Dominating Sets in Bergman Spaces on Strongly Pseudoconvex Domains

A. Walton Green and Nathan A. Wagner

ABSTRACT
We obtain local estimates, also called propagation of smallness or Remez-type inequalities, for analytic functions in several variables. Using Carleman estimates, we obtain a three sphere-type inequality, where the outer two spheres can be any sets satisfying a boundary separation property, and the inner sphere can be any set of positive Lebesgue measure. We apply this local result to characterize the dominating sets for Bergman spaces on strongly pseudoconvex domains in terms of a density condition or a testing condition on the reproducing kernels. Our methods also yield a sufficient condition for arbitrary domains and lower-dimensional sets.

1. Introduction

Let \( F \) be a function space defined on a metric-measure space \((\Omega, d, \mu)\). Finding the so-called dominating sets for \( F \) is to find \( E \subset \Omega \) such that functions in \( F \) can be continuously reconstructed from their values on \( E \). In other words, the restriction map \( f \mapsto f|_E \) is invertible.

Such questions have been considered by many authors, having complete solutions in many classical function spaces—see the survey [9]. Recently, there has been renewed interest in uncertainty principle versions of this problem due to the applications in control theory. In such a case, \( F \) is defined by some sort of Fourier decay or support condition. We take a different perspective here and consider the Bergman spaces, defined below.

When the underlying metric measure space \((\Omega, d, \mu)\) of a function space \( F \subset L^p(\Omega, d\mu) \) is acted on transitively and invariantly by a group, many simplifications can be made. It is not too hard to check that the following relative density conditions are equivalent and necessary conditions for \( E \) to be a dominating set:

\[
\inf_{z \in \Omega} \mu(E \cap B_z) > 0, \quad \text{and} \quad \inf_{z \in \Omega} \|\phi_z|_E\| > 0 \tag{1.1}
\]

for some ball \( B \) or some function \( \phi \). \( B_z \) or \( \phi_z \) mean \( B \) or \( \phi \) translated, by the group action, to the point \( z \in \Omega \).

This is the first novel feature of our paper. The problem of dominating sets in the homogeneous Bergman spaces (those whose domains have a transitive automorphism group) was completely solved by Luecking almost 40 years ago [21, 22], showing that relative density (1.1) is also sufficient. In such a setting, one can use the Euclidean geometry (say far from the boundary) and then using the automorphisms of the domain, connect this to the invariant complex geometry. Such features also enter into the recent work of Hartmann et. al. in [11], where they refine Luecking’s results on the disc and obtain the sharp form of the sampling
constant, polynomial in terms of the lower bound \( \| \), which is related to the norm of the inverse operator \( f \mid_E \mapsto f \).

Our main goal here is to extend both of these results to more general domains, with little to no automorphic structure. In general domains, there are many so-called invariant metrics, so it is not immediate what sort of measure-theoretic density condition is necessary. However, one which is both necessary and which acknowledges the invariant complex geometry can be given by the Berezin transform, which is defined in (1.2) below.

### 1.1. Main Result

To state our main result, let us introduce some definitions. We will use the notation \( \text{Hol}(X; Y) \) to denote the space of functions which are holomorphic on \( X \), taking values in \( Y \). When \( Y = \mathbb{C} \), we use \( \text{Hol}(X) \). For a domain \( \Omega \subset \mathbb{C}^n \), \( 1 \leq p \leq \infty \), and \( \alpha > -1 \), define the power-weighted Bergman spaces

\[
A^p_\alpha(\Omega) = \{ f \in \text{Hol}(\Omega) : \int_\Omega |f(z)|^p |\rho(z)|^\alpha dA(z) < \infty \}.
\]

\( \rho(z) \) is a defining function of the domain \( \Omega \) which means \( \Omega = \{ \rho < 0 \} \). \( dA \) denotes the volume element on \( \mathbb{C}^n \equiv \mathbb{R}^{2n} \). It is straightforward to show that \( A^p_\alpha(\Omega) \) is a Banach space and is a closed subspace of \( L^p_\alpha(\Omega) \), which is the weighted \( L^p \) space on \( \Omega \) with weight \( |\rho|^\alpha \). Bergman spaces with radial weights have been extensively studied (see for example [25], [7], [14]).

\( A^2_\alpha(\Omega) \) is a reproducing kernel Hilbert space. Let \( K_{\alpha}(z, w) \) denote its reproducing kernel and \( k_{z,\alpha}^p \) the \( L^p_\alpha \) normalization at \( z \in \Omega \):

\[
k_{z,\alpha}^p(w) = \frac{K_{\alpha}(z, w)}{\|K_{\alpha}(z, \cdot)\|_{L^p_\alpha(\Omega)}}.
\]

The following quantity will be of crucial importance in testing if a set \( E \) is a dominating set,

\[
\tilde{T}_{E,\alpha}^p(z) = \|k_{z,\alpha}^p\|_{L^p_\alpha(E)}.
\]

When \( p = 2 \), this is the well-known Berezin transform of the Toeplitz operator with symbol \( 1_E \). Broadly, our main result states that for \( E \) to be a dominating set for \( A^p_\alpha(\Omega) \), it is enough for \( \tilde{T}_{E,\alpha}^p \) to not vanish on \( \partial \Omega \).

**Theorem 1.** Let \( \Omega \) be a smoothly bounded strongly pseudoconvex domain and \( Y(w, r) \) be a ball in the Kobayashi metric on \( \Omega \) of radius \( \tanh^{-1} r \) centered at \( w \) (see Definition 3.1). Then, for any \( E \subset \Omega \), the following are equivalent.

(i) For any \( 1 < p < \infty \), \( \alpha > -1 \), there exists \( C > 0 \) such that

\[
\|f\|_{A^p_\alpha(\Omega)} \leq C \|f\|_{A^p_\alpha(E)}
\]

(ii) \( E \) is relatively dense, which means there exists \( r > 0 \) such that

\[
\inf_{w \in \Omega} \frac{|E \cap Y(w, r)|}{|Y(w, r)|} > 0.
\]
(iii) For some $1 < p < \infty$, $\alpha > -1$,
\[
\inf_{z \in \Omega} \tilde{T}_c^p,\alpha(z) > 0.
\]

Furthermore, if the infimum in (ii) is at least $\gamma$, then the form of the constant in “(ii) implies (i)” is $C\gamma^{-q}$ for $C, q > 0$ depending on $r, p, \alpha, \Omega$, but not on $E$. The same holds in “(iii) implies (i)” if we have a lower bound $\tilde{T}_c^p,\alpha(z) \geq \gamma$. Moreover, in both cases we can include the endpoints $p = 1$ or $\infty$. We also mention that this sharp dependence (polynomial in $\gamma$) was recently obtained for $\Omega = D$ in [11], with more information concerning the other parameters as well.

One application of this theorem is to the reproducing kernel hypothesis (RKH), which concerns the connection between an operator $T$ and its Berezin transform. For nonnegative function $\sigma$, let $T_\sigma : A^2_\alpha(\Omega) \to A^2_\alpha(\Omega)$ be the Toeplitz operator defined by
\[
T_\sigma(f) = P_\alpha(\sigma f)
\]
where $P_\alpha$ is the orthogonal projection from $L^2_\alpha(\Omega)$ to $A^2_\alpha(\Omega)$. For such a operator, its Berezin transform is
\[
\tilde{T}_\sigma^\alpha(z) = \langle T_\sigma^\alpha k_z^{2,\alpha}, k_z^{2,\alpha} \rangle.
\]
This coincides with the definition (1.2) when $p = 2$ and $\sigma = 1_E$.

**Corollary 1.1.** Let $\sigma \in L^\infty(\Omega)$, $\gamma > 0$. There exists $c > 0$ such that
\[
\langle T_\sigma^\alpha f, f \rangle \geq c\|f\|^2
\]
if and only if
\[
\liminf_{z \to \partial \Omega} \tilde{T}_\sigma^\alpha(z) > 0.
\]
Moreover, there exists $q > 0$ such that if $\tilde{T}_\sigma^\alpha(z) \geq \gamma$, then
\[
\langle T_\sigma^\alpha f, f \rangle \geq c\gamma^q\|f\|^2.
\]

This can be viewed as a version of the RKH for positivity of Toeplitz operators. This also implies a version of the RKH for boundedness. Initially one may hope to obtain $\|T_\sigma\| \leq C\sup_{z \in \Omega} |\tilde{T}_\sigma^\alpha(z)|$ where $C > 1$. However, if $\|\sigma\|_{L^\infty} \leq 1$, then this gives no improvement on $\|T_\sigma\| \leq \|\sigma\|_{\infty}$ unless $\tilde{T}_\sigma^\alpha(z)$ is very small. Applying some elementary functional analysis to Corollary 1.1, one obtains the following.

**Corollary 1.2.** There exists $0 < c < 1$ and $q > 0$ such that if $\tilde{T}_\sigma^\alpha(z) \leq \|\sigma\|_{\infty}(1 - \gamma)$, then
\[
\|T_\sigma^\alpha f\| \leq \|\sigma\|_{\infty}(1 - (c\gamma)^q)\|f\|.
\]
1.2. Sufficiency and Lower-Dimensional Sets

Dominating sets are a special class of reverse Carleson measures, which are measures $\mu$ such that for all $f \in A^p_\alpha(\Omega)$,

$$
\|f\|_{L^p(\Omega)} \leq C \mu \|f\|_{L^p(\Omega,\mu)}, \quad \|f\|_{L^p(\Omega,\mu)} = \left( \int_{\Omega} |f(z)|^p \rho(z)^\alpha d\mu(z) \right)^{1/p}.
$$

Even when $\Omega = \mathbb{D}$, there is not a complete characterization of such measures. Sufficient density conditions have been given by Luecking [23] and were recently extended by Calzi and Peloso [5] to the quite general case when $\Omega$ is a homogeneous type II Siegel domain. A characterization of when the norms above are equivalent on $A^p_\alpha(\Omega)$ can be given in terms of the automorphisms of uniqueness sets of functions in $A^p_\alpha(\Omega)$, yet such sets do not have a measure-theoretic characterization—see the discussion below.

Our main result above characterizes the reverse Carleson measures of the form $d\mu = 1_E dA$. The methods also apply to

$$
d\mu = 1_E d\mathcal{H}^{2n-2+\nu}, \quad \nu > 0
$$

where $\mathcal{H}^s$ is the $s$-dimensional Hausdorff measure.

