Abstract

In this paper we study the convex cone of not necessarily smooth measures satisfying the classical KMS condition within the context of Poisson geometry. We discuss the general properties of KMS measures and its relation with the underlying Poisson geometry in analogy to Weinstein’s seminal work in the smooth case. Moreover, by generalizing results from the symplectic case, we focus on the case of $b$-Poisson manifolds, where we provide a complete characterization of the convex cone of KMS measures.

1 Introduction

The quantum KMS condition has been introduced in the context of quantum statistical mechanics to describe states which are in thermal equilibrium at a given temperature [27, 31]. Its connection with $C^*$-dynamical systems has been studied extensively [9, 10] and nowadays it is an established milestone in the Tomita-Takesaki theory.

The classical version of the KMS condition has been introduced in [25] and studied in the context of infinite-dimensional classical systems [1, 2, 17, 18]. Abstractly, this condition can be naturally formulated within the context of Poisson geometry. Given a finite-dimensional Poisson manifold $(M, \Pi)$ together with a vector field $X \in \Gamma(TM)$, a linear, positive functional $\phi: C^\infty_c(M) \to \mathbb{C}$ is called $(X, \beta)$-KMS for $\beta > 0$ if

$$\phi(\{f, g\}) = \beta \phi(X(f)g) \quad \forall f, g \in C^\infty_c(M).$$

From the point of view of Poisson geometry, KMS functionals generalize $\Pi$-traces, which are included when $X = 0$. The link between KMS functionals and the underlying geometry of $(M, \Pi)$ has been described in [36]. Indeed, when $\phi$ is induced by a smooth density —that is, $\phi(f) = \int_M f\mu$ with $\mu$ being a strictly positive density on $M$— the vector field $X$ is forced to be Poisson and its cohomology class defines a Poisson invariant known as the modular class.

The classical KMS condition has also been investigated in the symplectic case by [4, 5] where the KMS condition for an Hamiltonian vector field $X = \{\cdot, h\}$ has been interpreted from the point of view of conformal symplectic geometry. These results have been corroborated in [6], where classical KMS functionals have been completely classified in the symplectic framework.
for all possible choices of \( X \). While being classically of interest already, in that work also the quantum situation has been clarified yielding a complete classification of KMS states for formal star products on symplectic manifolds.

In this paper we wish to push ahead these investigations. Our main goal is to show that, varying \( X \), the set of KMS functionals \( \text{KMS}(M, \Pi, X, \beta) \) captures information about the symplectic foliation of \( M \). This is clear for functionals \( \varphi \) induced by smooth densities —where \( X \) is forced to lie in the modular class— however, more information is achievable when considering more general functionals. The positivity requirement on \( \varphi \) plays a major rôle, as it implies that \( \varphi \) is a distribution of order 0, thus enforcing a minimal requirement of continuity.

Generally speaking the set \( \text{KMS}(M, \Pi, X, \beta) \) is a convex cone which heavily depends on the choice of \( X \) and \( \beta \). Per definition, a phase transition occurs whenever different choices for \( X, \beta \) produce non-isomorphic cones. For example, in [6] it is proved that \( \text{KMS}(M, \Pi, X, \beta) \) is non-empty if and only if \( X \) is Hamiltonian, in which case the cone of KMS functionals is isomorphic to the one of \( \Pi \)-traces (which can be shown to be a singleton up to multiplicative constant). We will recall the precise result later in Remark 4. In the general case we expect phase transitions to reflect the geometry of the underlying Poisson structure.

Given the large variety of Poisson manifolds, a general description of \( \text{KMS}(M, \Pi, X, \beta) \) for all \((M, \Pi)\) is probably too ambitious. In this paper we shall consider the particular class of \( b \)-Poisson manifolds [34]. These are even dimensional Poisson manifolds whose associated Poisson tensor \( \Pi \) is, roughly speaking, singular on a codimension 1 submanifold. These structures are degenerate in a very controlled way and they recently attracted a lot of interest [7, 8, 12, 20, 21, 22, 29, 30, 33].

Our main result is Theorem 37, which provides a complete classification of \( \text{KMS}(M, \Pi, X, \beta) \) for all choices of a Poisson vector field \( X \) and \( \beta > 0 \). A similar result concerning \( \Pi \)-traces is not available, however, we prove a uniqueness result for \( \Pi \)-traces which are invariant under the modular class in Theorem 19.

These results corroborate the geometrical intuition that \( \text{KMS}(M, \Pi, X, \beta) \) provides information about the geometry of \((M, \Pi)\). This correspondence is not completely settled, therefore, in Section 4 we provide several non-trivial examples where \( \text{KMS}(M, \Pi, X, \beta) \) can be computed explicitly. This allows us to build our intuition for future investigations.

The paper is organized as follows: In Section 2 we introduce and discuss the main properties of KMS functionals with a particular focus on symplectic and cosymplectic manifolds. Section 3 is devoted to the study of the convex cone of KMS functionals for the case of a \( b \)-Poisson manifold. Section 4 presents two non-trivial examples of regular Poisson manifolds for which the set of KMS functionals can be computed explicitly.

## 2 Main Properties of Classical KMS Functionals

Let \((M, \Pi)\) be a Poisson manifold of dimension \( \dim M = m \). For the sake of simplicity we shall always assume that \( M \) is orientable, however, we point out that this is a priori not necessary for stating Definition 1. In what follows \( X_g \) will denote the Hamiltonian vector field associated with \( g \in C^\infty(M) \), determined by \( X_g(f) = \{f, g\} \) for all \( f \in C^\infty(M) \). We shall denote by
Let $\Psi^{-1}$ denote the inverse of the linear positive functional $\Psi$ and let $\mu := \Psi^{-1}(1)$. In particular if $\mu$ is not normalized, therefore $\Psi^{-1}$ is not necessarily normalized, therefore $\Psi^{-1}$ is a convex cone. Positivity of $\Psi^{-1}$ entails that $\mu$ is a distribution of order $0$ that is, for all compact $K \subseteq M$ there exists $C_K > 0$ such that

$$|\mu| \leq C_K \sup_K |f|, \quad \forall f \in C_0^\infty(K).$$

In particular $\mu$ admits a unique extension $\tilde{\mu} \in M_+(M)$ to a positive measure over $M$.

In the limit case $X = 0$ Equation (1) identifies positive Poisson traces which we shall denote by KMS($M, t$). Moreover, for all $\beta > 0$ we have KMS($M, t$, $X, \beta$) = KMS($M, t$, $X, \beta$) while, for all $\beta, \beta' > 0$ it holds $\varphi \in$ KMS($M, t, X, \beta$) if and only if $\varphi \in$ KMS($M, t, X, \beta'$) if and only if $\varphi \in$ KMS($M, t$). This may happen whenever $\supp(\varphi) \cap \supp(\beta) = \emptyset$ as shown by the following example.

Example 3: Let $M = \mathbb{R} \times \mathbb{T}$ with Poisson structure $\Pi = x \partial_x \wedge \partial_y$ and let $X := x \partial_x$. Then any $\varphi \in$ KMS($M, t$) such that $\supp(\varphi) \subseteq \{x = 0\}$ defines an element $\varphi \in$ KMS($M, t, X, \beta$) for all $\beta > 0$. In fact, KMS($M, t, X, \beta$) is exactly made by these functionals as a consequence of Theorem 3.

Remark 4 (Symplectic manifolds): For a symplectic manifold the convex cone KMS($M, t, X, \beta$) have been classified for all Poisson vector field $X$, cf. [3] Thm. 8. In particular if $(M, t)$ is a connected symplectic manifold and $[X] \in H^1_t(M)$ denotes the Poisson cohomology class of $X$, then

$$\text{KMS}(M, t, X, \beta) \simeq \begin{cases} [0, +\infty) & \text{for } [X] = [0] \\ \{0\} & \text{for } X \neq [0] \end{cases},$$

where $\simeq$ denotes isomorphism of convex cone. In particular if $X = X_h$ we have

$$\text{KMS}(M, t, X_h, \beta) = \left\{ c I_{\mu_{\beta}} \mid \mu_{\beta} = e^{-\beta h} \mu_0, \ c > 0 \right\}, \quad I_{\mu}(f) := \int_M f \mu.$$
for a different though similar in spirit dynamical condition. Such condition generalizes the invariance of $\Pi$-traces under Hamiltonian flows and implies in particular a support constrain on symplectic leaves.

**Proposition 5:** Let $\varphi \in \text{KMS}(M, \Pi, X, \beta)$ as per Definition 1. Then:

1. $\varphi$ is invariant under the flow of $X$, that is
   \[\varphi \circ \Psi^X = \varphi.\]  
   \hfill (4)

2. For all complete Hamiltonian vector field $X_g$ it holds
   \[\varphi(f) = \varphi\left(\exp\left[\beta \int_0^t [\Psi_s^g]^*X(g)ds\right](\Psi_s^g)^*f\right), \quad \forall t \in \mathbb{R}.\]  
   \hfill (5)

3. If $M$ is compact then $x \in \text{supp}(\varphi)$ implies $L_x \subseteq \text{supp}(\varphi)$, where $L_x$ is the symplectic leaf through $x$. In particular
   \[\text{supp}(\varphi) = \bigcup_{x \in \text{supp}(\varphi)} L_x.\]

**Proof.**

1. For all $f \in C^\infty_c(M)$ let $1_f \in C^\infty(M)$ be such that $1_f|_{\text{supp}(f)} = 1$. A direct computation leads to
   \[\beta \varphi(X(f)) = \beta \varphi(1_fX(f)) = \varphi(1_f, f) = 0.\]

   If follow that $\varphi \circ X = 0$ which entails the invariance property $\varphi \circ \Psi^X = \varphi$.

2. For all $f \in C^\infty_c(M)$ a direct computation leads to
   \[\varphi(X_g(f)) = \varphi(\{f, g\}) = \varphi(\{f, 1_f g\}) = \beta \varphi(gX(f)) = -\beta \varphi(X(g)f).\]

   The previous equality entails $\varphi \circ D_{g,X} = 0$ where $D_{g,X}$ is the first order differential operator $D_{g,X} := X_g + \beta X(g)$. Integrating this equality leads to Equation (5).

3. Finally we prove that $L_x \subset \text{supp}(\varphi)$ if $x \in \text{supp}(\varphi)$. We recall that for any $y \in L_x$ there exist $n \in \mathbb{N}, t_1, \ldots, t_n \in \mathbb{R}$ and $g_1, \ldots, g_n \in C^\infty(M)$ such that $y = \Psi^{g_1}_{t_1} \circ \cdots \circ \Psi^{g_n}_{t_n}(x)$. Therefore it is enough to show that $\Psi_{-t}(x) \in \text{supp}(\varphi)$ if $x \in \text{supp}(\varphi)$.

   By definition, $x \in \text{supp}(\varphi)$ is equivalent to the existence of a positive function $f \in C^\infty_c(M)$ such that $x \in \text{supp}(f)$ and $\varphi(f) > 0$. Let now
   \[f_t := \exp\left(-\beta \int_0^t [\Psi_s^g]^*X(g)ds\right)[\Psi_t^g]^*f \in C^\infty_c(M).\]

   It follows that $\Psi_{-t}(x) \in \text{supp}(f_t)$ and $\varphi(f_t) = \varphi(f) > 0$ because of Equation (5). Therefore $\Psi_{-t}(x) \in \text{supp}(\varphi)$. 

\[\square\]
Remark 6: We stress that the completeness of \( X_g \) in Item 2 is assumed only for the sake of simplicity: If \( X \) is not complete Equation (5) still holds true on small open subsets of \( M \) provided \( t \) is chosen so that \( \Psi^s_t \) exists for all \( s \in [0, t] \). A similar comment applies concerning the compactness of \( M \) in Item 3.

2.2 Stability under Hamiltonian Perturbation and Relation with Weinstein’s Modular Class

Definition 1 does not require any particular assumption on \( X \in \Gamma(TM) \). However, the forthcoming Lemma 7 shows that under mild conditions the vector field \( X \) has to be a Poisson vector field. We recall that a positive functional \( \varphi: C_\infty(M) \to \mathbb{C} \) is called faithful if, for all positive \( f \in C_\infty(M) \), \( \varphi(f) = 0 \) implies \( f = 0 \).

Lemma 7: Let \( \varphi \in \text{KMS}(M, \Pi, X, \beta) \) be faithful. Then \( X \) is Poisson.

Proof. Let \( \varphi \in \text{KMS}(M, \Pi, X, \beta) \) and let us consider \( f, g, h \in C_\infty(M) \). A direct inspection leads to

\[
\begin{align*}
\beta \varphi(gX(\{f, h\})) &= \varphi(\{f, h\}, g) \\
&= -\varphi(\{g, \{h, f\}\}) - \varphi(\{g, f\}, h)
\end{align*}
\]

where we exploited the KMS condition \( (1) \). Moreover, the KMS condition also implies \( \beta \varphi(\{h, X(f)g\}) + \beta \varphi(\{g, X(f)h\}) = 0 \), so that we end up with

\[
\varphi(gX(\{f, h\}) - \{X(f), h\} - \{f, X(h)\})) = 0.
\]

If now \( \varphi \) is also faithful, then the arbitrariness of \( g \in C_\infty(M) \) entails \( X(\{f, h\}) = \{X(f), h\} + \{f, X(h)\} \), that is, \( X \) is Poisson. \( \square \)

On compact symplectic manifolds, Proposition 5 entails \( \text{supp}(\varphi) = M \) for all non-zero \( \varphi \in \text{KMS}(M, \Pi, X, \beta) \), no matter the choice of \( X \) and \( \beta \). If follows that \( \varphi \) is faithful and therefore \( X \) is Poisson because of Lemma 7. This entails in particular that \( \text{KMS}(M, \Pi, X, \beta) = \{0\} \) if \( X \) is not Poisson.

In the forthcoming discussion we shall also deal with non-faithful KMS functionals. The reason for this choice are twofold: on the one hand the global KMS condition \( (5) \) is a rather strong requirement which makes KMS functionals rare for generic \( X \). On the other hand choosing a Poisson vector field \( X \) provides a nicer interplay with the underlying Poisson structure. In fact Lemma 8 shows that, for a Poisson vector field \( X \), the set \( \text{KMS}(M, \Pi, X, \beta) \) only depends on the Poisson cohomology class of \( X \).
Lemma 8: Let $X \in \Gamma(TM)$ be a Poisson vector field. Then for all $\lambda \in C^\infty(M)$ and $\beta > 0$
\[
KMS(M, \Pi, X, \beta) \ni \varphi \mapsto \varphi_{\lambda} \in KMS(M, \Pi, X - X_{\lambda}, \beta), \quad \varphi_{\lambda}(f) := \varphi(e^{\beta \lambda} f),
\]
is an isomorphism of convex cones. In particular if $X = X_h$ is Hamiltonian, where $h \in C^\infty(M)$, then for all $\beta > 0$
\[
KMS(M, \Pi, X_h, \beta) \simeq KMS(M, \Pi).
\]

Proof. Let $\varphi \in KMS(M, \Pi, X, \beta)$ and set $\varphi_{\lambda}(f) := \varphi(e^{\beta \lambda} f)$ for all $f \in C^\infty_c(M)$. We claim that $\varphi_{\lambda} \in KMS(M, \Pi, X - X_{\lambda}, \beta)$. Indeed $\varphi_{\lambda}$ is linear and positive, while for all $f, g \in C^\infty_c(M)$ we have
\[
\varphi_{\lambda}\{f, g\} = \varphi(e^{\beta \lambda}\{f, g\}) = \varphi(\{fe^{\beta \lambda} - ge^{\beta \lambda}\}) = \beta \varphi(ge^{\beta \lambda}X(f)) - \beta \varphi(ge^{\beta \lambda}X_{\lambda}(f)).
\]
By direct inspection, the map $KMS(M, \Pi, X, \beta) \ni \varphi \mapsto \varphi_{\lambda} \in KMS(M, \Pi, X - X_{\lambda}, \beta)$ is an isomorphism of convex cones. \hfill \Box

Remark 9: Equation 6 in Lemma 8 can be interpreted as a stability property of the set of KMS functionals. Indeed, let $f \in C^\infty_c(M)$ and let $X \in \Gamma(TM)$ be a Poisson vector field: in this situation the vector field $X + X_f$ is interpreted as a small perturbation of the dynamics associated with $X$. Lemma 8 ensures that for any $\varphi \in KMS(M, \Pi, X, \beta)$ there exists a perturbed KMS functional $\varphi_f \in KMS(M, \Pi, X + X_f, \beta)$. In this sense we may say that $KMS(M, \Pi, X, \beta)$ is stable under small (in the sense of being inner) perturbation. This feature is the classical analogue of the stability property for quantum KMS functionals in the $C^*$-algebraic setting [3, 23, 24] – see also [13, 14, 15, 16] for similar results in the $\ast$-algebraic setting.

Lemma 7 and Lemma 8 suggest to restrict our investigation to the case of $(X, \beta)$-KMS functionals for Poisson vector fields only.

Definition 10: Let $X \in TM$ be a Poisson vector field. Under the identification proved in Lemma 8 we denote by $KMS(M, \Pi, [X], \beta)$ the set of classical KMS functionals associated with $[X] \in H^1_{\Pi}(M)$, where $H^1_{\Pi}(M)$ denotes the first Poisson cohomology group. We will also let $KMS(M, \Pi) = KMS(M, \Pi, [0])$ denote the set of positive II-traces over $M$.

We now show that, at least for a specific choice of $[X] \in H^1_{\Pi}(M)$ and $\beta > 0$ one has $KMS(M, \Pi, [X], \beta) \neq \{0\}$, cf. Remark 12. This also gives an indication on the connection between the convex cone of KMS functionals and the underlying Poisson structure.

Definition 11: A classical KMS functional $\varphi$ is called regular if there exists a volume form $\mu \in \Omega^m(M)$ such that
\[
\varphi(f) = I_\mu(f) := \int_M f \mu \quad \forall f \in C^\infty_c(M).
\]
If $\mu \in \Omega^m(M)$ is a volume form and $f, g \in C^\infty_c(M)$ we have
\[
I_\mu\{f, g\} = -\int_M \mathcal{L}_{X_f}(g) \mu = \int_M g \mathcal{L}_{X_f}(\mu) = \int_M g \text{div}_\mu(X_f) \mu.
\]
This leads to the following result:
Remark 12 (Weinstein [36]): Let $\mu \in \Omega^m(M)$ be a volume form and let
\[ Y_\mu(f) := \text{div}_\mu(X_f) \quad \forall f \in C^\infty(M). \]
Then $Y_\mu$ is a Poisson vector field and $I_\mu \in \text{KMS}(M, \Pi, [Y_\mu], 1)$. Moreover the Poisson cohomology class $[Y_\mu]$ does not depend on $\mu$. This Poisson cohomology class is called the \textbf{modular class} of $(M, \Pi)$ and it is denoted with $[Y_\Pi]$. A Poisson manifold with vanishing modular class is called \textbf{unimodular}.

Equation (8) entails in particular that regular $(X, \beta)$-KMS functionals exist if and only if $\beta X \in [Y_\Pi]$.

Remark 13: If $M$ is compact, any Poisson trace can be though as a positive linear functional on the first homology group $H^1_\Pi(M) := \frac{C^\infty(M)}{[C^\infty(M), C^\infty(M)\Pi]}$. A similar interpretation is possible for $(X, \beta)$-KMS functionals. For that we have to introduce the complex
\[ \{0\} \leftarrow \cdots \Omega^0(M) \leftarrow \Omega^1(M) \leftarrow \cdots \Omega^m(M), \]
where $\delta_\beta := d\Pi - \Pi d - \beta X$. A direct inspection shows that $\delta_\beta^2 = 0$, therefore we can define the $(X, \beta)$-homology group $H^*_\beta(M) := \frac{\ker \delta_\beta}{\text{im} \delta_\beta}$. Moreover a direct computation leads to
\[ \delta_\beta(gdf) = \{f, g\} - \beta gX(f), \]
which shows that positive linear functionals on $H^*_\beta(M)$ satisfies the classical KMS condition [1].

