\exists i : ||\mathcal{C}_{(i),K}|| - ||\mathcal{C}_{(i)}|| > \varepsilon n^{\alpha}) = 0.
$$

(3.72)

Indeed, if $\mathcal{C}_{(i),K} \neq \mathcal{C}_{(i)}$, then $\mathcal{C}_{(i)} = \max\{\mathcal{C}_{(i),j} : j > K\}$, and therefore

$$
||\mathcal{C}_{(i),K}|| - ||\mathcal{C}_{(i)}|| \leq \left( \sum_{j > K} ||\mathcal{C}_{(i),j}||^2 \right)^{1/2}.
$$

(3.73)

Next, on the event $\{\mathcal{C}_{(i),K} = \mathcal{C}_{(i)}\}$, we can similarly bound $||\mathcal{C}_{(i),K}|| - ||\mathcal{C}_{(i)}|| \leq (\sum_{j > K} ||\mathcal{C}_{(i),j}||^2)^{1/2}$ and in general on the event $\{\mathcal{C}_{(i),K} = \mathcal{C}_{(i)}, \forall i \in [r-1]\}$, we can also bound $||\mathcal{C}_{(i),K}|| - ||\mathcal{C}_{(i)}|| \leq (\sum_{j > K} ||\mathcal{C}_{(i),j}||^2)^{1/2}$. Thus (3.72) follows using Proposition 3.16.

Next, note that $(\mathcal{C}_{(i),j})_{j \in [K]}$ is the collection of components $(\mathcal{C}_{(j)})_{j \in [K]}$ with multiplicities removed and replaced by empty sets (recall (3.64)). Thus, $||\mathcal{C}_{(i),K}|| = \max_{j \in [K]} ||\mathcal{C}_{(j)}||$, and similar identities holds for $||\mathcal{C}_{(i)}||$. Thus, using (3.72) and Theorem 3.14, we conclude that $(n^{\alpha} \pi_\varepsilon)^{-1} ||\mathcal{C}_{(i)}||_{\ell^1}$ converges to our desired limiting object in finite-dimensional sense. The $\ell^2$-tightness follows by observing that $\sum_{j > K} ||\mathcal{C}_{(j)}||^2 \leq \sum_{j > K} ||\mathcal{C}_{(i),j}||^2$.

#### 3.7 Sub-critical behavior: proof of Theorem 2.2

The proof of Theorem 2.2 can be completed by modifying the arguments for the critical regime. In fact, if $\pi_n = \lambda_n n^{-1} = \infty$ for some $\lambda_n \to 0$, then the hub-connection probabilities tend to zero as shown in (3.26). Moreover, we can follow identical arguments as in Proposition 3.11 and Lemma 3.15 to show that $W(i) = w_i(1 + \alpha w_i(1 + \alpha w_i))$ and $||\mathcal{C}_{(i)}|| = \pi_n w_i(1 + \alpha w_i)$. To successfully apply Chebyshev’s inequality to get these asymptotics, we need $\pi_n w_i \to \infty$, which is true since $\pi_n \geq n^{-\alpha}$ by the assumptions of Theorem 2.2. Finally, we can use identical arguments as in Proposition 3.16 to deduce the $\ell^2$-tightness of the vector of component sizes and weights. Thus, the proof of Theorem 2.2 follows.

### 4 The giant in the embedded inhomogeneous random graph

Henceforth, we consider the supercritical case, i.e., $\pi_n = \lambda n^{-\nu}$ for $\lambda > \lambda_c$. In this section, we proceed to set up the main conceptual ingredients for the emergence of the giant for $\lambda > \lambda_c$. Fix a parameter $a > 0$, and define

$$
N_n(a) = \lfloor an^{(\delta-\tau)/2} \rfloor.
$$

(4.1)

We also denote

$$
N_n = N_n(1).
$$

(4.2)

By (2.6), we note that, for $i \in [N_n u]$ and $u \in (0, a]$

$$
w_i[u] = c_x u^{-\alpha}\left(\frac{n}{N_n}\right)^{\alpha} = c_x u^{-\alpha}\left(n^{(\alpha-1)/2}\right)^{\alpha} \approx \sqrt{n} c_x u^{-\alpha},
$$

(4.3)

and thus $[N_n(a)]$ consists of vertices with weight at least of order $\sqrt{na^{-\alpha}}$.

The key conceptual step is that, if $a$ is large enough, then a giant component emerges inside $[N_n(a)]$ that forms the core connectivity structure of the giant component in the whole graph. In turn, this graph is an inhomogeneous random graph, for which the critical value can be determined exactly, as we explain in more detail now.
To this end, consider the percolated graph \( NR_n(w, \pi_n) \), restricted to \( [N_n(a)]_\cdot \) and denote this subgraph by \( G_{N_n(a)} \). Then, \( G_{N_n(a)} \) is distributed as an inhomogeneous random graph that is sparse in that the number of edges grows linearly in the number of vertices in the graph. Thus, the emergence of the giant component within \( G_{N_n(a)} \) can be studied using the general setting of inhomogeneous random graphs developed by Bollobás, Janson and Riordan in [14]. In particular, the results of [14] gives a critical value \( \lambda_c(a) \), such that, for \( \lambda > \lambda_c(a) \), a unique and highly concentrated giant exists inside \( [N_n(a)]_\cdot \), that is stable to the addition of a small proportion of edges. The stability result is used later in Section 5 below to understand the perturbation on this giant after adding all the edges outside \( [N_n(a)]_\cdot \). In Section 4.1, we make the connection with the key results from [14] explicit and state the relevant results for our proof.

The rest of the section is devoted to analysis of the limiting quantities as \( a \to \infty \). In Section 4.2, we first show that \( \lim_{n \to \infty} \lambda_c(a) = \lambda_c \), where \( \lambda_c \) is given by (2.10). The connection between \( \lambda_c(a) \) and \( \lambda_c \) is quite remarkable given the vastly different descriptions of these quantities. We prove this fact by an explicit computation. The convergence of \( \lambda_c(a) \) is also a key conceptual step, since it shows that, whenever \( \lambda > \lambda_c \), one can choose \( a \) to be large enough to make a tiny giant appear inside \( [N_n(a)]_\cdot \). Finally, the asymptotics for functionals of the giant inside \( G_{N_n(a)} \) are given by survival probabilities of certain multitype branching processes that depend sensitively on \( a \). In Section 4.3, we analyze these survival probabilities as \( a \to \infty \). This sets the stage for Section 5, where we identify the primary contributions to the size of the giant in the whole graph using the giant inside \( [N_n(a)]_\cdot \), for \( a \) large enough.

### 4.1 Size and weight of the giant core

Consider the measure space \( S_a = ((0, a], B((0, a]), \Lambda_a) \), where \( B((0, a]) \) denotes the Borel sigma-algebra on \((0, a]\), and \( \Lambda_a(dx) = \frac{1}{a} dx \) is the normalized Lebesgue measure on \((0, a]\). Recall from (2.2) that the probability that there is an edge between \( i \) and \( j \) after percolation equals \( p_{ij} = \pi_n[1 - e^{-w_i w_j / \ell_n}] \). For \( u, v \in (0, a] \), define the kernel

\[
\kappa_n^{(a)}(u, v) = \frac{p_{uv}}{\lambda}.
\]

Then putting \( u_i^n = i/N_n \), we have that for all \( i \in [N_n(a)]_\cdot \), \( p_{ij} = \lambda \kappa_n^{(a)}(u_i^n, u_j^n)/N_n(a) \). Obviously, the empirical measure \( \Lambda_{n,a} \) of \((u_i^n)_{i \in [N_n(a)]_\cdot} \) converges in the weak topology, with limiting measure \( \Lambda_a \). This verifies [14, (2.2)], and thus \( (S_a, ((u_i^n)_{i \in [N_n(a)]_\cdot})_{n \geq 1}) \) is a vertex space according to the definition in [14, Section 2].

Next, we verify that \( (\kappa_n^{(a)})_{n \geq 1} \) is a sequence of graphical kernels on \( S_a \) according to [14, Definition 2.9]. For any \((u_n, v_n)_{n \geq 1}, (u, v) \in (0, a] \) and \( u_n \to u \) and \( v_n \to v \), it follows using (4.3) that

\[
\kappa_n^{(a)}(u_n, v_n) \to \kappa^{(a)}(u, v) := a[1 - e^{-\gamma^2(uv)^{-\alpha}/\mu}] \quad \text{for all } u, v \in (0, a] .
\]

Note that \( \kappa^{(a)} \) is bounded and continuous, and thus the first two conditions of [14, Definition 2.7] are satisfied. Next, note that Lemma 3.7 yields

\[
\frac{1}{N_n(a)} \sum_{i,j \in [N_n(a)]_\cdot; i < j} \pi_n[1 - e^{-w_i w_j / \ell_n}] \to \frac{\lambda}{2a} \int_0^a \int_0^a [1 - e^{-\gamma^2(uv)^{-\alpha}/\mu}]dudv = \frac{1}{2} \int_0^a \int_0^a \lambda \kappa^{(a)}(u, v)\Lambda_a(du)\Lambda_a(dv),
\]

which verifies [14, (2.11)], and thus all the conditions of [14, Definition 2.9] have now been verified. Finally, \( \kappa^{(a)} > 0 \), so that it is irreducible, according to [14, Definition 2.10]. Hence we have verified that \( G_{N_n(a)} \) is an inhomogeneous random graph with kernels \( (\kappa_n^{(a)})_{n \geq 1} \) satisfying all the requisite good properties in [14].
To describe the phase transition, define the integral operator $T_{\kappa^{(a)}} : L^2(S_a) \mapsto L^2(S_a)$ by
\[
(T_{\kappa^{(a)}} f)(u) = \int_0^a \kappa^{(a)}(u, v) f(v) \Delta_a(du) = \int_0^a [1 - e^{-\frac{\kappa^{(a)}(uv)}{\rho}}] f(v)dv,
\]
(4.7)
and let $\|T_{\kappa^{(a)}}\|$ denote its operator norm. Let $\mathcal{G}_{(i)}^{a}$ denote the size of $i$-th largest component of the graph $G_{Nn(a)}$. Also, let $T_{\kappa^{(a)}}^{a,k}$ denote the set of vertices that belong to some component of size at least $k$ in $G_{Nn(a)}$.

Throughout this section, we suppress $\pi_n$ in the notation. To describe the size of the giant component in $[N_n(a)]$, let $X_a^A(u)$ be a multi-type branching process with type space $S_a$, where we start from one vertex with type $u \in S_a$, and a particle of type $v \in S_a$ produces progeny in the next generation according to a Poisson process on $S_a$ with intensity $\lambda \kappa^{(a)}(v, x) \Delta_a(dx)$. Let $\rho^\lambda_a(u)$ be the survival probability of $X_a^A(u)$, and $\rho_{a,\geq k}^\lambda$ denote the probability that $X_a^A(u)$ has at least $k$ individuals. Define
\[
\rho^\lambda_a = \int_0^a \rho^\lambda_a(u) \Delta_a(du) = \frac{1}{a} \int_0^a \rho^\lambda_a(u)du,
\]
\[
\lambda_{a,\geq k}^\lambda = \int_0^a \rho_{a,\geq k}^\lambda(u) \Delta_a(du) = \frac{1}{a} \int_0^a \rho_{a,\geq k}^\lambda(u)du.
\]
(4.8)

The following proposition describes the emergence of the giant component for $G_{Nn(a)}$:

**Proposition 4.1** (Emergence of giant in $G_{Nn(a)}$). Under Assumption 2.1, the following hold for any $a > 0$:

(i) For $\lambda > \|T_{\kappa^{(a)}}||^{-1}$, $|\mathcal{G}_{(i)}^{a}| = N_n(a)\rho^\lambda_a(1 + o_\pi(1))$, and $|\mathcal{G}_{(a)}^{a}| = O_\pi(log(n))$. Further, for each fixed $k \geq 1$, $|T_{\kappa^{(a)}}^{a,k}| = N_n(a)\rho_{a,\geq k}^\lambda(1 + o_\pi(1))$. Finally, $T_{\kappa^{(a)}}^{a,k}$ is stable, in the sense that, for every $\varepsilon > 0$, there exists a $\delta > 0$ such that, with high probability, removing at most $\delta n$ edges from $G_{Nn(a)}$ changes $T_{\kappa^{(a)}}^{a,k}$ by at most $\varepsilon n$ vertices.

(ii) For $\lambda < \|T_{\kappa^{(a)}}||^{-1}$, $|\mathcal{G}_{(a)}^{a}| = O_\pi(log(n))$.

**Proof.** The asymptotics of $|\mathcal{G}_{(i)}^{a}|$ follow directly by applying [14, Corollary 3.2] and [14, Theorem 3.12], and further noting that $\sup_{n,x,y} \kappa^{(a)}_{Nn}(x, y) < \infty$. The asymptotics of $|T_{\kappa^{(a)}}^{a,k}|$ follows using [14, Theorem 9.1]. The stability of the giant in part (i) is proved in [14, Theorem 11.1].

We conclude this section by providing the asymptotics of the total weight inside $\mathcal{G}_{(i)}^{a}$:

**Proposition 4.2** (Weight of the giant in $G_{Nn(a)}$). Under Assumption 2.1, for any fixed $a > 0$, as $n \rightarrow \infty$,
\[
\sum_{i \in \mathcal{G}_{(i)}^{a}} \frac{\pi_n w_i}{\sqrt{n}} \rightarrow P \zeta^\lambda_a,
\]
(4.9)
where $\zeta^\lambda_a := \lambda \int_0^a c_\pi u^{-\alpha} \rho^\lambda_a(u)du$.