**Theorem 2.** Let $\Omega$ be a smoothly bounded strongly pseudoconvex domain. Suppose $E \subset \Omega$ satisfies, for some $r, \gamma > 0, \nu \in (0, 2)$

$$
\frac{|Y(w,r)|^{\frac{n-1}{n(n+1)}} \mathcal{H}^{2n-2+\nu}(E \cap Y(w,r))}{|Y(w,r)|^{(2n-2+\nu)/2n}} \geq \gamma \quad (1.3)
$$

for all $w \in \Omega$. Then,

$$
\|f\|_{L^p(\Omega)} \leq C \max \{C, \gamma^{-q}\} \|f\|_{L^p(E,\mathcal{H}^{2n-2+\nu})}
$$

for all $f \in A^p_\alpha(\Omega)$.

It is important to point out that this result does not hold when $\nu = 0$. This is because the zero sets of holomorphic functions of $n$ variables are $(2n-2)$-dimensional. So in this case, the only hope of a measure-theoretic condition is that the density $(1.3)$ be large enough, which can be derived from our methods, see Corollary 4.3 below. In this regard, when the domain $\Omega$ is the disk $\mathbb{D}$, the *sampling sequences*, collections of of points $\Lambda \subset \mathbb{D}$ for which

$$
\|f\|_{L^p(\mathbb{D})} \sim \left( \sum_{\lambda \in \Lambda} |f(\lambda)|^p \right)^{1/p} = \|f\|_{L^p(\Lambda,\mathcal{H}^\nu)}, \quad f \in A^p_0(\mathbb{D})
$$

were characterized by Seip [27] in terms of a suitable density on $\Lambda$ being large enough.

Since the condition $(1.3)$ may not be necessary, one may prefer to test over geometrically simpler sets than the Kobayashi balls, for example Euclidean balls or cubes. This is indeed possible.
Theorem 3. Let \( \Omega \subset \mathbb{C}^n \) be open. Suppose \( E \subset \Omega \) satisfies, for some \( r, \gamma > 0, \nu \in (0, 2] \),
\[
\frac{H^{2n-2+\nu}(E \cap Q)}{\ell(Q)^{2n-2+\nu}} \geq \gamma
\]
for all cubes \( Q \subset \Omega \) of side length \( r \) \( \text{dist}(Q, \Omega^c) \). Then, for any \( 1 \leq p \leq \infty, \alpha > -1 \), there exists \( C, q > 0 \) such that
\[
\|f\|_{L^p_\alpha(\Omega)} \leq C \max\{C, \gamma^{-q}\} \|f\|_{L^p_\alpha(E, H^{2n-2+\nu})}
\]
for all \( f \in A^p_\alpha(\Omega) \).

1.3. Orientation

The strategy we employ first shows that one can get a sufficient condition by completing ignoring the complex geometry of the domain, treating the analytic function as a solution to the \( \overline{\partial} \) equation in \( \Omega \subset \mathbb{R}^{2n} \). First, we use a Carleman estimate to prove a local Remez-type inequality uniform over many sets with a certain boundary separation. This is Section 2.

In Section 3, this is applied by decomposing the domain into Kobayashi balls. Section 3.1 proves (ii) implies (i) in Theorem 1. The other piece of Theorem 1, the connection between relative density and the Berezin transform, is established in Section 3.2. It relies on further understanding the geometry of Kobayashi balls in order to obtain a vanishing Rudin-Forelli estimate, which is the content of Section 3.3. Lastly, we extend to lower-dimensional sets in Section 4 modeled after the work of Logunov and Malinnikova in harmonic functions [20].

2. Local Estimate for Holomorphic functions of several variables

In this section, we will establish a three sphere-type inequality of the form
\[
\sup_Y |f| \leq (\sup_E |f|)^{\theta} (\sup_X |f|)^{1-\theta}, \quad f \text{ holomorphic on } X
\]
where \( X \) is a suitable “double” of \( Y \) and \( E \subset Y \) of positive measure. Past results of this type rely on any number of features; see [4, 24, 20, 15, 18] for five different perspectives. Despite the different approaches, each result is proved when \( X \) and \( Y \) have special geometry—usually both are Euclidean balls. The result which appears to be most readily extended to other geometries is the result of Lebeau and Moyano [18] which uses Carleman estimates.

This technique, which in recent history has dominated the field of unique continuation for PDEs, has strong historical connections to complex analysis and specifically pseudoconvex domains. In this regard, we mention the pioneering work of T. Carleman [6] on elliptic PDE and the remarkable development of his ideas by Hörmander [12, 13] in both real and complex analysis.

Our method for establishing (2.1) is a refinement of Section 3 in [18]. The first main difference is we would like to obtain the result in arbitrary dimensions. This requires us to consider each component of the \( \overline{\partial} \) operator. Second, if one only needed the result for two sets \( X \) and \( Y \) with regular boundary, the result from [18] applies. However, we will need the result to hold uniformly over many sets with varying geometry.
Examining their proof, it turns out that the constants one obtains depend only on the estimates for the Green functions associated to the larger set \( X \), specifically, that
\[
\sup_{y \in Y} G(x, y) \to 0 \text{ as } x \to \partial \Omega, \quad \text{and} \quad \inf_{x, y \in Y} G(x, y) > 0.
\]
To those well-versed in elliptic PDEs, it may be obvious that the convergence rate and lower bounds depend only on the regularity of the boundary \( X \) and the separation between \( \partial X \) and \( Y \). This principle is well-known, but in some sense has remained unexamined until very recently [8].

The modification we propose dispenses with the explicit regularity of \( \partial X \) and instead relies on the regularity of an intermediate domain \( Z \) which we will construct. Some definitions are now in order. For any \( s > 0 \) and \( Z \subset \mathbb{C}^n \), let us introduce the notation
\[
Z_s = \{ x \in Z : \text{dist}(x, \partial Z) \leq s \}, \quad Z'_s = Z \setminus Z_s.
\]

**Definition 2.1.** Let \( Z \) be a collection of bounded, open sets in \( \mathbb{R}^n \). We say \( Z \) is a regular boundary family if for each \( Z \in Z \) and \( p \in \partial Z \), there exists a barrier function \( \omega_p^Z \) satisfying the following:

(i) For each \( \eta > 0 \),
\[
\inf_{Z \in Z} \inf_{p \in \partial Z} \inf_{y \in Z'_\eta} \omega_p^Z(y) > 0. \tag{2.3}
\]

(ii) For each \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that for any \( Z \in Z \),
\[
\omega_p^Z(y) \leq \varepsilon \quad \text{whenever } |y - p| < \delta. \tag{2.4}
\]

A barrier function at \( p \in \partial Z \) is a nonnegative function on \( \partial Z \) which vanishes only at \( p \) and is superharmonic in \( Z \).

It will be important for us that the following class of domains forms a regular boundary family.

**Definition 2.2.** For \( d > 0 \), a domain \( Z \) satisfies the \( d \)-uniform exterior sphere condition if at each point \( p \in \partial Z \), there exists an open ball \( B \) of radius \( d \) such that
\[
\bar{B} \cap \bar{\Omega} = \{ p \}.
\]

For each \( d > 0 \), the collection of all domains satisfying the \( d \)-uniform exterior sphere condition forms a regular boundary family. In fact, one can explicitly construct the barrier functions in this case, see [10, p. 27].

**Definition 2.3.** Let \( \Gamma \) be the fundamental solution to the Poisson equation in \( \mathbb{R}^{2n} \) and \( Z \subset \mathbb{R}^{2n} \). We say \( G_Z(x, y) \) is the Green function for \( Z \) if
\[
G_Z(x, y) = \Gamma(x - y) - H_Z(x, y)
\]
where $H_Z(x, y)$ is the harmonic corrector satisfying, for each $x \in Z$,

\[
\begin{aligned}
    \Delta_y H_Z(x, y) &= 0 & y \in Z, \\
    H_Z(x, y) &= \Gamma(x - y) & y \in \partial Z
\end{aligned}
\]

**Proposition 2.4.** Let $Z$ be a regular boundary family such that $\text{diam } Z \leq \frac{1}{2}$ for each $Z \in Z$. Let $G_Z$ be the Green function for each $Z \in Z$. Then, for each $\eta > 0$,

\[
\inf_{Z \in Z} \inf_{x, y \in Z', x \neq y} G_Z(x, y) > 0,
\]

and for each $\varepsilon > 0$, there exists $\delta > 0$ such that for any $Z \in Z$,

\[
\sup_{y \in Z'} G_Z(x, y) \leq \varepsilon \text{ whenever } x \in Z_\delta.
\]

We will give an elementary proof of Proposition 2.4 at the end of this section. However, if one is content to accept this, we can obtain the following proposition extending the result of Lebeau and Moyano in [18].

**Proposition 2.5.** Let $d, \ell > 0$. There exists $C > 0$ such that if $Y \subset X \subset \mathbb{C}^n$ satisfy, for some affine map $D$,

(i) $\text{diam}(D(Y)) = 1/4$,

(ii) $|D(Y)| \geq \ell$,

(iii) $\text{dist}(\partial D(X), \partial D(Y)) \geq d$,

then

\[
\langle f \rangle_{2,Y} \leq Ce^{(N+C)S^*} \langle f \rangle_{2,E}
\]

(2.5)

for all $f \in A^2(X)$, where

\[
\langle f \rangle_{p,F} = \frac{\|f\|_{L^p(F)}}{|F|^{1/p}}, \quad N = \log \frac{\|f\|_{L^2(X)}}{\|f\|_{L^2(Y)}}, \quad S^* = \left\{ \begin{array}{ll} 1 + \log \frac{1}{\langle E \rangle_Y} & n = 1; \\
1 + \langle E \rangle_Y^{\frac{1}{n-1}} & n \geq 2. \end{array} \right.
\]

Let us also clarify that by affine, we mean some combination of translation, dilation, and rotation of the $n$ complex variables $(z_1, z_2, \ldots, z_n)$. By the invariance of the conclusion under such affine changes of variables, we can assume $X$ and $Y$ themselves satisfy (i)–(iii). As long as $d < 1/4$, we can also assume that $\text{diam } X \leq \frac{1}{2}$ by replacing $X$ with $X$ intersected with a ball of radius $\frac{1}{2}$. If $d > \frac{1}{4}$ then a much simpler proof can be given which uses explicit estimates on the fundamental solution $\Gamma$ instead of the Green functions. Let us give the proof of Proposition 2.5 assuming Proposition 2.4 for the time being.