For the case of a unimodular Poisson manifold, i.e. $[Y_\Pi] = [0]$, Poisson homology and cohomology are isomorphic [28, Prop. 4.18]. In fact, $H^k_\Pi(M) \ni [X] \mapsto [\iota_X \mu] \in H^{k-1}_\Pi(M)$ is an isomorphism. Here $\mu$ is any volume form such that $Y_\mu = 0$. Similarly we may define a $(X, \beta)$-Poisson cohomology $H^*_X(M)$ such that $[X] \mapsto [\iota_X \mu]$ descends to an isomorphism $H^*_X(M) \simeq H^*_\beta(M)$. To this avail it suffices to consider the complex
\[ C^\infty(M) \xrightarrow{d_\beta} \Gamma(TM) \xrightarrow{d_\beta} \Gamma(\wedge^2 TM) \xrightarrow{d_\beta} \cdots \xrightarrow{d_\beta} \Gamma(\wedge^m TM), \]
where $d_\beta = \Pi - \beta X$. A direct inspection shows that $d_\beta^2 = 0$, therefore $H^*_X(M) := \frac{\ker d_\beta}{\text{im} d_\beta}$ are well-defined. The proof that $H^k_\beta(M) \ni [X] \mapsto [\iota_X \mu] \in H^k_{m-k}(M)$ is a well-defined isomorphism follows the one presented in [28, Prop. 4.18].

2.3 Extremal KMS Functionals

By the very definition, the set of KMS functionals $\text{KMS}(M, \Pi, [X], \beta)$ is a convex cone. For a compact manifold $M$ we can normalize all KMS functionals by setting $\hat{\phi}(f) := \varphi(1)^{-1}\varphi(f)$. Such normalized positive functionals are referred to as \textbf{states}. In this way we are reduced to consider the convex set of KMS states which we shall denote by $\text{kms}(M, \Pi, [X], \beta)$.

We recall that for a convex subset $C$ of a vector space of a real $V$ a point $x \in C$ is called \textbf{extremal} if for all $x_1, x_2 \in C$ such that $x = \lambda_1 x_1 + \lambda_2 x_2$ for $\lambda_1, \lambda_2 \in (0, 1)$ with $\lambda_1 + \lambda_2 = 1$, we
have $x = x_1 = x_2$. In what follows we shall denote by $\text{kms}_0(M, \Pi, [X], \beta) \subseteq \text{kms}(M, \Pi, [X], \beta)$ the set of extremal KMS states.

A standard application of the Krein-Milman Theorem entails that the convex hull of extremal KMS states generates all KMS states:

$$\text{kms}(M, \Pi_c, [X], \beta) = \text{conv}(\text{kms}_0(M, \Pi_c, [X], \beta)),$$

where the bar denotes closure with respect to the weak* topology of $\mathcal{M}_+(M)$.

Indeed Equation (1) entails that $\text{kms}(M, \Pi, [X], \beta)$ is a weakly*-closed subset of the (weakly*-compact) unit ball of the Banach space $C(M)'$. Thus $\text{kms}(M, \Pi, [X], \beta)$ is weakly*-compact and the Krein-Milman theorem applies. Therefore, whenever $M$ is compact we may focus on $\text{kms}_0(M, \Pi, [X], \beta)$.

Extremal KMS states are interpreted as pure thermodynamical phases of the system under investigation and it is natural to conjecture that extremal states have to be supported on the leaves of $M$. Indeed, for leaves that embed nicely into $M$ we have the following statement.

**Proposition 14:** Let $M$ be compact, $[X] \in H^1_{TM}(M)$ and let $L \subset M$ be a leaf which is a smooth submanifold of $M$. Then any $\varphi \in \text{kms}(M, \Pi, [X], \beta)$ such that $\text{supp}(\varphi) \subseteq L$ is extremal.

**Proof.** Let $\varphi_1, \varphi_2 \in \text{kms}(M, \Pi, [X], \beta)$ be such that $\varphi = \lambda_1 \varphi_1 + \lambda_2 \varphi_2$, where $\lambda_1, \lambda_2 \in (0, 1)$ are such that $\lambda_1 + \lambda_2 = 1$. For every function $f \geq 0$ with $\text{supp}(f) \subseteq M \setminus L$ we have

$$0 = \varphi(f) = \lambda_1 \varphi_1(f) + \lambda_2 \varphi_2(f).$$

Positivity of $\varphi_1$ and $\varphi_2$ entails that $\varphi_1(f) = \varphi_2(f) = 0$, too. As non-negative functions are sufficient to test the support of positive functionals, we conclude that $\text{supp}(\varphi_1) \cup \text{supp}(\varphi_2) \subseteq \overline{L} = L$ as $L$ is proper. Therefore we have $\varphi = \varphi_1 = \varphi_2$ on account of Remark 4.

However, without any further assumption on the leaf $L$, Proposition 14 turns out to be false in general as shown in Section 4.1. Therein we discuss in detail an example of a compact Poisson manifold for which $\text{kms}_0(M, \Pi, [X], \beta)$ can be computed explicitly and which is such that no KMS states are supported on the leaves – cf. Proposition 14.

Even if $M$ is not compact the notion of extremal KMS functionals still make sense. In fact we shall call $\varphi \in \text{KMS}(M, \Pi, [X], \beta)$ **extremal** whenever $\varphi = \varphi_1 + \varphi_2$ for $\varphi_1, \varphi_2 \in \text{KMS}(M, \Pi, [X], \beta)$ implies that there exists $\lambda_1, \lambda_2 > 0$ such that $\varphi_1 = \lambda_1 \varphi$, $\varphi_2 = \lambda_2 \varphi$.

With this definition at hand one may try to apply a suitable generalization of the Krein-Milman theorem to the convex cone made of KMS functionals. However, at first glance this seems not directly applicable and we shall postpone this discussion to a future investigation.

**Remark 15:** Notice that the proof of Proposition 14 generalizes to the non-compact case. In fact, if $L \subset M$ is a leaf which is a smooth submanifold of $M$ and $\varphi \in \text{KMS}(M, \Pi, [X], \beta)$ is such that $\text{supp}(\varphi) \subseteq L$, then $\varphi$ is extremal.

**Example 16:** For the degenerate case of a trivial Poisson manifold $(M, \Pi)$, $\Pi = 0$, we find that, for any $X \in \Gamma(TM)$ and $\varphi \in \text{KMS}(M, \Pi, X, \beta)$ it holds

$$\text{supp}(\varphi) \subseteq \{ x \in M \mid X|_x = 0 \}.$$
Indeed for any \( x \in M \) such that \( X|_x \neq 0 \) we can find a neighbourhood \( U \) of \( x \) and \( f \in C_c^\infty(M) \) with \( U \subset \text{supp}(f) \) and such that \( X(f)|_U = 1 \). Applying the KMS condition we obtain, for all \( g \in C_c^\infty(U) \),

\[
\beta \varphi(g) = \beta \varphi(X(f)g) = \varphi(\{f, g\}) = 0.
\]

In particular \( \varphi \in \text{KMS}(M, \Pi, X, \beta) \) is an extremal point in \( \text{KMS}(M, \Pi, X, \beta) \) if and only if

\[\varphi \in \{\delta_x \mid x \in M, X|_x = 0\},\]

where \( \delta_x(f) := f(x) \) is the Dirac delta measure centred at \( x \in M \).

### 2.4 Cosymplectic Manifolds

Before starting with the study of the convex set of KMS functionals for \( b \)-Poisson manifolds, we shall consider the case of a cosymplectic manifold \((M, \Pi)\). The latter is a particular example of a Poisson manifold whose foliation is regular with codimension 1. Moreover, cosymplectic manifolds naturally arise in the study of \( b \)-Poisson manifold, see also Remark 24.

We shall now recall some basic facts on cosymplectic manifolds, see [11] and references therein for an extensive review. A smooth manifold \( M \) is called cosymplectic if \( \dim M = 2n + 1 \) and there exists \( \eta \in \Omega^1(M) \) and \( \omega \in \Omega^2(M) \) such that

\[
d\eta = 0, \quad d\omega = 0, \quad \eta \wedge \omega^n > 0.
\]  

Any cosymplectic manifold \((M, \eta, \omega)\) admits a Poisson manifold structure defined as follows. One first observes that the map

\[
b: \Gamma(TM) \rightarrow \Omega^1(M), \quad b(X) := \iota_X \omega + \eta(X)\eta,
\]

is an isomorphism of vector spaces. For later convenience we recall that the vector field \( \xi := b^{-1}(\eta) \in \Gamma(TM) \) is called Reeb vector field. The Poisson tensor \( \Pi \in \Gamma(\wedge^2 TM) \) is then defined by

\[
\Pi(\alpha, \sigma) := \omega(b^{-1}(\alpha), b^{-1}(\sigma)),
\]

for all \( \alpha, \sigma \in \Omega^1(M) \). The following remark recollects all relevant results for the forthcoming discussion [11].

**Remark 17:** Let \((M, \eta, \omega)\) be a cosymplectic manifold. Then:

1. The anchor map \( \sharp: \Omega^1(M) \rightarrow \Gamma(TM) \) associated with the Poisson tensor \( \Pi \) defined in Equation [11] is given by

\[
\alpha^\sharp = -\iota_{b^{-1}(\alpha)}\omega = b^{-1}(\alpha) - \alpha(\xi)\xi.
\]

Moreover, the symplectic foliation coincides with the foliation \( x \mapsto \ker \eta_x \) induced by \( \eta \in \Omega^1(M) \) and the symplectic form \( \omega_L \) associated with any leaf \( L \) is given by \( \omega_L = \iota_L^*\omega \).
2. For all \( k \in \mathbb{N} \cup \{0\} \), let \( \Omega^k(M) := \frac{\Omega^k(M)}{\ker d_\eta} \). Then the differential descends to a well-defined linear map \( d_k: \Omega^k(M) \to \Omega^{k+1}(M) \) and we shall denoted with \( H^k_\eta(M) := \frac{\ker d_k}{\im d_{k-1}} \) the associated cohomology group. Moreover, there is an isomorphism of vector spaces

\[
H^1_\Pi(M) \cong H^1_\eta(M) \oplus H^0_\eta(M).
\]

In particular any \([X] \in H^1_\Pi(M)\) can be written as \([X] = [\alpha + f\xi]\) where \([\alpha] \in H^1_\eta(M)\) and \(f \in H^0_\eta(M)\).

We now address the problem of describing the convex cone

\[
\text{KMS}([\sigma], f, \beta) := \text{KMS}(M, \Pi, [\sigma + f\xi], \beta),
\]

where \(f \in H^0_\eta(M)\) and \([\sigma] \in H^1_\eta(M)\). The begin with a result which holds for any regular codimension 1 Poisson manifold.

Lemma 18: Let \((M, \Pi)\) be a codimension 1 regular Poisson manifold. Let \([X] \in H^1_\Pi(M)\) be such that one (hence all) \(X \in [X]\) is transversal to the symplectic foliation of \(M\). Then \(\text{KMS}(M, \Pi, [X], \beta) = \{0\}\) for all \(\beta > 0\).

Proof. We shall prove that any \(\varphi \in \text{KMS}(M, \Pi, X, \beta)\) is the zero functional. For that let \(L \subseteq M\) be a leaf of \(M\) and \(K \subseteq L\) be any compact subset of \(L\). Let \(K_\epsilon\) be an \(\epsilon\)-tubular neigbourhood of \(K\) built out of the flow \(\Psi^X\) of \(X\) - that is \((-\epsilon, \epsilon) \times K \ni (t, x) \mapsto \Psi^X_t(x) \in K_\epsilon\) is a diffeomorphism. Notice that, since \(X\) is transversal to the symplectic foliation, \(\Psi^X_t(K)\) is a (compact subset of a) leaf for all \(t \in (-\epsilon, \epsilon)\). In particular this entails that the locally defined 1-form \(dt\) vanishes on all Hamiltonian vector fields.

For any \(g \in C^\infty_c(K_\epsilon)\) let \(1_g \in C^\infty_c(K_\epsilon)\) be such that \(1_g|_{\text{supp}(g)} = 1\) and set \(f(\Psi^X_t(x)) := t1_g(\Psi^X_t(x))\). Then \(f \in C^\infty_c(M)\) and \(X(f)|_{\text{supp}(g)} = 1\). The classical KMS condition implies that

\[
\beta \varphi(g) = \beta \varphi(gX(f)) \equiv \beta \varphi(\{f, g\}) = \beta \varphi(X_g(t)) = 0,
\]

where we used that \(X_g(f) = X_g(t1_g) = X_g(t) = 0\). The arbitrariness of \(g \in C^\infty_c(K_\epsilon)\) and \(K\) ensures that \(\varphi = 0\). \(\square\)

Lemma 18 entails that \(\text{KMS}([\sigma], f, \beta) = \{0\}\) unless \(f = 0\). For what concern the remaining cases we have the following theorem.

Theorem 19: Let \((M, \eta, \omega)\) be a cosymplectic manifold. Moreover, let \([\sigma] \in H^1_\eta(M)\) as well as \(\xi := b^{-1}(\eta)\) and let \(\mu := \eta \wedge \omega^n\). Then

1. setting \(\varphi_\mu := I_\mu\) we have that \(\varphi_\mu \in \text{KMS}(M, \Pi)\) as well as \(\varphi_\mu \circ \xi = 0\). In particular \(M\) is unimodular. Moreover any \(\varphi \in \text{KMS}(M, \Pi)\) which is invariant under \(\xi\) is a multiple of \(\varphi_\mu\).
2. if $M$ is compact and there exists a proper leaf $L_0 \hookrightarrow M$ then $\varphi \in \text{kms}_0([\sigma], \beta) := \text{kms}_0(M, \Pi, [\sigma^*], \beta)$ implies that $\text{supp}(\varphi) \subseteq L$ where $L$ is a leaf such that $\iota_L \sigma$ is exact. In particular

$$\text{kms}_0([\sigma], \beta) \simeq \left\{ I_L^* \omega^n \mid L \text{ leaf , } \iota_L^* \sigma \text{ is exact} \right\}.$$

where $I_L^* \omega^n$ is the Liouville form associated with the leaf $L$. In particular the support of $\varphi \in \text{kms}([\sigma], \beta)$ is contained in the union of the leaves $L$ such that $\iota_L^* \sigma$ is exact.

**Proof.** We first observe that, for all $f \in C^\infty(M)$,

$$\mathcal{L}_{X_f}(\mu) = \mathcal{L}_{X_f}(\eta) \wedge \omega^n - \eta \wedge \mathcal{L}_{X_f}(\omega^n) = d\mathcal{L}_{X_f}(\eta) \wedge \omega^n - \eta \wedge d\mathcal{L}_{X_f}(\omega^n) = 0,$$

where we used $\eta(X_f) = 0$ as well as $\iota_{X_f} \omega = df$. This shows that $I_\mu$ induces a Poisson trace – in fact, it also shows that $[Y_\Pi] = [0]$, i.e. $M$ is unimodular. Moreover we have

$$\mathcal{L}_\xi(\mu) = \mathcal{L}_\xi(\eta) \wedge \omega^n + \eta \wedge \mathcal{L}_\xi(\omega^n) = 0,$$

which entails that $\varphi_\mu$ is $\xi$-invariant.

Conversely, let $\varphi \in \text{KMS}(M, \Pi)$ be $\xi$-invariant. We consider the symplectification \[\mathrm{I}\] of $(M, \eta, \omega)$, that is, the symplectic manifold $(\tilde{M}, \tilde{\omega})$ given by

$$\tilde{M} = M \times \mathbb{T}, \quad \tilde{\omega} = \omega + \eta \wedge d\theta,$$

where $\theta$ is the usual quasi-global angle coordinate on the circle. Let $\hat{\varphi}$ be the functional

$$\hat{\varphi} : C^\infty_c(\tilde{M}) \to \mathbb{C}, \quad \hat{\varphi}(f) := \frac{1}{2\pi} \int_0^{2\pi} \varphi(f_\theta)d\theta,$$

where $f_\theta \in C^\infty_c(M)$ denotes the restriction of $f \in C^\infty_c(\tilde{M})$ to $M \times \{e^{i\theta}\}$. A direct inspection leads to

$$\hat{\varphi}(\{ f, g \}_{\tilde{M}}) = \frac{1}{2\pi} \int_0^{2\pi} [\varphi(\{ f_\theta, g_\theta \}_{\tilde{M}}) + \varphi(\xi(f_\theta)\partial_0 g_\theta) - \varphi(\partial_0 f_\theta \xi(g_\theta))] d\theta$$

$$= \frac{1}{2\pi} \int_0^{2\pi} \frac{d}{d\theta} \varphi(\xi(f_\theta)g_\theta) d\theta = 0,$$

where we used the $\xi$-invariance to obtain the equality $\varphi(\partial_0 f_\theta \xi(g_\theta)) = -\varphi(\partial_0 \xi(f_\theta) g_\theta)$. It follows that $\hat{\varphi} \in \text{KMS}(\tilde{M}, \tilde{H})$: on account of Remark \[\mathrm{II}\] there exists $c > 0$ such that

$$\hat{\varphi}(f) = \frac{c}{2\pi} \int_0^{2\pi} f d\theta \wedge \eta \wedge \omega^n, \quad \forall f \in C^\infty_c(\tilde{M}).$$

Finally $\hat{\varphi}(f) = \varphi(f)$ for all $f \in C^\infty_c(M) \subset C^\infty_c(\tilde{M})$, therefore $\varphi = c \varphi_\mu$. 

12
As we assumed $M$ to be compact, we are reduced to consider the convex set $\text{kms}([\sigma], \beta)$ of KMS states. We shall now prove that an extremal KMS state $\varphi \in \text{kms}_0([\sigma], \beta)$ is necessarily supported on a leaf $L$. Indeed, since $M$ admits a proper leaf $L_0$, all leaves are proper and diffeomorphic to $L_0$, the diffeomorphism being given by the flow $\Phi^\xi$ associate with $\xi$, see [19, Thm. 13]. As a matter of fact $M$ is a mapping torus so that $\Phi^\xi$ is periodic. By Proposition 14 any KMS state supported on a leaf is necessarily extremal.

Conversely if $\varphi \in \text{kms}([\sigma], \beta)$ is extremal it has to be supported on a leaf. Indeed, let $t, s \in \mathbb{R}$ be such that the leaves $L_t = \Phi^\xi_t(L_0)$ and $L_s = \Phi^\xi_s(L_0)$ are such that $L_t \cap \text{supp}(\varphi) \neq \emptyset$, $L_s \cap \text{supp}(\varphi) \neq \emptyset$. By Proposition 9 we necessarily have $L_t \cup L_s \subseteq \text{supp}(\varphi)$. We shall now built $\varphi_1 \in \text{kms}([\sigma], \beta)$ such that $\lambda \varphi_1 \leq \varphi$ for $0 < \lambda < 1$. This shows that $\varphi$ is not extremal as

$$\varphi = \lambda \varphi_1 + (1 - \lambda) \varphi_2,$$

$$\varphi_2 := \frac{1}{1 - \lambda} (\varphi - \lambda \varphi_1).$$

Let $\chi \in C^\infty_c(\mathbb{R})$ be such that $0 \leq \chi \leq 1$, $\chi(t) = 1$ and $s \notin \text{supp} \chi$. Let $h_\chi \in C^\infty(M)$ be defined by $h(\Phi^\xi_t(x)) = \chi(\tau)$ where $x \in L_0$ and $\tau \in \mathbb{R}$. Notice that $h_\chi$ is a well-defined function provided we shrink $\text{supp} \chi$ enough so that it stays within the period of the flow $\Phi^\xi$. Moreover, per construction $h_\chi \in C^\infty_c(M) \cap H^0_{\text{Hil}}(M)$.