**Proof.** We apply [14, Theorem 9.10]. First the contribution due to $i \leq N_n(\varepsilon)$ can be almost surely bounded by
\[
\frac{1}{N_n(a)} \sum_{i \in [N_n(\varepsilon)]} \frac{w_i}{\sqrt{n}} \leq \frac{c_\pi n^\alpha}{N_n(a) \sqrt{n}} \sum_{i \leq N_n(\varepsilon)} i^{-\alpha} \leq \frac{C_\pi^{1-\alpha}}{a},
\]
(4.10)
Further, for all $i \in [N_n(a)] \setminus [N_n(\varepsilon)]$, the function $i \mapsto w_i / \sqrt{n}$ is bounded. Thus, [14, Theorem 9.10] is applicable and we have
\[
\sum_{i \in \mathcal{G}_{(i)}^{a}} \frac{\pi_n w_i}{\sqrt{n}} = \frac{\lambda a}{N_n(a)} \sum_{i \in \mathcal{G}_{(a)}} \frac{w_i}{\sqrt{n}} \rightarrow a\lambda \int_0^a c_\pi u^{-\alpha} \rho^\lambda_a(u) \Delta_a(du) = \zeta^\lambda_a,
\]
(4.11)
and the proof follows. 

\[\]
4.2 Equality of the critical values

In this section, we relate the critical values in the inhomogeneous random graph \( G_{N_n(a)} \), for \( a \) large, to the critical value \( \lambda_c \) defined in (2.10). Let us denote \( \lambda_c(a) = \| T_{\kappa(a)} \|^{-1} \). We start by observing a monotonicity of \( \lambda_c(a) \):

**Lemma 4.3 (Monotonicity of \( a \mapsto \lambda_c(a) \)).** The function \( a \mapsto \lambda_c(a) \) is non-increasing on \([0, \infty)\).

*Proof.* Fix \( b > a \), and let \( N_n(a) \) be as in (4.1). Fix \( \lambda > \lambda_c(a) \). We will prove that then also \( \lambda > \lambda_c(b) \), which proves that \( \lambda_c(a) \geq \lambda_c(b) \), as required.

Since \( \lambda > \lambda_c(a) \), Proposition 4.1 implies that the graph \( G_{N_n(a)} \) on vertex set \([N_n(a)]\) has a giant component of size \( \rho_a^N N_n(a)(1 + o_T(1)) \), where \( \rho_a^N > 0 \) since \( \lambda > \lambda_c(a) \). Denote this component by \( \mathcal{C}^a_{(1)} \). Since \([N_n(a)] \subseteq [N_n(b)]\), and since the edge probabilities in \( G_{N_n(a)} \) and \( G_{N_n(b)} \) are equal on \([N_n(a)]\), we can find a coupling under which \( G_{N_n(a)} \) is a subgraph of \( G_{N_n(b)} \) with probability one. Under this coupling, there exists a component of \( \mathcal{C} \subseteq G_{N_n(b)} \) such that \( \mathcal{C}^a_{(1)} \subseteq \mathcal{C} \).

For any \( q > 0 \), if \( |\mathcal{C}^a_{(1)}| \geq q N_n(a) \), then \( |\mathcal{C}| \geq q N_n(a) \geq q(a/b) N_n(b) \). Thus, as \( n \to \infty \), \( P(\mathcal{C}^a_{(1)} / N_n(b) \geq q(\rho_a^N)^{1/q}) \to 1 \), and therefore \( \lambda > \lambda_c(b) \) by Proposition 4.1, as required. \( \blacksquare \)

Lemma 4.3 implies that \( \lim_{a \to \infty} \lambda_c(a) \) exists and is finite. Let

\[
\lambda_c^{RG} := \lim_{a \to \infty} \lambda_c(a) = \inf_{a > 0} \lambda_c(a). \tag{4.12}
\]

We next show that \( \lambda_c^{RG} = \lambda_c \):

**Lemma 4.4 (Equality of critical values).** \( \lambda_c^{RG} = \lambda_c \), with \( \lambda_c, \lambda_c^{RG} \) defined in (2.10), (4.12) respectively.

*Proof.* Fix \( a > 0 \). For two functions \( f, g : \lbrack 0, a \rbrack^2 \to \lbrack 0, \infty \)\), we define the operation

\[
(f * g)(x, y) = \int_0^a f(x, v)g(v, y)\Lambda_a(dv). \tag{4.13}
\]

We also recursively define \( f^{*n+1} = f * f^n \), with \( f^{*1} = f \). We claim that

\[
\| T_{\kappa(a)} \| = \lim_{k \to \infty} \left( \int_0^a \int_0^a (\kappa^{a})^{*2k}(u, v)\Lambda_a(du)\Lambda_a(dv) \right)^{1/(2k)}. \tag{4.14}
\]

Indeed, \( \kappa^{a} \) is a bounded function, so that the integral operator \( T_{\kappa^{a}} \) defined on \( L^2([0, a], \Lambda_a) \) given by (4.7) is Hilbert-Schmidt and thus compact [35, Theorem 4 in Chapter 22]. Further, it is a positive and self-adjoint operator, since \( \kappa^{(a)} \) is positive and symmetric. Thus, the largest eigenvalue of \( T_{\kappa^{a}} \) is positive and separated from the second largest in absolute value [35, Theorem 1 in Chapter 23]. Finally, as a compact and self-adjoint operator, it has an orthonormal basis of eigenfunctions [35, Theorem 3 in Chapter 28], so that the claim follows by an expansion in terms of the eigenfunctions. We can rewrite this with \( \kappa^{(a)}_{2}(u, v) = (\kappa^{a} * \kappa^{a})(u, v) \) as

\[
\| T_{\kappa^{(a)}} \| = \lim_{k \to \infty} \left( \int_0^a \int_0^a (\kappa^{(a)}_{2})^{*k}(u, v)\Lambda_a(du)\Lambda_a(dv) \right)^{1/(2k)}. \tag{4.15}
\]

As a result,

\[
\| T_{\kappa^{(a)}} \| = \| T_{\kappa^{(a)}_{2}} \|^{1/2}. \tag{4.16}
\]

Next, note that, for any \( u, v \in (0, a) \),

\[
\kappa^{(a)}_{2}(u, v) = \int_0^a \kappa^{a}(u, x)\kappa^{a}(v, x)\Lambda_a(dx) = a \int_0^a [1 - e^{-\phi(x)^{-a}/\mu}] \int_0^a [1 - e^{-\phi(x)^{-a}/\mu}] dx
\]

\[
= a \int_0^a \Theta_u(x)\Theta_v(x) dx,
\]

24
where we recall (2.13). When the integral is evaluated on $[0, \infty)$, $n_2^{(o)}(u, v)$ would be equal to $a \lambda_{uv}/\lambda^2$. Thus,

$$\|T_{n_2^{(o)}}\| = \|T_{\lambda^{(o)}}\|_{L^2(0, \infty)} = \|T_{\lambda^{(o)}}\|_{L^2(0, \infty)},$$  \hspace{1cm} (4.17)

where, for $u, v \in (0, a]$, we let

$$\bar{\lambda}^{(o)}(u, v) = 1_{(u, v) \in (0, a]} \int_0^u \Theta_u(x) \Theta_v(x) dx.$$  \hspace{1cm} (4.18)

Obviously, $a \mapsto \bar{\lambda}^{(o)}(u, v)$ is increasing, and it converges pointwise to $\lambda_{uv}/\lambda^2$. As a result, also

$$\|T_{\bar{\lambda}^{(o)}}\| = \|T_{\lambda^{(o)}}\|_{L^2(0, \infty)} \rightarrow \|T_{\lambda}\|_{L^2(0, \infty)},$$  \hspace{1cm} (4.19)

where $\lambda(u, v) = \lambda_{uv}/\lambda^2$. Next, recall $h(\cdot, \cdot)$ from (3.1). An argument identical to (3.4) yields

$$\lim_{u \to \infty} \lim_{v \to \infty} \lambda(u, v)/h(u, v) = 1.$$  

Thus, by [27, Lemma 1],

$$\|T_{\lambda}\|_{L^2(0, \infty)} = \int_0^\infty \frac{h(1, u)}{\sqrt{u}} du = 4B_\alpha/\eta,$$  \hspace{1cm} (4.20)

where the last step follows using (3.2). Therefore,

$$\lambda_c^{\text{large}} = \lim_{a \to \infty} \|T_{\lambda^{(o)}}\|^{-1} = \lim_{a \to \infty} \frac{1}{\|T_{n_2^{(o)}}\|^{1/2}} = \sqrt{\frac{\eta}{4B_\alpha}} = \lambda_c,$$  \hspace{1cm} (4.21)

as required. 

4.3 Survival probability of the multi-type branching process

In this section, we analyze the asymptotics in Proposition 4.2 as $a \to \infty$. Recall the multi-type Poisson branching process $\Lambda_a^{\alpha}(u)$, and its survival probability $\rho_a^{\lambda}(u)$ from Section 4.1. Recall the definition of $\zeta_a^{\lambda}$ from Proposition 4.2. The following is the main result of this section:

**Proposition 4.5** (Large $a$ asymptotics of one-neighborhood giant). For any $\lambda > \lambda_c$, as $a \to \infty$,

$$\zeta_a^{\lambda} := \lambda \int_0^a c_x u^{-\alpha} \rho_a^{\lambda}(u) du \to \zeta^{\lambda} \in (0, \infty).$$  \hspace{1cm} (4.22)

Before starting with the proof, we give some background on the object in (4.22). $\rho_a^{\lambda}(u)$ is the survival probability of a vertex of type $u$, which in the pre-limit corresponds to vertex $[uN_n]$. The factor $c_x u^{-\alpha}$ then corresponds to the rescaled version of $w_{[uN_n]}$, recall (4.3). Thus, $\zeta_a^{\lambda}$ can be viewed as the rescaled total weight or the rescaled size of the one-neighborhood of the giant in $[N_n(a)]$. Since, for $a$ large, this one-neighborhood is approximately the entire connected component of this giant in $[n]$, as shown in Section 5, this explains the relevance of Proposition 4.5.

We would like to stress some subtleties. First, $u \mapsto c_x u^{-\alpha}$ is not integrable, so we cannot think of $\zeta_a^{\lambda}$ as a survival probability of a branching process starting with a type chosen in a size-biased manner. Further, $\kappa(u, v) = 1 - e^{-c_x (u-v)^{-\alpha}/\mu}$ is not integrable on $((0, \infty), dx \otimes dy)$. As a result, we cannot express the limit of survival probabilities $(\rho_a^{\lambda}(u))_{u \geq 0}$ in terms of a maximum fixed point equation, as a survival probability would be expressed. This is reflected in the fact that the maximum solution of the previous fixed point equation $f = 1 - e^{-T_x f}$ is always 1 for non-integrable $\kappa$. However, the limit of $\zeta_a^{\lambda}$ still exists, and we can prove this using alternative arguments.

The proof is organised as follows. We start by stating an upper bound on our random graph in terms of an unpercolated Norros-Reittu model. This upper bound is also useful in Section 5. Then, we perform a limiting argument on the survival probabilities to prove Proposition 4.5.
Upper bound by an unpercolated Norros-Reittu model. We next discuss a Norros-Reittu model without percolation, which contains the graph $\mathcal{G}_{N_n(a)}$ as a subgraph. The nice thing about unpercolated Norros-Reittu models is that the total progeny can be coupled to a branching process as shown in [38], and it is possible to do direct computations on the limiting branching process as we will see below in Lemma 4.7. This will be useful in showing finiteness of limiting quantities such as $\zeta^\lambda$ in (4.22). Note that

$$\pi_n p_{ij} = \pi_n [1 - e^{-w_i/w_j/\ell_n}] \leq 1 - e^{-\pi_n w_i/w_j/\ell_n}. \quad (4.23)$$

Indeed, the inequality in the second step of (4.23) is equivalent to the fact that, for every $p \in [0, 1]$ and $x \geq 0$,

$$1 - e^{-x} \leq \frac{1}{p} [1 - e^{-px}]. \quad (4.24)$$

For $x = 0$, both sides are equal. Differentiating with respect to $x$ gives that $e^{-x} \leq e^{-px}$, which is true since $p \in [0, 1], x \geq 0$. Now, recall the connection probabilities in the original model from (2.2). Then (4.23) shows that there exists a coupling such that $\mathcal{N}_n(w, \pi_n)$ is a subgraph of $\mathcal{N}_n(\pi_n w)$ with probability one. Henceforth, we will always work under this coupling.

For $\mathcal{N}_n(\pi_n w)$, it is known that, starting from any vertex $j$, the size of the connected component of $j$ can be bounded from above by the total progeny of a branching process, where the root has offspring distribution that is Poisson $(\pi_n w_j)$, while for all other vertices, the offspring distribution is mixed Poisson with mixing distribution $\pi_n W^*_n$, where $W^*_n$ has a size-biased distribution, i.e.,

$$\mathbb{P}(W^*_n \leq x) = \frac{\sum_{i \in [n]} w_i \mathbb{1}(w_i \leq x)}{\sum_{i \in [n]} w_i}. \quad (4.25)$$

This is proved by Norros and Reittu in [38]. Similar results can be proven when we restrict connected components to fixed subsets of $[n]$, as we will frequently rely on below. In particular, we can use this observation to the restricted set $[N_n(a)]$ when considering the graph $\mathcal{G}_{N_n(a)}$. For this, we start by introducing some notation. For $A \subseteq [n]$, denote

$$w(A) = \sum_{a \in A} w_a. \quad (4.26)$$

Then, we note that when restricting to $[N_n(a)]$, the parameter of the Poisson random variable of the root when starting from vertex $j \in [N_n(a)]$ is replaced with $\pi_n w_j/[N_n(a)]/\ell_n$, and that, for other vertices, the offspring becomes Poisson with mixing distribution

$$W^\lambda_{[N_n(a)]} := \pi_n W^*_{[N_n(a)]} w([N_n(a)])/\ell_n, \quad (4.27)$$

where now

$$\mathbb{P}(W^\lambda_{[N_n(a)]} \leq x) = \frac{\sum_{i \in [N_n(a)]} w_i \mathbb{1}(w_i \leq x)}{w([N_n(a)])}. \quad (4.28)$$

This is formalized in the following lemma, which we state more generally, as we will rely upon it in various parts of the proof as well:

**Lemma 4.6** (Branching process upper bound on components restricted to subsets). Let $A \subseteq [n]$, and consider the connected component of $\mathcal{N}_n(\pi_n w)$ of a vertex $j \in A$ restricted to $A$. The size of this connected component is stochastically upper bounded by the total progeny of a mixed-Poisson branching process, where the root has Poisson offspring with parameter $\pi_n w_j w(A)/\ell_n$, and all other vertices have mixed-Poisson offspring with mixing distribution $\pi_n W^\lambda_{A} w([N_n(a)])/\ell_n$ with

$$\mathbb{P}(W^\lambda_{A} \leq x) = \frac{\sum_{i \in A} w_i \mathbb{1}(w_i \leq x)}{w(A)}. \quad (4.29)$$
Proof. Fix \( A \subseteq [n] \). In \( NR_{\ell_n}(\pi_n w) \), two vertices \( i \) and \( j \) with \( i, j \in A \) share at least one edge with probability \( 1 - e^{-\pi_n w_i w_j/\ell_n} \), and all edges are independent. We now present another way to generate such independent edges.