**2.1. Carleman Estimate**

Recall that a holomorphic function $f : \mathbb{C}^n \to \mathbb{C}$ is holomorphic in each complex variable and therefore it satisfies the $\bar{\partial}$ equation in each variable. Denote elements in $\mathbb{C}^n$ by $z =
\((z_1, \ldots, z_n) = (x_1, x_2, \ldots, x_{2n}) \in \mathbb{R}^{2n}\) and by \(\overline{\partial}_k\) the \(k\)-th component of the \(\partial\) operator,\

\[
\overline{\partial}_k = \frac{1}{2} \left( \frac{\partial}{\partial x_{2k-1}} + i \frac{\partial}{\partial x_{2k}} \right).
\]

We have that \(\overline{\partial}_k f = 0\) for each \(k\). We will first prove a Carleman estimate for each \(\overline{\partial}_k\).

Let \(Z \subset \mathbb{C}^n\) and \(\phi\) real-valued. Set \(P_h = e^{\phi/h} \frac{\overline{\partial}_k e^{-\phi/h}}{i}\). Then, we can compute

\[
P_h = (-\overline{\partial}_k x_{2k} + h\overline{\partial}_k x_{2k}) - i(-\overline{\partial}_k x_{2k-1} + h\overline{\partial}_k x_{2k-1})
\]

\[
= (\frac{h}{i} \overline{\partial}_k x_{2k-1} - \phi x_{2k}) + i(\frac{h}{i} \overline{\partial}_k x_{2k} + \phi x_{2k-1})
\]

\[
=: A + iB.
\]

If \(f \in C_0^\infty(Z)\), integration by parts yields

\[
\|P_h f\|^2 = \|A f\|^2 + \|B f\|^2 + i \langle [A, B] f, f \rangle.
\]

It is simple to compute \([A, B] = -ih(\partial^2_{x_{2k-1}} \phi + \partial^2_{x_{2k}} \phi)\). Taking \(f = e^{\phi/h} g\) for some \(g \in C_0^\infty\), we obtain

\[
4h^2 \int_Z e^{2\phi/h} |\partial_k g|^2 \geq h \int_Z e^{2\phi/h} |g|^2 (\partial^2_{x_{2k-1}} \phi + \partial^2_{x_{2k}} \phi).
\]

Summing over all \(k\) and picking \(g = \psi f\) where \(f\) is holomorphic in \(Z\) and \(\psi \in C_0^\infty(Z)\) with \(\psi = 1\) on \(\bar{Y} \subset Z\), we obtain, with \(M = \sum_{k=1}^n \|\partial_k \psi\|_\infty^2\),

\[
4Mh^2 \int_{Z \setminus \{\psi = 1\}} e^{2\phi/h} |f|^2 \geq h \int_Y e^{2\phi/h} |f|^2 \Delta \phi.
\]

We used the fact that \(\partial_k(\psi f) = (\partial_k \psi) f\) since \(f\) is holomorphic.

### 2.2. Choice of \(Z\) and \(\phi\)

Cover \(\partial X\) with a collection \(B\) of open balls centered on \(\partial X\) with radius \(d/2\). Set

\[
Z = X \setminus \bigcup_{B \in B} B.
\]

\(Z\) belongs to the regular boundary family

\[
Z_{d/4} := \{Z : Z\text{ satisfies the }d/4\text{-uniform exterior sphere condition}\}.
\]

Indeed, if \(q \in \partial Z\), then \(q \in \partial B_q\) for some \(B_q\). However, we can fit a ball \(B_q^*\) of radius \(d/4\) inside \(B_q\) such that \(B_q^* \cap B_q^c = \{q\}\). Therefore,

\[
\{q\} \subset \bar{B}_q^* \cap Z = \bar{B}_q^* \cap X \cap_{B \in B} B^c \subset \bar{B}_q^* \cap B_q^c = \{q\}.
\]
We are ready to construct $\phi$. Set $\phi = \phi_1 - \rho \phi_2$ where for $j = 1, 2,$

$$
\left\{ \begin{array}{ll}
-\Delta \phi_j &= \tilde{\chi}_j \quad \text{in } Z; \\
\phi_j &= 0 \quad \text{on } \partial Z; \\
\tilde{\chi}_1 &= \frac{\chi_E}{\langle E \rangle_Y}, \\
\tilde{\chi}_2 &= \chi_Y.
\end{array} \right.
$$

In order to utilize the exponential weights in the Carleman estimate, we want $\phi$ to be smaller on $Z\{\psi = 1\}$ than on $Y$.

First, since $\phi_j(x) = \int_Y G_Z(x,y) \tilde{\chi}_j(y) \, dy$, by Proposition 2.4 and assumption (ii), there exists $c_1$ depending only on $d$ such that

$$
\inf_Y \phi_1 > 0.
$$

Furthermore, since $Z \subset X \subset B(0,1/2)$, the fundamental solution, $\Gamma$, is positive on the boundary, so by the maximum principle $\phi_j \leq \Gamma \ast \tilde{\chi}_j$. This upper bound is maximized when $E$ and $Y$ are balls in which case the integral can be estimated above by

$$
\sup_Y \phi_1 \leq C \begin{cases} 
1 + \log \frac{\langle E \rangle_Y}{\langle E \rangle_{Y}} & n = 1 \\
\frac{1}{\rho} & n \geq 2
\end{cases}, \\
\sup_Y \phi_2 \leq C
$$

for some $C$ depending on $n$. Therefore, picking $\rho = c_1/2C$, $\inf_Y \phi \geq c_1/2$. Using the second property of the Green function in Proposition 2.4, there exists $s$ (depending only on $d$ and $c_1$) such that $\phi(x) \leq c_1/4$ if $x \in Z_s$.

Pick the cutoff $\psi \in C_0^\infty(Z)$ from above to be equal to 1 on $Z'_s$. Therefore we obtain, for $S = \sup_Y \phi$ and $\delta = c_1/2$,

$$
Che^{\delta/h} \int_X |f|^2 + \langle E \rangle_y^{-1} e^{2S/h} \int_E |f|^2 \geq \rho e^{2\delta/h} \int_Y |f|^2.
$$

This can be turned into the desired product form using a now standard trick of optimizing in $h$. For ease of notation, set

$$
\nu = 2(S - \delta), \quad \theta = \frac{\delta}{\nu + \delta}, \\
A = \int_X |f|^2, \quad B = \langle E \rangle_y^{-1} \int_E |f|^2.
$$

$\nu$ is positive which can be seen from the definitions of $S$ and $\delta$. (2.7) reads

$$
Che^{-\delta/h} A + e^{\nu/h} B \geq \rho \int_Y |f|^2.
$$

Set $G(h) = (Ch)^{-1} \exp((\nu + \delta)/h)$. $G$ is decreasing and takes all values in $(0, \infty)$. Assume $B \neq 0$ and pick $h_0$ such that $G(h_0) = \frac{A}{2}$. If $h_0 \geq 1$, then

$$
\int_Y |f|^2 \leq A = G(h_0)^\theta B^\theta A^{1-\theta} \leq G(1)^\theta B^\theta A^{1-\theta} = C^{-\theta} e^\delta B^\theta A^{1-\theta}.
$$
On the other hand, if \( h_0 < 1 \), then we have

\[
B \exp\left(\frac{\nu}{h_0}\right) = \exp\left(-\frac{\delta}{h_0}\right)Ch_0A \leq \exp\left(-\frac{\delta}{h_0}\right)CA.
\]

Therefore,

\[
\rho \int_Y |f|^2 \leq \exp\left(\frac{\nu}{h_0}\right)B + Ch_0e^{-\frac{\delta}{h_0}}A
\]

\[
= 2 \exp\left(\frac{\nu}{h_0}\right)B
\]

\[
\leq 2 \exp\left(\frac{\nu}{h_0}\right)\theta \exp\left(-\frac{\delta}{h_0}\right)CA^{1-\theta}
\]

\[
= 2C^{-1-\theta}B^\theta A^{1-\theta}
\]

verifying in the last line that \( \nu \theta - \delta + \delta \theta = 0 \). Elementary manipulations yield the final form of the inequality (2.5).

### 2.3. Green function estimates

Let us now prove Proposition 2.4 on the convergence and quantitative positivity of the Green functions. We follow the classical textbook of Gilbarg and Trudinger [10, pp. 25-27].

We begin by proving the convergence to zero. Fix \( \eta, \varepsilon > 0 \). \( \Gamma \) is uniformly continuous away from zero. Therefore, there exists \( 0 < \delta < \eta \) such that

\[
|\Gamma(x - y) - \Gamma(x - y')| \leq \varepsilon/3
\]

for all \( x \in Z_\eta' \) and \( y, y' \in Z_{\eta/2} \) with \( |y - y'| \leq \delta \). By (2.3) pick \( M \) (depending on \( \eta, \delta \), and \( \mathcal{Z} \)) large enough that for all \( p \in \partial B \),

\[
M \inf_{|y-p|>\delta} \omega_p(y) \geq 2 \sup_{x \in Z_\eta} \sup_{y \in Z_{\eta/2}} |\Gamma(x - y')|
\]

For each \( x \in Z_\eta' \), consider the two functions \( h_1(y) = \Gamma(x - p) - \varepsilon/3 - M\omega_p(y) \) and \( h_2(y) = \Gamma(x - p) + \varepsilon/3 + M\omega_p(y) \). On the boundary \( h_1 \leq H_Z(x, \cdot) \leq h_2 \). Indeed, if \( |p - q| \leq \delta \) then

\[
|H_Z(x, q) - \Gamma(x - p)| = |\Gamma(x - q) - \Gamma(x - p)| \leq \varepsilon/3,
\]

and if \( |p - q| > \delta \), then by our choice of \( M \), \( |H_Z(x, q) - \Gamma(x - p)| \leq M\omega_p(q) \). Furthermore, \( h_1 \) is subharmonic and \( h_2 \) is superharmonic so by the maximum/minimum principles, \( h_1 \leq H_Z(x, \cdot) \leq h_2 \) on all of \( Z \). Finally, by property (2.4) of the regular boundary family, there exists \( \delta' > 0 \) such that \( \omega_p(y) \leq \varepsilon/(3M) \) if \( |y - p| \leq \delta' \). Therefore, if \( y \in Z_{\min\{\delta, \delta'\}} \),

\[
|H_Z(x, y) - \Gamma(x - y)| \leq |H_Z(x, y) - \Gamma(x - \pi(y))|
\]

\[
+ |\Gamma(x - \pi(y)) - \Gamma(x - y)|
\]

\[
\leq \varepsilon/3 + M\omega_{\pi(y)}(y) + \varepsilon/3
\]

\[
\leq \varepsilon.
\]