We then define $\varphi_\chi : C^\infty_c(M) \to \mathbb{C}$ by $\varphi_\chi(f) := \varphi(h_\chi)^{-1} \varphi(h_\chi f)$. It follows that $\varphi_\chi$ is a state: In fact, $\varphi_\chi \in \text{kms}([\sigma], \beta)$ as

$$\varphi_\chi(\{f, g\}) = \varphi(\{f, h_\chi g\}) = \beta \varphi_\chi(\sigma^2 h_\chi f).$$

Finally $\varphi_\chi \leq \lambda \varphi$ for $\lambda := \varphi(h)$.

Therefore $\varphi \in \text{kms}_0([\sigma], \beta)$ is necessarily supported on a leaf $L$: By Remark 4 this implies that $\iota^*_L \sigma$ is exact and that $\varphi = I_{\mu_\beta}$ where $\mu_\beta = e^{\beta H_L} \iota^*_L \omega^{\wedge n}$, where $H_L \in C^\infty(L)$ is such that $dH_L = \iota^*_L \omega^{\wedge n}$ is the associated Liouville form. This shows that $\text{kms}_0([\sigma], \beta)$ can be identified with the collection

$$\left\{ I_{\iota^*_L \omega^{\wedge n}} \mid L \text{ leaf, } \iota^*_L \sigma \text{ is exact} \right\}.$$

The last statement follows from the equality $\text{kms}([\sigma], \beta) = \overline{\text{kms}_0([\sigma], \beta)}$.

Theorem 19 shows that the convex cone of KMS functionals associated with a cosymplectic structure is essentially made by Poisson traces with support constraints. Remarkably, among all Poisson traces, there exists a preferred one, which is invariant under the flow of the vector field $\xi$. The result in item 2 is obtained under the assumption of compactness of $M$ together with the existence of a proper leaf $L$. We conjecture that such a result still holds true when dropping the last assumption.
Example 20: We shall discuss the convex cone of KMS functional for the non-compact cosymplectic manifold defined by

\[ M := \mathbb{R}^2 \times T, \quad \eta := dx, \quad \omega = dy \wedge d\theta, \]

where \( \theta \in [0, 2\pi) \). By direct inspection we have

\[ H^1_{f}(M) \cong C^\infty(\mathbb{R})^2, \quad [X] = [a\partial_x + b\partial_y], \]

where \( a, b \in C^\infty(\mathbb{R}) \) only depend on \( x \). We shall now discuss the convex cone

\[ \text{KMS}(a, b, \beta) := \text{KMS}(M, \Pi, [X], \beta) \]

for all \( a, b \in C^\infty(\mathbb{R}) \). Let \( \varphi \in \text{KMS}(a, b, \beta) \). Whenever \( x \in \mathbb{R} \) is such that \( a(x) \neq 0 \) we can find a neighbourhood \( U \) of \( M \) such that \( X \) is transversal to the leaves in \( U \): Lemma \[18\] entails that \( \varphi|_{C^\infty(U)} = 0 \) so that \( \text{supp}(\varphi) \cap \text{supp}(a) = \emptyset \). Henceforth we shall assume \( a = 0 \).

Similarly, let \( x \in \mathbb{R} \) be such that \( b(x) > 0 \) and let \( U = (x - \varepsilon, x + \varepsilon) \times \mathbb{R} \times T \) be an neighbourhood of \( M \) such that \( b > 0 \). A direct computation shows that, for all \( g \in C^\infty_c(U) \),

\[ \beta \varphi(bg) = \beta \varphi(gX) = \varphi(\{y, g\}) = -\varphi(\partial_y g). \]

Since \( \eta \) and \( U \) are invariant under the flow \( \Psi \) associated with \( \partial_\theta \) we find

\[ \varphi(\Psi^*_t g) = \varphi(e^{-\beta t} g), \]

which is nothing but Equation \[5\]. Since \( e^{-\beta t} \Psi^*_t \mathbb{g} \to 0 \) as \( t \to +\infty \) in \( C^\infty_c(M) \) we find

\[ \varphi(g) = \lim_{t \to +\infty} \varphi(e^{-\beta t} \Psi^*_t g) = 0, \]

since the measure \( \varphi \) is continuous for locally uniform convergence. This arguments shows that \( \varphi \in \text{KMS}(a, b, \beta) \) is supported outside \( \text{supp}(a) \cup \text{supp}(b) \). If follows that \( \text{KMS}(a, b, \beta) \) embeds in the convex cone \( \text{KMS}(M, \Pi) \) made by \( \Pi \)-traces.

We shall now consider \( \varphi \in \text{KMS}(M, \Pi) \). We first observe that \( \varphi \) is invariant under the flow of \( \partial_\theta \). Indeed, let \( \chi_1, \chi_2 \) be a partition of unity subordinated to the cover \( [0, 2\pi) = [0, \frac{\pi}{2}) \cup (\pi, 2\pi) \). Then for all \( f \in C^\infty_c(M) \) we have

\[ \varphi(\partial_\theta f) = \varphi(\partial_\theta (\chi_1 f)) + \varphi(\partial_\theta (\chi_2 f)) = \varphi(\{\theta f_1, \chi_1 f\}) + \varphi(\{\theta f, \chi_2 f\}) = 0, \]

where \( f_1 \in C^\infty_c(M) \) is such that \( f_1|_{\text{supp}(f)} = 1 \).

Let \( \mu_\varphi \in M_+(M) \) be the positive measure on \( M \) associated to the natural extension of \( \varphi \) on \( C(M) \), cf. Remark \[2\]. Let \( \chi \in C^\infty(\mathbb{R}) \) be such that \( \chi \geq 0 \) and \( \int \chi(y) dy = 1 \) and for all \( I \subseteq \mathbb{R} \) we define

\[ \nu_\varphi(I) := \int_I \varphi I(x) \chi(y) d\mu_\varphi(x, y, \theta) = \varphi(\varphi I \chi), \]

14
where $g_I$ is the characteristic function over $I$. It follows that $\nu_\varphi$ defines a positive Borel measure on $\mathbb{R}$. Notice that $\nu_\varphi$ does not depend on $\chi$: Indeed, if $\chi, \hat{\chi} \in C_c^\infty(\mathbb{R})$ are such that $\int [\chi - \hat{\chi}] (y) dy = 0$ then $\chi - \hat{\chi} = g_y$ for $g \in C_c^\infty(\mathbb{R})$ and

$$\varphi(g_I \chi) - \varphi(g_I \hat{\chi}) = \varphi(\partial_y (g_I g)) = 0.$$  

Finally, for all $f \in C_c^\infty(\mathbb{R})$ we have

$$f = f - \int_0^{2\pi} f d\theta + \int_0^{2\pi} f d\theta - \chi \int_0^{2\pi} \int_\mathbb{R} f(\cdot, \theta, y) dy d\theta + \chi \int_0^{2\pi} \int_\mathbb{R} f(\cdot, \theta, y) dy d\theta$$

$$= \partial_y g + \partial_y h + \chi \int_0^{2\pi} \int_\mathbb{R} f(\cdot, \theta, y) dy d\theta,$$

where $g, h \in C_c^\infty(M)$. The II-trace property of $\varphi$ implies that

$$\varphi(f) = \int_M f(x, \theta, y) dv_\varphi(x) d\theta dy .$$

The correspondence $\varphi \to \nu_\varphi$ is thus 1-1, therefore, $\text{KMS}(M, \Pi) \simeq M_+(\mathbb{R})$, where $M_+(\mathbb{R})$ denotes the convex cone of positive Borel measure over $\mathbb{R}$.

Summing up, the KMS convex cones for $(M, \Pi)$ satisfy

$$\text{KMS}(M, \Pi) \simeq M_+(\mathbb{R}),$$

$$\text{KMS}(M, \Pi, [a \partial_x + b \partial_y], \beta) \simeq \{ \nu \in M_+(\mathbb{R}) \mid \text{supp}(\nu) \cap (\text{supp}(a) \cup \text{supp}(b)) = \emptyset \} .$$  

(16a)  

(16b)

## 3 KMS Convex Cone for $b$-Poisson Manifolds

In this section we discuss the convex cone of KMS functionals for the case of a $b$-Poisson manifold [22][34]. To this avail we recall the basic definitions and properties of $b$-Poisson manifolds whose proofs can be found in the literature [7][8][12][20][21][22][29][30][33][34].

### 3.1 $b$-Poisson Manifolds

To fix our notation we need to recall some basic facts about $b$-Poisson manifolds in this preliminary section [20][30]. A Poisson manifold $(M, \Pi)$ is called $b$-Poisson if $\dim M = 2n$ and $\Pi|_{\Pi^n}$ is transversal to the zero section in $\Gamma(\wedge^{2n} TM)$. In what follows we shall denote by $Z := \{ x \in M \mid \Pi|_{\Pi^n} x = 0 \}$ the zero locus of $\Pi|_{\Pi^n}$. A $Z$-defining function is a smooth function $\zeta \in C^\infty(M)$ such that $Z = \{ x \in M \mid \zeta(x) = 0 \}$ and $d\zeta|_Z \neq 0$.

**Remark 21:** Since we are assuming that $M$ is orientable we can always find a $Z$-defining function $\zeta \in C^\infty(M)$. Indeed, for a given volume form $\mu \in \Omega^\wedge(\Pi)$ we can set $\zeta_\mu := \iota_{\Pi|_{\Pi^n}} \mu$. Moreover, given a $Z$-defining function $\zeta_0$, all other $Z$-defining functions are of the form $h \zeta_0$ for a non-vanishing $h \in C^\infty(M)$. Notice in particular that $\zeta_\mu Y_\mu = -X_{\zeta_\mu}$.  

15
As \( b \)-Poisson manifolds are best understood in the context of \( b \)-geometry we recall a few basic fact of \( b \)-geometry introduced in \[32\ \[34\]. The \( b \)-tangent bundle relative to the pair \((M, Z)\) is the unique (up to vector bundle isomorphisms) vector bundle \( bT M \) whose sections are isomorphic to the subspace \( \Gamma(TM)_Z \) of vector fields in \( M \) which are tangent to \( Z \), that is,

\[
\Gamma(bTM) \simeq \Gamma(TM)_Z := \{ X \in \Gamma(TM) \mid X|_{Z} \in \Gamma(TZ) \}.
\]

In what follows we shall identify \( \Gamma(bTM) \) and \( \Gamma(TM)_Z \).

Existence and uniqueness of \( bTM \) is ensured by the fact that, on a coordinate neighbourhood \( U \), we have the local frame \( \{ z \partial_z, \partial_{a_1}, \ldots, \partial_{a_{2n-1}} \} \) spanning the sections \( \Gamma(TM)_Z \), where \( z \) is a defining function for \( Z \cap U \).

By definition it also follows that \( bT_x M = T_x M \) for all \( x \in M \setminus Z \). For points \( x \in Z \) we have \( bT_x M = T_x Z \oplus \text{sp} \omega_x \), where \( \omega_x \) is the canonical non-vanishing section of the line bundle \( bTM|_Z \to TZ \) cf. \[20\ Prop. 4\]. Roughly speaking, the latter bundle is induced by the restriction map \( \Gamma(bTM) \to \Gamma(TZ) \), while \( w \) is defined by considering a \( Z \)-defining function \( \zeta \) and setting \( w := \zeta Y \) where \( Z_\zeta \in \Gamma(TM) \) is any vector field such that \( Z_\zeta(\zeta) = 1 \) - the definition does not depend on the chosen \( \zeta \).

By duality one can introduce the \( b \)-cotangent bundle \( bT^\ast M \). As for \( bTM \), we have that

\[
bT^\ast_x M = \begin{cases} T^\ast_x M & \text{for } x \in M \setminus Z \\ T^\ast_x Z \oplus \text{sp} \nu_w & \text{for } x \in Z. \end{cases}
\]  

Here \( \nu_w \in \Gamma(bT^\ast M) \) is defined by the requirement that \( \nu_w(w) = 1 \). In what follows we shall adopt the notation \( \nu_w = \frac{d\zeta}{\zeta} \) once a \( Z \)-defining function \( \zeta \) has been fixed.

Let \( b\Omega^k(M) := \Gamma(\wedge^k bT^\ast M) \) be the space of \( b \)-forms of degree \( k \). Notice that any \( \eta \in b\Omega^k(M) \) can be decomposed as

\[
\eta = \alpha \wedge \frac{d\zeta}{\zeta} + \sigma,
\]

where \( \alpha \in \Omega^{k-1}(M) \) and \( \sigma \in \Omega^k(M) \) while \( \zeta \) is a \( Z \)-defining function. In Equation \((18)\) we interpreted elements in \( \Omega^\ast(M) \) as \( b \)-forms \( b\Omega^\ast(M) \) according to the following convention

\[
\alpha_x = \begin{cases} \alpha_x & \text{for } x \in M \setminus Z \\ \iota_Z^\ast \alpha_x & \text{for } x \in Z, \end{cases}
\]

being \( \iota_Z : Z \hookrightarrow M \). This convention is consistent with Equation \((17)\).

**Remark 22**: Notice that the forms \( \alpha \) and \( \sigma \) appearing in Equation \((18)\) are not unique: \( \alpha \mapsto \alpha + h d\zeta \) does not affect Equation \((18)\) as well as the simultaneous replacement \( \alpha \mapsto \alpha + \zeta \alpha' \), \( \sigma \mapsto \sigma - \alpha' \wedge d\zeta \), where \( h \in C^\infty(M) \) and \( \alpha' \in \Omega^{k-1}(M) \). Finally if \( \zeta_\lambda = \lambda \zeta \) is another \( Z \)-defining form - where \( \lambda \in C^\infty(M) \) is no-where vanishing - then the form \( \sigma \) in Equation \((18)\) gets shifted by \( d \log |\lambda| \). Nevertheless, on account of Equation \((17)\), the decomposition appearing in Equation \((18)\) is unique on \( Z \) - cf. \[20\ Prop. 5\].
On account of Equation (18) we can extend the differential $d$ to $b\Omega^\bullet(M)$. Recall from [32] that the $b$-de Rham differential $b d$: $b\Omega^\bullet(M) \to b\Omega^{\bullet+1}(M)$ is defined by
\[
b d\eta := d\alpha \wedge \frac{d\zeta}{\zeta} + d\sigma ,
\]
for all $\eta \in b\Omega^k(M)$. The $b$-de Rham complex is the chain complex
\[
0 \xrightarrow{b d} b\Omega^1(M) \xrightarrow{b d} \cdots \xrightarrow{b d} b\Omega^n(M) \xrightarrow{b d} 0 .
\]
The associated cohomology groups $bH^\bullet(M)$ are called $b$-de Rham cohomology group.

**Remark 23 ([32]):** Notice that the definition of $b d$ does not depend on the chosen $Z$-defining function $\zeta$ – cf. Remark [22]. Moreover, since the forms $\alpha$ and $\sigma$ appearing in Equation (18) are not unique, the identity $b d\eta = 0$ does not imply $d\alpha = 0$ and $d\sigma = 0$ in general. However, one can exploit the non-uniqueness of $\alpha$, $\sigma$ to prove that, for a suitable choice of a $Z$-defining function $\zeta$, the forms $\alpha$, $\sigma$ can be chosen to be closed. This leads to the following result [32, Prop. 2.49]: for the $b$-cohomology groups one has
\[
b H^\bullet(M) \simeq H^\bullet(M) \oplus H^{\bullet-1}(Z) ,
\]
where $H^\bullet(M)$, $H^\bullet(Z)$ denote the standard de-Rham cohomology groups of $M$ and $Z$ respectively.

We now discuss the relation between $b$-Poisson manifolds and $b$-geometry – cf. [20] for an extensive treatment. If $(M, \Pi)$ is a $b$-Poisson manifold, then $\Pi \in \Gamma(\wedge^2 b TM)$. Therefore, though $\Pi$ is degenerate at $Z$ as an element of $\Gamma(\wedge^2 TM)$, it is non-degenerate as a bivector field in the $b$-tangent bundle – this is actually the main reason for considering the $b$-geometrical setting. It follows that there exists a unique non-degenerate closed $b$-form $\omega \in b\Omega^2(M)$ such that $t_\Pi \omega = 1$. Manifolds $M$ equipped with such a $b$-form $\omega$ are usually called $b$-symplectic manifolds – cf. [20, Def. 8]. We collect some of the properties needed later [20, 30]:

**Remark 24:** Let $(M, \Pi)$ be a $b$-Poisson manifold. Let $\omega \in b\Omega^2(M)$ be the unique non-degenerate closed $b$-form such that $t_\Pi \omega = 1$.

1. For all $x \in M$ there exists a coordinate neighbourhood $U$ of $x$ such that
\[
\Pi|_U = z \partial_z \wedge \partial_t + \sum_{\ell=1}^{n-1} \partial_x^\ell \wedge \partial_y^\ell , \quad \omega|_U = \frac{dz}{z} \wedge dt + \sum_{\ell=1}^{n-1} dx^\ell \wedge dy^\ell ,
\]
where $z$ is a defining function for $Z \cap U$.

2. Let $\omega = \alpha \wedge \frac{d\zeta}{\zeta} + \sigma$ be the decomposition of $\omega$ according to Equation (18). Then $\alpha_Z := \iota^*_Z \alpha \in \Omega^1(Z)$ is uniquely defined and closed. Moreover it is possible to choose $\alpha$ and $\sigma$ so that $(Z, \alpha_Z, \sigma_Z)$ is a cosymplectic manifold, where $\sigma_Z := \iota^*_Z \sigma \in \Omega^2(Z)$. In fact the inclusion $(Z, \iota_Z) \hookrightarrow (M, \Pi)$ is a Poisson morphism. Finally, any representative $X \in [Y_\Pi]$ of the modular class is tangent to $Z$ and $X|_Z$ is the Reeb vector field associated with $(Z, \alpha_Z, \sigma_Z)$ – cf. Equation (10).
3. For the Poisson cohomology $H^*_\Pi(M)$ of $(M,\Pi)$ one has

$$H^*_\Pi(M) \cong b\Omega^*(M) \cong \Omega^*(M) \oplus \Omega^{*-1}(Z). \tag{22}$$

In particular an element $[X] \in H^1_{\Pi}(M)$ is always of the form $X = \Theta^\sharp$ for a closed $b$-form $\Theta \in bH^1(M)$. Under this identification the modular class $[Y_\Pi]$ is associated with the $b$-de Rham cohomology class $[\frac{d\zeta}{\zeta}]$ for a given choice of a $Z$-defining function $\zeta$.

### 3.2 An Explicit Example

To make the forthcoming discussion more concrete, we will consider the following toy example. Let $(M,\Pi)$ be the $b$-Poisson manifold defined by

$$M := \mathbb{T} \times \mathbb{R}, \quad \Pi := \sin(\theta)\partial_\theta \wedge \partial_y, \tag{23}$$

where $\theta$ denotes the quasi-global angular coordinate on $\mathbb{T}$ as before. Notice that $Z = (\{0\} \times \mathbb{R}) \cup (\{\pi\} \times \mathbb{R}) =: Z_0 \cup Z_\pi$, so that this is actually an example of a $b$-Poisson manifold with non-connected $Z$.