For \( j \in A \), we draw a Poisson random variable with parameter \( \pi_n w_i w(A)/\ell_n \). We consider these to be the potential neighbors of \( j \). Then we assign a label to each of these potential neighbors, and this label equals \( i \) with probability

\[
q_A(i) = \frac{w_i}{w(A)}, \quad i \in A.
\]

(4.30)

Retain an edge between \( i \) and \( j \) when there is at least one potential neighbor of \( j \) with label \( i \). Then, for fixed \( j \), the numbers of neighbors with label \( i \) are independent Poisson random variables with parameters

\[
q_A(i) \frac{\pi_n w_j w(A)}{\ell_n} = \frac{\pi_n w_i w_j}{\ell_n},
\]

so that the probability that there is at least one potential neighbor with label \( j \) equals \( 1 - e^{-\pi_n w_i w_j/\ell_n} \), as required.

The above shows how the neighbors of a vertex \( i \) can be chosen. In order to obtain the stochastic upper bound on the connected components in Lemma 4.6, we explore the connected component in a breadth-first way. Then, it follows that the connected components with edge probabilities \( 1 - e^{-\pi_n w_i w_j/\ell_n} \) are obtained through a thinning of the above construction, where vertices in the tree are ordered in the breadth-first manner, and repetitions of the labels (as well as all their offspring) are removed.

Finally, we note that the above process of potential neighbors is a Poisson branching process with mixing distribution given by \( W_{\lambda}^* \) in (4.29). Indeed, we explore a single potential neighbors by first drawing its mark, and, given that its mark equals \( i \), drawing a Poisson random variable with parameter \( \pi_n w_i w(A)/\ell_n \) of potential neighbors. Then, the collection of potential neighbors (which includes the percolation component, due to the thinning) is a mixed-Poisson branching process where the root (which corresponds to the vertex with label \( j \)) has a Poisson offspring with parameter \( \pi_n w_j w(A)/\ell_n \), while all other vertices have offspring of a mixed-Poisson distribution with mixing parameter \( W_{\lambda}^* \) in (4.29). Thus the proof of Lemma 4.6 is complete.

Next, let us investigate the survival probabilities of the above branching process for \( A = [N_n(a)] \). Let \( \bar{\rho}_{n, \lambda}^* \) denote the survival probability of the above branching process with root also having the mixed Poisson offspring distribution with \( W_{\lambda}^* \) in (4.27). Also, let \( \bar{\rho}_{n, \lambda}^*(u) \) denote the survival probability when we start with vertex \( j = [u N_n] \). The following lemma investigates the asymptotics of these survival probabilities when \( n \to \infty \):

Lemma 4.7 (Survival probability for upper bounding branching process). For any \( \lambda > \lambda_c(a) \), as \( n \to \infty \), \( \bar{\rho}_{n, \lambda}^* \to \bar{\rho}_{\lambda}^* \), where \( \bar{\rho}_{\lambda}^* \) is the maximum solution satisfying

\[
\bar{\rho}_{\lambda}^* = (1 - \alpha)\alpha^{-1} \int_0^a u^{-\alpha}[1 - e^{-\lambda \bar{\rho}_{u-\alpha a}^*}]du,
\]

(4.32)

with \( \bar{\rho}_{\lambda}^* = \frac{\bar{\rho}_{\lambda}^*}{(1 - \alpha)\mu} \). Moreover, for all sufficiently large \( n \),

\[
\bar{\rho}_{n, \lambda}^*(u) \leq C \min\{1, u^{-\alpha}\},
\]

(4.33)

for some constant \( C = C(\lambda, \alpha) > 0 \) independent of \( a \).

Proof. We write

\[
\bar{w}_i = \frac{w_i \pi_n w(\lfloor N_n(a) \rfloor)}{\ell_n},
\]

(4.34)
Note that \( \mathbb{E}[(1-t)^X] = e^{-ct} \) for \( X \sim \text{Poisson}(c) \). Now, conditioning on the type of the root, the branching process dies out precisely when all the progeny of generation one dies out. Equating these probabilities, we get

\[
\bar{\rho}_{n,a}^\lambda = 1 - \sum_{i \in [N_n(a)]} \frac{w_i}{w([N_n(a)])} e^{-\bar{w}_i \bar{\rho}_{n,a}^\lambda} = \sum_{i \in [N_n(a)]} \frac{w_i}{w([N_n(a)])} [1 - e^{-\bar{w}_i \bar{\rho}_{n,a}^\lambda}]. \tag{4.35}
\]

Recalling \( N_n \) from (4.2), we rewrite the sum in an integral to obtain

\[
\bar{\rho}_{n,a}^\lambda = N_n \int_0^\alpha \frac{w_{[uN_n]}}{w([N_n(a)])} [1 - e^{-\bar{w}_{[uN_n]} \bar{\rho}_{n,a}^\lambda}] \, du. \tag{4.36}
\]

We further simplify

\[
w([N_n(a)]) = c_F \sum_{j=1}^{N_n(a)} \frac{(n/j)^\alpha}{\ell_n} \times \frac{c_F}{1 - \alpha} N_n(a)^{1-\alpha} = \frac{c_F}{1 - \alpha} \sqrt{n} N_n a^{1-\alpha}, \tag{4.37}
\]

while \( w_{[uN_n]} \propto c_F \sqrt{n} u^{-\alpha} \) by (4.3). We then conclude that

\[
\bar{w}_{[uN_n]} = w_{[uN_n]} \pi_n \frac{w([N_n(a)])}{\ell_n} \times \frac{c_F \sqrt{n} u^{-\alpha}}{1 - \alpha} \left( \frac{c_F}{1 - \alpha} \sqrt{n} N_n a^{1-\alpha} \right) \frac{\pi_n}{\mu n} = \lambda c_F u^{-\alpha} a^{1-\alpha}. \tag{4.38}
\]

Thus, by (4.28), and using \( \bar{w}_i \) defined in (4.38),

\[
\mathbb{P}(W_{N_n(a)}^\lambda \leq x) = \frac{1}{w([N_n(a)])} \sum_{i \in N_n(a)} w_i \mathbb{1}\{\bar{w}_i \leq x\} \times \frac{N_n}{w([N_n(a)])} \int_0^a \frac{w_{[uN_n]}}{w([N_n(a)])} \mathbb{1}\{\bar{w}_{[uN_n]} \leq x\} \, du
\]

\[
\sim (1 - \alpha) a^{\alpha - 1} \int_0^a u^{-\alpha} \mathbb{1}\{\lambda c_F u^{-\alpha} a^{1-\alpha} \leq x\} \, du. \tag{4.39}
\]

Let \( W_{\infty,a}^\lambda \) be a random variable with distribution function given by the right hand side of (4.39). Then \( W_{N_n(a)}^\lambda \xrightarrow{d} W_{\infty,a}^\lambda \). Thus, if \( \bar{\rho}_{n,a}^\lambda \) denotes the survival probability of the branching process with starting distribution and progeny distribution given by a mixed-Poisson random variable with parameter \( W_{\infty,a}^\lambda \), also

\[
\bar{\rho}_{n,a}^\lambda \to \bar{\rho}_{a}^\lambda. \tag{4.40}
\]

We conclude (4.32) by taking limit as \( n \to \infty \) in (4.36).

For (4.33), let us start with vertex \( j = [uN_n] \). The limit of \( \bar{\rho}_{n,a}^\lambda(u) \) exists using (4.39). By the fact that the branching process is i.i.d. after the first generation, using a union bound, this survival probability is at most the expected offspring of \( j = [uN_n] \) times \( \bar{\rho}_{n,a}^\lambda \). The expected offspring is

\[
\pi_n w_{[uN_n]} \frac{w_{[N_n(a)]}}{\ell_n} = \frac{c_F}{\mu} u^{-\alpha} \pi_n n^{-1/2} \sum_{j=1}^{N_n(a)} \left( \frac{n}{j} \right)^\alpha = C u^{-\alpha} \pi_n N_n(a)^{1-\alpha} n^{\alpha-1/2} = C u^{-\alpha} a^{1-\alpha}. \tag{4.41}
\]

Thus, for all sufficiently large \( n \),

\[
\bar{\rho}_{n,a}^\lambda(u) \leq C u^{-\alpha} a^{1-\alpha} \bar{\rho}_{a}^\lambda. \tag{4.42}
\]
The proof of (4.33) follows if we can show that \( \limsup_{a \to \infty} a^{1-\alpha} \rho_{a}^{\lambda} < \infty \). Using (4.32), and writing \( z_{a} = a^{1-\alpha} \rho_{a}^{\lambda} \),
\[
 z_{a} = (1-\alpha) \int_{0}^{a} u^{-\alpha} \left[ 1 - e^{-\lambda \bar{c} u^{-a} z_{a}} \right] du 
 \leq (1-\alpha) \int_{0}^{a} u^{-\alpha} \min\{1, \lambda \bar{c} u^{-a} z_{a} \} du 
 \leq C_{1} \left[ \int_{0}^{a} C_{2} z_{a}^{\frac{1}{\alpha}} du + z_{a} \int_{C_{2} z_{a}^{\frac{1}{\alpha}}}^{\infty} u^{-2\alpha} du \right] 
 \leq C z_{a}^{\frac{1-\alpha}{\alpha}}. 
\] (4.43)

Since \( \frac{1-\alpha}{\alpha} < 1 \), it follows that \( \limsup_{a \to \infty} z_{a} = \limsup_{a \to \infty} a^{1-\alpha} \rho_{a}^{\lambda} < \infty \). The proof of (4.33) is now completed using (4.42).

**Proof of Proposition 4.5.** First, note that \( \zeta_{a}^{\lambda} \) is non-decreasing in \( a \). Indeed, for \( b > a \), there exists a coupling under which \( \mathcal{G}_{N_{n}(a)} \subset \mathcal{G}_{N_{n}(b)} \). Under this coupling, by Proposition 4.1, the component of \( \mathcal{G}_{N_{n}(b)} \) containing \( \mathcal{C}_{(1)}^{a} \) has size \( \Theta_{p}(\log n) \), and since \( \mathcal{C}_{(1)}^{b} = O_{p}(\log n) \), it must be the case that \( \mathcal{C}_{(1)}^{a} \subset \mathcal{C}_{(1)}^{b} \) with high probability. By Proposition 4.2, it now follows that \( \zeta_{a}^{\lambda} \leq \zeta_{b}^{\lambda} \). Thus \( \lim_{a \to \infty} \zeta_{a}^{\lambda} \) exists and is positive.

Next, using (4.23), we have that, for any \( a > 0 \), \( \rho_{a}^{\lambda}(u) \leq \limsup_{n \to \infty} \rho_{n,a}^{\lambda}(u) \). Therefore, an application of (4.33) yields that
\[
 \lim_{a \to \infty} \zeta_{a}^{\lambda} \leq C \int_{0}^{\infty} u^{-\alpha} \min\{1, u^{-a} \} du < \infty,
\] (4.44)
and the proof of Proposition 4.5 follows.

### 5 Size of the tiny giant

In this section, we complete the proof of Theorem 2.6. To this end, fix \( \lambda > \lambda_{c} \). By Lemmas 4.3 and 4.4, \( \lambda > \lambda_{c}(a) \) for all sufficiently large \( a \). Therefore, by Proposition 4.1, the graph restricted to \( [N_{n}(a)] \) has a giant component \( \mathcal{C}_{(1)}^{a} \) of approximate size \( N_{n}(a) \rho_{a}^{\lambda} \), where \( \rho_{a}^{\lambda} > 0 \). We denote by \( \mathcal{C}_{(1)}^{a,*} \) the component of \( \text{NR}_{a}(w, \pi_{n}) \) containing \( \mathcal{C}_{(1)}^{a} \). The main idea is to show that the component \( \mathcal{C}_{(1)}^{a,*} \) is the unique giant component \( \mathcal{C}_{(1)} \) of \( \text{NR}_{n}(w, \pi_{n}) \), in the iterated limit as first \( n \to \infty \), followed by \( a \to \infty \).

Let us now explain in more detail how we aim to approach the proof. For \( j \in [N_{n}(a)] \), define \( \text{Span}_{a}(\{j\}) \) to be the set of vertices \( v \in [N_{n}(a)]^{c} \) such that there exists a path between \( j \) and \( v \) that lies entirely in \([N_{n}(a)]^{c} \). For \( V \subset [N_{n}(a)] \), we write \( \text{Span}_{a}(V) = \cup_{j \in V} \text{Span}_{a}(\{j\}) \).

We have that \( \text{Span}_{a}(\mathcal{C}_{(1)}^{a}) \subset \mathcal{C}_{(1)}^{a,*} \), but \( \mathcal{C}_{(1)}^{a,*} \) may be larger since \( \text{Span}_{a}(\mathcal{C}_{(1)}^{a}) \) may intersect with \( \text{Span}_{a}(\mathcal{C}_{(1)}^{0}) \) for some \( j \geq 2 \), in which case \( \mathcal{C}_{(1)}^{a,*} \) gets merged with \( \mathcal{C}_{(0)}^{a,*} \). To study the effect of such mergers, let us say that there is a **return path** between \( i, j \in [N_{n}(a)] \) if a path exists between \( i \) and \( j \) with at least one intermediate vertex in \([N_{n}(a)]^{c} \). In other words, the existence of a return path between \( i, j \in [N_{n}(a)] \) means that \( i, j \) become part of the same component only after adding the edges in \([N_{n}(a)]^{c} \).