On the other hand, the positivity of \( G_Z \) is controlled by the distance between \( H_Z \) and \( \Gamma \) near the boundary. Fixing \( x \in Z_\eta' \), let \( \pi(x) \) be a closest point to \( x \) in \( \partial Z \). This guarantees
\[ \Gamma(x - \pi(x)) \geq \Gamma(x - p) \] for all \( p \in \partial Z \). The line segment \((1 - t)x + t\pi(x), t \in (0, 1)\) is contained in \( Z \) (if it was not contained in \( Z \), then \( \pi(x) \) would not be the closest boundary point). Define \( y_0 = \frac{x + \pi(x)}{2} \) so that \( d(y_0, \partial Z) = \frac{1}{2}d(x, \partial Z) \). There exists \( \varepsilon_0 \in (0, 1) \) such that
\[ \Gamma(x - \pi(x)) \leq \varepsilon_0 \Gamma(x - y_0). \]

Set
\[ \theta = \frac{(1 - \varepsilon_0) \Gamma(x - y_0)}{2M}, \quad M = \sup_{y,p \in Z} \omega_p(y), \]
so that \( h_3(y) := \theta \omega_{\pi(x)}(y) + \Gamma(x - \pi(x)) \leq \frac{1 + \varepsilon_0}{2} \Gamma(x - y_0) \) for all \( y \in Z \). Comparing the boundary values, for any \( p \in \partial Z \),
\[ h_3(p) \geq \Gamma(x - \pi(x)) \geq \Gamma(x - p) = H_Z(x, p). \]

Applying the maximum principle again, this inequality extends to the interior and
\[ G_Z(x, y_0) = \Gamma(x - y_0) - H_Z(x, y_0) \geq \Gamma(x - y_0) - h_3(y_0) \geq \frac{1 - \varepsilon_0}{2} \Gamma(x - y_0). \]

Finally, by the minimum principle and Harnack’s inequality,
\[ \inf_{y \in Z_n^*} G_Z(x, y) \geq \inf_{d(y, \partial Z) = \eta/2} G_Z(x, y) \gtrsim G_Z(x, y_0) \gtrsim 1 \]
and the implicit constants only depend on \( \eta \) and \( M \). Most importantly, they are independent of \( x \) and \( Z \), which proves the proposition.

3. Application to Pseudoconvex Domains

On the face of it, one could actually decompose a domain \( \Omega \) in a variety of ways and apply the results of the previous sections (e.g. a Whitney decomposition yields Theorem 3—see Section 4). However, to obtain a characterization of the dominating sets on pseudoconvex domains, we decompose into Kobayashi balls due to their relationship to the Bergman kernel.

**Definition 3.1.** Let \( \Omega \subset \mathbb{C}^n \) be a domain with smooth defining function \( \rho \). That is, \( \Omega = \{ z : \rho(z) < 0 \} \) and \( \nabla \rho \neq 0 \) on \( \partial \Omega \). We say \( \Omega \) is (strongly) pseudoconvex if its defining function \( \rho \) is (strictly) plurisubharmonic.

For a pseudoconvex domain \( \Omega \), the *Kobayashi distance* can be defined by its infinitesimal Finsler metric [16],
\[ F_K(z, \xi) = \inf\{ \alpha > 0 : \phi \in \text{Hol}(D; \Omega), \phi(0) = z, \phi'(0) = \xi/\alpha \}, \quad (z, \xi) \in \Omega \times \mathbb{C}^n \]
\[ d_\Omega(z, w) = \inf\{ \int_0^1 F_K(\gamma(t), \gamma'(t)) dt : \gamma \in C^1([0, 1]; \Omega), \gamma(0) = z, \gamma(1) = w \} \quad z, w \in \Omega. \]
\[d_\Omega\] is also the smallest distance which is bounded below by the Lempert function,
\[
\inf\{d_D(\zeta, \omega), \quad \phi \in \text{Hol}(\Omega; \mathbb{D}) \}
\[
\phi(z) = \zeta, \quad \phi(w) = \omega\}
\]
\[z, w \in \Omega.\]

The Kobayashi distance on the disk, \(d_D\), coincides with the usual Poincaré distance. The property concerning the Lempert function actually gives an equivalent definition of \(d_\Omega\), see [11, 12]. Since \(\Omega\) is fixed throughout, we will just write \(d(z, w)\) for \(d_\Omega(z, w)\). We will denote Euclidean distance by \(| \cdot |\) and the Euclidean distance of the point \(z\) to \(\partial \Omega\) by \(\delta(z)\).

Denote by \(Y(w, r)\) the Kobayashi ball centered at \(w\) with radius \(\tanh^{-1} r\). The local results of Section 2 can be strengthened in the context of Kobayashi balls. We will show that for any \(R > r > 0\), one can take \(Y = Y(w, r)\) and \(X = Y(w, R)\) in Proposition 2.5.

To do so we will need some properties of the Kobayashi balls which we collect here. Denote by \(P(w, r_1, r_2)\) the polydisc
\[
P(w, r_1, r_2) := \{z \in \mathbb{C}^n : |z_1 - w_1| < r_1, |z_2 - w_2| < r_2, \ldots, |z_n - w_n| < r_2\}
\]

The first lemma concerns the geometric properties of Kobayashi balls, and will allow us to show that the geometric conditions (i)-(iii) from Proposition 2.5 are satisfied by \(Y = Y(w, r)\) and \(X = Y(w, R)\) for any \(R > r > 0\).

**Lemma 3.2.** Let \(\Omega\) be smoothly bounded strongly pseudoconvex domain. There exists functions \(a, b, A, B, C : (0, 1) \to (0, \infty)\) such that for all \(w \in \Omega\) and \(r > 0\),
\[
U(w)^{-1}P(w, a(r)\delta(w), b(r)\delta(w)^{1/2}) \subset Y(w, r) \subset U(w)^{-1}P(w, A(r)\delta(w), B(r)\delta(w)^{1/2})
\]
where \(U(w)\) is the rotation on \(n\) complex variables which rotates the complex normal vector at \(\pi(w)\) so it lies in the plane \(\mathbb{C} \times \{0\} \times \cdots \times \{0\}\). As a consequence,
\[
C(r)^{-1}\delta(w)^{n+1} \leq |Y(w, r)| \leq C(r)\delta(w)^{n+1}.
\]
Moreover, if \(d(z, w) \leq r\), then
\[
C(r)^{-1}\delta(w) \leq \delta(z) \leq C(r)\delta(w).
\]

**Proof.** For the first statement, we refer to [17, 19] and the second is proved in [2]. \(\square\)

The other ingredient will allow us to extend from \(p = 2\) to all values of \(1 \leq p \leq \infty\) and obtain the desired form of the constant, polynomial in \(\gamma^{-1}\) is all dimensions, not just \(n = 1\).

**Lemma 3.3.** Let \(\Omega\) be a strongly pseudoconvex domain and \(R > r > 0\). There exists \(C > 0\) such that for all \(1 \leq p, q \leq \infty\), \(z \in \Omega\), and \(f\) which are holomorphic on \(Y(z, R)\),
\[
\langle f \rangle_{p, Y(z, r)} \leq C \langle f \rangle_{q, Y(z, R)}.
\]

**Proof.** First we use the mean value property of the Kobayashi balls from [2, Cor. 1.7]: For each \(s > 0\), there exists \(C > 0\) such that
\[
|f(w)| \leq C \langle f \rangle_{1, Y(w, s)}
\]
for all \( w \in \Omega \). For \( R > r > 0 \), the triangle inequality shows that \( Y(w, R - r) \subset Y(z, R) \) for all \( w \in Y(z, r) \). Applying the mean value property with \( s = R - r \) and Hölder’s inequality,

\[
\langle f \rangle_{p,Y(z,r)} \leq C \sup_{w \in Y(z,r)} \langle f \rangle_{q,Y(w,R-r)} \leq \sup_{w \in Y(z,r)} \frac{C \|f\|_{L^p(Y,z,R)}}{|Y(w, R - r)|^{1/q}},
\]

However, \(|Y(w, R - r)|\) and \(|Y(z, R)|\) are only off by a constant depending on \( R \) and \( r \) by Lemma 3.2.

Now we are ready to prove our first local estimate for Kobayshi balls. The lower dimensional one will be proved later, in Section 4. We introduce the doubling index

\[
N_p(f, z, r, R) = \log \frac{\|f\|_{L^p(Y,z,R)}}{\|f\|_{L^p(Y,z,r)}},
\]

When any of the parameters \( p, f, z, r, R \) are apparent, we will drop them from the notation. Also recall the notation \( \Omega_\varepsilon = \{ z \in \Omega : \delta(z) \leq \varepsilon \} \) from (7.2).

**Lemma 3.4.** Let \( \Omega \subset \mathbb{C}^n \) be a smoothly bounded strongly pseudoconvex domain, \( R > r > 0 \), and \( 1 \leq p \leq \infty \). There exists \( C, \varepsilon > 0 \) such that for all \( z \in \Omega_\varepsilon \) and \( E \subset Y(z, r) \) satisfying \( \langle E \rangle_{Y(z,r)} \geq \gamma \),

\[
\|f\|_{L^p(Y(z,r))} \leq \left(\frac{C}{\gamma}\right)^{CN} \|f\|_{L^p(E)}, \quad N = N_p(f, z, r, R),
\]

for all \( f \in A^p(Y(z, R)) \).