It is instructive to compute $H^1_{\Pi}(M)$ without exploiting Remark 21. A vector field $X = a\partial_\theta + b\partial_y$ where $a,b \in C^\infty(M)$ is Poisson if and only if

$$\cos(\theta)a - \sin(\theta)a_\theta + \sin(\theta)b_y = 0,$$

where the sub-indexes $\theta$ and $y$ are short notations for $\partial_\theta, \partial_y$. Evaluating the previous equation for $\theta = 0$ and $\theta = \pi$ we find that $a(0,y) = a(\pi,y) = 0$, therefore $a(\theta,y) = \sin(\theta)a(\theta,y)$ for $a \in C^\infty(M)$. We thus obtain

$$-\sin(\theta)^2a_\theta + \sin(\theta)b_y = 0.$$ 

Differentiation in $\theta$ and evaluation at $\theta = 0$ and $\theta = \pi$ leads to $b_y(0,y) = b_y(\pi,y) = 0$, that is, $b_0 := b(0,y)$ and $b_\pi := b(\pi,y)$ are constant. If $b_0 = b_\pi = 0$ we have $b(\theta,y) = \sin(\theta)\beta(\theta,y)$ for $\beta \in C^\infty(M)$, moreover,

$$-\alpha_\theta + \beta_y = 0,$$

which implies that $\Theta := \alpha dy + \beta dz$ is closed. It follows that $[X] = [\Theta^\sharp]$ for $[\Theta] \in \mathrm{sp}[d\theta]$. For the general case let

$$\psi_0(\theta) := \frac{1}{2}(1 + \cos(\theta)) = \cos(\theta/2)^2, \quad \psi_\pi(\theta) := \frac{1}{2}(1 - \cos(\theta)) = \sin(\theta/2)^2. \tag{24}$$

Notice that $\psi_0\partial_y$ and $\psi_\pi\partial_y$ are Poisson vector fields. Moreover, $[\psi_0\partial_y] \neq [0] \neq [\psi_\pi\partial_y]$; Indeed $\psi_0\partial_y = X_f$ would imply

$$f_y = 0, \quad \psi_0 = -\sin(\theta)f_\theta.$$
However the left-hand side of the last equation is 1 for $\theta = 0$ while the right-hand side gives 0. A similar argument applies for $\psi_\pi \partial_y$. Since $\psi_0(0) = \psi_\pi(\pi) = 1$ as well as $\psi_0(\pi) = \psi_\pi(0) = 0$, we have

$$[X] = [\sin(\theta)\alpha \partial_\theta + (b - b_0\psi_0 - b_\pi \psi_\pi)\partial_y] + [b_0\psi_0 \partial_y] + [b_\pi \psi_\pi \partial_y]$$

$$= [cd\theta^2] + [b_0\psi_0 \partial_y] + [b_\pi \psi_\pi \partial_y],$$

for $c \in \mathbb{R}$. It then follows that $H^1_{\Pi}(M) \ni X \to (b_0, b_\pi, c) \in \mathbb{R}^3$ realizes the general isomorphism in Equation (22).

### 3.3 KMS Convex Cone

We now investigate the convex cone of KMS functionals $\text{KMS}(M, \Pi, [X], \beta)$ for all $[X] \in H^1_{\Pi}(M)$ and $\beta > 0$.

**Remark 25:** For the easy of the presentation we shall assume that both $M, Z$ are connected. The non-connected case would not spoil the results of our analysis – cf. Example 36 – however we point out the main differences in a series of Remarks 28, 33, and 35. Notice that if $M, Z$ are connected then $M_Z := M \setminus Z$ has only two connected components $M_Z = M_Z^+ \cup M_Z^−$. Once a $Z$-defining function has been fixed – cf. Remark 21 – the latter can be realized as $M_Z^\pm = \{\pm \zeta > 0\}$.

According to Remark 24, we parametrize $[X] = [\Theta^2] \in H^1_{\Pi}(M)$ with $[\Theta] \in \mathfrak{b}\Omega^1(M)$. Moreover, we shall consider a defining function $\zeta$ such that

$$\Theta = -a \frac{d\zeta}{\zeta} + \theta, \quad a \in \mathbb{R}, [\theta] \in H^1(M).$$

(The minus sign is inserted so that $a \frac{d\zeta}{\zeta} \in [aY_{\Pi}]$.) Notice that any other defining function would not change the $b$-de Rham class of $[\Theta]$. For later convenience we shall adopt the notation

$$\text{KMS}(a, \theta, \beta) := \text{KMS}(M, \Pi, \Theta^2, \beta).$$

In what follows $\mu$ will denote the volume form associated with the $Z$-defining function $\zeta$.

As a first step we will consider the restriction of $\varphi \in \text{KMS}(a, \theta, \beta)$ to either the symplectic leaf $M_Z := M \setminus Z$ or the cosymplectic manifold $Z$. This provides a strong constraint on the chosen $\Theta$.

**Lemma 26:** Let $\varphi: C^\infty_c(M) \to \mathbb{C}$ be a (non-necessarily positive) distribution of order 0 satisfying Equation (1) for $X = \Theta^2$, where $\Theta \in \mathfrak{b}\Omega^1(M)$ decomposes as in Equation (25). If $\text{supp}(\varphi) \subseteq Z$ and $a \neq 0$, then $\varphi = 0$.

**Proof.** Since $\varphi$ is of order 0 and $\text{supp}(\varphi) \subseteq Z$, it follows that there exists a (non necessarily positive) distribution $\psi: C^\infty_c(Z) \to \mathbb{C}$ of order 0 such that $\varphi(f) = \psi(f|Z)$. (Actually $\psi$ is defined by $\psi(g) = \varphi(\hat{g})$ where $\hat{g} \in C^\infty_c(M)$ is any function such that $\hat{g}|Z = g$.) Moreover, $\psi$ satisfies the KMS condition (1)

$$\psi(\{f, g\}_Z) = \beta \psi(g\Theta^2|Z(f)), \quad \forall f, g \in C^\infty_c(Z),$$

19
where \( \{, \} \) is the Poisson structure induced on \( Z \). Notice that \( \Theta|_Z \in \Gamma(TZ) \) because \( \Theta^Z \in \Gamma(bTM) \). Moreover, \( X|_Z \) is transverse to the symplectic foliation of \( Z \), because \( a \neq 0 \). Thus Lemma 18 applies and we find \( \psi = 0 \).

Lemma 20 shows that there cannot be KMS functionals supported on \( Z \) for dynamics \( \Theta^Z \) where \( a \neq 0 \) in Equation (25). Similarly the following lemma implies that there cannot be KMS functionals supported in \( M_Z \) whenever \( [\vartheta]_{M_Z} \neq [0] \).

**Lemma 27:** Let \( [\Theta] \in bH^1(M) \) and let \( a \in \mathbb{R} \) and \([\vartheta] \in H^1(M) \) be as in Equation (25). For \( \varphi \in \text{KMS}(a, \vartheta, \beta) \), let \( \varphi_{M_Z} \) be the restriction of \( \varphi \) to \( C^\infty_c(M_Z) \). Then:

1. If \([\vartheta]_{M_Z} \neq [0] \), then \( \varphi_{M_Z} = 0 \).

2. If \( \vartheta|_{M_Z} = dH \) for \( H \in C^\infty(M_Z) \), then there exist two positive constants \( c_\pm \in [0, +\infty) \) such that

\[
\varphi_{M_Z}(f) = \sum_{\pm} c_\pm \int_{M^\pm_Z} fe^{-\beta H} |\xi|^\alpha |\mu|, \quad \forall f \in C_c^\infty(M_Z),
\]

where \( M^\pm_Z \) are the two connected components of \( M_Z \) — cf. Remark 25 — and \( H := H|_{M^\pm_Z} \)

while \( \mu \in \Omega^{2n}(M) \) is the volume form associated to the chosen defining function \( \zeta \).

**Proof.** For all \( \varphi \in \text{KMS}(a, \varphi, \beta) \) we have that \( \varphi_{M_Z} \) is a \((\Theta^Z|_{M_Z}, \beta)\)-KMS on \( M_Z \). Since \((M_Z, \Pi|_{M_Z}) \) is a symplectic manifold, Remark 4 entails that, if \( \varphi_{M_Z} \neq 0 \), then \( [\Theta]_{M_Z} = [0] \). As \( a \frac{d\zeta}{\zeta}|_{M_Z} = ad\log |\xi| \) we find \([0] = [\Theta]_{M_Z} = [\vartheta]_{M_Z} \). This proves item 1. Equation (26) is a direct application of Remark 4 — cf. Equation (3). \( \square \)

**Remark 28:** It is worth commenting what would happen to Lemma 27 by allowing \( Z \) to have many connected components. Let \( \{Z_k\}_k \) be the (possibly countably infinite) collection of connected components of \( Z \) and let \( M_{Z,c} \) be the collection of all connected components of \( M_Z \). For each \( k \), let \( Z_k^{\pm} \) be a \( \varepsilon_k \)-tubular neighbourhood of \( Z_k \) such that \( Z_k^{\pm} \cap Z_j^{\pm} = \emptyset \) for at most finitely many \( k, j \). Moreover, since \( Z_k \) has codimension 1, we may choose \( \varepsilon_k \) small enough so that \( Z_k^+ \setminus Z_k \) is made by two connected component, say \( Z_k^{+\pm} \) and \( Z_k^{-\pm} \). We can then find a locally defined \( Z_k \)-defining function \( \zeta_k \) — cf. Section 3.1 — with the property that \( \zeta_k|_{(Z_k \setminus Z_k^{+\pm}) \cup Z_k^{-\pm}} = \pm 1 \).

Though \( \zeta_k \) is only locally defined around \( Z_k \), the \( b \)-form \( \frac{d\zeta_k}{\zeta_k} \) are globally well-defined \( b \)-forms, \( \frac{d\zeta_k}{\zeta_k} \in b\Omega^1(M) \) —as a matter of fact \( \frac{d\zeta_k}{\zeta_k} \) vanishes outside \( Z_k^{+\pm} \). Such \( b \)-forms provide a representation of any \( \Theta \in bH^1(M) \) given by

\[
\Theta = \vartheta - \sum_k a_k \frac{d\zeta_k}{\zeta_k},
\]

where \( a_k \in \mathbb{R} \) and \([\vartheta] \in H^1(M) \) —notice that the sum over \( k \) is locally finite. Finally, notice that \( |\zeta_k| \) extends to a globally defined continuous function such that \( |\zeta_k| \big|_{M \setminus Z_k^{+\pm}} = 1 \).
With these preliminaries the results of Lemma 27 would then be modified as follows. If \( [\vartheta]_{M_Z} \neq [0] \) then \( \varphi_{M_Z} = 0 \) for all \( \varphi \in \text{KMS}(\{a_k\}_k, \vartheta, \beta) = \text{KMS}(X, \Pi, \Theta^\vartheta, \beta) \). If instead \( \vartheta|_{M_Z} = dH \) for \( H \in C^\infty(M_Z) \), then there exists \( c = \{c_j\} \in [0, +\infty)^{M_Z, c} \) such that

\[
\varphi_{M_Z}(f) = \sum_j c_j \int_{M_{Z,j}} f e^{-\beta H_j} \prod_k |\zeta_k|^{a_k \beta - 1} \mu, \quad \forall f \in C_c^\infty(M_Z).
\]

(27)

where \( H_j := H|_{M_{Z,j}} \). Notice that both the sum over \( j \) as well as the product over \( k \) are finite on account of the compactness of \( \text{supp}(f) \).

**Example 29:** Let \( M = \mathbb{R}^2 \) be the \( b \)-Poisson manifold defined by \( \Pi := \sin(z) \partial_z \wedge \partial_t \). In this case \( Z \) is made by infinitely many connected components \( Z_k := \{ z = \pi k \} \), moreover, \( b\Omega^1(M) \simeq \bigoplus_{k \geq 0} H^0(Z_k) \). It is tempting to factorize the defining function \( \sin(z) \) by exploiting the product formula

\[
\sin(z) = z \prod_{k \geq 1} \left( 1 - \frac{z^2}{(\pi k)^2} \right).
\]

This way we decompose any \( [\Theta] \in b\Omega^1(M) \) as

\[
\Theta = -a_0 d \log |z| - \sum_{k \geq 1} a_k d \log \left| 1 - \frac{z}{\pi k} \right| - \sum_{k \geq 1} a_{-k} d \log \left| 1 + \frac{z}{\pi k} \right|
\]

which leads to the representation of \( \varphi \in \text{KMS}(\{a_k\}_k, \beta) \) as

\[
\varphi(f) = \int f(z,t)|z|^{a_0 \beta - 1} \prod_{k \geq 1} \left| 1 - \frac{z}{\pi k} \right|^{a_k \beta - 1} \left| 1 + \frac{z}{\pi k} \right|^{a_{-k} \beta - 1} \, dz \, dt,
\]

for \( f \in C_c^\infty(M_Z) \).

Unfortunately, though these formulas are rather explicit, they do not fit with the previous setting. In particular the sum defining \( \Theta \) is not locally finite and the same holds true for the product appearing in the definition of \( \varphi \). Therefore, the formulas for \( \Theta \) and \( \varphi \) make sense only for particular choices of the sequence \( \{a_k\}_k \) – for example they converge whenever \( \sum_k \frac{a_k}{k} \) converges.

As a matter of fact, none of the functions in the product formula for \( \sin z \) fulfills the property required in Remark 28. To cope with this problem we have to replace each function \( z, 1 + \frac{z}{\pi}, 1 - \frac{z}{\pi}, \ldots \) with functions \( \zeta_0, \zeta_1, \ldots \) with the properties described in Remark 28.

**Example 30:** Notice that item 2 of Lemma 27 does not imply that \( [\vartheta] = [0] \) as shown by the example in Section 3.2. Indeed, therein we have \( M_Z = M_{Z,0} \cup M_{Z,\pi} \), where \( M_{Z,0} = (0, \pi) \times \mathbb{R} \) while \( M_{Z,\pi} = (\pi, 2\pi) \times \mathbb{R} \). Choosing \( \Theta = \vartheta = d\theta \) we clearly have \([d\theta]|_{M_{Z,0}} = [d\theta]|_{M_{Z,\pi}} = [0] \) while \([d\theta] \neq [0] \).

Lemma 27 implies that \((\Theta^\vartheta, \beta)\)-KMS functionals cannot be supported on \( M_Z \) if \([\vartheta]|_{M_Z} \neq [0] \) – cf. Equation (25). Moreover, the restriction \( \varphi_{M_Z} \) of any such functional is rather explicit. The next theorem characterizes when a given KMS functional on \( M_Z \) extends to a KMS functional on \( M \). This provides a classification of the convex set of KMS functionals for the case \([\vartheta]|_{M_Z} = [0] \).

For later convenience we shall prove the following technical lemma:
Lemma 31: Let \( d_+, \beta \geq 0 \) and let \( T \in C_0^\infty(\mathbb{R} \setminus \{0\})' \) be the positive distribution defined by

\[
T(f) = \int_{\mathbb{R} \setminus \{0\}} f(z)D(z)|z|^{-(1+\beta)}dz ,
\]

where

\[
D(z) = \begin{cases} 
  d_+ & z > 0 \\
  d_- & z < 0
\end{cases}
\]

with constants \( d_+, d_- \in \mathbb{R} \). Then there is no extension \( \hat{T} \in C_0^\infty(\mathbb{R})' \) of \( T \) which is positive unless \( d_+ = d_- = 0 \).

Proof. By contradiction, let assume that at least one among \( d_+, d_- \), say \( d_+ \), is strictly positive and let \( \hat{T} \in C_0^\infty(\mathbb{R}) \) be a positive extension of \( T \). We obtain a more explicit form of \( \hat{T} \): Let \( C_{c,|\beta|}(\mathbb{R}) \) be the subspace defined by

\[
C_{c,|\beta|}(\mathbb{R}) := \{ f \in C_0^\infty(\mathbb{R}) \mid f^{(k)}(0) = 0 \ \forall k \leq |\beta| \},
\]

where \((k)\) is a short notation for \( \frac{d^k}{dz^k} \) and \(|\beta| := \max\{n \in \mathbb{N} \mid n \leq \beta \} \).

Notice that \( T \) extends uniquely to a positive functional \( T_{[\beta]} \) on \( C_{c,|\beta|}(\mathbb{R}) \). Indeed, a direct inspection shows that \( T(f) \) is actually well-defined for \( f \in C_{c,|\beta|}(\mathbb{R}) \). Moreover, given two different positive distributions \( T_1, T_2 \in C_0^\infty(\mathbb{R})' \) extending \( T \) we have \( T_1 - T_2 = c\delta \) for \( c \in \mathbb{R} \) and therefore \( T_1(f) = T_2(f) \) for all \( C_{c,|\beta|}(\mathbb{R}) \).

It follows that \( \hat{T}(f) = T_{[\beta]}(f) \) for all \( f \in C_{c,|\beta|}(\mathbb{R}) \). Moreover, let \( \psi \in C_0^\infty(\mathbb{R}) \) be such that \( \psi^{(k)}(0) = \delta_0^k \) for all \( k \in \mathbb{N} \cup \{0\} \). For \( f \in C_0^\infty(\mathbb{R}) \) we consider \( p_\psi(f) \in C_{c,|\beta|}(\mathbb{R}) \) with

\[
p_\psi(f)(z) := f(z) - \sum_{k \leq |\beta|} \frac{z^k}{k!} \psi(z)f^{(k)}(0).
\]

Uniqueness of \( T_{[\beta]} \) ensures that

\[
\hat{T}(f) = T_{[\beta]}(p_\psi(f)) + \sum_{k \leq |\beta|} \hat{T}_k f^{(k)}(0),
\]

where \( \hat{T}_k = -\hat{T}(\frac{1}{k!} z^k \psi) \). In what follows we choose \( \psi \) so that \( \psi_k := \sum_{l=0}^k \frac{z^l}{l!} \psi \geq 0 \) for all \( k \leq |\beta| \) – this can be achieved by shrinking enough supp(\( \psi \)).

We now claim that at least one of the constants \( \{\hat{T}_k\}_{k \leq |\beta|} \) is non-vanishing. Indeed, let us assume that \( \hat{T}_k = 0 \) – that is, \( \hat{T}(z^k \psi) = 0 \) – for all \( k \leq |\beta| \). It follows that for all \( f \in C_0^\infty(\mathbb{R}) \) with \( 0 \leq f \leq 1 \) we have \( f\psi_k \geq 0 \) and

\[
0 \leq \hat{T}(f \psi_k) = \hat{T}((f-1) \psi_k) \leq 0.
\]
This implies that \( \hat{T}(\psi_k f) = 0 \) for all \( f \in C_c^\infty(\mathbb{R}) \) with \( f \geq 0 \). Therefore \( \hat{T}\psi_k = 0 \) and, since \( \hat{T}\psi_k \geq 0 \), this entails that \( \text{supp}(\psi_k) \cap \text{supp}(\hat{T}) = 0 \). Therefore \( 0 \notin \text{supp}(\hat{T}) \) because \( 0 \in \text{supp}(\psi_k) \). However, this would imply \( 0 \notin \text{supp}(T) \) too, a contradiction. Thus there is at least one non-vanishing constant \( \hat{T}_k \)’s.

Let now \( \kappa := \max\{k \mid \hat{T}_k = 0 \ \forall \ell < k\} \leq |\beta| \) and set \( \psi_{n,\kappa} := g_n \psi_n \in C_c^\infty(\mathbb{R}) \), where we choose \( g \in C_c^\infty(\mathbb{R}) \) such that \( 0 \leq g \leq 1 \) and \( g = 1 \) in a neighbourhood of \( z = 0 \) and set \( g_n(z) := g(2^n z) \). Notice that \( \psi_{n,\kappa} \geq 0 \) as well as

\[
\psi_{n,\kappa}^{(\ell)}(0) = \begin{cases} 1 & \text{for } \ell \leq \kappa \\ 0 & \text{for } \ell > \kappa. \end{cases}
\]

It follows that \( \hat{T}(\psi_{n,\kappa}) \geq 0 \), which entails

\[
\hat{T}_{\kappa} \geq \sup_n T((1 - g_n)\psi_n) \geq 0,
\]

where we used Equation (28) together with \( p_\psi\psi_{n,\kappa} = (g_n - 1)\psi_n \). We shall now prove that \( \text{sup}_{n} T((1 - g_n)\psi_n) \) diverges. In what follows we shall indicate with \( O(1) \) a contribution which stays bounded in the limit \( n \to +\infty \).