Let \( \mathcal{R}_{(1)}^{a} \) denote the set of vertices \( v \in [N_{n}(a)] \) such that \( v \) is connected to some \( j \in \mathcal{C}_{(1)}^{a} \) only via a return path. Then,
\[
 \mathcal{C}_{(1)}^{a,*} = \mathcal{C}_{(1)} \cup \text{Span}_{a}(\mathcal{C}_{(1)}^{a}) \cup \mathcal{R}_{(1)}^{a} \cup \text{Span}_{a}(\mathcal{R}_{(1)}^{a}).
\] (5.1)

Our objective is to show that, for \( \lambda > \lambda_{c}(a) \) and large enough \( a \), the main contribution in \( \mathcal{C}_{(1)}^{a,*} \) comes from \( \text{Span}_{a}(\mathcal{C}_{(1)}^{a}) \). An important ingredient to such a proof is that \( |\text{Span}_{a}(\mathcal{C}_{(1)}^{a})| \) is asymptotically close to the size of the one-neighborhood of \( \mathcal{C}_{(1)}^{a} \) (see also Proposition 4.5 and the intuition below it).

The remainder of this section is organised as follows: We start by proving a lower and an upper bound on the span of \( \mathcal{C}_{(1)}^{a} \) in Sections 5.1 and 5.2 respectively. In Section 5.3, we show
that the contributions to the spans due to return paths is asymptotically negligible. In fact, we will show that the span of small subsets of vertices is small uniformly over the choice of the vertex sets (see Lemma 5.9). In Section 5.4 we show that with high probability there is no large component outside of \( [N_n(a)] \). We conclude with the proof of Theorem 2.6 in Section 5.5.

5.1 Concentration of the spans: lower bound

Fix \( a > 0 \) and recall the definitions of \( \mathcal{C} \) from Section 4, and that of Span\(_n\)\((V)\) for \( V \subseteq [N_n(a)] \) above (5.1). In this section, we obtain a lower bound on the asymptotic size of Span\(_n\)\((\mathcal{C}_1^{(1)})\), by proving a sharp approximation for the 1-neighborhood of \( \mathcal{C}_1^{(1)} \):

**Proposition 5.1** (Lower bound for the span). Fix \( \lambda > \lambda_c \). For any \( \varepsilon > 0 \), there exists \( a_1 = a_1(\varepsilon) > 0 \) such that, for all \( a \geq a_1 \),

\[
\lim_{n \to \infty} \mathbb{P} \left( \frac{\text{Span}_n(\mathcal{C}_1^{(1)})}{\sqrt{n}} \geq \zeta^\lambda - \varepsilon \right) = 1, \tag{5.2}
\]

where \( \zeta^\lambda \) is as in (4.22).

For \( V \subseteq [N_n(a)] \), let \( \mathcal{N}_l(V) \) denote the vertices in Span\(_n\)\((V)\) that are at distance \( l \) from \( V \), and let \( \mathcal{N}_{\geq l}(V) = \bigcup_{l' \leq l} \mathcal{N}_{l'}(V) \). Thus,

\[
\text{Span}_n(V) = \mathcal{N}_1(V) \cup \mathcal{N}_{\geq l}(V). \tag{5.3}
\]

Lemma 5.2 below identifies the asymptotics of the first term in (5.3). In the next section, where we analyze the upper bound on \( \text{Span}_n(\mathcal{C}_1^{(1)})\), we show that the second term in (5.3) gives a negligible contribution (see Lemma 5.5 below), but this is not needed for the lower bound in Proposition 5.1:

**Lemma 5.2** (Direct neighbors of \( [N_n(a)] \)). Let \( V \subseteq [N_n(a)] \) be such that \( \sum_{i \in V} \pi_n w_i \geq c_0 \sqrt{n} \) for some constant \( c_0 > 0 \). Then, for any fixed \( a > 0 \), and \( \varepsilon > 0 \), as \( n \to \infty \),

\[
\mathbb{P} \left( \left| \mathcal{N}_1(V) \right| - \sum_{i \in V} \pi_n w_i > \varepsilon \sqrt{n} \middle| \mathcal{G}_{N_n(a)} \right) \xrightarrow{P} 0. \tag{5.4}
\]

**Proof.** Let \( \mathbb{P}_1 \) and \( \mathbb{E}_1 \) denote the conditional probability and expectation, respectively, conditionally on \( \mathcal{G}_{N_n(a)} \). Let us first show that

\[
\mathbb{E}_1 \left[ \left| \mathcal{N}_1(V) \right| \right] = (1 + o(1)) \sum_{i \in V} \pi_n w_i + o(\sqrt{n}). \tag{5.5}
\]

Note that

\[
\left| \mathcal{N}_1(V) \right| = \sum_{j \notin [N_n(a)]} 1 \{ (i,j) \text{ create an edge for some } i \in V \}. \tag{5.6}
\]

Thus, by a union bound,

\[
\mathbb{E}_1 \left[ \left| \mathcal{N}_1(V) \right| \right] \leq \sum_{i \in V} \sum_{j \in [n]} \pi_n (1 - e^{-w_i w_j / \ell_n}). \tag{5.7}
\]

Moreover, using inclusion-exclusion, the expectation in (5.5) is at least

\[
\sum_{i \in V} \sum_{j \notin [N_n(a)]} \pi_n (1 - e^{-w_i w_j / \ell_n}) - \sum_{i_1, i_2 \in V} \sum_{j \notin [N_n(a)]} \pi_n^2 (1 - e^{-w_{i_1} w_j / \ell_n}) (1 - e^{-w_{i_2} w_j / \ell_n}). \tag{5.8}
\]
Now, by (4.37), \( \sum_{i \in V} w_i \leq \sum_{i \in [N_n(a)]} w_i \leq Ca^{1-\alpha}N_n\sqrt{n} \), and thus, using \( 1 - e^{-x} \leq x \), the second term is at most

\[
\frac{1}{n^2} \sum_{j \notin [N_n(a)]} w_j^2 \leq C a^{-2}\frac{1}{n^2}\sum_{j > N_n(a)} j^{-2\alpha} \leq C a^{-4}\alpha n^{(3-\tau)/2} = o(\sqrt{n}).
\]

Moreover,

\[
\sum_{i \in V} \sum_{j \in [N_n(a)]} \pi_n(1 - e^{-w_iw_j/\xi_n}) \leq \pi_n N_n(a)^2 \leq C a^2 n^{(3-\tau)/2} = o(\sqrt{n}).
\]

Thus, (5.7) and (5.8) together imply that

\[
\mathbb{E}_1 [\mid N_1(V) \mid] = \sum_{i \in V} \sum_{j \in [n]} \pi_n(1 - e^{-w_iw_j/\xi_n}) + o(\sqrt{n}).
\]

Let \( \varepsilon_n \) be such that \( \varepsilon_n \downarrow 0 \) sufficiently slowly (to be specified later). Let us split the first term of (5.11) in two parts by restricting the sum over \( j \in [n] \) to \( \{ j : w_iw_j \leq \varepsilon_n \xi_n \} \) and \( \{ j : w_iw_j > \varepsilon_n \xi_n \} \), respectively. Denote the two terms by (I) and (II), respectively. Note that

\[
\text{(II)} \leq \pi_n \sum_{i \in [N_n(a)]} \#\{ j : w_iw_j \leq \varepsilon_n \xi_n \} = C \pi_n \varepsilon_n^{-(\tau-1)} n^{2-\tau} \sum_{i \in [N_n(a)]} w_i^{\tau-1}
\]

\[
= C n^{(3-\tau)/2} \varepsilon_n^{-(\tau-1)} \sum_{i \in a(n^{(\tau-1)/2})} \frac{1}{i} = C n^{(3-\tau)/2} \varepsilon_n^{-(\tau-1)} \log(an^{(\tau-1)/2}) = o(n^{1/2}),
\]

where in the second step we have used Lemma 3.7, and the choice of \( \varepsilon_n \) is such that the final step holds. Moreover, since \( 1 - e^{-x} = x(1 + o(1)) \) as \( x \to 0 \),

\[
\text{(I)} \geq (1 + o(1)) \sum_{i \in V} \sum_{j \in \varepsilon_n \xi_n / w_i} \pi_n \frac{w_iw_j}{\xi_n} \\
\geq (1 + o(1)) \sum_{i \in V} \sum_{j : w_j \leq C \varepsilon_n n^p} \pi_n \frac{w_iw_j}{\xi_n} = (1 + o(1)) \sum_{i \in V} \pi_n w_i.
\]

Also, (I) \( \leq \sum_{i \in V} \pi_n w_i \). We conclude that

\[
\sum_{i \in V} \sum_{j \in [n]} \pi_n(1 - e^{-w_iw_j/\xi_n}) = (1 + o(1)) \sum_{i \in V} \pi_n w_i + o(\sqrt{n}),
\]

and thus (5.5) follows by combining (5.11) and (5.14).

To complete the proof of (5.4), we apply Chebyshev’s inequality for which we need to bound the variance of \( |N_1(V)| \). Let \( \text{Var}_1 \) denote the variance conditionally on \( \mathcal{G}_{N_n(a)} \). Note that (5.6) is a sum of conditionally independent indicators, given \( \mathcal{G}_{N_n(a)} \). Therefore,

\[
\text{Var}_1 (|N_1(V)|) \leq \mathbb{E}_1 [\mid N_1(V) \mid],
\]

and an application of Chebyshev’s inequality completes the proof.

Now we are ready to complete the proof of Proposition 5.1:

**Proof of Proposition 5.1.** Clearly, \( |\text{Span}_n(V)| \geq |N_1(V)| \) by (5.3). We apply Lemma 5.2 with \( V = \mathcal{G}_{a(1)} \), and rely on Proposition 4.2 to estimate \( |N_1(\mathcal{G}_{a(1)})| \). Finally, by Proposition 4.5, we can take \( a > 1 \) sufficiently large, so that \( C^a \geq \zeta^\lambda - \varepsilon/2 \). Thus, Proposition 5.1 follows.
5.2 Concentration of the spans: upper bound

Fix $a > 0$ and recall the definition of $T_{2k}^a$ from Section 4, and that of $\text{Span}_a(V)$ for $V \subseteq [N_n(a)]$ above (5.1). In this section, we obtain an upper bound on $\text{Span}_a(T_{2k}^a)$.

Proposition 5.3 (Upper bound on the span of large clusters). Fix $\lambda > \lambda_c$. For any $\varepsilon > 0$, there exists $a_1 = a_1(\varepsilon) > 0$ such that for all $a \geq a_1$ there exists $k_0 = k_0(\varepsilon, a)$ such that, for all $k \geq k_0$,

$$\lim_{n \to \infty} \mathbb{P}
\left(\frac{|\text{Span}_a(T_{2k}^a)|}{\sqrt{n}} \leq \zeta^\lambda + \varepsilon\right) = 1,
$$

where $\zeta^\lambda$ is as in (4.22).

Together with Proposition 5.1, Proposition 5.3 provides the following law of large numbers on $\text{Span}_a(\mathcal{E}_1^a)$:

Corollary 5.4 (Law of large numbers for $\text{Span}_a(\mathcal{E}_1^a)$). Under the conditions of Proposition 5.3, with high probability $\zeta^\lambda - \varepsilon \leq |\text{Span}_a(\mathcal{E}_1^a)|/\sqrt{n} \leq \zeta^\lambda + \varepsilon$.

Our goal will be to first show that, given any arbitrary $V \subseteq [N_n(a)]$, the $\text{Span}_a(V)$ is predominantly carried by the one-neighborhood of $\zeta$, $N_{2k}(V)$ before (5.3), and that $\text{Span}_a(V) = N_1(V) \cup N_{2k}(V)$. Lemma 5.2 has studied $N_1(V)$ in detail, and now we focus on studying $N_{2k}(V)$ for $a > 1$ large:

Lemma 5.5 (Additional neighborhood of $[N_n(a)]$). Let $V \subseteq [N_n(a)]$ be such that $\sum_{i \in V} \pi_n w_i \leq C_0 \sqrt{n}$, for some constant $C_0 > 0$ (independent of $a$). Then, for any $\varepsilon > 0$, there exists $a_0 = a_0(\varepsilon) > 0$ such that for any $a > a_0$, as $n \to \infty$,

$$\mathbb{P}(\{|N_{2k}(V)| > \varepsilon \sqrt{n} \mid G_{N_n(a)}\} \not\rightarrow 0.}
$$

Proof. Recall that $\mathbb{P}_1$ and $\mathbb{E}_1$ denote the conditional probability and expectation, respectively, given $G_{N_n(a)}$. We first show that there exists $a_0 = a_0(\varepsilon) > 0$ such that for all $a > a_0$,

$$\frac{\mathbb{E}_1[|N_{2k}(V)|]}{\sqrt{n}} < \frac{\varepsilon}{2}
$$

with high probability. (5.18)

For any $i, j \in [n]$, let $A_i(i, j)$ denote the event that there exists $l - 1$ vertices $i_1, \ldots, i_{l-1} \in [N_n(a)]^c$ such that $(i, i_1, \ldots, i_{l-1}, j)$ is a path in $\text{NR}_n(w, \pi_n)$. In words, $A_i(i, j)$ is the event that there exists a path of length $l$ between $i$ and $j$ in $\text{NR}_n(w, \pi_n)$ with all the intermediate vertices in $[N_n(a)]^c$. Now, with $i_0 = i, i_l = j$, note that

$$\mathbb{P}_1(A_i(i, j)) \leq \sum_{i_1, \ldots, i_{l-1} \notin [N_n(a)]} \prod_{s=1}^{l} \frac{\pi_n w_{i_{s-1}} w_{i_s}}{\ell_n} \leq \frac{\pi_n w_i w_j}{\ell_n} \left(\sum_{v \notin [N_n(a)]} \pi_n w_v^2\right)^{l-1} = \frac{\pi_n w_i w_j}{\ell_n} \tilde{\nu}_n(a)^{l-1},
$$

where

$$\tilde{\nu}_n(a) = \frac{1}{\ell_n} \sum_{v \notin [N_n(a)]} \pi_n w_v^2 = \frac{C_n 2\alpha n_1}{n} \sum_{v > an^{(3-\tau)/2}} v^{-2\alpha} = \frac{C_n 2\alpha n_1}{n} \left(\frac{an^{(3-\tau)/2}}{n}\right)^{1-2\alpha} = C_0 a^{-(3-\tau)/(\tau-1)}.$$

32
Thus, using $\sum_{i \in V} \pi_n w_i \leq C_0 \sqrt{n}$,

$$E_1[|\mathcal{N}_{\geq 2}(V)|] \leq \sum_{i \geq 2} \sum_{i \in V} \sum_{j \in |N_n(a)|} \mathbb{P}_1(A_i(i, j))$$

$$\leq Cn(a) \pi_n \sum_{i \in V} w_i \sum_{j \in |N_n(a)|} w_j \leq Cn(a) \sqrt{n},$$

and (5.18) follows using (5.20).