**Proof.** The natural affine map to take is \( D = \Lambda_\delta(w) \circ U(w) \) where \( \Lambda_\delta(w) \) is defined by the scaling \((z_1, z_2, \ldots, z_n) \mapsto \lambda(z_1, \delta(w)^{1/2}z_2, \ldots, \delta(w)^{1/2}z_n)\). In this way, choosing \( \lambda \) so that \( \text{diam } D[Y(w, r)] = \frac{1}{2} \),

\[
4^{-2n} = \text{diam } D[Y(w, r)]^{2n} \leq |\lambda \delta(w)|^{2n}[n-1]B(r)^2 + A(r)^2]^{n},
\]

\[
|D[Y(w, r)]| \geq (\lambda \delta(w))^{2n}b(r)^{2n-2}a(r)^2.
\]

It remains to establish the boundary separation property. The triangle inequality shows that one can fit \( Y(v, (R - r)/2) \subset Y(w, r) \) as long as \( d(v, w) = (R + r)/2 \). Therefore, on applying \( D \),

\[
\text{dist}(\partial D(Y(w, R)), \partial D(Y(w, r))) \geq \inf_{d(v, w) = \frac{R+r}{2}} \inf \{|2|x - v| : x \in \partial D(Y(v, \frac{R-r}{2}))\} \]

\[
\geq \inf_{d(v, w) = \frac{R+r}{2}} \inf \{|2|\Lambda_\delta(w)U(w)U^{-1}x| : x \in \partial P(0, \delta(v)a(\frac{R-r}{2}), \delta(v)^{1/2}b(\frac{R-r}{2}))\}
\]

Since \( \Omega \) is smooth, for every \( \eta > 0 \), there exists \( \varepsilon > 0 \) such that if \( p, q \in \partial \Omega \) with \( |p - q| \leq \varepsilon \),
then

\[ |n(p) - n(q)| \leq \eta |p - q|. \]

\(n(p)\) is the outward normal vector at \(p \in \partial \Omega\). For \(w \in \Omega\), let \(n(w) = n(\pi(w))\). On the other hand, since \(U\) is unitary, for any \(x \in \mathbb{C}^n\),

\[ |U(w)U(v)^{-1}x - x| = |x||n(w) - n(v)|, \]

and if \(|\pi(w) - \pi(v)| \leq \varepsilon\), then

\[ |\Lambda_\delta U(w)U(v)^{-1}x - \Lambda_\delta x| \leq \eta \lambda |\pi(w) - \pi(v)| \cdot |x|. \]

So, if \(d(w, v) \leq R\), then \(|\pi(w) - \pi(v)| \leq (1 + C(R) + B(R))\delta(w)^{1/2}\). Therefore, restricting to \(\delta(w)^{1/2} \leq \varepsilon(1 + C(R) + B(R))^{-1}\), we obtain \(c > 0\) (depending only on \(R, r\)) such that \(c\) is bounded below by

\[(c - \eta)\lambda \delta(w).\]

But \(\eta\) can be made arbitrarily small by taking \(\delta(w)\) smaller than some threshold, let us call it \(\varepsilon\). Thus the boundary separation property follows from the normalizing choice of \(\lambda\) at the beginning.

Applying Proposition 2.5 to \(Y(w_k, s) \subset Y(w_k, S)\) for \(r < s < S < R\), we obtain

\[ \langle f \rangle_{p, Y(w, r)} \leq C \langle f \rangle_{2, Y(w, s)} \leq C e^{(N_2(s, S)+C)S^*} \langle f \rangle_{2, E}, \quad (3.4) \]

for any \(E \subset Y(w_k, r) \subset Y(w_k, s)\). However,

\[ \frac{N_2(s, S) = \log \frac{\|f\|_{L^2(Y(w_k, S))}}{\|f\|_{L^2(Y(w_k, s))}} \leq C + \log \frac{\|f\|_{L^\infty(Y(w_k, S))}}{\|f\|_{L^\infty(Y(w_k, r))}} = C + N_\infty(r, S). \]

Therefore,

\[ \sup_{Y(z, r)} |f| \leq C e^{(N_\infty(r, S)+C)S^*} \sup_E |f|. \]

We can now address the form of the constant in Lemma 3.4 for all \(n \geq 1\) using the following rotation argument which is common in results of this type [15, 18]. There exists \(z_0 \in Y(z, r)\) such that \(\sup_{Y(z, r)} |f| \leq 2|f(z_0)|\). There exists a dimensional constant \(c_\infty\) and a rotation of \(\mathbb{C}\), let us call it \(\theta \mathbb{C}\), containing \(z_0\) such that \(\mathcal{H}^2(\theta \mathbb{C} \cap E) \geq c_\infty \gamma \mathcal{H}^2(\theta \mathbb{C} \cap Y_r). \)

\(f|_{\theta \mathbb{C}}\) is still holomorphic, \(Y(z, r) \cap \theta \mathbb{C}\) still satisfies the above geometric properties, and the mean value property is immediate in the plane \(\theta \mathbb{C}\), so

\[ \sup_{Y(z, r)} |f| \leq 2|f(z_0)| \leq \left( \frac{C}{\gamma} \right)^{\frac{C \tilde{N}}{2}} \sup_E |f| \leq \left( \frac{C}{\gamma} \right)^{CN_\infty(r, S)} \sup_E |f|, \quad (3.5) \]
where
\[ \tilde{N} = \log \sup_{\theta \in \mathcal{Y}(z, S)} |f| \leq \log \sup_{\theta \in \mathcal{Y}(z, S)} |f| \leq \log 2 + N_{\infty}(r, S). \]

Finally, we extend (3.5) to all \( 1 \leq p < \infty \) which will conclude the proof. Define
\[ F = \{ z \in E : |f(z)| \leq 2^{1/p} \langle f, E \rangle \}. \]

Then, \( |E \setminus F| \leq |E|/2 \) so \( \langle F, Y(w, r) \rangle \geq \gamma/2 \). Therefore, applying (3.5) with \( F \) in place of \( E \), one obtains
\[ \langle f, Y(w, r) \rangle \leq \sup_{Y(w, r)} |f| \leq \left( \frac{2C}{\gamma} \right)^{CN_{\infty}(r, S)} \sup_{F} |f| \leq \left( \frac{C}{\gamma} \right)^{CN_{p}(r, R)} 2^{1/p} \langle f, p, E \rangle. \]

It will also be important later that Lemma 3.4 holds when \( Y(z, R) \) and \( Y(z, r) \) are replaced by any Euclidean balls \( B(z, R) \) and \( B(z, r) \) or Euclidean cubes \( Q(z, R) \) and \( Q(z, r) \) with a fixed ratio \( \frac{R}{r} = d \). This can be proved following the same path as above, yet with many simplifications since the precise geometry is known. For this reason, and because this result follows from a theorem of A. Brudnyi in [4], we omit the proof.

### 3.1. Sufficiency

We are now in the position to prove “(ii) implies (i)” in Theorem 1.

**Proposition 3.5.** Let \( \Omega \) be a smoothly bounded strongly pseudoconvex domain, \( 0 < r < 1 \), \( 1 \leq p \leq \infty \), \( \alpha > -1 \). There exists \( C, q > 0 \) such that for all \( 0 < \gamma < 1 \) and \( E \subset \Omega \) satisfying
\[ \frac{|E \cap Y(z, r)|}{|Y(z, r)|} \geq \gamma, \quad \forall z \in \Omega, \tag{3.6} \]
\[ \|f\|_{L^p_\alpha(\Omega)} \leq C\gamma^{-q}\|f\|_{L^p_\alpha(E)}, \quad \forall f \in A^p_\alpha(\Omega). \]

**Proof.** Fix \( R > r \), \( 1 \leq p \leq \infty \), and \( \varepsilon \) from Lemma 3.4. We first claim that \( \Omega_\varepsilon \) is a dominating set. If not, then we can find \( \{f_n\} \subset A^p_\alpha(\Omega) \), with \( \|f_n\|_{L^p_\alpha(\Omega)} = 1 \) and \( \|f_n\|_{L^p_\alpha(\Omega_\varepsilon)} \to 0 \). The second property implies the existence of subsequence \( \{f_{n_k}\} \) such that
\[ \lim_{k \to \infty} f_{n_k}(z) = 0, \quad z \in \Omega_\varepsilon \text{ a.e.} \tag{3.7} \]

On the other hand, since point evaluation is a bounded linear functional on \( L^p_\alpha(\Omega) \), \( \{f_{n_k}\} \) is a normal family. Consider the compact set \( K = \overline{\Omega \setminus \Omega_{3\varepsilon/2}} \). There exists a subsequence \( f_{m_k} \subset \{f_{n_k}\} \) and \( f_0 \in \text{Hol}(K) \) such that
\[ \lim_{k \to \infty} f_{m_k}(z) = f_0(z), \quad z \in K. \]
By (3.7), \( f_0(z) = 0 \) for \( z \in K \cap \Omega_\varepsilon \) which implies \( f_0(z) = 0 \) for all \( z \in K \). However, since \( K \cup \Omega_\varepsilon = \Omega \),

\[
0 = \|f_0\|_{L^p(K)} = \lim_{k \to \infty} \|f_{m_k}\|_{L^p(K)} \geq \lim_{k \to \infty} \|f_{m_k}\|_{L^p(\Omega)} - \|f_{m_k}\|_{L^p(\Omega_\varepsilon)} = 1
\]

which is a contradiction. Therefore, there exists \( C_\varepsilon > 0 \) such that

\[
\|f\|_{L^p(\Omega)} \leq C_\varepsilon \|f\|_{L^p(\Omega_\varepsilon)}.
\]

Now, \( \Omega \) can be covered with Kobayashi balls \( Y_k = Y(w_k, r) \) such that \( X_k = Y(w_k, R) \) have finite overlap of say \( M > 0 \), see [2] Lemma 1.5. For \( 1 \leq p < \infty \), call an index \( k \) good if

\[
(2C_\varepsilon M)^{1/p} \|f\|_{L^p(\Omega_k)} \geq \|f\|_{L^p(\Omega_k)}.
\]

Define

\[
\mathcal{G} = \{ k : k \text{ is good and } w_k \in \Omega_\varepsilon \}, \quad \mathcal{B} = \{ k : w_k \in \Omega_\varepsilon \} \setminus \mathcal{G}.
\]

In this way

\[
\sum_{k \in \mathcal{B}} \|f\|_{L^p(\Omega_k)}^p \leq \frac{1}{2C_\varepsilon M} \sum_{k \in \mathcal{B}} \|f\|_{L^p(\Omega_k)}^p \leq \frac{1}{2C_\varepsilon} \sum_{k \in \mathcal{B}} \|f\|_{L^p(\Omega_k)}^p \leq \frac{1}{2} \|f\|_{L^p(\Omega_\varepsilon)}.
\]

so \( \sum_{k \in \mathcal{G}} \|f\|_{L^p(\Omega_k)}^p \geq \frac{1}{2} \|f\|_{L^p(\Omega_\varepsilon)}^p \). Thus, for each good \( k \), we apply Lemma 3.4 and the last statement of Lemma 3.2 to obtain

\[
\|f\|_{L^p(\Omega_k)} \leq C(r) \rho(w_k)^\alpha \|f\|_{L^p(\Omega_k)} \leq C(r) \rho(w_k)^\alpha \left( \frac{C}{\gamma} \right)^{CN} \|f\|_{L^p(\Omega_k)} \leq C(r)^2 \left( \frac{C}{\gamma} \right)^{C'} \|f\|_{L^p(\Omega_k)}.
\]

We crucially used the fact that \( N_p(w_k, f, r, R) \) is bounded by some constant depending on \( C(r) \), \( M \) and \( C_\varepsilon \) when \( k \) is good. Therefore,

\[
\|f\|_{L^p(\Omega)}^p \leq 2C_\varepsilon^{2p} \sum_{k \in \mathcal{G}} \|f\|_{L^p(\Omega_k)}^p \leq C \gamma^{-C'} \|f\|_{L^p(\Omega)}^p.
\]

When \( p = \infty \), the proof is easier, noticing that there exists \( z_0 \in \Omega \) such that \( \|f\|_\infty \leq 2\|f(z_0)\| \). Then, \( \sup_{Y(z_0, R)} |f| \leq 2 \sup_{Y(z_0, r)} \) so \( N \leq \log 2 \) and Proposition 2.5 implies

\[
\|f\|_\infty \leq 2 \sup_{Y(z_0, r)} |f| \leq C \gamma^{-C'} \sup_E |f|.
\]

\[ \square \]
Remark 3.6. From the proof, it is clear that the only property of the weight $\rho^\alpha$ that we used was that it is approximately constant on each Kobayashi ball. So Proposition 3.5 holds for any $L^p_w$ space with a weight $w$ satisfying this assumption.