We need to distinguish between two cases: \( \beta > \kappa \) or \( \beta = \kappa \). In the former case integration by parts leads to

\[
T((1 - g_n)\psi_n) = \int (1 - g_n)\psi_n D(z) \frac{dz}{|z|^{1+\beta}}
\]

\[
= \int (1 - g_n)\psi_{\kappa}^{(\kappa+1)} D_{\kappa+1}(z) \frac{dz}{|z|^{\beta-\kappa}} - \sum_{j+\ell=\kappa+1, j \geq 1, \ell \geq 0} \frac{(\kappa+1)!}{j!\ell!} 2^{nj} \int g^{(j)}(2^n z)\psi_{\kappa}^{(\ell)}(z) D_{\kappa+1}(z) \frac{dz}{|z|^{\beta-\kappa}} ,
\]

where we used that \( (1 - g_n)\psi_n \in C_c^\infty(\mathbb{R} \setminus \{0\}) \). Here \( D_{\kappa+1}(z) = D_{+,\kappa} \) for \( z > 0 \) while \( D_{\kappa+1}(z) = D_{-,\kappa} \) for \( z < 0 \) for suitable constants \( D_{\pm,\kappa} > 0 \) whose exact values are not necessary in what follows. Notice that \( (\psi_{\kappa}^{(\kappa+1)})^{(\ell)}(0) = 0 \) for all \( \ell \), therefore the first contribution is \( O(1) \). We find

\[
T((1 - g_n)\psi_n) = O(1) - \sum_{j+\ell=\kappa+1, j \geq 1, \ell \geq 0} \frac{(\kappa+1)!}{j!\ell!} 2^{nj} \int g^{(j)}(y)\psi_{\kappa}^{(\ell)}(2^{-n} y) D_{\kappa+1}(y) \frac{dy}{|y|^{\beta-\kappa}} .
\]

Since \( g^{(j)} \in C_c^\infty(\mathbb{R} \setminus \{0\}) \) for all \( j \geq 1 \), it holds

\[
\lim_{n \to +\infty} \int g^{(j)}(y)\psi_{\kappa}^{(\ell)}(2^{-n} y) D_{\kappa+1}(y) \frac{dy}{|y|^{\beta-\kappa}} = \int g^{(j)}(y) D_{\kappa+1}(y) \frac{dy}{|y|^{\beta-\kappa}} = O(1) ,
\]

where we used that \( \psi_{\kappa}^{(\ell)}(0) = 1 \) for all \( \ell \leq \kappa \). The previous integral is not vanishing for a suitable choice of \( g \). It follows that

\[
T((1 - g_n)\psi_n) = O(1) + \alpha 2^{n(\beta-\kappa)} ,
\]

23
for $\alpha > 0$ because $T((1-g_n)\psi_\kappa) \geq 0$. This shows that $\sup_n T((1-g_n)\psi_\kappa) = +\infty$ when $\beta - \kappa > 0$. Whenever $\beta = \kappa > 0$ the same procedure leads to

$$T((1-g_n)\psi_\kappa) = O(1) - \int_{\mathbb{R}} \sum_{j+l+1 \geq j \geq 0} \frac{\kappa + 1)!}{j!l!} 2^{\alpha_j} \psi_\kappa^{(j)}(z) \psi_\kappa^{(l)}(\kappa) \log |z|dz$$

where the linear contribution arises from the term corresponding to $j = 1$ in the previous sum. Similarly when $\beta = \kappa = 0$ we have $T((1-g_n)\psi_\kappa) = O(1) + \alpha n$, therefore, in all cases $\sup_n T((1-g_n)\psi_\kappa) = +\infty$. It follows that there are no positive extensions $\hat{T}$ of $T$.

**Theorem 32:** Let $[\Theta] \in b\Omega^1(M)$ and let $a \in \mathbb{R}$ and $[\vartheta] \in H^1(M)$ be as in Equation (25) with $\vartheta|_{M_\pm} = dH$ and $H \in C^\infty(M_Z)$. Let $\mu \in \Omega^{2n}(M)$ be the volume form associated to the chosen defining function $\zeta$ and let $M_\pm$ be the two connected components of $M_Z$. Then:

1. There is an isomorphism of convex cones

$$KMS(a, \vartheta, \beta) \simeq \begin{cases} \{0\} & \text{for } a < 0 \\ (0, +\infty)^2 & \text{for } a > 0 \end{cases} \quad (29)$$

In particular, if $a > 0$ and for all $c_\pm \geq 0$, the unique KMS functional $\varphi \in KMS(M, \Pi, [\Theta^2], \beta)$ associated with $c_\pm$ is given by

$$\varphi(f) = \sum_{\pm} c_\pm \int_{M_\pm} f e^{-\beta H} |\zeta|^{\alpha_j-1} \mu, \quad \forall f \in C^\infty_c(M), \quad (30)$$

where $H_\pm := H|_{M_\pm}$.

2. If $\varphi \in KMS(M, \Pi)$ then $\text{supp}(\varphi) \subseteq Z$.

**Proof.** We consider the cases $a > 0$ and $a \leq 0$ separately:

- **$a > 0$:** Let $\varphi \in KMS(a, \vartheta, \beta)$. On account of Lemma 27 there exists a unique pair $(c_+, c_-) \in [0, +\infty)$ such that Equation (26) holds true. This leads to a map of convex cones

$$\Phi: KMS(a, \vartheta, \beta) \to [0, +\infty)^2, \quad \varphi \mapsto (c_+, c_-).$$

We now show that $\Phi$ is bijective. Indeed $\Phi$ is injective: if $\Phi(\varphi) = (0, 0)$, then $\text{supp}(\varphi) \subseteq Z$ and therefore $\varphi = 0$ because of Lemma 26.

Moreover, $\Phi$ is surjective: for all $c_\pm \in [0, +\infty)$, let $\varphi_{M_\pm}: C^\infty_c(M_Z) \to \mathbb{C}$ be the linear functional defined by Equation (26). Notice that $|\zeta|^{\alpha_j-1} \mu$ is locally integrable on $M$ as one can see by considering a Darboux chart. Remark 24. Moreover also $e^{-\beta H} \mu$ is locally integrable, though $H$ may diverge at $Z$. To see this we exploit a Darboux chart...
For simplicity, we shall set \( a \leq 0 \) and \( a = -1 \) in the forthcoming discussion, so that \( \Theta^a = -Y_\mu \). Different values for \( H \) and \( a \) would not spoil the final result. Let \( \varphi \in \text{KMS}(a, \vartheta, \beta) \). Notice that, by allowing \( \beta = 0 \), the following argument will also prove item 2. Lemma 27 entails that there exist \( c_+, c_\in [0, +\infty) \) such that, for all \( f \in C_c^\infty(M_Z) \),

\[
\varphi(f) = \sum_{\pm} c_{\pm} \int_{M_Z^\pm} f|\zeta|^{-\beta-1} \mu.
\]

We now show that there are no positive extensions of \( \varphi_{M_Z} \) to a functional on \( C_c^\infty(M) \): this entails that \( \varphi = 0 \). By contradiction, let \( \tilde{\varphi} : C_c^\infty(M) \to \mathbb{C} \) be a positive functional such that \( \tilde{\varphi}(f) = \varphi(f) \) for all \( f \in C_c^\infty(M) \).

The idea is to localize \( \tilde{\varphi} \) on a Darboux chart, reducing the problem to the extension of a positive distribution on \( C_c^\infty(\mathbb{R}) \). For that, let consider a (small enough) local Darboux chart \( U \to \mathbb{R}^{2n} \) near \( Z \) and consider the restriction of \( \tilde{\varphi} \) on functions supported in that chart. This leads to a functional \( \tilde{\varphi} : C_c^\infty(\mathbb{R}^{2n}) \to \mathbb{C} \) such that

\[
\tilde{\varphi}(f) = \int_{\mathbb{R}^{2n}} f(z, x) C(z)|z|^{-\beta-1} \rho(z, x) dxdn^{-1}x,
\]

where \( C(z) = c_\pm \) for \( \pm z > 0 \) begin \( c_\pm > 0 \), while \( \rho > 0 \) is smooth and strictly positive. By a suitable redefinition of \( \zeta \) and thus of \( \mu \) we can assume that \( \rho(z, x) = \rho(x) \) is constant in \( z \). Let now \( h \in C_c^\infty(\mathbb{R}^{2n-1}) \) be positive and let us consider the positive distribution \( \tilde{T} \in C_c^\infty(\mathbb{R}') \) defined by \( \tilde{T}(f) := \tilde{\varphi}(fh) \). In particular we find that \( \tilde{T} \supset T \) where \( T \in C_c^\infty(\mathbb{R} \setminus \{0\})' \) is defined by

\[
T(f) := \int_{\mathbb{R}} f(z) D(z)|z|^{-\beta-1} dz,
\]

where \( D(z) = d_+ 1_{R_+}(z) + d_- 1_{R_-}(z) \) for \( d_\pm = c_\pm \int_{\mathbb{R}^{2n-1}} h(x) \rho(x) d^{n-1}x \). We then apply Lemma 31 which entails that \( c_+ = c_- = 0 \). This proves that \( \text{supp}(\varphi) \subseteq Z \): Lemma 26 entails that \( \varphi = 0 \).
Remark 33: With reference to Remark 28 we comment on the generalization of Theorem 37 to the case of non-connected $Z$. For each connected component $Z_k$ of $Z$ let $M_{Z,Z_k} \subseteq M_{Z,c}$ be the collection of all connected components of $M_Z$ whose closure in $M$ have non-empty intersection with $Z_k$. Moreover, for any sequence $a = \{a_k\}_k$ let $M_{Z,a_k}$ be defined by

$$M_{Z,(a_k)} := \{N \in M_{Z,c} \mid \forall k: N \in M_{Z,Z_k} \Rightarrow a_k > 0\}.$$ 

The results of Theorem 37 are then generalized as follows: Item 2 remains unaffected whereas Item 1 is replaced by

$$KMS(\{a_k\}_k, \vartheta, \beta) \simeq [0, +\infty)^{M_{Z,(a_k)}}.$$ 

Out of Equation (29) we can identify those KMS functionals which leads to extreme rays – cf. Section 3.3. The case $a \leq 0$ is trivial while for $a > 0$ we have the following result.

Corollary 34: In the hypothesis of Theorem 32 and assuming $a > 0$ let $\varphi \in KMS(a, \vartheta, \beta)$. Let $\varphi_+, \varphi_- \in KMS(a, \vartheta, \beta)$ be defined by Equation (30) with the particular choice $(1, 0)$ and $(0, 1)$. Then $\varphi \in KMS(a, \vartheta, \beta)$ is extremal if and only if either $\varphi \in \mathbb{R}_+ \varphi_+$ or $\varphi \in \mathbb{R}_+ \varphi_-.$

Proof. We prove the two implications: Let $\varphi \in KMS(a, \vartheta, \beta)$ be associated with $c_+, c_- \in [0, +\infty)$ – cf. Equation (30) – such that $c_+ c_- > 0$. We observe that $\varphi = c_+ \varphi_+ + c_- \varphi_-$, where $\varphi_+, \varphi_-$ are defined by Equation (30) with the particular choice $(1, 0)$ and $(0, 1)$. Then $\varphi \in KMS(a, \vartheta, \beta)$ and $\varphi \in \mathbb{R}_+ \varphi$: it follows that $\varphi$ is not extremal.

Conversely we shall prove that $\varphi_+$ are extremal – the proof for $\varphi_-$ is analogous. Let $\varphi_1, \varphi_2 \in KMS(a, \vartheta, \beta)$ be such that $\varphi_+ = \varphi_1 + \varphi_2$: We shall prove that $\varphi_1, \varphi_2 \in \mathbb{R}_+ \varphi$. For all $f \in C_c^\infty(M \setminus M_Z^+, \vartheta)$ we have

$$0 = \varphi_+(f) = \varphi_1(f) + \varphi_2(f).$$

Positivity of $\varphi_1, \varphi_2$ entails that $\varphi_1(f) = \varphi_2(f) = 0$ for all $f \in C_c^\infty(M \setminus M_Z^+)$ so that $\text{supp}(\varphi_1) \cup \text{supp}(\varphi_2) \subseteq M_Z^+$. This entails in particular that $\varphi_1, \varphi_2$ are $(\Theta|_{M_Z^+}, \beta)$-KMS on $M_Z^+$, where $\Theta := -a \frac{d\vartheta}{\vartheta} + \vartheta$. As $M_Z^+$ is a connected symplectic manifold, Remark 4 entails that there exists $\lambda_1, \lambda_2 \in \mathbb{R}_+$ such that $\varphi_+ = \lambda_1 \varphi_1 = \lambda_2 \varphi_2$.  

Remark 35: Corollary 34 can be proved also for the case of non-connected $Z$. With reference to Remarks 28 and 33 we find that the extremal elements in $KMS(\{a_k\}, \vartheta, \beta)$ are those supported on a single $N \in M_{Z,(a_k)}$.

Example 36: With reference to the example in Section 3.2 we investigate the convex cone $KMS(M, \Pi, \{X\}, \beta)$, providing results in accordance with Theorem 32 – see also Remark 33. This also discusses an example of KMS functionals for a $b$-Poisson manifold with non-connected
Z. As explained in the example any Poisson vector field $X$ is of the form, up to Hamiltonian vector fields,

$$X = a_0 \theta^\phi + a_0 \psi_0(\theta) \partial_y + a_\pi \psi_\pi(\theta) \partial_y,$$

for suitable constants $c_\phi, c_0, c_\pi \in \mathbb{R}$ – here $\psi_0, \psi_\pi$ have been defined in Equation (24). It follows that, on $M_Z$, vector field $X$ is Hamiltonian $X = X_H$, with

$$H(\theta) = \begin{cases} 
\alpha_0 + a_\theta \theta - a_0 \log|\sin(\theta/2)| - a_\pi \log|\cos(\theta/2)| & \text{for } 0 < \theta < \pi \\
\alpha_\pi + a_\theta \theta - a_0 \log|\sin(\theta/2)| - a_\pi \log|\cos(\theta/2)| & \text{for } \pi < \theta < 2\pi,
\end{cases}$$

where $\alpha_0, \alpha_\pi \in \mathbb{R}$. This entails that the restriction $\varphi_{M_Z} = M_{Z,0} \cup M_{Z,\pi}$ to $M_Z$ of any $\varphi \in \text{KMS}(M, \pi, X, \beta)$ can be written as

$$\varphi_{M_Z}(f) = \sum_{j \in \{0, \pi\}} c_j \int_{M_{Z,j}} f(\theta, y) e^{-\beta a_\phi \theta} \sin(\theta/2)^{\alpha_0 \beta - 1} |\cos(\theta/2)|^{\alpha_\pi \beta - 1} \theta d\theta dy,$$

for all $f \in C_c^\infty(M_Z)$, where $c_0, c_\pi > 0$ – the constants $\alpha_0, \alpha_\pi$ have been absorbed into the definition of $c_0, c_\pi$. The latter functional admits a positive extension to $M$ if and only if $a_0, a_\pi > 0$. This provides an isomorphism of convex cones $\text{KMS}(M, \Pi, X, \beta) \simeq [0, +\infty)^2$ as claimed in Theorem 32.

Lemma 27 and Theorem 32 provide a description of $\text{KMS}(a, \vartheta, \beta)$ for all $\varnothing \neq 0$ and $[\vartheta|_{M_Z}] = [0]$. It remains to discuss the case of $[\vartheta|_{M_Z}] \neq [0]$ and $\alpha = 0$. However, Lemma 27 entails that any $\varphi \in \text{KMS}(0, \vartheta, \beta)$ is necessarily supported on $Z$. Since $\vartheta$ is tangent to $Z$ this reduces the problem to the discussion of $(\vartheta|_Z, \beta)$-KMS functionals on $Z$, for which we may apply Theorem 19. This completes the classification of $\text{KMS}(a, \vartheta, \beta)$.

We summarize our results in a single theorem.

**Theorem 37:** Let $(M, \Pi)$ be a $b$-Poisson manifold with (connected) critical locus $Z$. Let $\vartheta \in [\vartheta] \in H^1(M)$ and $a \in \mathbb{R}$ and set $[\Theta] := [-a \frac{d\kappa}{\zeta} + \vartheta] \in bH^1(M)$, where $\zeta$ is a $Z$-defining function.

1. Then the convex cone $\text{KMS}(a, \vartheta, \beta) := \text{KMS}(M, \Pi, \Theta^\phi, \beta)$ sits in one of the following cases:

| $[\vartheta|_{M_Z}]$ | $a > 0$ | $a = 0$ | $a < 0$ |
|-------------------|----------|----------|--------|
| $[\vartheta|_{M_Z}] = [0]$ | $[0, +\infty)^2$ | $\text{KMS}(Z, \Pi_Z)$ | $\{0\}$ |
| $[\vartheta|_{M_Z}] \neq [0]$ | $\{0\}$ | $\text{KMS}(Z, \Pi_Z, \vartheta^\phi|_{Z}, \beta)$ | $\{0\}$ |

2. There exists a unique (up to isomorphism) regular KMS functional, obtained for $a = 1$ and $[\vartheta] = [0]$: Such a functional is induced by the smooth density $\mu$ such that $\zeta := \iota_{\Pi}\mu$.

3. Poisson traces are supported on $Z$ and there exists a unique Poisson trace which is invariant under the modular vector field $[Y_{\Pi}]$: The latter is induced by the smooth density on $Z$ given by $\alpha_Z \wedge \sigma_Z^{(n-1)} - \text{cf. Remark 24}$. 

27
Example 38: We consider the $b$-Poisson manifold

$$M = \mathbb{R} \times T \times T \times \mathbb{R}, \quad \Pi = z\partial_z \wedge \partial_{\theta_1} + \partial_{\theta_2} \wedge \partial_y,$$

where $\theta_1, \theta_2 \in [0, 2\pi)$ while $z, y \in \mathbb{R}$. Comparing with Remark 21 we have $\alpha = d\theta_1$ and $\sigma = d\theta_2 \wedge dy$. Moreover, the isomorphism (22) leads $H^1_\Pi(M) \simeq \mathbb{R}^3$: In fact, the generic Poisson vector field $X$ is, modulo Hamiltonian vector fields,

$$X = a_1d\theta_1^2 + a_2d\theta_2^2 - a \frac{dz}{z} = a_1z\partial_z - a_2\partial_y + a\partial_{\theta_1},$$

for $a, a_1, a_2 \in \mathbb{R}$. Setting $\text{KMS}(a, a_1, a_2, \beta) := \text{KMS}(M, \Pi, X, \beta)$, Theorem 37 and a direct inspection leads to the following classification:

<table>
<thead>
<tr>
<th>$a_1 = a_2 = 0$</th>
<th>$a &gt; 0$</th>
<th>$a = 0$</th>
<th>$a &lt; 0$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a_1 \neq 0$ $a_2 = 0$</td>
<td>$[0, +\infty)^2$</td>
<td>$\mathcal{M}_+(T)$</td>
<td>${0}$</td>
</tr>
<tr>
<td>$a_1 = 0$ $a_2 \neq 0$</td>
<td>${0}$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$a_1 a_2 &gt; 0$</td>
<td>${0}$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In fact for $a \neq 0$ we necessarily have $a_1 = a_2 = 0$ and $a > 0$, otherwise $\text{KMS}(a, a_1, a_2, \beta) = \{0\}$. For the latter case $\text{KMS}(a, 0, 0, \beta) \simeq [0, +\infty)^2$ as any $(a\partial_{\theta_1}, \beta)$-KMS functional is given by

$$\varphi(f) = \int_M f(z, \theta_1, \theta_2, y)c(z)|z|^{\alpha-1}dz d\theta_1 d\theta_2 dy, \quad c(z) := \begin{cases} c_+ & z > 0 \\ c_- & z < 0, \end{cases}$$

where $c_+ \geq 0$. If we focus on Poisson traces, i.e. $a = a_1 = a_2 = 0$, we are reduced to the classification of Poisson traces for the cosymplectic manifold $Z = \mathbb{R} \times T^2$ with $\eta = d\theta_1$ and $\omega = d\theta_2 \wedge dy$. The latter space is isomorphic to the convex cone $\mathcal{M}_+(T)$ of positive measure on $T$: Actually, for all $\varphi \in \text{KMS}(M, \Pi) \simeq \text{KMS}(Z, \Pi_Z)$ there exists $\nu \in \mathcal{M}_+(T)$ such that

$$\varphi(f) = \int f(0, \theta_1, \theta_2, y)d\nu(\theta_1)d\theta_2 dy, \quad \forall f \in C_c^\infty(M).$$

The proof of this result goes along the same line of Example 20.