Next, we compute $\text{Var}_1(|\mathcal{N}_{\geq 2}(V)|)$, where $\text{Var}_1$ denotes the conditional variance given $\mathcal{G}_{N_n(a)}$. Let $I_{ij}(a)$ be the indicator of the event $\cup_{i \geq 2} A_i(i, j)$. Note that

$$E_1[|\mathcal{N}_{\geq 2}(V)|^2] \leq \sum_{i_1, i_2 \in V} \sum_{j_1, j_2 \in |N_n(a)|^c} \mathbb{P}_1(I_{i_1j_1}(a) = 1, I_{i_2j_2}(a) = 1).$$

We split the sum over possible choices of $i_1, i_2, j_1, j_2$. If $i_1 = i_2$ and $j_1 = j_2$, then we get the same bound as in (5.20). Let $i_1 = i_2 = i$ and $j_1 \neq j_2$. If $I_{ij}(a) = 1$ and $I_{i_2j_2}(a) = 1$, then we have two cases.

- **Case 1**: There are two vertex-disjoint paths $[i, j_1]$ and $[i, j_2]$ with all intermediate vertices in $[N_n(a)]^c$.

- **Case 2**: There exists a vertex $k \in [N_n(a)]^c$ such that there are three vertex-disjoint paths $[i, k], [k, j_1]$ and $[k, j_2]$ with all intermediate vertices in $[N_n(a)]^c$.

Since the paths described above are vertex-disjoint, we can apply the BK-inequality [7, Theorem 3.3]. Let $A(i, k) = \cup_{i \geq 1} A_i(i, k)$. By (5.19), $\mathbb{P}_1(A(i, k)) \leq C \pi_n w_i w_k / \ell_n$ for any $i, k$. Thus, when Case 1 occurs, we can bound the term in (5.21) by

$$\sum_{i \in V} \sum_{j_1, j_2 \in |N_n(a)|^c} \mathbb{P}_1(I_{i_1j_1}(a) = 1, I_{i_2j_2}(a) = 1, \text{Case 1 occurs})$$

$$\leq \sum_{i \in V} \sum_{j_1, j_2 \in |N_n(a)|^c} \sum_{k \in |N_n(a)|^c} \mathbb{P}_1(A(i, k)) \mathbb{P}_1(A(j_1, k)) \mathbb{P}_1(A(j_2, k))$$

$$\leq C \pi_n^3 \sum_{i \in V} \sum_{j_1, j_2 \in |N_n(a)|^c} \sum_{k \in |N_n(a)|^c} w_i w_j w_k \leq C \sqrt{n} \pi_n \sum_{k \in |N_n(a)|^c} w_k \leq C a^{1-3\alpha} n \pi_n,$$

where in the one-but-last step we have used our assumption that $\sum_{i \in V} \pi_n w_i \leq C_0 \sqrt{n}$, and the final step follows by using

$$\sum_{k \in |N_n(a)|^c} w_k^3 \leq \sum_{k > N_n(a)} \frac{c_3 \ell_n^{3\alpha}}{k^{3\alpha}} = C n^{3\alpha} (a N_n)^{1-3\alpha} = C a^{1-3\alpha} N_n r^{3/2}. \quad (5.24)$$

33
We can similarly treat the case $i_1 \neq i_2$ and $j_1 = j_2$. In that case, we no longer have to split in two cases as above, since $k$ may be equal to $j$. Thus, the same argument as (5.23) shows that

$$\sum_{i_1, i_2 \in V} \sum_{j \in [N_n(a)]} \mathbb{P}(I_{i_1 j}(a) = I_{i_2 j}(a) = 1) \leq C a^{1-3\alpha} \sqrt{n}.$$  \hfill (5.25)

Note also that $|N_{\geq 2}(V)| = \sum_{j \notin [N_n(a)]} \mathbb{1}_{\{A(i,j) \text{ occurs for some } i \in V\}}$, and thus (5.25) also implies that

$$\mathbb{E}_1 \left[|N_{\geq 2}(V)|\right] \geq \sum_{i \in V} \sum_{j \in [N_n(a)]} \mathbb{P}(I_{i j}(a) = 1) - \sum_{i_1, i_2 \in V} \sum_{j \in [N_n(a)]} \mathbb{P}(I_{i_1 j}(a) = I_{i_2 j}(a) = 1)$$

$$= \sum_{i \in V} \sum_{j \in [N_n(a)]} \mathbb{P}(I_{i j}(a) = 1) - o(\sqrt{n}).$$  \hfill (5.26)

Next, consider the case where $i_1, i_2, j_1, j_2$ are all distinct. Let $B(i_1, j_1, i_2, j_2)$ denote the event that the paths $[i_1, j_1]$ and $[i_2, j_2]$ are disjoint. By the BK-inequality

$$\sum_{i_1, i_2 \in V, j_1, j_2 \in [N_n(a)]} \mathbb{P}(B(i_1, j_1, i_2, j_2))$$

$$\leq \sum_{i_1, i_2 \in V, j_1, j_2 \in [N_n(a)]} \mathbb{P}(I_{i_1 j_1}(a) = 1) \mathbb{P}(I_{i_2 j_2}(a) = 1) \leq \left(\mathbb{E}_1 \left[|N_{\geq 2}(V)|\right] + o(\sqrt{n})\right)^2,$$  \hfill (5.27)

where we have used (5.26) in the last step.

Let $B'(i_1, j_1, i_2, j_2)$ denote the event that $[i_1, j_1]$ and $[i_2, j_2]$ intersect. If $B'(i_1, j_1, i_2, j_2)$ occurs, then there are two vertices $k_1, k_2 \in [N_n(a)]$ in $[i_1, j_1]$ such that $[i_1, k_1], [k_1, k_2], [k_2, j_1], [i_2, k_1]$ and $[j_2, k_2]$ are edge-disjoint. There are two cases depending on whether $k_1 = k_2$ (we denote this event by $B'_1(i_1, j_1, i_2, j_2)$) or $k_1 \neq k_2$ (and we denote this event by $B'_2(i_1, j_1, i_2, j_2)$). The BK-inequality implies that

$$\sum_{i_1, i_2 \in V} \sum_{j_1, j_2 \in [N_n(a)]} \mathbb{P}(B'_1(i_1, j_1, i_2, j_2))$$

$$\leq \sum_{i_1, i_2 \in V} \sum_{j_1, j_2 \in [N_n(a)]} \sum_{k \in [N_n(a)]} \mathbb{P}(A(i_1, k)) \mathbb{P}(A(j_1, k)) \mathbb{P}(A(i_2, k)) \mathbb{P}(A(j_2, k))$$

$$\leq C n \pi_n^4 \sum_{i_1, i_2 \in V} \sum_{j_1, j_2 \in [N_n(a)]} \sum_{k \in [N_n(a)]} w_{i_1} w_{i_2} w_{j_1} w_{j_2} w_k^4$$

$$\leq C n \pi_n^4 \sum_{k \in [N_n(a)]} w_k^4 \leq C a^{1-4\alpha} n \pi_n,$$  \hfill (5.28)

where we have used that $\sum_{k \in [N_n(a)]} w_k^4 \leq C a^{1-4\alpha} N_n n^2$, as can be derived similarly as in (5.24).

To compute $\mathbb{P}(B'_2(i_1, j_1, i_2, j_2))$, we again apply the BK-inequality, and (5.24) again implies...
that
\[
\sum_{i_1, i_2 \in V, j_1, j_2 \in [N_n]} \mathbb{P}(B_2'(i_1, j_1, i_2, j_2)) \\
\leq \sum_{i_1, i_2 \in V, j_1, j_2 \in [N_n]} \sum_{k_1, k_2 \in [N_n]} \mathbb{P}(A(i_1, k_1)) \mathbb{P}(A(k_1, k_2)) \mathbb{P}(A(j_1, k_2)) \mathbb{P}(A(j_2, k_1)) \mathbb{P}(A(j_2, k_2)) \\
\leq C \pi_n^{20} \sum_{i_1, i_2 \in V, j_1, j_2 \in [N_n]} \sum_{k \in [N_n]} w_{i_1} w_{i_2} w_{j_1} w_{j_2} w_k^3 \\
\leq C n \pi_n^{20} \left( \sum_{k \in [N_n]} \right)^2 \leq C a^{2-6n} \pi_n.
\]

(5.29)

Finally, we conclude from (5.22), (5.23), (5.25), (5.27), (5.28) and (5.29) that \( \text{Var}_1(|N_{\geq 2}(V)|) = o(n) \) for each fixed \( a > 0 \). Thus, on the event that \( \mathbb{E}_1[|N_{\geq 2}(V)|] \leq \varepsilon \sqrt{n} \), which occurs with high probability, (5.18) and the Chebychev inequality imply that
\[
\mathbb{P}_1(|N_{\geq 2}(V)| > \varepsilon \sqrt{n}) \leq \mathbb{P}_1\left(\left|\mathbb{E}_1[|N_{\geq 2}(V)|] - \mathbb{E}_1[|N_{\geq 2}(V)|]\right| > \varepsilon \sqrt{n}/2\right) \\
\leq \frac{4 \text{Var}_1(|N_{\geq 2}(V)|)}{\varepsilon^2 n} \mathbb{P} \to 0,
\]

and thus the proof of Lemma 5.5 follows. \( \blacksquare \)

Next we bound the total weight of small sets of vertices which will be required in the proof of Proposition 5.3:

**Lemma 5.6** (Small sets have small weight). Fix any \( \delta > 0 \), and \( V \subset [N_n] \) such that \( |V| \leq \delta N_n \). Then \( \frac{1}{\sqrt{n}} \sum_{k \in V} \pi_n w_k \leq c_\delta \delta^{1-\alpha} \).

**Proof.** Note that \( \frac{1}{\sqrt{n}} \sum_{k \in V} \pi_n w_k \leq \frac{1}{\sqrt{n}} \sum_{k \leq \delta N_n} \pi_n w_k \). Using (2.6), we conclude that
\[
\frac{1}{\sqrt{n}} \sum_{k \leq \delta N_n} \pi_n w_k \leq c_\delta n^{-\frac{1}{2} - \frac{1}{2} - \frac{1}{2} + \alpha} \sum_{k \leq \delta N_n} k^{-\alpha} \leq \frac{c_\delta}{1 - \alpha} \delta^{1-\alpha}.
\]

(5.31)

\( \blacksquare \)

We are now ready to prove Proposition 5.3:

**Proof of Proposition 5.3.** Let \( \lambda > \lambda_c \) and fix any \( \varepsilon > 0 \). Using Propositions 4.2 and 4.5, there exists \( a_1 = a_1(\varepsilon) > 0 \) such that for all \( a \geq a_1 \) there exists \( k_0 = k_0(\varepsilon, a) \) such that for all \( k \geq k_0 \)
\[
\lim_{n \to \infty} \mathbb{P}\left(\frac{1}{\sqrt{n}} \sum_{i \in T_{\geq k}^n} \pi_n w_i \leq \zeta^\lambda + \frac{\varepsilon}{2}\right) = 1,
\]

(5.32)

Next, we take \( \delta = (\varepsilon/4 C_0)^{(1-\alpha)} \), where \( C_0 = c_\rho / (1 - \alpha) \) as in Lemma 5.6, i.e., \( \sum_{k \in V} \pi_n w_k \leq \varepsilon \sqrt{n}/4 \), whenever \( |V| \leq \delta N_n \). Recall the notation \( p_{a, k}^\lambda \) as in (4.8). Since \( p_{a, k}^\lambda \leq p_{a}^\lambda \) as \( k \to \infty \), we can choose \( k_0 = k_0(\varepsilon, a) \) such that, for all \( k \geq k_0 \), \( p_{a, k}^\lambda \leq \rho_{a}^\lambda + \delta/2a \). Using Proposition 4.1, with high probability,

\[
|T_{\geq k}^n| \leq |\mathcal{E}_{(1)}^n| + \delta N_n \quad \Rightarrow \quad |T_{\geq k}^n \setminus \mathcal{E}_{(1)}^n| \leq \delta N_n.
\]

(5.33)
where the last implication uses that \( \mathcal{E}_{(i)}^a \subset T_{2k}^a \) with high probability, since \( |\mathcal{E}_{(i)}^a| = \Theta_P(N_n(a)) \).

By our choice of \( \delta \), and Lemma 5.6, with high probability

\[
\frac{1}{\sqrt{n}} \sum_{i \in T_{2k}^a} \pi_n w_i \leq \frac{1}{\sqrt{n}} \sum_{i \in \mathcal{E}_{(i)}^a} \pi_n w_i + \frac{\varepsilon}{4} \leq \zeta^\lambda + \frac{\varepsilon}{2}.
\]  

(5.34)

This concludes the proof of (5.32).