3.2. Necessity

Recall from the introduction (1.2) that $T_{p,\alpha}^E(z) = \|k_{p,\alpha}^z\|_{L^p(E)}$. An obvious necessary condition for $E$ to be a dominating set for $A^p_\alpha(\Omega)$ is that

$$\inf_{z \in \Omega} T_{p,\alpha}^E(z) > 0.$$ 

Recall also that $k_{p,\alpha}^z$ is the $L^p_\alpha$-normalized reproducing kernel for $A^2_\alpha(\Omega)$. If $\|k_{p,\alpha}^z\|_{L^p_\alpha(E)}$ can be connected to the density condition, then we can find dominating sets simply by testing on certain functions. The following two properties of the reproducing kernel facilitate this connection.

**Lemma 3.7.** Let $\Omega$ be a smoothly bounded strongly pseudoconvex domain. Let $1 < p < \infty$ and $\alpha > -1$. Then,

$$\lim_{r \to 1^-} \sup_{z \in \Omega} \|k_{p,\alpha}^z\|_{L^p_\alpha(\Omega \setminus Y(z,r))} = 0$$

(3.8)

and for each $r \in (0,1)$,

$$\sup_{w \in Y(z,r)} |Y(z,r)|^{1/p} \cdot |k_{p,\alpha}^z(w)|\rho(w)^{\alpha/p} < \infty.$$ 

(3.9)

We will prove this Lemma in Section 3.3. Assuming it for now, we can complete the proof of Theorem 1 characterizing the dominating sets for $A^p_\alpha(\Omega)$.

**Proof of Theorem 1.** Proposition 3.5 from the last section proves (ii) implies (i). (i) implies (iii) is obvious so it remains to prove (iii) implies (ii) using Lemma 3.7. Let $c = \inf_{z \in \Omega} \|k_{p,\alpha}^z\|_{L^p_\alpha(E)}$, and

$$C_r = \sup_{w \in Y(z,r)} |Y(z,r)|^{1/p} \cdot |k_{p,\alpha}^z(w)|\rho(w)^{\alpha/p}.$$ 

Pick $r$ such that

$$\sup_{z \in \Omega} \|k_{p,\alpha}^z(w)\|_{L^p_\alpha(\Omega \setminus Y(z,r))} < \frac{c}{2^{1/p}}$$

and then

$$c^p \leq \|k_{p,\alpha}^z\|_{L^p_\alpha(E \cap Y(z,r))}^p + \|k_{p,\alpha}^z\|_{L^p_\alpha(\Omega \setminus Y(z,r))}^p \leq C_r^p \frac{|E \cap Y(z,r)|}{|Y(z,r)|} + \frac{c^p}{2}$$

which shows that $E$ is relatively dense. □
3.3. Bergman kernel

In this section, we prove Lemma 3.7 establishing estimates (3.8) and (3.9) on the Bergman kernel. Concerning the $L^\infty$ estimate (3.9), we first establish it for $z$ away from the boundary. Consider the region

$$U_\delta = \{(z, w) \in \bar{\Omega} \times \bar{\Omega} : \rho(z) + \rho(w) + |z - w|^2 \leq \delta\}.$$ 

If $(z, w)$ are not in $U_\delta$, then the function $(z, w) \mapsto k_z(w)$ is $C^\infty$. Therefore it is bounded. Moreover, $|Y(z, r)| \sim r\delta(z)^{n+1}$ which shows for any $r, \delta > 0$ using the fact that $\alpha > -1$ and $|\rho(z)| \sim |\rho(w)|$ for $w \in Y(z, r)$,

$$\sup_{z, w \in (\Omega \times \Omega) \setminus U_\delta, w \in Y(z, r)} |Y(z, r)|^{1/p} |k_z^{p, \alpha}(w)||\rho(w)|^{\alpha/p} \leq C_{r, \delta}.$$

On the other hand, pick $\delta$ so small that we have the asymptotic expansion for $(z, w) \in U_\delta$ (see [24]):

$$K^\alpha(z, w) = a(w)\Psi(z, w)^{-n-1-\alpha} + E(z, w),$$

where $a$ is a non-vanishing smooth function, $\Psi(z, w)$ is a smooth function that is a perturbation of the Levi polynomial, and $E(z, w)$ satisfies $|E(z, w)| \lesssim |\Psi(z, w)|^{-n-1-\alpha+1/2}|\log |\Psi(z, w)||$. In particular, $\Psi$ satisfies

$$|\Psi(z, w)| \sim |\rho(z)| + |\rho(w)| + |z - w|^2 + |\text{Im}\Psi(z, w)|.$$

Then, note that for these $z, w$ there holds

$$|K^\alpha(z, w)| \sim |\Psi(z, w)|^{(-n-1-\alpha)} \lesssim \delta(z)^{-n-1-\alpha}.$$

Moreover, a computation using the Rudin-Forelli estimates given in [28] shows that

$$\|K^\alpha(z, \cdot)\|_{L^p_c(\Omega)} \sim \delta(z)^{-(n+1+\alpha)/p'}.$$

Finally, we estimate

$$\sup_{z, w \in U_\delta, w \in Y(z, r)} |Y(z, r)|^{1/p} |k_z^{p, \alpha}(w)||\rho(w)|^{\alpha/p} \leq C_{r, \delta} \delta(z)^{(n+1)/p'} \delta(z)^{n+1+\alpha}/p' \delta(z)^{-n-1-\alpha} \delta(z)^{\alpha/p} = C_{r, \delta},$$

which completes the proof of (3.9).

Next, we aim to show (3.8) holds. We need the following Lemma concerning the behavior of the Kobayashi metric. Let $z = (z_1, z')$ and $w = (w_1, w')$ be the splitting of $z$ and $w$ into the complex normal and tangential directions based at $\pi(z)$, where $\pi$ denotes the normal
Estimate [3, Prop. 3.1] which states that there exist \( C, \varepsilon \) such that for any \( N \in \mathbb{N} \), there exists a radius \( R_N \in (0, 1) \) such that if \( \delta(z) \leq \varepsilon_0 \) and \( d(z,w) \geq \tanh^{-1} R_N \), then

\[
|z' - w'|^2 + |z_1 - w_1| \geq N \delta(z) \text{ or } \delta(w) < \frac{1}{N} \delta(z).
\]

To prove this, we will use the following bounds derived by Balogh and Bonk for the Kobayashi metric [3 Cor. 1.3]. There exists \( C > 0 \) such that

\[
g(z, w) - C \leq d(z, w) \leq g(z, w) + C
\]

where

\[
g(z, w) := 2 \log \left[ \frac{d_H(\pi(z), \pi(w)) + h(z) \vee h(w)}{\sqrt{h(z)h(w)}} \right].
\]

Here \( \pi(z) \) denotes the normal projection of \( z \) to the boundary, \( d_H \) denotes the Carnot-Carathéodory metric on \( \partial \Omega \) and \( h(z) \vee h(w) = \max \{h(z), h(w)\} \), where \( h(z) = (\delta(z))^{1/2} \). The Carnot-Carathéodory metric \( d_H \), also called the horizontal metric, is defined by

\[
d_H(p, q) = \inf \{ \int_0^1 L_\rho(\gamma(t), \gamma'(t)) \ dt : \gamma \in C^1([0, 1]; \partial \Omega), \gamma'(t) \in H_{\gamma(t)} \partial \Omega, \gamma(0) = p, \gamma(1) = q \} \quad p, q \in \partial \Omega.
\]

Here \( L_\rho \) denotes the Levi form, and \( H_{\gamma(t)} \) the “horizontal” or complex tangential subspace at the boundary point \( \gamma(t) \). The important estimate for us concerning \( d_H \) is the Box-Ball Estimate [3 Prop. 3.1] which states that there exist \( C, \varepsilon_0 > 0 \) such that

\[
\text{Box}(p, \varepsilon/C) \subset B_H(p, \varepsilon) \subset \text{Box}(p, C\varepsilon) \tag{3.10}
\]

where \( B_H(p, \varepsilon) = \{ q \in \partial \Omega : d_H(p, q) \leq \varepsilon \} \) and \( \text{Box}(p, \varepsilon) = \{ q \in \partial \Omega : |(p-q)_1| \leq \varepsilon, |(p-q)'| \leq \varepsilon^2 \} \) where the splitting \( z = (z_1, z') \) into complex radial and tangential directions is done at \( p \).

We remark that if \( w \) is far from the boundary, the projection \( \pi \) may not be uniquely defined, but this does not cause problems. In this case, we simply choose \( \pi(w) \) to be a point on the boundary satisfying \( |\pi(w) - w| = \delta(w) \). In this way, we can extend \( \pi \) to a (non-unique) map \( \Omega \to \partial \Omega \) that will satisfy the above estimate.

**Proof of Lemma 3.8.** Suppose \( d(z, w) \geq R \). Then \( g(z, w) \geq R' \), where \( R' = R - C \). Equivalently,

\[
\left[ \frac{d_H(\pi(z), \pi(w)) + h(z) \vee h(w)}{\sqrt{h(z)h(w)}} \right] \geq R',
\]
where $R'' = \exp(R'/2)$. This implies either $\frac{d_H(\pi(z), \pi(w))}{\sqrt{h(z)h(w)}} \geq \frac{R''}{2}$ (Case 1) or $\frac{h(z)w(h(w))}{\sqrt{h(z)h(w)}} \geq \frac{R''}{2}$ (Case 2).