Finally if $a = 0$ and $a_2 = 0$ we have $\text{KMS}(0, a_1, 0) = \text{KMS}(M, \Pi) \simeq \mathcal{M}_+(\mathbb{R})$ no matter the value of $a_1$: This is due to the fact that $a_1\partial_{\theta_1}^2|_{z=0} = 0$. If $a = 0$ and $a_2 \neq 0$ then $\text{KMS}(0, a_1, a_2) = \{0\}$. Indeed, let assume for simplicity $a_2 = 1$: then for all $\varphi \in \text{KMS}(0, a_1, 1)$ and $f \in C_c^\infty(M)$ we have

$$\beta \varphi(f) = \beta \varphi(\partial_y(y1_f)f) = -\beta \varphi(\{f, y1_f\}) = -\beta \varphi(\partial_{\theta_2}f),$$

where $1_f \in C_c^\infty(M)$ is such that $1_f|_{\text{supp}(f)} = 1$. It follows that $\varphi(f) = e^{-\beta t}\varphi(\Psi^*_t f)$ where $\Psi_t$ is the flow associated with $\partial_{\theta_2}$. As $\varphi(\Psi^*_t f)$ is bounded in $t$ we have $\varphi(f) = \lim_{t \to +\infty} e^{-\beta t}\varphi(\Psi^*_t f) = 0.$
As expected, the structure of the convex cone \( \text{KMS}(M, \Pi, [X], \beta) \) for \( b \)-Poisson manifold is way richer than the corresponding convex cone for symplectic manifolds. In particular, the \( b \)-Poisson case supports KMS functionals for dynamics \([X] \neq [Y_\Pi]\), though none of these functionals is induced by smooth densities. In fact for \([X] \neq [Y_\Pi]\) the non-trivial cases include the KMS convex cone of the cosymplectic manifold \( Z \hookrightarrow M \), where the results of Theorem 19 apply. Moreover, the behaviour of \( \text{KMS}(M, \Pi, [\alpha Y_\Pi], \beta) \) shows a phase transition for \( \alpha = 0 \). In fact \( \text{KMS}(M, \Pi, [\alpha Y_\Pi], \beta) \) is empty for \( \alpha < 0 \) and isomorphic to \([0, +\infty)^2\) for \( \alpha > 0 \) while it reduces to Poisson traces on the cosymplectic manifold \( Z \) for \( \alpha = 0 \). It would be interesting to see whether or not the pattern shown in the \( b \)-Poisson case holds true for \( b^k \)-Poisson manifolds [33]: in the latter case we expect a phase transition to occur also in the parameter \( \beta > 0 \) as shown by the following example.

**Example 39:** Let consider the Poisson manifold defined by

\[
M = \mathbb{R}^2, \quad \Pi = z^k \partial_z \wedge \partial_y, \quad k \in \mathbb{N}.
\]

According to [33] Def. 2.8 this Poisson manifold \((M, \Pi)\) is an example of \( b^k \)-Poisson manifold. Focusing for simplicity on the modular class, we have \([Y_\Pi] = [kz^{k-1} \partial_y] \neq [0] \). Setting \( Z := \{ z = 0 \} \) and \( M_Z := M \setminus Z \) a direct inspection shows that the restriction to \( M_Z \) of any \( \varphi \in \text{KMS}(M, \Pi, kz^{k-1} \partial_y, \beta) \) is necessarily of the form

\[
\varphi(f) = \int_{M_Z} f(z, y) c(z) |z|^{k(\beta-1)} \, dz \, dy, \quad \forall f \in C_c^\infty(M_Z),
\]

where

\[
c(z) := \begin{cases} 
c_+ & z > 0 \\
c_- & z < 0,
\end{cases}
\]

with \( c_\pm \geq 0 \). A slight modification of Lemma 31 shows that the positive functional defined on the right-hand side of the latter equation has no positive extension to \( M \) if \( \beta \leq k - 1 \). Therefore in the latter case we have \( \text{supp}(\varphi) \subseteq Z \) where both \( \Pi \) and \( Y_\Pi \) vanish. This shows that

\[
\text{KMS}(M, \Pi, [Y_\Pi], \beta) \simeq \begin{cases} 
[0, +\infty)^2 & \text{for } \beta > \frac{k-1}{k} \\
M_+(\mathbb{R}) & \text{for } \beta \leq \frac{k-1}{k},
\end{cases}
\]

This shows the occurrence of a phase transition in the parameter \( \beta > 0 \) at \( \beta = \frac{k-1}{k} \).

### 4 Examples

In this section we discuss in details two examples of regular codimension 1 Poisson manifolds \((M, \Pi)\) for which \( \text{KMS}(M, \Pi, [X], \beta) \) can be computed explicitly for all \([X] \in H^1_\Pi(M)\). This investigation is mainly motivated by the need of building some intuition on which properties of the geometry of \((M, \Pi)\) are codified by \( \text{KMS}(M, \Pi, [X], \beta) \).
For example, on account of Remark 4 and Proposition 13 one may think that extremal elements \( \varphi \) of KMS(\( M, \Pi, [X], \beta \)) are necessarily supported on leaves \( L \) of \( M \), which can then be interpreted as “pure thermodynamical phases” of the system under consideration. However, this point of view disregards cases where the natural KMS state defined on \( C^\infty_c(\mathcal{L}) \) cannot be pushed forward to well-defined functionals on \( C^\infty_c(\mathcal{M}) \) – this would happen when \( L \) is not a closed submanifold in \( M \). In this situation there may exist KMS functionals on \( M \), though each leaf \( L \) has none: Section 4.1 provides an example in this direction.

Thus it appears that KMS(\( M, \Pi, [X], \beta \)) is capable to capture whether a leaf \( L \) is a nice submanifold or not. The example considered in Section 4.2 is even more specific: Therein, one can find \([X] \in H^3_{\Pi}(\mathcal{M})\) for which there are KMS functionals on \( M \) supported on leaves \( L \) which are not submanifolds. This is particularly interesting as it seems to provide some information about how badly \( L \) fails to be a submanifold.

### 4.1 The Torus \( T^3 \) with a Cosymplectic Poisson Structure

We now consider the example of a family of compact cosymplectic Poisson manifolds \((M, \Pi_c)\) which depends on a parameter \( c \in \mathbb{R} \). We shall analyse in details the convex set of KMS states \( \text{kms}(M, \Pi_c, [X], \beta) \) for a given \([X] \in H^3_{\Pi_c}(\mathcal{M})\) and \( \beta > 0 \). As already discussed in Section 2 we shall focus on the set \( \text{kms}_0(M, \Pi_c, [X], \beta) \) of extremal KMS states. As we shall see, the structure of \( \text{kms}_0(M, \Pi_c, [X], \beta) \) strongly depends on whether \( c \) is chosen to be rational or not.

Let \( c \in \mathbb{R} \) and let \((M, \Pi_c)\) be the cosymplectic Poisson manifold defined by

\[
M := T^3, \quad \eta_c := c d\theta_2 - d\theta_3, \quad \omega := d\theta_1 \wedge d\theta_2,
\]

whose associated Poisson vector by Equation (11) is given by

\[
\Pi_c := \partial_{\theta_1} \wedge (\partial_{\theta_2} + c \partial_{\theta_3}),
\]

(31)

where \( \theta_1, \theta_2, \theta_3 \) are the usual quasi-global coordinates on \( T^3 \).

As discussed in Section 2.4 the symplectic foliation of \((M, \Pi_c)\) coincides with the foliation associated with the 1-form \( \eta_c \), see Remark 17. In particular, if \( c = \frac{p}{q} \in \mathbb{Q} \) – here \( p, q \in \mathbb{Z} \) are such that \( \text{GCD}(p, q) = 1 \) – then the symplectic leaf through \((\bar{\theta}_1, \bar{\theta}_2, \bar{\theta}_3)\) is the proper submanifold of \( T^3 \) which in terms of quasi-global coordinates is defined by

\[
L((\bar{\theta}_1, \bar{\theta}_2, \bar{\theta}_3)) = L(0, \bar{\theta}_2, \bar{\theta}_3) = \{ (u_1, \bar{\theta}_2 + qu_2, \bar{\theta}_3 + pu_2) \mid u_1, u_2 \in [0, 2\pi) \}.
\]

(32)

If instead \( c \in \mathbb{R} \setminus \mathbb{Q} \) we have

\[
L((\bar{\theta}_1, \bar{\theta}_2, \bar{\theta}_3)) = L(0, \bar{\theta}_2, \bar{\theta}_3) = \{ (u_1, \Psi^\theta_{t\partial_{\theta_2} + c\partial_{\theta_3}}(\bar{\theta}_2, \bar{\theta}_3)) \mid u_1 \in [0, 2\pi), \ t \in \mathbb{R} \},
\]

(33)

where \( \Psi^\theta_{t\partial_{\theta_2} + c\partial_{\theta_3}} \) denotes the flow along the vector field \( \partial_{\theta_2} + c \partial_{\theta_3} \).

We now compute explicitly \( H^1_{\Pi_c}(\mathcal{M}) \). Notice that, using the isomorphism (12), the first Poisson cohomology \( H^1_{\Pi_c}(\mathcal{M}) \) is isomorphic to \( H^1_{\Pi_c}(\mathcal{M}) \oplus H^1_{\Pi_c}(\mathcal{M}) \). Since in computing the latter spaces one faces the same complexity, we preferred to proceed with a direct computation. To deal with the irrational case \( c \in \mathbb{R} \setminus \mathbb{Q} \) the following lemma will be helpful.
\textbf{Lemma 40:} Let $c \in \mathbb{R} \setminus \mathbb{Q}$. Then for all $n \in \mathbb{N}$ there exists a $k \in \mathbb{N}$ such that

$$\forall p, q \in \mathbb{Z}: |p - cq| < \frac{1}{kn}, \quad 1 \leq q \leq kn \implies q \geq n.$$ 

\textit{Proof.} Let $A_n \subseteq Q$ be the set defined by

$$A_n := \left\{ \frac{p}{q} \in \mathbb{Q} \left| |p - cq| \leq \frac{1}{n}, \quad 1 \leq q \leq n \right. \right\}.$$ 

A pigeonhole principle argument shows that $A_n \neq \emptyset$. Indeed let us consider the $n + 1$ elements

$$\{jc\} := jc - [jc] \in (0, 1) \text{ for } j \in \{0, \ldots, n\}, \text{ where } [x] := \sup\{m \in \mathbb{N} | m \leq x\}.$$ 

Considering the partition $(0, 1) = \bigcup_{j=0}^{n-1} \left(\frac{j}{n}, \frac{j+1}{n}\right)$ of $(0, 1)$ into $n$ disjoint intervals, the pigeonhole principle entails that there exists $i, j, h \in \{0, \ldots, n\}$ such that $i < j$ and $\{ic\}, \{jc\} \in \left(\frac{k}{n}, \frac{k+1}{n}\right)$. This implies that

$$|jc - [jc] - (j - i)c| < \frac{1}{n}, \quad 1 \leq (j - i) \leq n,$$

so that $\frac{p}{q} \in A_n$ there $p = [ic] - [jc]$ and $q = j - i$. The set $A_n$ is finite and therefore closed. Moreover, $c \notin A_n$ so that

$$0 < d(A_n, c) = \min_{\frac{p}{q} \in A_n} \frac{|p - q|}{q} < \frac{1}{n}.$$ 

Since $d(A_n, c) > 0$ there exists $k \in \mathbb{N}$ such that $\frac{1}{kn} < d(A_n, c) \leq \frac{1}{n}$. Let now $p, q \in \mathbb{Z}$ such that $|p - cq| < \frac{1}{kn}$ and $1 \leq q \leq kn$. It follows that $\frac{p}{q} \notin A_n$ and therefore $q \geq n$. \hfill \Box

\textbf{Lemma 41:} For the Poisson manifold defined in Equation (31) we have that

$$H^1_{\Pi_c}(M) \simeq H^0_{\Pi_c}(M)^{\oplus 3}, \tag{35}$$

where $H^0_{\Pi_c}(M) = \{ f \in C^\infty(M) | \partial_1 f = 0, \ (\partial_2 + c\partial_3) f = 0 \}$ —notice in particular that $H^0_{\Pi_c}(M) \simeq \mathbb{R}$ for $c \in \mathbb{R} \setminus \mathbb{Q}$. Actually any $[X] \in H^1_{\Pi_c}(M)$ is of the form

$$[X] = [t_1\partial_1 + t_2(\partial_2 + c\partial_3) + t_3\partial_3], \quad t_1, t_2, t_3 \in H^0_{\Pi_c}(M). \tag{36}$$

\textit{Proof.} Let $X \in \Gamma(TM)$ be a Poisson vector field: We decompose $X$ as

$$X = \tau_1\partial_1 + \tau_2\partial_2 + \tau_3\partial_3,$$

and we impose the condition $\mathcal{L}_X(\Pi_c) = 0$. This leads to

$$\begin{align*}
\partial_1 \tau_1 + (\partial_2 + c\partial_3) \tau_2 &= 0 \tag{37a}
\partial_2 \tau_1 + (\partial_2 + c\partial_3) \tau_3 &= 0 \tag{37b}
\partial_3 \tau_2 - \partial_3 \tau_3 &= 0. \tag{37c}
\end{align*}$$

It follows that

$$X = \tau_1\partial_1 + \tau_2(\partial_2 + c\partial_3) + t_3\partial_3,$$

where $\tau_1, \tau_2$ are related by Equation (37a) while $t_3 \in H^0_{\Pi_c}(M)$. We shall now discuss the cases $c \in \mathbb{Q}$ and $c \notin \mathbb{Q}$ separately.
Let \( c = \frac{p}{q} \in \mathbb{Q} \) where \( p, q \in \mathbb{Z}_+ \) are such that GCD\((p, q) = 1\). We now look for \( f \in C^\infty(M) \) such that \( \tau_1 \partial_{\theta_1} + \tau_2 (\partial_{\theta_2} + c \partial_{\theta_3}) = X_f \) which implies
\[
\tau_1 = (f_{\theta_2} + cf_{\theta_3}), \quad \tau_2 = -f_{\theta_1}.
\] (38)

Any such function would satisfy
\[
f(\theta_1, \theta_2 + qu, \theta_3 + pu) := f(0, \theta_2, \theta_3) - \int_0^{\theta_1} \tau_2(s_1, \theta_2, \theta_3)ds_1 + \int_0^u \tau_1(\theta_1, \theta_2 + qu, \theta_3 + pu)ds_2.
\] (39)

In particular, evaluation at \( \theta_1 = 2\pi \) or \( u = 2\pi \) implies the following consistency relations:
\[
(P_{\theta_1} \tau_2)(\theta_2, \theta_3) := \int_0^{2\pi} \tau_2(\theta_1, \theta_2, \theta_3)d\theta_1 = 0,
\] (40a)
\[
(P_c\tau_1)(\theta_1, \theta_2, \theta_3) := \int_0^{2\pi} \tau_1(\theta_1, \theta_2 + qu, \theta_3 + pu)du = 0.
\] (40b)

Notice that on account of equation (37a) we have \( P_{\theta_1} \tau_2, P_c \tau_1 \in H^1_{\Pi_c}(M) \). Whenever Equation (40) are satisfied, Equation (39) can be used to define a smooth function \( f \in C^\infty(M) \).

In fact it suffices to specify \( f \) on, say, the submanifold \( \{(0, \theta_2, \theta_3) \in [0, 2\pi)^3 | p\theta_2 = q\theta_3 = 0\} \), and then use Equation (39). We write
\[
[X] = [P_c \tau_1 \partial_{\theta_1} + P_{\theta_1} \tau_2 (\partial_{\theta_2} + c \partial_{\theta_3}) + t_3 \partial_{\theta_3}],
\]
so that the linear map
\[
H^1(M; \Pi_c) \ni [X] \mapsto (P_c \tau_1, P_{\theta_1}, t_3) \in H^1_{\Pi_c}(M)^{\oplus 3},
\]
completes the proof.

The strategy of the proof is similar to the case of rational \( c \). In particular, we look for a solution \( f \in C^\infty(M) \) of the system (38). This implies that
\[
(P_{\theta_1} \tau_2)(\theta_2, \theta_3) := \int_0^{2\pi} \tau_2(\theta_1, \theta_2, \theta_3)d\theta_1 = 0,
\] (41a)
\[
(P_{\theta_2} P_{\theta_1} \tau_1)(\theta_1) := \int_0^{2\pi} \int_0^{2\pi} \tau_1(\theta_1, \theta_2, \theta_3)d\theta_2 d\theta_3 = 0.
\] (41b)

We shall now show that the Equations (41) are sufficient for proving the existence of \( f \). In particular the condition \( (P_{\theta_1} \tau_2)(\theta_2, \theta_3) = 0 \) entails that we can define \( f \) as
\[
f(\theta_1, \theta_2, \theta_3) = f(0, \theta_2, \theta_3) - \int_0^{\theta_1} \tau_2(u, \theta_2, \theta_3)du.
\]
so that it suffices to determine \( f_0(\theta_2, \theta_3) = f(0, \theta_2, \theta_3) \) in a way compatible with the first equation in \([38]\). We now show that the equation

\[
(\partial_{\theta_2} + c \partial_{\theta_3}) f_0 = \tau_1,
\]

admits a solution which is unique up to a constant. Regarding the uniqueness statement, let \( g := f_0 - \hat{f}_0 \in C^\infty(M) \) be the difference of two solutions. Then \((\partial_{\theta_2} + c \partial_{\theta_3}) g = 0\) so that \( g \) is constant on the leaves of \( M \). Since \( c \in \mathbb{R} \setminus \mathbb{Q} \), any such leaf is dense in \( M \) and therefore \( g \) is constant on \( M \).

For the existence part we shall define \( f_0 \) using Fourier series. In particular, as \( \tau_1 \in C^\infty(M) \) we can write

\[
\tau_1(\theta_2, \theta_3) = \sum_{p,q \in \mathbb{Z}} \hat{\tau}_1(p, q) e^{-i(p\theta_2 + q\theta_3)},
\]

where \( \hat{\tau}(p, q) \) is fast decreasing in \( p, q \), that is, for all \( k \in \mathbb{N} \) it holds

\[
\lim_{(p,q) \to \infty} (1 + |p|^2 + |q|^2)^k \hat{\tau}_1(p, q) = 0.
\]

Notice that \( \hat{\tau}_1(0, 0) = \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} \tau_1 = 0 \). We shall then define \( f_0 \) as

\[
f_0(\theta_2, \theta_3) = \sum_{p,q \in \mathbb{Z}} \frac{\hat{\tau}(p, q)}{i(p + cq)} e^{-i(p\theta_2 + q\theta_3)}.
\]

This definition defines a solution provided the sequence \( \frac{\hat{\tau}_1(p,q)}{i(p+cq)} \) is fast decreasing in \( p,q \). As \( \hat{\tau}_1(p,q) \) is fast decreasing we have only to discuss what happens when \( p,q \) are such that \( p + cq \) is small. However, Lemma \([40]\) implies that for all \( N \in \mathbb{N} \) and \( p,q \in \mathbb{Z} \) such that \( |p - cq| < \frac{1}{N} \) we have \( q = O(N) \) as well as \( p = O(N) \). This implies that \( \frac{\hat{\tau}_1(p,q)}{i(p+cq)} \) is fast decreasing.