Using (5.32), we can now apply Lemmas 5.2 and 5.5 for \( T_{2k}^a \), to conclude that, for any \( a > \max\{a_0, a_1\} \),

\[
\frac{|\text{Span}_a(T_{2k}^a)|}{\sqrt{n}} = (1 + o_P(1)) \sum_{j \in T_{2k}^a} \frac{\pi_n w_j}{\sqrt{n}},
\]  

(5.35)

where \( a_0 \) is as in Lemma 5.5. This concludes the proof of Proposition 5.3.

\[\square\]

5.3 Negligible contribution due to return paths

Let us start by constructing the graph \( \tilde{G}_{N_n(a)} \) as follows: \( \{i, j\} \) is an edge of \( \tilde{G}_{N_n(a)} \) if and only if \( \{i, j\} \) is an edge of \( G_{N_n(a)} \), or there exists a path from \( i \) to \( j \) with all intermediate vertices in \( \lfloor N_n(a) \rfloor \). We will term the additional edges in \( \tilde{G}_{N_n(a)} \) as return edges. Henceforth, we augment a previously notation with bar to denote the corresponding quantity for \( \tilde{G}_{N_n(a)} \). For example, \( \mathcal{E}_{(i)}^a \) and \( T_{2k}^a \) respectively denote the \( i \)-th largest component and the number of vertices in components of size \( i \).

Our candidate giant component in the whole graph \( NR_n(w, \pi_n) \) is \( \mathcal{E}_{(i)}^a \cup \text{Span}_a(\mathcal{E}_{(i)}^a) \) for large \( a \). Note that the vertices in \( \mathcal{E}_{(i)}^a \setminus \mathcal{E}_{(i)}^a \) added due to the return edges are precisely the return vertices, as explained before (5.1). In particular, \( \mathcal{E}_{(i)}^a = \mathcal{E}_{(i)}^a \cup \mathcal{R}_{(i)}^a \), so that also

\[
\mathcal{E}_{(i)}^a \cup \text{Span}_a(\mathcal{E}_{(i)}^a) = \mathcal{E}_{(i)}^a \cup \text{Span}_a(\mathcal{E}_{(i)}^a) \cup \mathcal{R}_{(i)}^a \cup \text{Span}_a(\mathcal{R}_{(i)}^a) = \mathcal{E}_{(i)}^a^*.
\]  

(5.36)

The goal of this section is to show that the addition of the return edges can only increase the asymptotics of the span by a negligible amount:

**Proposition 5.7 (Span with return vertices).** There exists \( \varepsilon_0 > 0 \) such that for any \( \varepsilon \in (0, \varepsilon_0) \), there exists \( a_2 = a_2(\varepsilon) > 0 \) such that, for all \( a \geq a_2 \), there exists \( k_1 = k_1(\varepsilon, a) \) such that, for all \( k \geq k_1 \),

\[
\lim_{n \to \infty} \mathbb{P} \left( \frac{|\text{Span}_a(T_{2k}^a)|}{\sqrt{n}} \leq \zeta^\lambda + \varepsilon \right) = 1,
\]  

(5.37)

where \( \zeta^\lambda \) is as in (4.22).

Let us explain the intuition behind the proof. The main idea is that \( T_{2k}^a \) is robust in the sense that its size does not change too much by adding edges to the graph arbitrarily, as long as the number of added edges is small (see Lemma 5.8 below). For this reason, the span of the added vertices is also small (see Lemma 5.9 below). In order to make use of this idea, we later show that there are not many return edges for large \( a \) (see Lemma 5.11 below). To make these ideas precise, we start with the following elementary fact from [14, Lemma 9.4]:

**Lemma 5.8 ([14, Lemma 9.4]).** Let \( G_1, G_2 \) be two graphs on the same set of vertices and the edge set of \( G_1 \) is contained in that of \( G_2 \). Let \( k \geq 1 \) and \( N_{\geq k}(G_i) \) be the set of vertices with component size at least \( k \) in \( G_i \), for \( i = 1, 2 \). Then \( N_{\geq k}(G_1) \leq N_{\geq k}(G_2) \leq N_{\geq k}(G_1) + k\Delta \), where \( \Delta \) is the difference between the number of edges in \( G_1, G_2 \).

The next lemma shows that spans of small subsets of \( \lfloor N_n(a) \rfloor \) are uniformly small:
Lemma 5.9 (Span of small sets in \([N_n(a)]\)). Given any \(\varepsilon_1 > 0\), there exists \(a_0 = a_0(\varepsilon_1) > 0\) such that, for all \(a \geq a_0\),

\[
\lim_{n \to \infty} \mathbb{P} \left( \max_{V \subseteq [N_n(a)]: |V| \leq \varepsilon_1 N_n} \text{Span}_a(V) \leq C_0 \varepsilon_1^{1-\alpha} \sqrt{n} \right) = 1,
\]

for some absolute constant \(C_0 > 0\).

Proof. Recall that \(\bar{\nu}_n(a) = \frac{1}{\ell_n} \sum_{i,j} \pi_n w_{ij}^2\), and \(A_l(i,j)\) is the event that there exists a path of length \(l\) between \(i\) and \(j\) in \(NR(w, \pi_n)\) with all the intermediate vertices in \([N_n(a)]\). Let \(Z_L := \sum_{i,j} \pi_n w_{ij}^2\) for all \(l \geq L\). Fix any \(\delta > 0\). Recall that \(\pi_n w_{ij} = C a^{1-\alpha} \sqrt{n}\). By Markov’s inequality,

\[
\mathbb{P} \left( Z_L > \frac{C_0}{2} \varepsilon_1^{1-\alpha} \sqrt{n} \right) \leq \frac{2}{C_0 \varepsilon_1^{1-\alpha} \sqrt{n}} \sum_{i,j} \pi_n w_{ij} = C \varepsilon_1^{1-\alpha} \sqrt{n} \sum_{i,j} \pi_n w_{ij} \leq C_1 e^{-C_2 L \log a + C_3 \log a + C_4 \log \frac{1}{\varepsilon_1} \leq \delta},
\]

for some \(L = L_0 = L_0(\delta)\) (the choice of \(L_0\) does not depend on \(\varepsilon, a\) as long as \(a \geq \min\{2, \frac{1}{\varepsilon_1}\}\). Next, fix any \(V \subseteq [N_n(a)]\) such that \(|V| \leq \varepsilon_1 N_n\). We claim that, for any \(1 \leq l \leq L_0\), and any choice of \(V\) above,

\[
\mathbb{P} \left( |\mathcal{N}_l(V)| > \frac{C_0}{2} \varepsilon_1^{1-\alpha} \sqrt{n} \right) \leq e^{-C N_n a^{1-\alpha}/8},
\]

where \(C\) may depend only on \(\varepsilon_1\), and the inequality holds for all sufficiently large \(n\). We first check that (5.40) implies Lemma 5.9, and then prove (5.40). Indeed, by (5.39),

\[
\mathbb{P} \left( \max_{V \subseteq [N_n(a)]: |V| \leq \varepsilon_1 N_n} \text{Span}_a(V) > C_0 \varepsilon_1^{1-\alpha} \sqrt{n} \right)
\]

\[
\leq \delta + \left( \frac{N_n(a)}{\varepsilon_1 N_n} \right) \mathbb{P} \left( \text{Span}_a(V) > C_0 \varepsilon_1^{1-\alpha} \sqrt{n}, Z_L \leq \frac{C_0}{2} \varepsilon_1^{1-\alpha} \sqrt{n} \right)
\]

\[
\leq \delta + L_0 e^{\varepsilon_1 N_n \log \frac{a}{\varepsilon_1 N_n}} \mathbb{P} \left( \max_{V \subseteq [N_n(a)]: |V| \leq \varepsilon_1 N_n} \text{Span}_a(V) > C_0 \varepsilon_1^{1-\alpha} \sqrt{n} \right)
\]

\[
\leq \delta + n e^{\varepsilon_1 N_n \log \frac{a}{\varepsilon_1 N_n}} e^{-C N_n a^{1-\alpha}/8} = \delta + o(1),
\]

for all large enough \(a\), where in the third step we have used Stirling’s approximation

\[
\left( \frac{N_n(a)}{\varepsilon_1 N_n} \right) \leq \left( \frac{N_n(a) e^{\varepsilon_1 N_n}}{(\varepsilon_1 N_n)} \right)^{\varepsilon_1 N_n} \sim e^{\varepsilon_1 N_n \log(a/\varepsilon_1 e)}.
\]

Since \(\delta > 0\) is arbitrary, this completes the proof of Lemma 5.9.

It remains to prove (5.40). We will prove (5.40) inductively, along also with the companion estimate

\[
\mathbb{P} \left( \sum_{j \in \mathcal{N}_l(V)} \pi_n w_{ij} > \frac{C_0}{14} \varepsilon_1^{1-\alpha} \sqrt{n} \right) \leq e^{-C N_n a^{1-\alpha}/8}.
\]

For \(l = 0\), (5.40) holds trivially and (5.43) holds by Lemma 5.6. At step \(l \geq 1\), let \(\mathcal{E}_l\) denote the good event that the events in (5.40) and (5.43) do not occur. Then,

\[
\mathbb{E} \left[ |\mathcal{N}_{l+1}(V)| \mid \mathcal{N}_l(V), \mathcal{E}_l \right] \leq \sum_{i \in \mathcal{N}_l(V)} \sum_{j \in [n]} \pi_n w_{ij} = \sum_{i \in \mathcal{N}_l(V)} \pi_n w_i \leq \frac{C_0}{14} \varepsilon_1^{1-\alpha} \sqrt{n},
\]
where the last step uses (5.43). Note that $\mathcal{N}_{i+1}(V)$ is, conditionally on $\cup_{r \leq i} \mathcal{N}_r(V)$, a sum of independent indicators. Thus, standard concentration inequalities [33, Corollary 2.4, Theorem 2.8] imply

$$\mathbb{P}\left(|\mathcal{N}_{i+1}(V)| > \frac{C_0 \varepsilon_1^{1-\alpha}}{2} \sqrt{n}\right) \leq \mathbb{P}(E_i) + e^{-C \sqrt{n}}. \tag{5.45}$$

Thus (5.40) follows. To inductively verify (5.43), note that

$$\mathbb{E}\left[ \sum_{j \in \mathcal{N}_{i+1}(V)} \pi_n w_j \mid \mathcal{N}_i(V), E_i \right] \leq \sum_{j \in [N_n(a)]^c} \sum_{i \in \mathcal{N}_i(V)} \pi_n w_j \tau_{n} w_{i,j} \ell_n \leq \frac{C_0}{14} \varepsilon_1^{1-\alpha} \sqrt{n} \times \sum_{j \in [N_n(a)]^c} \pi_n w_j^2 \leq \frac{C_0}{14} \sum_{i \in [N_n(a)]^c} \mu a^{1-2\alpha} \varepsilon_1^{1-\alpha} \sqrt{n} = \frac{C_0}{14} a^{-\alpha} \varepsilon_1^{1-\alpha} \sqrt{n}, \tag{5.46}$$

for all large enough $a$. For the concentration, we will use the following elementary fact:

**Fact 5.10.** Fix $k \geq 1$, let $X_i \sim \text{Bernoulli} (p_i)$ independently for $i \in [k]$, and let $a_i$ be such that $\max_i a_i > 0$ and $\sum_i a_i p_i \leq x$. Then,

$$\mathbb{P}\left( \sum_i a_i X_i > 3x \right) \leq e^{-\frac{x}{\max_i a_i}}. \tag{5.47}$$

**Proof.** For any $t \leq 1/\max_i a_i$, Markov’s inequality and the independence of $(X_i)_{i \geq 1}$ imply that

$$\mathbb{P}\left( \sum_{i \in [k]} a_i X_i > 3x \right) \leq e^{-3tx} \prod_{i \in [k]} \mathbb{E}[e^{a_i X_i}] = e^{-3tx} \prod_{i \in [r]} (1 - p_i + p_i e^{a_i}) \leq e^{-tx} e^{\sum_{i \in [k]} p_i (e^{a_i} - 1)} \leq e^{-tx}, \tag{5.48}$$

where in the third step we have used that $1 + x \leq e^x$ for any $x \geq 0$, and in the final step we have used that $e^x - 1 \leq 2x$ for all $x \in [0, 1]$. The proof follows by taking $t = 1/\max_i a_i$. $\blacksquare$

Using Fact 5.10, and $w_i \leq c_r a^{-\alpha} \sqrt{n}$ for $i \in [N_n(a)]^c$, (5.46) now yields (5.43) at step $l + 1$. This completes the proof of Lemma 5.9. $\blacksquare$

We now wish to use Lemmas 5.8 and 5.9. The most direct approach would be to apply these lemmas to large $a$, using the fact that with increasing $a$, only few return edges are added. However, this is not possible, as the choice of $\delta$ in Lemma 5.8 also depend on $a$. Therefore, we introduce an additional parameter $b \gg a$, and apply Lemmas 5.8 and 5.9 to all the return edges that arise due to paths also touching $[N_n(b)]^c$.

Let us now present the details of this argument. Fix $b > a$. We say that $i$ and $j$ have a return path **touching** $[N_n(b)]^c$ when there is a path between $i$ to $j$ with intermediate vertices in $[N_n(a)]^c$, and at least one of the intermediate vertices in $[N_n(b)]^c$. Let $r_n(a, b) \text{ total number of such paths between vertices in } [N_n(a)]$. The following lemma shows that, given $a$, we can choose $b$ so large that the number of return paths touching $[N_n(b)]$ can be made arbitrarily small by choosing $b$ sufficiently large:

**Lemma 5.11** (Return touching $[N_n(b)]^c$). There exists $a_1 > 0$ such that for any $\delta > 0$ and $a > a_1$,

$$\lim_{b \to \infty} \lim_{n \to \infty} \mathbb{P}(r_n(a, b) \leq \delta N_n) = 1. \tag{5.49}$$

**Proof.** By the Markov inequality, it is enough to show that, for every $a > 0$ fixed,

$$\lim_{b \to \infty} \limsup_{n \to \infty} \frac{\mathbb{E}[r_n(a, b)]}{N_n} = 0. \tag{5.50}$$
For \( i, j \in [N_n(a)] \), let \( I_{ij}(a, b) \) denote the indicator that there is a return path from \( i \) to \( j \) touching \([N_n(b)]^c\). We recycle some notation from the proof of Lemma 5.5. We write \( A_l(i, j) \) to denote the event that there exists \( l - 1 \) vertices \( i_1, \ldots, i_{l-1} \), with \( i_k \notin [N_n(a)] \) for all \( k \leq l - 1 \) and \( i_j \notin [N_n(b)] \) for at least one \( j \), such that \((i, i_1, \ldots, i_{l-1}, j)\) is a path in \( NR_n(w, \pi_n) \). In words, \( A_l(i, j) \) is the event that there exists a path of length \( l \) between \( i \) and \( j \) in \( NR_n(w, \pi_n) \) with all the intermediate vertices in \([N_n(a)]^c\) and at least one intermediate vertex in \([N_n(b)]^c\).