**Case 1:**

In Case 1, we first consider the further subcase where $\delta(w) > \frac{1}{R''}\delta(z)$. Note that the condition for Case 1 implies

$$d_H(\pi(z), \pi(w)) \geq \frac{R''}{2}\delta(z)^{1/4}\delta(w)^{1/4}$$

and the sub-condition further implies

$$d_H(\pi(z), \pi(w)) \geq \frac{(R'')^{3/4}}{2}\delta(z)^{1/2}.$$

This is a good bound. We may assume without loss of generality that $\frac{(R'')^{3/4}}{2}\delta(z)^{1/2} \leq \varepsilon_0$, where $\varepsilon_0$ is chosen so that (3.10) holds. If not, we may replace $R$ with a sufficiently large value to force one of the other cases (note that the horizontal metric $d_H$ is a bounded function).

Assuming the reduction, write $\pi(z) = (\pi(z)_1, \pi(z)'')$ and $\pi(w) = (\pi(w)_1, \pi(w)')$, where the decomposition of a point $p \in \partial\Omega$ by $p = (p_1, p')$ is given by splitting into the complex normal and tangential directions at $\pi(z)$. Similarly, write $z = (z_1, z'')$ and $w = (w_1, w')$ with the splitting based at $\pi(z)$. Then we have, using (3.10):

$$|\pi(z)_1 - \pi(w)_1| \geq C(R'')^{3/2}\delta(z), \text{ or } |\pi(z)' - \pi(w)'| \geq C(R'')^{3/4}\delta(z)^{1/2},$$

where $C$ is an independent constant. In the first case, we obtain, using the triangle inequality:

$$|z_1 - w_1| \geq |\pi(z)_1 - \pi(w)_1| - |\pi(z)_1 - z_1| - |\pi(w)_1 - w_1|$$

$$\geq C(R'')^{3/2}\delta(z) - \delta(z) - \delta(w)$$

$$= (C(R'')^{3/2} - 1)\delta(z) - \delta(w).$$

Now, if $\delta(w) > \frac{(C(R'')^{3/2} - 1)}{2}\delta(z)$, then we can proceed as in Case 2a (see below). Otherwise, we have

$$|z_1 - w_1| \geq \frac{(C(R'')^{3/2} - 1)}{2}\delta(z),$$

and we are done in this case.

In the second case, we obtain

$$|z' - w'| \geq |\pi(z)' - \pi(w)'| - |\pi(z)' - z'| - |\pi(w)' - w'|$$

$$\geq C(R'')^{3/4}\delta(z)^{1/2} - \delta(z) - \delta(w)$$

$$\geq (C(R'')^{3/4} - c)\delta(z)^{1/2} - \delta(w).$$
where \( c \) is some constant that only depends on the domain \( \Omega \). We can split into further subcases as before depending on the size of \( \delta(w) \) to obtain the desired result.

**Case 1b:**
The second sub-case of Case 1 implies
\[
\delta(w) \leq \frac{1}{R''} \delta(z),
\]
so we are done in that case.

Now we turn to Case 2.

**Case 2a:**
First suppose that \( h(z) \leq h(w) \). Then the condition reads
\[
\sqrt{h(w)} \geq \frac{R''}{2} \sqrt{h(z)}
\]
or equivalently
\[
\delta(w) \geq \frac{(R'')^4}{16} \delta(z).
\]
This is the bound we want. Indeed, Taylor expansion of \( \rho \) shows that if \( |z - w|^2 + |\langle z - w, \bar{\partial}\rho(z) \rangle| < R\delta(z) \), then we have
\[
\delta(w) \lesssim \rho(w) \leq |\rho(z)| + |\rho(z) - \rho(w)| \leq c(1 + R)\delta(z),
\]
where \( c \) is a constant that depends on the domain \( \Omega \). The contrapositive of this argument then shows that the bound we obtained provides a desired lower bound on \( |z - w|^2 + |\langle z - w, \bar{\partial}\rho(z) \rangle| \).

**Case 2b:**
The final sub-case to consider is when \( h(z) \geq h(w) \). In this case, we can directly verify that
\[
\delta(w) \leq \frac{16}{(R'')^4} \delta(z).
\]

\( \square \)

Now we are ready to prove (3.8) in Lemma 3.7. Let \( \delta_0 = \delta(z_0) \). We now apply Lemma 3.8. We assume \( n, p > 1 \) (for the case \( n = 1 \), make the obvious modifications to the proof). By compactness,
\[
\lim_{r \to 1^-} \sup_{\delta(z) \geq \varepsilon_0} \|k_{z}^{p,\alpha}\|_{\Omega \setminus Y(z, r)} = 0
\]
so we can also assume that \( \delta_0 < \varepsilon_0 \). By a unitary rotation and translation, we can assume that the coordinates \( w = (w_1, w') \) are centered at \( z_0 \) and split into the complex normal
and tangential directions at $\pi(z_0)$. Moreover, we note that well-known asymptotics for the Bergman kernel in the strongly pseudoconvex case together with the Rudin-Forelli estimates (see [25, 28]) give the estimate in these coordinates, for any $w \in \Omega$:

$$|k_{z_0}^{p,\alpha}(w)| \lesssim \frac{\delta_0^{(n+1+\alpha)/p'}}{(\delta_0 + |\rho(w)| + |\overline{z_0 - w}, \partial \rho(z_0)| + |z_0 - w|^2)^{(n+1+\alpha)}}$$

We additionally have

$$|k_{z_0}^{p,\alpha}(w)| \lesssim \frac{\delta_0^{(n+1+\alpha)/p'}}{(\delta_0 + |\rho(w)| + |\Im \Psi(z_0, w)| + |z_0 - w|^2)^{(n+1+\alpha)}}$$

Choose $R_N \in (0, 1)$ as in Lemma 3.8. These facts together give that, for any $z_0 \in \Omega$ and $N \in \mathbb{N}$:

$$\int_{\Omega \setminus Y(z_0, R_N)} |k_{z_0}^{p,\alpha}(w)|^p |\rho(w)|^\alpha \, dA(w) \lesssim \int_{\sqrt{N\delta_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w_1| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{(\delta_0 + |\rho(w)| + |w_1| + |w'|^2)^{p(n+1)+(p-1)\alpha}} \, dw_1 \, dA(w')$$

$$+ \int_{|w'| \leq \sqrt{M}} \int_{N\delta_0/2 < |w_1| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{(\delta_0 + |w_1| + |w'|^2)^{p(n+1)+(p-1)\alpha}} \, dw_1 \, dA(w')$$

$$+ \int_{\{w : \delta(w) < \frac{4\delta_0}{2} \}} \delta_0^{(n+1+\alpha)(p-1)} |\rho(w)|^\alpha |K_\alpha(z_0, w)|^p \, dA(w)$$

where $M$ is some bounded constant that only depends on the underlying domain $\Omega$. The first and second terms can be estimated in somewhat similar ways, while the third term requires a slightly more delicate analysis and a new coordinate system. We have, using polar coordinates in $\mathbb{C}^{n-1} = \mathbb{R}^{2n-2}$:
\[
\int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + |w_1| + |w'|^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
\leq C_{n,p,\alpha} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + |w_1| + |w'|^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
= C'_{n,p,\alpha} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
= C''_{n,p,\alpha} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
\leq C''_{n,p,\alpha} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \int_{0 < |w| < M} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]

and this last integral clearly goes to 0 as \( N \to \infty \). Notice the final bound is completely independent of \( z_0 \).

On the other hand, for the second term we have

\[
\int_{|w'| \leq \sqrt{M}} \int_{N_0^{\delta_0/2}} M \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + |w_1| + |w'|^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
\leq C_{n,p,\alpha} \int_{|w'| \leq \sqrt{M}} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + |w_1| + |w'|^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
= C'_{n,p,\alpha} \int_{|w'| \leq \sqrt{M}} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
= C''_{n,p,\alpha} \int_{|w'| \leq \sqrt{M}} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]
\[
\leq C''_{n,p,\alpha} \int_{|w'| \leq \sqrt{M}} \int_{\sqrt{N_0} \leq |w'| \leq \sqrt{M}} \frac{\delta_0^{(n+1+\alpha)(p-1)}}{\delta_0^{(n+1+\alpha)(p-1)}} \left( \delta_0 + r^2 \right)^{p(n+1)+(p-1)\alpha} dA' \ dA(w')
\]

This integral goes to 0 as \( N \to \infty \) by the Dominated Convergence Theorem.

For the last term, we use the coordinates given in Lemma 2.6 in [25]. In particular, for \( \rho(z_0) < \varepsilon_0' \) and \( w \) satisfying \( |z_0 - w| < \delta_0' \), there exists a \( C^\infty \) diffeomorphism \( t(w, z_0) \) with bounded Jacobian and non-vanishing Jacobian determinant such that the coordinates \((t_1, t_2, t') = t(w, z_0)\) satisfy

\[
t_1(w, z_0) = -\rho(w), \quad t_2(w, z_0) = \text{Im}(\Psi(z_0, w)).
\]
We may assume without loss of generality that the quantity \( \varepsilon_0' \) in the Lemma, which only depends on \( \Omega \), is less than \( \varepsilon_0 \).