Thus, proceeding as in the case of rational \( c \) we have

\[
[X] = [\mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} \tau_1 \partial_{\theta_1} + \mathcal{P}_{\theta_2} \tau_2 (\partial_{\theta_2} + c \partial_{\theta_3}) + t_3 \partial_{\theta_3}],
\]

so that the linear map \( H^1(M; \Pi_c) \ni [X] \mapsto (\mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} \tau_1, \mathcal{P}_{\theta_2} \tau_2, t_3) \in H^0_{\Pi_c}(M)^{\oplus 3} \) completes the proof. Notice that since \( c \in \mathbb{R} \setminus \mathbb{Q} \) we have \( H^0_{\Pi_c}(M) \simeq \mathbb{R} \) as any smooth function satisfying \( f_{\theta_1} = 0 = f_{\theta_2} + cf_{\theta_3} \) is necessarily constant.

We now investigate the convex set \( \text{kms}(M, \Pi_c, [X], \beta) \) of KMS states, focusing in particular on the subset \( \text{kms}_0(M, \Pi_c, [X], \beta) \) of extremal KMS states.

The result will depend on whether \( c \in \mathbb{Q} \) or not. In particular for \( c \in \mathbb{Q} \), item \([2]\) of Theorem \([19]\) applies: The convex set \( \text{kms}(M, \Pi_c) \) is therefore generated by Poisson traces supported
on the leaves of $M$, while there are no KMS states for non-trivial dynamics. This justifies the interpretation of the leaves as pure thermodynamical phases.

Conversely, if $c$ is irrational, the scenario changes abruptly. None of the leaves is proper and we cannot rely on the results of Theorem 19 specifically item 2 does not apply. It turns out that also in this situation there are no KMS states for non-Hamiltonian dynamics. Concerning Poisson traces, their convex set is rather small. Actually there exists a unique trace, which necessarily coincides with the regular one induced by the smooth density $\mu$ such that $Y_\mu = 0$ – recall that cosymplectic manifolds are unimodular $\nu$. In this situation interpreting leaves as thermodynamical phases seems not plausible.

Notice that the existence of a unique Poisson trace can be expected recalling item 3 of Proposition 5. In fact, if $x \in \text{supp}(\varphi)$ then $L_x \subseteq \text{supp}(\varphi)$ and therefore $\text{supp}(\varphi) = M$ as all leaves are dense in $M$.

**Proposition 42**: Let $(M, \Pi_c)$ be the Poisson structure defined in (31).

1. If $c = \frac{p}{q} \in \mathbb{Q}$ then $\kms(M, \Pi_c, [X], \beta) = \{0\}$ unless $[X] = 0$. Moreover, extremal $\Pi_c$-traces corresponds to the canonical traces obtained on each leaf $L$ of $M$.

2. If $c \in \mathbb{R} \setminus \mathbb{Q}$ then $\kms(M, \Pi_c, [X], \beta) = \{0\}$ unless $[X] = 0$. Moreover $\kms(M, \Pi_c) = \{I_\mu\}$ is a singleton where

$$I_\mu(f) = \frac{1}{(2\pi)^3} \int_{[0,2\pi)^3} f(\theta_1, \theta_2, \theta_3) d\theta_1 d\theta_2 d\theta_3.$$ 

**Proof.** Let $X \in [X]$ be as in Equation (36).

1. Since $M$ is compact with a proper leaf, we may apply item 2 of Theorem 19. This proves the claim on Poisson traces, moreover, it entails that $\varphi \in \kms_0(M, \Pi_c, [X], \beta)$ is supported on a leaf $L$ such that $[X]_L$ is Hamiltonian. However, $X|_L$ is not Hamiltonian for any leaf unless $X = 0$, therefore $\kms(M, \Pi_c, [X], \beta) = \{0\}$ for non trivial $[X]$.

2. Let $X = t_1 \partial_{\theta_1} + t_2 (\partial_{\theta_2} + c \partial_{\theta_3}) + t_3 \partial_{\theta_3} \in [X]$, where $t_1$, $t_2$, $t_3$ $\in \mathbb{R}$, and let $\varphi \in \kms(M, \Pi, [X], \beta)$. We shall show that $\varphi \neq 0$ implies that $t_1 = t_2 = t_3 = 0$. Lemma 29 entails that $\kms(M, \Pi_c, [X], \beta) = \{0\}$ unless $t_3 = 0$. We now prove that $t_2 = 0$. For all $f \in C^\infty_c(M)$ we shall consider Equation (5). Let $\chi_1, \chi_2$ be a partition of unity associated with the covering $(0, 2\pi) = [(0, \frac{\pi}{2}) \cup (\frac{3\pi}{4}, 2\pi)] \cup (\frac{\pi}{4}, \pi)$. We may then compute

$$\varphi(\partial_{\theta_2} f) = \varphi(\partial_{\theta_2} (f \chi_1)) + \varphi(\partial_{\theta_2} (f \chi_2))$$

$$= \varphi(f \chi_1, \theta_2 1_f) + \varphi(f \chi_2, \theta_2 1_f)$$

$$= -\beta \varphi(X(\theta_2) f \chi_1) - \beta \varphi(X(\theta_2) f \chi_2)$$

$$= -\beta t_2 \varphi(f),$$

where $1_f \in C^\infty_c(M)$ is such that $1_f|_{\text{supp}(f)} = 1$. Overall we find $\varphi(f) = e^{\beta t_2 s} \varphi(\Psi^s_x f)$ for all $s \in \mathbb{R}$, where $\Psi_s = \Psi_s(\partial_{\theta_1})$ denotes the flow associated with $\partial_{\theta_1}$. As $|\varphi(\Psi^s_x f)|$ is bounded in

34
s ∈ ℝ we find
\[
\varphi(f) = \begin{cases} 
\lim_{s \to +\infty} e^{3t_2 s} \varphi(\Psi_s f) = 0 & \text{for } t_2 < 0 \\
\lim_{s \to -\infty} e^{3t_2 s} \varphi(\Psi_s f) = 0 & \text{for } t_2 > 0,
\end{cases}
\]
which shows that \( t_2 = 0 \) if \( \varphi \neq 0 \). With a similar argument we find
\[
\varphi(f) = e^{3t_1 s} \varphi(\Psi_s f), \quad \forall s \in \mathbb{R},
\]
where \( \Psi_t \) denotes the flow associated with \( \partial_{\theta_2} + c \partial_{\theta_3} \). Again, \(|\varphi(\Psi_s f)|\) is bounded in \( s \) and therefore
\[
\varphi(f) = \begin{cases} 
\lim_{s \to +\infty} e^{3t_1 s} \varphi(\Psi_s f) = 0 & \text{for } t_1 > 0 \\
\lim_{s \to -\infty} e^{3t_1 s} \varphi(\Psi_s f) = 0 & \text{for } t_1 < 0.
\end{cases}
\]
It follows that \( \varphi \neq 0 \) entails \( t_1 = 0 \) as well.

It remains to prove that there exists a unique trace. Let \( \varphi \in \text{KMS}(M, \Pi_\epsilon) \) and let \( 0 \leq \chi_j \in C^\infty(M) \) such that \( \mathcal{P}_{\theta_j} \chi_j = 1 \) for all \( j \in \{1, 2, 3\} \). If follows that for all \( f \in C^\infty_c(M) \)
\[
f = f - (\mathcal{P}_{\theta_1} f) \chi_1 + [(\mathcal{P}_{\theta_1} f) \chi_1 - (\mathcal{P}_{\theta_1} \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f) \chi_1 \chi_2 \chi_3] + (\mathcal{P}_{\theta_1} \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f) \chi_1 \chi_2 \chi_3
\]
\[
= \partial_{\theta_1} g_1 + (\partial_{\theta_2} + c \partial_{\theta_3}) g_2 + (\mathcal{P}_{\theta_1} \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f) \chi_1 \chi_2 \chi_3,
\]
where \( g_1, g_2 \in C^\infty_c(M) \) solves
\[
\partial_{\theta_1} g_1 = f - (\mathcal{P}_{\theta_1} f) \chi_1 =: f_1, \quad (\partial_{\theta_2} + c \partial_{\theta_3}) g_2 = (\mathcal{P}_{\theta_1} f) \chi_1 - (\mathcal{P}_{\theta_1} \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f) \chi_1 \chi_2 \chi_3 =: f_2.
\]
Notice that \( g_1, g_2 \) exist on account of the conditions \( \mathcal{P}_{\theta_1} f_1 = 0 \) and \( \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f_2 = 0 \) – cf. the proof of Lemma 41. Since \( \partial_{\theta_1}, \partial_{\theta_2} + c \partial_{\theta_3} \) are locally Hamiltonian a partition of unity argument leads to
\[
\varphi(f) = (\mathcal{P}_{\theta_1} \mathcal{P}_{\theta_2} \mathcal{P}_{\theta_3} f) \varphi(\chi_1 \chi_2 \chi_3) = c \int_{T^3} f(\theta_1, \theta_2, \theta_3) d\theta_1 d\theta_2 d\theta_3,
\]
where \( c = \frac{1}{(2\pi)^3} \) on account of the condition \( \varphi(1) = 1 \).

\qed

4.2 A Regular Poisson Structure on \( \mathbb{R}^2 \times \mathbb{T} \)

We now provide an example of a non-compact non-unimodular regular Poisson manifold \((M, \Pi)\).
In particular, the symplectic foliation of \( M \) is made by leaves which are not submanifolds of \( M \) – with one exception. Nevertheless, the structure of the KMS convex cone is rather rich – cf. Proposition 47. In fact, there exist KMS functionals for dynamics \([X]\) which differs from the
modular class \([Y_\Pi]\). Moreover, we can still find KMS functionals supported on leaves. This is a hint of the fact that these leaves fail to be submanifolds of \(M\) in a rather controlled way.

We consider
\[
M = \mathbb{R}^2 \times T, \quad \Pi = (x\partial_x + \partial_\theta) \wedge \partial_y,
\]
where \(x, y \in \mathbb{R}\) while \(\theta\) is the usual quasi-global coordinate on \(T\). The symplectic foliation of \((M, \Pi)\) is easily computed to be the collections of codimension 1 manifolds
\[
L_{(x_0, \theta_0, y_0)} := \begin{cases}
\{(x_0 e^u \theta_0 + u, y) \mid u, y \in \mathbb{R}\} & \text{for } x_0 \neq 0 \\
\{(0, \theta, y) \mid y \in \mathbb{R}, \theta \in [0, 2\pi)\} & \text{for } x_0 = 0.
\end{cases}
\]
As \(L_{(x_0, \theta_0, y_0)} = L_{(x_0 e^{\theta_0}, 0, 0)}\) in what follows we shall denote the leaves as \(L_x := L_{(x, 0, 0)}\). Notice in particular that \(L_{x e^{2\pi}} = L_x\), therefore, the leaf space is the collection
\[
\{L_x \mid x \in (-e^{-2\pi}, -1] \cup \{0\} \cup [1, e^{2\pi})\}.
\]
Notice that none of these leaves is a proper submanifold of \(M\) except for the case \(x_0 = 0\) – cf. Figure 1.

Remark 43: Denoting \(\eta := x d\theta - dx\) we have that \(\eta \in \Omega^1(M)\) is no-where vanishing while the symplectic foliation \((43)\) coincides with the one induced by \(\eta\). Moreover, if we consider \(\omega := dy \wedge d\theta \in \Omega^2(M)\) we have that \(\eta \wedge \omega\) is never vanishing. In this situation the Poisson tensor \(\Pi\) of \(M\) is shown to coincide with the one defined in \((11)\). However, notice that \(\eta\) is not closed and therefore \(M\) is not cosymplectic. In fact, \(M\) is called an almost cosymplectic manifold, see \([11, \text{Def. 2.1}]\). This entails in particular that this example is not covered by the results discussed in the previous sections.

In order to study KMS functionals on \((M, \Pi)\) we first compute the first Poisson cohomology class \(H_1^\Pi(M)\) of \((M, \Pi)\).

Lemma 44: For the Poisson manifold given by Equation \((42)\) one has
\[
H_1^\Pi(M) \simeq \mathbb{R}^2.
\]
More precisely, any element \([X] \in H_1^\Pi(M)\) is a linear combination of \([\partial_\theta]\) and \([\partial_y]\). Finally, the modular class \(Y_\Pi\) of \((M, \Pi)\) corresponds to \([\partial_y]\).

Proof. Let \(X = \xi \partial_x + \eta \partial_y + \tau \partial_\theta\) be a Poisson vector field on \((M, \Pi)\) where \(\xi, \eta, \tau \in C^\infty(M)\). The condition \(L_X(\Pi) = 0\) implies the following equations:
\[
\begin{align*}
\xi - x\xi_x - \xi_\theta - x\eta_y &= 0 \quad (45a) \\
x\tau_x + \tau_\theta + \eta_y &= 0 \quad (45b) \\
\xi_y - x\tau_y &= 0 \quad (45c)
\end{align*}
\]
Figure 1: The regular foliation of $(M, \Pi)$ visualized in the plane – barring the $y$-direction – where the radial coordinate $r$ is identified by $\log(r) = x_0 e^u$ – cf. Equation (43). Symplectic leaves with $x_0 > 0$ are spirals with flows anticlockwise at infinity, starting (at $-\infty$) at the disk $D_1$ of radius $r = 1$ – cf. curves $a_1, a_2$. For $x_0 < 0$ we get a spiral which flows anticlockwise from the disk $D_1$ to the origin – cf. curves $b_1, b_2$. Finally $x_0 = 0$ is $D_1$. 

37
Evaluation of Equation (45a) at \( x = 0 \) ensures that \( \xi(0, y, \theta) = 0 \), that is, \( \xi(x, y, \theta) = x\alpha(x, y, \theta) \) for \( \alpha \in C^\infty(M) \). Equations (45a) and (45c) simplify to

\[
x\alpha_x + \alpha_\theta + \eta_y = 0, \quad \alpha_y = \tau_y.
\]

(46)

Combining the found equations with (45b) it follows that

\[
X = \alpha(x\partial_x + \partial_\theta) + \eta \partial_y + A\partial_\theta,
\]

where

\[
\eta_y = -(x\alpha_x + \alpha_\theta), \quad A_y = 0, \quad xA_x + A_\theta = 0.
\]

(47)

The equations for \( A \) imply that \( A \) is a function of \( x \) and \( \theta \) only. Moreover, \( A(0, \theta) \) is constant. Furthermore one has

\[
A(x, \theta) = A(x e^s, \theta + s)^{s=-2\pi} A(x e^{-2\pi}, \theta) = \lim_{n \to +\infty} A(x e^{-2\pi n}, \theta) = A(0, \theta),
\]

which proves that, in fact, \( A \in \mathbb{R} \) is constant.

We now consider the cohomology class \([X] \in H_1(\Pi(M)) \) of \( X \). We observe that, for all \( f \in C^\infty(M) \),

\[
X_f = f_y(x\partial_x + \partial_\theta) - (xf_x + f_\theta)\partial_y.
\]

(48)

Let \( f \in C^\infty(M) \) be such that \( f_y = \alpha \). Equation (45b) implies that \( \eta = b - (xf_x + f_\theta) \), being \( b \in C^\infty(M) \) with \( b_y = 0 \). Comparing with (48) we have

\[
[X] = [b\partial_y + A\partial_\theta].
\]

We now consider the task of finding \( f \in C^\infty(M) \) such that \( X_f = b\partial_y \): Equation (48) entails

\[
x f_x + f_\theta = -b, \quad f_y = 0.
\]

These last equations give

\[
f(x e^s, \theta + s) = f(x, \theta) - \int_0^s b(x e^t, \theta + t)dt,
\]

(49)

which in particular implies the condition

\[
\int_0^{2\pi} b(0, \theta) d\theta = 0.
\]

(50)

The latter condition is necessary and sufficient to determine \( f \) up to a constant, as we shall see now. Indeed, by assuming Equation (50) and letting \( s = -2\pi n, n \in \mathbb{N} \), in Equation (49) we find

\[
f(x e^{-2\pi n}, \theta) = f(x, \theta) - \int_0^{-2\pi n} b(x e^t, \theta + t)dt = f(x, \theta) - \int_0^{-2\pi n} [b(x e^t, \theta + t) - b(0, \theta + t)]dt,
\]
where we exploited the assumption on $b$. We also observe that $f(0, \theta)$ is determined up to a constant by $b(0, \theta)$ as one can see by evaluating at $x = 0$ the differential equation $xf_x + f_\theta = -b$ —this is another way to recover the necessary condition in Equation \((50)\). Therefore, considering the limit $n \to +\infty$ of the previous equation we obtain

$$f(x, \theta) = f(0, 0) - \int_0^\theta b(0, s)ds - \int_{-\infty}^0 [b(xe^t, \theta + t) - b(0, \theta + t)]dt.$$  \hspace{1cm} (51)

Notice that integral on $(-\infty, 0)$ converges because the function $c(x, t) := b(x, \theta) - b(0, \theta)$ vanishes at $x = 0$, therefore, we can find $\tilde{c} \in C^\infty(M)$ such that $c(x, \theta) = x\tilde{c}(x, \theta)$. This entails that $|c(xe^t, \theta + t)| = |xe^t\tilde{c}(xe^t, \theta + t)| \leq |x|e^t$, which proves the convergence of the integral.

Equation \((51)\) provide an explicit formula for $f$ under the assumption of Equation \((50)\). As a matter of fact an explicit computation shows that Equation \((51)\), together with the choice of the constant $f(0, 0) \in \mathbb{R}$, defines a smooth function $f \in C^\infty(M)$ which solves $xf_x + f_\theta = b$. Indeed, smoothness of $f$ as per Equation \((51)\) is clear —notice that $\theta$-periodicity is ensured by the periodicity condition of $b$ as well as Equation \((50)\) — whereas by direct inspection we have

$$(x\partial_x + \partial_\theta)f(x, \theta) = -b(0, \theta) - \int_{-\infty}^0 \frac{d}{dt} [b(xe^t, \theta + t) - b(0, \theta + t)] dt = b(x, \theta).$$

Overall we have that, setting $B := \frac{1}{2\pi} \int_0^{2\pi} b(0, \theta)d\theta$,

$$[X] = [(b - B)\partial_y + B\partial_\theta + A\partial_\theta] = [B\partial_\theta + A\partial_\theta].$$

It remains to show that $[B\partial_\theta] \neq [0]$ if $B \neq 0$: This has already been shown in \([36]\). Indeed, $B\partial_\theta = Xf$ for $f \in C^\infty(M)$ would imply

$$xf_x + f_\theta = B, \quad f_\theta = 0.$$ 

Considering $F(x) := \int_0^{2\pi} f(x, \theta)d\theta$, the first equation leads to $xF'(x) = B$ which leads to a contradiction as $F \in C^\infty(\mathbb{R})$.

The modular class $Y_\Pi$ can be computed considering $\mu = dx dy d\theta$, thus proving the rest of the assertion. \hfill \Box

We now investigate the convex cone $\text{KMS}(M, \Pi, [X], \beta)$ for all $[X] \in H^1_\Pi(M)$. To this avail the following lemma with be relevant.