A return path has minimum length two, so that \( l \geq 2 \). Thus,

\[
\mathbb{E}[r_n(a, b)] = \sum_{i,j \in [N_n(a)], i < j} \mathbb{P}(I_{ij}(a, b) = 1) \leq \sum_{l \geq 2} \sum_{i,j \in [N_n(a)]} \mathbb{P}(A_l(i, j)). \tag{5.51}
\]

We first consider the sum with \( l = 2 \). Recall the notation from (4.5) that \( \kappa(u, v) = 1 - e^{-c_2 (uv)^{-\alpha}/\mu} \). Let \( i = [uN_n] \) and \( j = [vN_n] \), where \( u, v \in (0, a) \). Consider another vertex \([xN_n]\) with \( x > b \), which corresponds to the vertex outside \([N_n(b)]^c\) from which the return happens. Note that

\[
\mathbb{P}(A_2(i, j)) = \sum_{k \in [N_n(b)]^c} \pi_n^2(1 - e^{-w_i w_k / \ell_n})(1 - e^{-w_j w_k / \ell_n}) \leq \frac{\lambda^2}{N_n} \int_b^\infty \kappa(u, x) \kappa(v, x) dx, \tag{5.52}
\]

and thus

\[
\frac{1}{N_n} \sum_{i,j \in [N_n(a)]} \mathbb{P}(A_2(i, j)) \leq \lambda^2 \int_0^a \int_0^a \int_b^\infty \kappa(u, x) \kappa(v, x) dx dx dv,
\]

which tends to zero in the iterated limit where \( \lim_{b \to \infty} \limsup_{n \to \infty} \) since the above integral over \( x \in [0, \infty) \) is finite for all \( a \) fixed.

For \( l \geq 3 \), the path is of the form \((i_0, i_1, \ldots, i_{l-1}, i_l)\) with \( i_0 = i \), \( i_l = j \). We split these sums in three cases. We say that \( A_l(i, j, 1) \) happens if \( i_1 \in [N_n(b)]^c \), \( A_l(i, j, 2) \) happens if \( i_{l-1} \in [N_n(b)]^c \), and \( A_l(i, j, 3) \) happens if \( i_j \in [N_n(b)]^c \) for some \( 1 < j < l - 1 \). We compute

\[
\mathbb{P}(A_l(i, j, 1)) \leq \sum_{i_2, \ldots, i_{l-1} \in [N_n(a)]^c, i_1 \in [N_n(b)]^c} \prod_{s=0}^{l-1} \pi_n(1 - e^{-w_{is} w_{i,s+1} / \ell_n}) \leq \frac{\pi_n}{\ell_n} \left( \sum_{k \in [N_n(a)]^c} \frac{\pi_n w_k^2}{\ell_n} \right)^{l-3} \sum_{i_1 \in [N_n(b)]^c} \pi_n w_{i_1} \left( 1 - e^{-w_{i_1} w_{i_{l-1}} / \ell_n} \right) \sum_{i_{l-1} \in [N_n(a)]^c} \pi_n w_{i_{l-1}} \left( 1 - e^{-w_{i_{l-1}} w_{i_1} / \ell_n} \right) \leq (\bar{\nu}_n(a))^{l-3} \frac{\lambda^2 c_2^2}{\mu} \pi_n \int_b^\infty x^{-\alpha} \kappa(u, x) dx \int_a^\infty y^{-\alpha} \kappa(v, y) dy. \tag{5.54}
\]

Similarly,

\[
\mathbb{P}(A_l(i, j, 2)) \leq (\bar{\nu}_n(a))^{l-3} \frac{\lambda^2 c_2^2}{\mu} \pi_n \int_a^\infty x^{-\alpha} \kappa(u, x) dx \int_b^\infty y^{-\alpha} \kappa(v, y) dy, \tag{5.55}
\]

and

\[
\mathbb{P}(A_l(i, j, 3)) \leq \bar{\nu}_n(b)(\bar{\nu}_n(a))^{l-4} \frac{\lambda^2 c_2^2}{\mu} \pi_n \int_a^\infty x^{-\alpha} \kappa(u, x) dx \int_a^\infty y^{-\alpha} \kappa(v, y) dy. \tag{5.56}
\]

Taking \( a \) large enough so that \( \bar{\nu}_n(a) < 1 \), it follows that

\[
\frac{1}{N_n} \sum_{l \geq 3} \sum_{i,j \in [N_n(a)]} \mathbb{P}(A_l(i, j)) \leq C \left[ \left( \int_0^a \int_b^\infty x^{-\alpha} \kappa(u, x) dx du \right)^2 + \bar{\nu}_n(b) \left( \int_0^a \int_a^\infty x^{-\alpha} \kappa(u, x) dx du \right)^2 \right]. \tag{5.57}
\]
Since \( \int_0^a \int_b^\infty x^{-\alpha} \kappa(u,x) \,dx \,du < \infty \) for every fixed \( a > 0 \), the expression in (5.57) tends to zero in the iterated limit \( \lim_{b \to \infty} \limsup_{n \to \infty} \). Thus, the proof of (5.50) follows by combining (5.51), (5.53) and (5.57) and the proof of Lemma 5.11 is thus complete. \( \blacksquare \)

We need one final fact before completing the proof of Proposition 5.7. Fix \( b > a \), and define \( V_0(b) \subset [N_n(b)]^c \) to be the collection of \( j \in [N_n(b)]^c \) such that there is a path from \( j \) to some vertex \( i \in [N_n(a)] \) with all intermediate vertices in \([N_n(a)]^c \) and at least one intermediate vertex in \([N_n(b)]^c \). The following lemma proves an upper bound on the size of \( V_0(b) \):

**Lemma 5.12 (Span touching \([N_n(b)]^c \)).** There exists \( a_1 \) such that for any \( \varepsilon > 0 \) and \( a > a_1 \),

\[
\lim_{b \to \infty} \limsup_{n \to \infty} \mathbb{P}(|V_0(b)| > \varepsilon \sqrt{n}) = 0. \tag{5.58}
\]

**Proof.** Fix any \( i \in [N_n(a)] \) and \( j \in [N_n(b)]^c \). Let \( A'_l(i,j) \) be the event that there is a path from \( j \) to \( i \) of length \( l \) with all intermediate vertices in \([N_n(a)]^c \) and at least one intermediate vertex in \([N_n(b)]^c \). Using identical computations as (5.19), for any \( l \geq 2 \),

\[
\mathbb{P}(A'_l(i,j)) \leq \frac{\pi_n w_i w_j}{\ell_n} (\bar{\nu}_n(a))^l - \bar{\nu}_n(b). \tag{5.59}
\]

The \( \bar{\nu}_n(b) \) term comes due to one intermediate vertex in \([N_n(b)]^c \). Take \( a_1 \) to be large enough such that \( \bar{\nu}_n(a) < 1 \) for all \( a > a_1 \). Then,

\[
\mathbb{E}[V_0(b)] \leq \sum_{i \in [N_n(a)]} \sum_{j \in [N_n(b)]^c} \mathbb{P}(A'_l(i,j)) \leq \frac{\bar{\nu}_n(b)}{1 - \nu_n(a)} \sum_{i \in [N_n(a)]} \pi_n w_i, \tag{5.60}
\]

where in the last step we have used that \( \sum_{j \in [N_n(b)]^c} w_j \leq \ell_n \). Using (4.37), \( \sum_{i \in [N_n(a)]} \pi_n w_i \leq C a^{1-\alpha} \sqrt{n} \) and \( \bar{\nu}_n(b) \leq C b^{-(3-\gamma)/(\gamma-1)} \) by (5.20). Therefore, \( \lim_{b \to \infty} \limsup_{n \to \infty} \mathbb{E}[V_0(b)] = 0 \), and the proof follows using Markov’s inequality. \( \blacksquare \)

Let us close this section by completing the proof of Proposition 5.7:

**Proof of Proposition 5.7.** Fix \( \varepsilon > 0 \) small enough. Take \( \varepsilon_1 = [\varepsilon/C_0]^{1/(1-\alpha)} \), so that the bound on the span from Lemma 5.9 is \( \varepsilon \). Next, choose \( a_2 \) such that Lemmas 5.9, 5.11, 5.12 and Propositions 5.1, 5.3 hold. Fix \( a \geq a_2 \) and let \( k_0 = k_0(\varepsilon, a) \) be such that the above results work. Also, the perturbation \( k \Delta \) in Lemma 5.8 will be taken to be at most \( \varepsilon_1 N_n \). Fix any \( \delta > 0 \) (sufficiently small) such that Lemma 5.11 holds. This sets the stage for our proof, and fixes the necessary parameters.

Fix \( b > a \) large. We add the additional edges due to return paths leaving \([N_n(a)] \) in two stages, by first adding the edges due to return paths not touching \([N_n(b)]^c \) (i.e., with all intermediate vertices in \([N_n(b)] \setminus [N_n(a)] \)), and then adding edges due to return paths touching \([N_n(b)]^c \).

**Stage 1:** Suppose that we first add the edges due to return paths not touching \([N_n(b)]^c \) to \( G_{N_n(a)} \). Let \( G_{N_n(a)}^k \) be the graph obtained by starting with \( G_{N_n(a)} \), and additionally creating an edge between two vertices if such a return path exists between them. Define \( T_{2k}^+ \) for the set of vertices with components size at least \( k \) in \( G_{N_n(a)}^k \). We seek to upper bound \( \text{Span}_a(T_{2k}^+) \).

Let \( v \in \text{Span}_a(T_{2k}^+) \). By definition, there exists a path \((v, i_1, \ldots, i_l, u) \) such that \( i_l \in [N_n(a)]^c \) for all \( l' \in [l] \), and \( u \in T_{2k}^+ \). We write \( P \) as a shorthand for \((i_1, \ldots, i_l) \). Consider the following set of exhaustive cases (where in fact several cases can occur at the same time, due to the fact that \( P \) is not necessarily unique):

1. If \( v \in [N_n(b)] \), then there are at most \( N_n(b) = o(\sqrt{n}) \) choices of \( v \) for any fixed \( b \).
(2) If \( v \in [N_n(b)]^c \) and \( P = \emptyset \), then also \( v \in \text{Span}_b(T_{\geq k}) \) (in fact \( v \) lies in the one-neighborhood of \( T_{\geq k} \)).

(3) If \( v \in [N_n(b)]^c \) and \( P \neq \emptyset \), then we have the following sub-cases:

(a) If \( P \subset [N_n(b)]^c \), then \( v \in \text{Span}_b(T_{\geq k}^\ast) \), using that \( T_{\geq k}^\ast \subset T_{\geq k}^0 \);

(b) If \( P \subset [N_n(b)] \setminus [N_n(a)] \), then \( v \in \text{Span}_b(T_{\geq k}^\ast) \) (since \( v \) lies in the one-neighborhood of \( T_{\geq k}^0 \));

(c) If \( P \) intersects both \( [N_n(b)]^c \) and \( [N_n(b)] \setminus [N_n(a)] \), then \( v \in V_0(b) \), where \( V_0(b) \) is defined in Lemma 5.12.

The above shows that

\[
|\text{Span}_a(T_{\geq k}^\ast)| \leq o(\sqrt{n}) + |\text{Span}_b(T_{\geq k}^\ast)| + |V_0(b)|. \tag{5.61}
\]

Using Proposition 5.3 and Lemma 5.12, for all \( a \geq a_2 \),

\[
\lim_{b \to \infty} \lim_{n \to \infty} P \left( \frac{|\text{Span}_a(T_{\geq k}^\ast)|}{\sqrt{n}} \leq \zeta^\lambda + \varepsilon \right) = 1. \tag{5.62}
\]

**Stage 2**: Next, we add the return paths touching \( [N_n(b)]^c \) to \( \mathcal{G}_{N_n(a)}^r \). On top of \( \mathcal{G}_{N_n(a)}^r \), if we additionally create an edge between two vertices if a return path touching \( [N_n(b)]^c \) exists between them, then the resulting graph \( \tilde{T}_{\geq k}^\ast \) is defined above Proposition 5.7. By Lemma 5.8, \( |\tilde{T}_{\geq k}^\ast \setminus T_{\geq k}^\ast| \leq \varepsilon_1 N_n \) on the event that \( \{r_n(a, b) \leq \delta N_n\} \). Thus, Lemmas 5.9 and 5.11 show that for all \( a \geq a_2 \) and \( k \geq k_0 \)

\[
\lim_{b \to \infty} \lim_{n \to \infty} P \left( |\text{Span}_a(\tilde{T}_{\geq k}^\ast \setminus T_{\geq k}^\ast)| \leq \varepsilon \sqrt{n} \right) = 1. \tag{5.63}
\]

The proof of Proposition 5.7 now follows by combining (5.62) and (5.63).

**5.4 No large components outside of \([N_n(a)]\)**

So far, we have studied the maximal component involving vertices from \([N_n(a)]\). We are left to study the maximal size of clusters that are completely outside of \([N_n(a)]\). Recall from (3.64) that \( \mathcal{C}(j) \) is empty when \( j \neq \min\{i : i \in \mathcal{C}(j)\} \) and equals \( \mathcal{C}(j) \) otherwise. The main estimate on the cluster size outside of \([N_n(a)]\) is the following lemma:

**Lemma 5.13** (No large components outside \([N_n(a)]\)). For each fixed \( a > 0 \), as \( n \to \infty \),

\[
(\pi_n n^a)^{-1} \max_{j \in [n] \setminus [N_n(a)]} |\mathcal{C}_\leq(j)| \longrightarrow P \to 0. \tag{5.64}
\]

**Proof.** It suffices to prove the statement for \( |\mathcal{C}_\leq(j) \setminus \{j\}| \). Let \( D_j \) denote the degree of \( j \). Fix \( \varepsilon > 0 \). We bound

\[
P \left( \max_{j \in [n] \setminus [N_n(a)]} |\mathcal{C}_\leq(j) \setminus \{j\}| \geq 2\varepsilon \pi_n n^a \right) \leq \sum_{j > N_n(a)} \left[ P(D_j \geq \varepsilon \pi_n n^a) + P(|N_{\geq 2}(j) \setminus \varepsilon \pi_n n^a|) \right], \tag{5.65}
\]

where \( N_{\geq 2}(j) \) is the part of the cluster of \( \mathcal{C}_\leq(j) \) at distance at least 2 away from \( j \). Now \( D_j \) is a sum of independent Bernoulli \( (\pi_n(1 - e^{-w_j/|w_j|})) \) random variables, and \( E[D_j] \leq \pi_n w_j \). Since \( \pi_n w_j = o(\pi_n n^a) \), standard concentration arguments [33, Corollary 2.4, Theorem 2.8] show that

\[
P(D_j \geq \varepsilon \pi_n n^a) \leq e^{-\pi_n n^a}, \tag{5.66}
\]

for all sufficiently large \( n \).
For the second summand in (5.65), we use the Markov inequality to bound
\[
\mathbb{P}(|\mathcal{N}_{\geq 2}(j)| \geq \varepsilon \pi_n n^\alpha) \leq (\varepsilon \pi_n n^\alpha)^{-2} \mathbb{E}[|\mathcal{N}_{\geq 2}(j)|^2].
\] (5.67)

The expectation can be computed using path counting again similar to (5.21). Since \( j \) is the minimum index of \( \mathcal{C}_2(j) \), we will need the paths to have vertices with indices higher than \( j \) only. Let \( J_{ij} \) denote the indicator that \( i \) and \( j \) are connected via a path of length at least 2 with all intermediate vertices having index at least \( j \).

Thus
\[
\mathbb{E}[|\mathcal{N}_{\geq 2}(j)|^2] = \sum_{i_1, i_2 \geq j} \mathbb{P}(I_{i_1 j} = 1, I_{i_2 j} = 1),
\] (5.68)

where \( I_{ij} \) is the indicator that there is a path from \( i \) to \( j \) with all intermediate vertices having index at least \( j \). We can decompose the above in two cases depending on whether the paths \([i_1, j]\) and \([i_2, j]\) are disjoint or not. Denote the two cases by (I) and (II), respectively. Using the BK-inequality [7, Theorem 3.3] again yields

(I) \[
\leq \left( \sum_{i_1 \geq j} \mathbb{P}(I_{i_1 j} = 1) \right)^2 \leq \left( \sum_{i_1 \geq j} \sum_{k_0 = 1}^{\left\lfloor \frac{j}{\ell_n} \right\rfloor} \prod_{s=1}^{l} \frac{\pi_n u_{k_s-1} w_{k_s}}{\ell_n} \right)^2
\] (5.69)

where now
\[
\nu_n(j) = \pi_n \sum_{k \geq j} \frac{w_k^2}{\ell_n} \leq C \pi_n n^{2\alpha-1-j+1-2\alpha}.
\] (5.70)

If the paths \([i_1, j]\) and \([i_2, j]\) are not disjoint, then three disjoint paths exist \([i_1, k]\), \([i_2, k]\) and \([k, j]\) for some \( k > j \). Therefore, applying the BK-inequality [7, Theorem 3.3] once again,

(II) \[
\leq \sum_{i_1, i_2, k > j} \prod_{k_0 \in \{i_1, i_2, j\}} \sum_{l \geq 1} \sum_{k_1, k_l = k}^{\left\lfloor \frac{j}{\ell_n} \right\rfloor} \prod_{s=1}^{l} \frac{\pi_n u_{k_s-1} w_{k_s}}{\ell_n}
\] (5.71)

since \( \nu_n(j) \leq C \pi_n n(j)^{2\alpha-1} \leq \frac{1}{2} \) for \( j > N_n(a) \). Using \( \sum_{k > j} w_k^3/\ell_n = O(n^{3\alpha-1-j+1-3\alpha}) \), we conclude that
\[
\mathbb{P}(|\mathcal{N}_{\geq 2}(j)| \geq \varepsilon \pi_n n^\alpha) \leq O(1)(\varepsilon \pi_n n^\alpha)^{-2} \left[ \pi_n^4 n^{6\alpha-2-j-2-6\alpha} + \pi_n^4 n^{4\alpha-1-j+1-4\alpha} \right]
\] (5.72)

so that
\[
\sum_{j > N_n(a)} \mathbb{P}(|\mathcal{N}_{\geq 2}(j)| \geq \varepsilon \pi_n n^\alpha) \leq O(1) \sum_{j > N_n(a)} \left[ \pi_n^2 n^{4\alpha-2-j-2-6\alpha} + \pi_n n^{2\alpha-1-j+1-4\alpha} \right]
\] (5.73)

since \( \alpha > \frac{1}{2} \). This proves Lemma 5.13. ■

42
5.5 Completing the proof of Theorem 2.6

We now have all the ingredients to complete the proof of Theorem 2.6. First, by Lemma 5.13, the giant component $C_{(1)}$ for the whole graph is one of the components of vertices in $[N_n(a)]$ with high probability. Recall from the beginning of Section 5 that $C_{(1)}^{a,*}$ the component of $NR_n(w, \pi_n)$ containing $C_{(1)}^a$. Also, recall the definition of $\mathcal{G}_{N_n(a)}$ and its functionals from Section 5.3. Fix $\varepsilon > 0$. Since $C_{(1)}^a \subset C_{(1)}^{a,*} \subset T_{\geq k}^a$ with high probability, Propositions 5.1 and 5.7 show that we can choose $a_0 > 0$ so large that, for $a > a_0$,

$$
\lim_{n \to \infty} P \left( \sqrt{n}(\zeta^{'(a)} - \varepsilon) \leq |C_{(1)}^{a,*}| \leq \sqrt{n}(\zeta^{'(a)} + \varepsilon) \right) = 1.
$$

(5.74)

Moreover, Proposition 5.7 and (5.74) also show that there exists a large enough $k_0 = k_0(\varepsilon, a)$ such that for all $a > a_0$ and $k \geq k_0$,

$$
\lim_{n \to \infty} P \left( \max_{\mathcal{C} \subset T_{\geq k}^a \setminus C_{(1)}^a} |\mathcal{C} \cup Span_a(\mathcal{C})| \leq \varepsilon \sqrt{n} \right) = 1.
$$

(5.75)

Further, since all components outside $T_{\geq k}^a$ have size at most $k_0$, an application of by Lemma 5.9 shows that

$$
\lim_{n \to \infty} P \left( \max_{\mathcal{C} \subset T_{\geq k}^a} |\mathcal{C} \cup Span_a(\mathcal{C})| \leq \varepsilon \sqrt{n} \right) = 1,
$$

(5.76)

where the maximum runs over all connected components $\mathcal{C} \subset (T_{\geq k}^a)^c$. Finally, in Lemma 5.13 we have shown that the components not involving vertices in $[N_n(a)]$ have size at most $o(\sqrt{n})$. Thus, with high probability, $C_{(1)}^{a,*}$ is the unique giant component of $NR_n(w, \pi_n)$ with size given by (5.74), and the second largest component has size at most $\varepsilon \sqrt{n}$. This proves the statements in Theorem 2.6 about the uniqueness of the giant component.

We complete the proof by showing that hubs are very likely to be in the newly born giant. Fix $a > 0$, and consider the set of hubs given by $H = \{h : w_h \geq n^{1/2 + \delta}\}$. We will show that $H \subseteq C_{(1)}(\pi_n)$ with high probability. Remove the set of hubs $H$ from the graph. The giant $C_{(1)}^{a,H}$ in $[N_n(a)] \setminus H$ has all the same characteristics as the original giant in $[N_n(a)]$, since the removal of a small fraction of vertices has hardly any effect on the giant, as shown by our previous analysis.

Fix $h \in H$. We will condition on $C_{(1)}^{a,H}$, and consider the two-hop paths between $h$ and $C_{(1)}^{a,H}$ consisting of paths $h \rightarrow j \rightarrow C_{(1)}^{a,H}$ for $j \in [n] \setminus [N_n(a)]$. Write

$$
M_{n,h} = \sum_{j \in [n] \setminus [N_n(a)]} 1_{\{h \rightarrow j \rightarrow C_{(1)}^{a,H}\}}
$$

(5.77)

for the number of $j$ that are forming the two-hop paths. For fixed $h$, and conditionally on $C_{(1)}^{a,H}$, the indicators are independent. We next consider their success probabilities.

Denote the conditional probability given $C_{(1)}^{a,H}$ by $P_{1,H}$. Note that, for $v \in C_{(1)}^{a,H}$, the probability that $v$ is not connected to $j$ after percolation equals $1 - \pi_n + \pi_n e^{-w_v w_j / \ell_n}$. Thus, the conditional probability given $C_{(1)}^{a,H}$ that $j$ is connected to some $v \in C_{(1)}^{a,H}$ equals

$$
P_{1,H}(j \rightarrow C_{(1)}^{a,H}) = 1 - \prod_{v \in C_{(1)}^{a,H}} (1 - \pi_n + \pi_n e^{-w_v w_j / \ell_n}).
$$

(5.78)

Since the event $\{v \leftrightarrow j\}$ is independent of the event $\{j \rightarrow C_{(1)}^{a,H}\}$, this leads to

$$
P_{1,H}(h \rightarrow j \rightarrow C_{(1)}^{a,H}) = \pi_n [1 - e^{-w_h w_j / \ell_n} - 1 - \prod_{v \in C_{(1)}^{a,H}} (1 - \pi_n + \pi_n e^{-w_v w_j / \ell_n})].
$$

(5.79)
Restrict the product over $v$ to $v \in \mathcal{C}^{a, H}_{(1)} \setminus [N_n(1)]$. Then, $w_v w_j/\ell_n \leq \frac{1}{2}$ for $a$ large, since $j > N_n(a)$, and, in turn, $e^{-x} \leq 1 - x/2$ when $x \leq \frac{1}{2}$. This leads to the upper bound

$$1 - \pi_n + \pi_n e^{-w_v w_j/\ell_n} \leq 1 - \frac{w_v w_j \pi_n}{2\ell_n} \leq e^{-\frac{n \pi w_v w_j}{2\pi_n}}, \quad (5.80)$$

which in turn implies the lower bound

$$\mathbb{P}_{1,H}(h \rightarrow j \rightarrow \mathcal{C}^{a, H}_{(1)}) \geq \pi_n [1 - e^{-w_h w_j/\ell_n}] \left[ 1 - \prod_{v \in \mathcal{C}^{a, H}_{(1)} \setminus [N_n(1)]} e^{-\frac{n \pi w_v w_j}{2\pi_n}} \right] = \pi_n [1 - e^{-w_h w_j/\ell_n}] \left[ 1 - \exp \left( - \pi_n w_j \sum_{v \in \mathcal{C}^{a, H}_{(1)} \setminus [N_n(1)]} \frac{w_v}{2\ell_n} \right) \right]. \quad (5.81)$$

Since Proposition 4.2 implies that $\pi_n \sum_{v \in \mathcal{C}^{a, H}_{(1)} \setminus [N_n(1)]} w_v \geq \varepsilon \ell_n / \sqrt{n}$ whp for $\varepsilon > 0$ sufficiently small, we obtain, whp and for some $\varepsilon' > 0$, small,

$$\mathbb{P}_{1,H}(h \rightarrow j \rightarrow \mathcal{C}^{a, H}_{(1)}) \geq \pi_n [1 - e^{-w_h w_j/\ell_n}] [1 - e^{-\varepsilon w_j / \sqrt{n}}] \geq \varepsilon' \frac{w_j}{\sqrt{n}} \pi_n [1 - e^{-w_h w_j/\ell_n}]. \quad (5.82)$$

This is true for all $j > N_n(a)$. By independence, we conclude that

$$\mathbb{P}_{1,H}(M_n, h = 0) \leq \prod_{j > N_n(a)} \left( 1 - \varepsilon' \frac{w_j}{\sqrt{n}} \pi_n [1 - e^{-w_h w_j/\ell_n}] \right). \quad (5.83)$$

We compute

$$\sum_{j > N_n(a)} \frac{w_j}{\sqrt{n}} \pi_n [1 - e^{-w_h w_j/\ell_n}] \geq \sum_{j > N_n(a)} \frac{w_j}{\sqrt{n}} \pi_n [1 - e^{-w_j n^{1/2 - \delta}/\ell_n}] \geq [1 - e^{-n/\ell_n}] \sum_{j > N_n(a) : w_j \leq n^{1/2 - \delta}} \frac{w_j \pi_n}{\sqrt{n}}, \quad (5.84)$$

and

$$\sum_{j > N_n(a) : w_j \leq n^{1/2 - \delta}} \frac{w_j \pi_n}{\sqrt{n}} = (1 + o(1)) \frac{\ell_n \pi_n}{\sqrt{n}} \to \infty. \quad (5.85)$$

faster than any power of $\log n$. Therefore, $\mathbb{P}_{1,H}(M_n, h = 0) = o(1/n)$, and thus,

$$\mathbb{P}_{1,H}(\exists h \in H : M_n, h = 0) \to 0. \quad (5.86)$$

which completes the proof of the fact that all the hubs are in the giant component. Hence, the proof of Theorem 2.6 is also complete.