**Lemma 45:** Let $D_\beta$ be the differential operator defined by

$$D_\beta f := xf_x + f_\theta + \beta f.$$ \hspace{1cm} (52)

Moreover, for all $\theta$ and $x \in (-e^{2\pi}, -1] \cup [1, e^{2\pi})$ let $x\psi_\beta$ be the linear functional

$$x\psi_\beta : C^\infty_c(\mathbb{R} \times T) \to \mathbb{C}, \quad x\psi_\beta(f) := \int_{\mathbb{R}} f(xe^u, \theta + u)e^{\beta u}du.$$ \hspace{1cm} (53)

Let $f \in C^\infty_c(\mathbb{R} \times T)$. Then the following two conditions are equivalent:

39
1. There exists a function \( g \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \) such that \( D_\beta g = f \).

2. One has \( x \psi^\beta_\theta(f) = 0 \) for all \( \theta \) and \( x \in (-e^{2\pi}, -1] \cup [1, e^{2\pi}) \).

**Proof.** We first notice that, for all \( \theta \) and all \( x \in (-e^{2\pi}, -1] \cup [1, e^{2\pi}) \) as well as \( f \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \), \( x \psi^\beta_\theta(f) \) is well-defined on account of the exponential decay of \( e^{\beta u} \) as \( u \to -\infty \) and thanks to the compact support of \( f \) for \( u \to \infty \). We prove the two implications separately.

**[1] \to [2]** Let \( g \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \) be such that \( D_\beta g = f \). For all \( \theta \in [0, 2\pi) \) and \( x \in (-e^{2\pi}, -1] \cup [1, e^{2\pi}) \) a direct computation leads to

\[
x \psi^\beta_\theta(f) = \int_\mathbb{R} (D_\beta g)(xe^u, \theta + u)e^{\beta u} \, du = \int_\mathbb{R} \frac{d}{du}[g(xe^u, \theta + u)e^{\beta u}] \, du = 0.
\]

**[2] \to [1]** Let \( f \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \) be such that \( x \psi^\beta_\theta(f) = 0 \) for all \( \theta \in [0, 2\pi) \) and \( x \in (-e^{2\pi}, -1] \cup [1, e^{2\pi}) \). Any smooth solution \( g \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \) of \( D_\beta g = f \) would satisfy

\[
g(x, \theta) = e^{\beta u}g(xe^u, \theta + u) - \int_0^u f(xe^v, \theta + v)e^{\beta v} \, dv, \quad \forall u \in \mathbb{R}.
\]

Letting \( u = -2\pi n, n \in \mathbb{N} \), and considering the limit \( n \to +\infty \) the previous equation leads to

\[
g(x, \theta) = \int_{-\infty}^0 f(xe^u, \theta + v)e^{\beta v} \, dv. \tag{54}
\]

On the other hand, Equation (54) defines a smooth function \( g \in C^\infty(\mathbb{R} \times \mathbb{T}) \) which satisfies \( D_\beta g = f \)—notice that the \( \theta \)-periodicity condition on \( g \) is ensured by the one on \( f \) together with the fact that the above integral is uniformly bounded by \( \|f\|_\infty \int_{-\infty}^0 e^{\beta u} \, du \). We shall now prove that in fact \( g \in C_c^\infty(\mathbb{R} \times \mathbb{T}) \). If \( \text{supp}(f) \subseteq (-\infty, x_0] \times \mathbb{T}, x_0 > 0 \), then for all \( x > x_0 \)

\[
g(x, \theta) = \int_{-\infty}^0 f(xe^u, \theta + u)e^{\beta u} \, du = \int_{-\infty}^\infty f(xe^u, \theta + u)e^{\beta u} \, du = x \psi^\beta_\theta(f) = 0,
\]

since the integration for positive \( u \) will not contribute. Conversely, for \( x_0 < 0 \) such that \( \text{supp}(f) \subseteq [x_0, \infty) \times \mathbb{T} \) we can again extend the integration from \((-\infty, 0)\) to all of \( \mathbb{R} \) by the same argument, proving that \( g(x, \theta) = 0 \) for all \( x < x_0 \). Since \( f \) has compact support, we find a large enough \( x > 0 \) with \( \text{supp}(f) \subseteq [-x, x] \times \mathbb{T} \) and then the function \( g \) has support in this compact subset as well.

\[\square\]

**Remark 46:** Notice that, for all \( s \in \mathbb{R} \), it holds

\[
x^{se^\beta} \psi^\beta_{\theta+s}(f) = e^{-\beta s} x \psi^\beta_\theta(f).
\]

This entails that condition [2] of Lemma [45] is equivalent to

\[
\pm_1 \psi^\beta_\theta(f) = 0, \quad \forall \theta \in [0, 2\pi).
\]

40
We now have the following complete characterization for
\[
KMS(A, B, \beta) := KMS(M, \Pi, [A\partial_\theta + B\partial_y], \beta).
\]
This example is particularly interesting because the convex cone of KMS functionals is non-trivial for several dynamics. First of all there exists a unique (up to a prefactor) Poisson trace, induced by the unique proper leaf of \(M\). The existence of such a leaf makes also possible to have a unique (up to a prefactor) KMS functional associated with \([\partial_\theta]\). The latter provides an example of a convex cone of KMS functionals which is non-trivial though it does not contain regular functionals as per Definition 11.

KMS functionals associated with multiples of the modular class \([Y_\mu] = [\partial_y]\) lead to more interesting results. In fact \(KMS(0, B, \beta) := KMS(0, B, \beta)\) is non-empty for all \(B > 0\) and \(\beta > 0\). While for \(\beta = 1\) this follows from Remark 12, all other values of \(\beta\) are not for free and the rather large class of functionals found is somehow surprising. In fact, \(KMS(1, \beta)\) is “generated” by KMS functionals supported on non-compact leaves of \(M\), where \(Y_\Pi\) is Hamiltonian. Conversely, for \(B < 0\) the set \(KMS(B, \beta) = KMS(-1, |B|\beta)\) reduces to \(\{0\}\) for all \(\beta > 0\). This is interesting, because it shows that the restriction of \(-Y_\Pi\) on non-compact leaves does not lead to a suitable Hamiltonian, providing indirect information on how badly those leaves embed in \(M\). Overall \(KMS(B, \beta)\) shows a phase transition in the parameter \(B \in \mathbb{R}\). In fact \(KMS(B, \beta)\) is isomorphic to a measure space for \(B > 0\), a singleton for \(B = 0\) and \(\{0\}\) for \(B < 0\).

**Proposition 47:** Let \((M, \Pi)\) be the Poisson manifold \((M, \Pi)\) defined by Equation (42) and let \([X] = [A\partial_\theta + B\partial_y] \in H^1_\Pi(M)\) where \(A, B \in \mathbb{R}\). Then \(KMS(A, B, \beta) := KMS(M, \Pi, A\partial_\theta + B\partial_y, \beta)\) fits in one of the following cases:

<table>
<thead>
<tr>
<th>(A)</th>
<th>(B &lt; 0)</th>
<th>(B = 0)</th>
<th>(B &gt; 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(A \neq 0)</td>
<td>{0}</td>
<td>([0, +\infty))</td>
<td>{0}</td>
</tr>
<tr>
<td>(A = 0)</td>
<td>{0}</td>
<td>([0, +\infty))</td>
<td>(\mathbb{M}_+(\mathbb{T})^2)</td>
</tr>
</tbody>
</table>

where \(\mathbb{M}_+(\mathbb{T})\) denotes the set of positive Borel measures on \(\mathbb{T}\). In particular:

1. The unique (up to multiplicative constant) element \(\varphi \in KMS(A, 0, \beta)\) is given by
   \[
   \varphi(f) := \int_0^{2\pi} \int_\mathbb{R} f(0, \theta, y) e^{-\beta y} d\theta dy.
   \]

2. The unique (up to multiplicative constant) \(\Pi\)-trace \(\varphi \in KMS(M, \Pi)\) is given by
   \[
   \varphi(f) := \int_0^{2\pi} \int_\mathbb{R} f(0, \theta, y) d\theta dy.
   \]

3. For all \(\varphi \in KMS(0, 1, \beta)\) there exists positive measures \(\nu^\pm_\varphi \in \mathbb{M}_+(\mathbb{T})\) such that
   \[
   \varphi(f) = \sum_{\pm} \int_0^{2\pi} 1_\varphi^\beta(f) d\nu^\pm_\varphi(\theta),
   \]
   (55)
where for all $x \neq 0$ and $\theta \in [0, 2\pi)$, $x \varphi^\beta_\theta$ is the KMS functional defined by

$$x \varphi^\beta_\theta(f) := \int_{\mathbb{R}^2} f(xe^u, \theta + u, y)e^{\beta u}dy.$$  

(56)

It follows that $\varphi \in \text{KMS}(0, 1, \beta)$ is extremal if and only if $\varphi = 1 \varphi^\beta_\theta$ for $\theta \in [0, 2\pi)$.

Proof. Let $X = A\partial_\theta + B\partial_y \in [X]$. 

$AB \neq 0$: Let $Z := M \cap \{x = 0\}$ and consider the regular codimension 1 Poisson manifold $(M_Z := M \setminus Z, \Pi|_{M_Z})$. Since $A \neq 0$ it follows that $X|_{M_Z}$ is transverse to the symplectic foliation of $M_Z$. Moreover if $\varphi \in \text{KMS}(M, \Pi, X, \beta)$ then $\varphi|_{C_c^\infty(M_Z)} \in \text{KMS}(M_Z, \Pi|M_Z, X, \beta)$ and, by Lemma 18, we have $\varphi|_{C_c^\infty(M_Z)} = 0$.

Therefore $\text{supp}(\varphi) \subseteq Z$ for all $\varphi \in \text{KMS}(A, B, \beta)$. This entails that $\varphi(f) = \psi(f|_Z)$ for all $f \in C_c^\infty(M)$ where $\psi : C^\infty_c(Z) \to \mathbb{C}$ is a positive linear functional. Moreover, $\psi \in \text{KMS}(Z, \Pi|_Z, X, \beta)$, because $X$ is tangent to $Z$. But $(Z, \Pi|_Z)$ is symplectic and therefore Remark 4 ensures that $\psi \neq 0$ would imply

$$[0] = [X|_Z] = [B\partial_y|_Z] = [Bd\theta^0|_Z],$$

a contradiction as $B \neq 0$. It follows that $\varphi = 0$.

$A \neq B \neq 0$: Proceeding as in the previous case we have that $\varphi \in \text{KMS}(A, 0, \beta)$ implies that $\text{supp}(\varphi) \subseteq Z$. Therefore $\varphi(f) = \psi(f|_Z)$ for all $f \in C_c^\infty(M)$, where $\psi \in \text{KMS}(Z, \Pi|_Z, A\partial_\theta, \beta)$. Remark 4 implies that there exists $c > 0$ such that

$$\varphi(f) = c \int_0^{2\pi} \int_\mathbb{R} f(0, \theta, y)e^{-\beta Ay}d\theta dy.$$  

$A = 0, B \leq 0$: Let $\varphi \in \text{KMS}(0, B, \beta)$ where $B \leq 0$. For all $f \in C^\infty_c(M)$ we apply Equation (5) for $g = y1_f$ where $1_f \in C^\infty_c(M)$ is such that $1_f|_{\text{supp}(f)} = 1$. It follows that, denoting by $\Psi_t = \Psi_t^x\partial_x + \partial_\theta$ the flow associated with the vector field $X_y = x\partial_x + \partial_\theta$, it holds

$$\varphi(f) = e^{\beta Bt}\varphi(\Psi_t^*f).$$

The above argument shows that $\varphi$ has to be supported on $Z$: indeed let $f \in C^\infty_c(M_Z)$. Then, for all $t_0 \in \mathbb{R}$ there exists $K_{t_0}$ such that $\text{supp}(\Psi_t^*f) \subseteq K_{t_0}$ for all $t \geq t_0$. Since $\varphi$ is positive we have the bound $|\varphi(\Psi_t^*f)| \leq C_{t_0}\|f\|_{\infty}$ for all $t \geq t_0$ with $C_{t_0} > 0$. It then follows that

$$\varphi(f) = \lim_{t \to +\infty} e^{B\beta t}\varphi(\Psi_t^*f) = 0,$$

where we used that $B \leq 0$. Notice that for $B = 0$ we have $\lim_{t \to +\infty} \varphi(\Psi_t^*f) = 0$ by dominated convergence: Indeed $\varphi$ is positive, while $\lim_{t \to +\infty} \Psi_t^*f = 0$ pointwise and $|\Psi_t^*f| \leq \|f\|_{\infty}\theta_{K_{t_0}}$ for $t \geq t_0$ —here $\theta_{K_{t_0}}$ denotes the characteristic function over $K_{t_0}$. 

42
As $Z$ is symplectic Remark 4 entails that $\varphi \neq 0$ would imply $0 = [B\partial_y] = [Bd\theta^2]$. It follows that $B < 0$ implies $\varphi = 0$, moreover, if $B = 0$ then there is a constant $c > 0$ such that

$$\varphi(f) = c \int_0^{2\pi} \int_\mathbb{R} f(0, \theta, y) dy d\theta.$$ 

As $KMS(0, B, \beta) = KMS(0, 1, |B|\beta)$ we shall restrict to $B = 1$. We first observe that the functionals $x\varphi_\theta^\beta$ defined in Equation (56) are $(\partial_y, \beta)$-KMS functionals: in fact $x\varphi_\theta^\beta$ is the pull-back on $M$ of the unique (up to multiplicative constant) KMS functional on $L_x$.

Notice that, recalling Equation (53), we have

$$x\varphi_\theta^\beta(f) = \int_\mathbb{R} x\psi_\theta^\beta(f(\cdot, \cdot, y)) dy = [I_y \circ x\psi_\theta^\beta](f),$$

where $(I_y f)(x, \theta) := \int_\mathbb{R} f(x, \theta, y) dy$. Let $\varphi \in KMS(0, 1, \beta)$ and let $\eta, \chi \pm \in C^\infty_c(\mathbb{R})$ be such that $\eta, \chi \pm \geq 0$, $\int_\mathbb{R} \eta(y) dy = 1$, $\int_0^{\pm\infty} \chi \pm(z) \frac{dz}{z} = 1$, $\text{supp}(\chi \pm) \subseteq (0, \pm\infty)$. (57)

For all $f \in C^\infty_c(\mathbb{R} \times \mathbb{T})$ we set

$$f_\chi \in C^\infty_c(\mathbb{R} \times \mathbb{T}), \quad f_\chi(x, \theta) := f(x, \theta) - \sum_\pm x\psi_\theta^\beta(f)\chi \pm(x).$$

Notice that the well-definedness of $f_\chi$ is due to the support properties of $\chi$, in particular $0 \notin \text{supp}(\chi)$. A direct computation shows that, for all $x \neq 0$ and $\theta \in [0, 2\pi)$,

$$x\psi_\theta^\beta(f_\chi) = x\psi_\theta^\beta(f) - \sum_\pm \int_\mathbb{R} x e^u \psi_{\theta+u}(f) \chi \pm(x e^u) e^{\beta u} du$$

$$= x\psi_\theta^\beta(f) \left[1 - \sum_\pm \int_0^{\text{sgn}(x)\infty} \chi \pm(z) \frac{dz}{z} \right]$$

$$= 0,$$

where we used that $x e^u \psi_{\theta+u}(f) e^{\beta u} = x\psi_\theta^\beta(f)$. Lemma 45 entails that $f_\chi = D_\beta g$ for $g \in C^\infty_c(\mathbb{R} \times \mathbb{T})$.

Moreover a direct computation shows that, for all $f \in C^\infty_c(M)$,

$$\varphi(x f_\chi + f_\delta) = \varphi(\{f, y_1 f\}) = -\beta \varphi(f) \implies \varphi \circ D_\beta = 0.$$

With these preliminaries we now come to the characterization of $KMS(0, 1, \beta)$. At first we shall define two positive Borel measures $\nu_\varphi^\pm \in M_+(\mathbb{T})$ associated to $\varphi$. For that let
$F : \mathbb{R} \setminus \{0\} \times T \to T$ be defined by $F(x, e^{i\theta}) := e^{i(\theta - \log|x|)}$. For all open subsets $U \subseteq T$ we then set

$$\nu^\pm_\varphi(U) := \varphi(\varrho_{F^{-1}(U)} \eta x^{-\beta} \chi^\pm),$$

where $\varrho_{F^{-1}(U)}$ denotes the characteristic function over $F^{-1}(U)$. Notice that $x^{-\beta} \chi^\pm \in C_c^\infty(\mathbb{R})$ on account of the hypothesis on $\chi^\pm$ while we regarded $\varphi$ as a positive measure on $M$ – cf. Remark 2.

The last equation defines two positive Borel measures $\nu^\pm_\varphi \in M_+(T)$ which do not depend on the choice of neither $\eta$ nor $\chi^\pm$. Indeed, for any other $\tilde{\eta}$ and $\tilde{\chi}^\pm$ which satisfies Equation (57) we have $\eta - \tilde{\eta} = h_g$ and $\chi^\pm - \tilde{\chi}^\pm = xg^\pm$ for $h, g \in C_c^\infty(\mathbb{R})$. We therefore have

$$\varphi(\varrho_{F^{-1}(U)}(\eta - \tilde{\eta}) x^{-\beta} \chi^\pm) = (\varphi \circ \partial_y)(\varrho_{F^{-1}(U)} h x^{-\beta} \chi^\pm) = 0, \quad \varphi(\varrho_{F^{-1}(U)} \eta x^{-\beta} (\chi^\pm - \tilde{\chi}^\pm)) = (\varphi \circ D_\beta)(\varrho_{F^{-1}(U)} \eta x^{-\beta} g^\pm) = 0,$$

where we used $x^{-\beta+1}g^\pm = D_\beta(x^{-\beta}g^\pm)$ as well as the fact that $D_\beta f \circ F^{-1} = 0$ for all $f \in C^\infty(\mathbb{R} \times T)$.

We now prove Equation (55). For any $f \in C_c^\infty(M)$ we have

$$f = f + \underbrace{I_0(f) \eta}_{=h_y} + \underbrace{[I_0(f) \eta] \chi}_{=D_\beta g} + \sum \pm \varphi_g(f) \chi^\pm \eta,$$

where $h, g \in C_c^\infty(M)$. Since $x^\beta f(f) = x^{-\beta} 1_{\varphi-\log} x(f)$ we find

$$\varphi(f) = \sum \pm \varphi(\varphi_g(f) \chi^\pm \eta) = \sum \pm \int_0^{2\pi} 1_{\varphi_g(f) \eta} d\nu^\pm_\varphi(\theta).$$

Example 48 (Symmetry breaking): As an example of Equation (55) we consider the case $d\nu^\pm_\varphi(\theta) = d\theta$, $\nu^-_\varphi = 0$. This leads to

$$\varphi(f) = \int_0^{+\infty} \int_0^{2\pi} \int_{\mathbb{R}} f(x, \theta, y) x^{\beta-1} dxd\theta dy,$$

Notice that the KMS functional obtained with such a choice is invariant under the flow of $\partial_\theta$. A direct inspection shows that $(\partial_y, \beta)$-KMS functionals which are $\partial_\theta$-invariant correspond to the choice $d\nu^\pm_\varphi(\theta) = c_{\pm} d\theta$ with $c_{\pm} \in [0, +\infty]$. On account of Theorem 17 none of these functionals is extremal in KMS$(M, \Pi, \partial_y, \beta)$. Stated differently, any $\varphi \in$ KMS$(M, \Pi, \partial_y, \beta)$ is either extremal or $\partial_\theta$-invariant but not both. In physics jargon such a phenomenon is known with the name of symmetry breaking.