To use this coordinate system, we further split the last term into

\[
\int_{\{w: \delta(w) < \frac{\delta_0}{N}, |z_0 - w| \geq \delta_0'\}} \delta_0^{(n+1+\alpha)(p-1)} |\rho(w)|^{\alpha} |K_{\alpha}(z_0, w)|^p \, dA(w)
\]

\[
+ \int_{\{w: \delta(w) < \frac{\delta_0}{N}, |z_0 - w| < \delta_0'\}} \delta_0^{(n+1+\alpha)(p-1)} |\rho(w)|^{\alpha} |K_{\alpha}(z_0, w)|^p \, dA(w)
\]

where \( \delta_0' \) is as in the Lemma and only depends on the underlying domain \( \Omega \). Let \( dA_\alpha = |\rho|^{\alpha} \, dA \) and note \( dA_\alpha \) is a finite measure. The first term is easily handled:

\[
\int_{\{w: \delta(w) < \frac{\delta_0}{N}, |z_0 - w| \geq \delta_0'\}} \delta_0^{(n+1+\alpha)(p-1)} |\rho(w)|^{\alpha} |K_{\alpha}(z_0, w)|^p \, dA(w) \leq C \Omega A_\alpha \left( \left\{ w \in \Omega : \delta(w) < \frac{\delta_0}{N} \right\} \right),
\]

which clearly goes to 0 as \( N \to \infty \) independently of \( z_0 \). For the second term, we integrate in the coordinates given by the Lemma and use the fact that the change of coordinates map is a \( C^\infty \) diffeomorphism:

\[
\int_{\{w: \delta(w) < \frac{\delta_0}{N}, |z_0 - w| < \delta_0'\}} \delta_0^{(n+1+\alpha)(p-1)} |\rho(w)|^{\alpha} |K_{\alpha}(z_0, w)|^p \, dA(w)
\]

\[
\leq \int_0^{\frac{\delta_0}{N}} \int_{-M}^M \int_0^{\sqrt{M}} (\delta_0 + t_1 + |t_2| + |t'|^2)^{p(n+1+\alpha)} \, dt' \, dt_2 \, dt_1
\]

\[
\leq \int_0^{\frac{\delta_0}{N}} \int_{-M}^M \int_0^{\sqrt{M}} (\delta_0 + t_1 + |t_2| + |t'|^2)^{p(n+1+\alpha)(p-1)} \, dt' \, dt_2 \, dt_1
\]

\[
= C_n \int_0^{\frac{\delta_0}{N}} \int_{-M}^M \int_0^{\sqrt{M}} (\delta_0 + t_1 + |t_2| + r^2)^{p(n+1+\alpha)(p-1)} r^{2n-3} \, dr \, dt_2 \, dt_1
\]

\[
= C_n \int_0^{\frac{\delta_0}{N}} \int_{-M}^M \int_0^{\sqrt{M}} (\delta_0 + t_1 + |t_2| + r')^{p(n+1+\alpha)(p-1)} r^{(n-2)} \, dr' \, dt_2 \, dt_1
\]

\[
= C_n \int_0^{\frac{\delta_0}{N}} \int_{-M}^M \int_0^{\sqrt{M}} (\delta_0 + t_1 + |t_2| + (r'/\delta_0)^{(n-2)} \, dr' \, dt_2 \, dt_1
\]

\[
\leq C_n' \int_{\frac{\delta_0}{N}}^\infty \int_0^\infty \int_0^\infty \frac{u_1^{n-2}}{[1 + v_1 + v_2 + u_1]^{p(n+1)+p-1}} \, du_1 \, dv_2 \, dv_1.
\]

This last integral can again be seen to approach zero independent of \( z_0 \) by the Dominated Convergence Theorem.
4. Lower Dimensional Sets

In this section we will prove Theorems 2 and 3. The good/bad decomposition used to go from the local estimate to global estimate in Section 3.1 carries over to the lower-dimensional setting. So it is enough to prove the analogous local estimate. To do so, we will use the following estimates on the $H^{2n-2}$ measure of the zero set of a holomorphic function.

**Lemma 4.1.** Let $Q \subset \mathbb{C}^n$ be a Euclidean cube. For any $f \in \text{Hol}(2Q)$,

$$H^{2n-2}(\{f = 0\} \cap Q) \leq C \ell(Q)^{2n-2} \log \frac{\sup_{2Q}|f|}{\sup_{Q}|f|}.$$  

Moreover, if $f(c(Q)) = 0$, then

$$H^{2n-2}(\{f = 0\} \cap Q) \geq c \ell(Q)^{2n-2}. $$

If $\Omega$ is a smoothly bounded strongly pseudoconvex domain, then there exists $C, \varepsilon > 0$ such that for all $z \in \Omega_\varepsilon$ and $f \in \text{Hol}(Y(z, R))$,

$$H^{2n-2}(\{f = 0\} \cap Y(z, r)) \leq C \delta(z)^{n-1} \log \frac{\sup_{Y(z, R)}|f|}{\sup_{Y(z, r)}|f|}. $$

**Proof.** The first two statements are classical and we refer to the textbook [26, p. 230]. By the argument of (3.3), for each $w \in Y(z, r)$, we obtain a suitably rotated polydisc

$$P^*(w) \subset Y(w, \frac{R-r}{2}) \subset Y(z, \frac{R+r}{2}). $$

Using the fact that $Y(z, r)$ is contained in a large polydisc, the pigeonhole principle provides a $z_0 \in Y(z, r)$ and $c_0 > 0$ such that

$$H^{2n-2}(\{f = 0\} \cap \frac{1}{4} P^*(z_0)) \geq c_0 H^{2n-2}(\{f = 0\} \cap Y(z, r)).$$

Let $z_1 \in \frac{1}{4} P^*(z_0)$ such that $|f(z_1)| = \sup_{P^*(z_0)} |f|$. Then, there exists $C > 0$ from Jensen’s formula for polydiscs [26, Thm 4.2.5] such that

$$H^{2n-2}(\{f = 0\} \cap \frac{1}{2} P^*(z_1)) \leq C \delta(z)^{n-1} \log \frac{\sup_{P^*(z_1)}|f|}{|f(z_1)|}.$$ 

On one hand, $H^{2n-2}(\{f = 0\} \cap \frac{1}{2} P^*(z_1)) \geq H^{2n-2}(\{f = 0\} \cap \frac{1}{4} P^*(z_0)) \geq c_0 H^{2n-2}(\{f = 0\} \cap Y(z, r))$. At the same time, we want to connect $|f(z_1)|$ with $\sup_{Y(z, r)} |f|$. Applying Lemma 3.4 with $p = \infty$,

$$|f(z_1)| = \sup_{\frac{1}{4} P^*(z_0)} |f| \geq C^{-CN(\frac{R-r}{2}, R)} \sup_{Y(z, \frac{R+r}{2})} |f| \geq C^{-CN(\frac{R-r}{2}, R)} \sup_{Y(z, r)} |f|. $$
Therefore,
\[
\log \frac{\sup_{P^* (z_1)} |f|}{|f(z_1)|} \leq \log \frac{\sup_{Y(z,R)} |f|}{C^{-CN \frac{\nu p + \rho}{2}} \sup_{Y(z,r)} |f|} \\
= \log \frac{\sup_{Y(z,R)} |f|}{\sup_{Y(z,r)} |f|} + C \log \frac{\sup_{Y(z,R)} |f|}{\sup_{Y\left(\frac{r}{2}\right)} |f|} \log C \\
\leq (1 + C \log C) \log \frac{\sup_{Y(z,R)} |f|}{\sup_{Y(z,r)} |f|}.
\]

We have the following local estimates for Kobayashi balls.

Lemma 4.2. Let \( \Omega \subset \mathbb{C}^n \) be a strongly pseudoconvex domain, \( R > r > 0 \), \( 1 \leq p \leq \infty \), \( N^*, \nu > 0 \). There exists \( C, c, \varepsilon > 0 \) such that for any \( 0 < \gamma < c \),
\[
\|f\|_{L^p(Y(z,r))} \leq \left( \frac{C}{\gamma} \right)^C \|f\|_{L^p(E, \mathcal{H}^{2n-2+\nu})} \tag{4.1}
\]
for all \( z \in \Omega, f \in \text{Hol}(Y(z,R)) \) with \( N_p(z, f, r, R) \leq N^* \), and \( E \subset Y(z, r) \) satisfying
\[
\frac{|Y(z, r)|^{\frac{2n-2+\nu}{2n}} \mathcal{H}^{2n-2+\nu}(E)}{|Y(z, r)|^{(2n-2+\nu)/2n}} \geq \gamma.
\]

One might be bothered by the extra factor \( |Y_r|^{\frac{n-1}{n+1}} \), however it occurs because the Hausdorff measure does not scale according to the determinant of an affine map, but rather according to the map’s most extreme directions. For example, if \( D \) is a diagonal matrix with all entries \( \lambda_i \), then \( \min \{\lambda_i\} \mathcal{H}^1(E) \leq \mathcal{H}^1(DE) \leq \max \{\lambda_i\} \mathcal{H}(E) \) and one can find sets \( E_{\text{max}} \) and \( E_{\text{min}} \) which attain the upper and lower bounds, respectively.

Proof. We will only prove the case \( p = \infty \). One may go back to any \( 1 \leq p \leq \infty \) by repeating the steps at the end of the proof of Lemma 3.4. Normalize \( f \) so that \( \sup_{Y(z,r)} |f| = 1 \). In this way, it is enough to obtain a lower bound on \( \sup_{E} |f| \). Using the local estimate (Lemma 3.4),
we will connect the Hausdorff measure of small sublevel sets
\[
F_a = Y(z, r) \cap \{|f| \leq e^{-a}\}
\]
to that of the zero set. Cover \( Y(z, r) \) with \( K \) cubes of side length \( \ell \sim (|Y_r|/K)^{1/n} \). If \( K \) is chosen appropriately, and \( a \) is large, then any cube that intersects \( F \) must have a zero. Indeed, if \( f \) does not have a zero in \( Q \), but \( Q \) intersects \( F \), then by Harnack’s inequality,
\[
\sup_{Q} |f| \leq c \inf_{Q} |f| \leq ce^{-a}.
\]
On the other hand, applying the local estimate Lemma 3.4,
\[
(CK)^{-CN} \leq \sup_{Q} |f|, \quad N = N_{\infty}(r, R)
\]

26
we obtain a contradiction for $K = C^{-1}e^{a/(2CN)}$ and then $a$ large.

Now, $H^{2n-2+\nu}(F_a) \leq \sum_{Q \cap F \neq \emptyset} \ell^{2n-2+\nu}$ so it remains to estimate the number of cubes intersecting $F_a$, which we have just shown to be bounded above by the number of cubes with zeroes. By the first statement in Lemma 4.1

$$H^{2n-2}(\{f = 0\} \cap Y_r) \geq \sum_{Q \cap F \neq \emptyset} H^{2n-2}(\{f = 0\} \cap Q) \gtrsim \sum \ell^{2n-2}.$$  

From Lemma 4.1 we also have $H^{2n-2}(\{f = 0\} \cap Y(z,r)) \leq C\delta(z)^{n-1}N$. Altogether, this implies

$$H^{2n-2+\nu}(F_a) \leq C\ell^\nu N\delta(z)^{n-1}$$

$$\leq CN\delta(z)^{n-1}|Y(z,r)|^{\nu/2n}K^{-\nu/2n}$$

$$\leq CN|Y(z,r)|^{q^*}K^{-\nu/2n},$$

where, recalling the fact that $|Y_r| \sim \delta(z)^{n+1}$ from Lemma 3.2

$$q^* = 1 - \frac{2}{n+1} + \frac{\nu}{2n} = \frac{2n-2+\nu}{2n} - \frac{n-1}{n(n+1)}.$$

Moreover, plugging in the value of $K$ from above, we have shown that for $a$ large enough,

$$H^{2n-2+\nu}(\{|f| \leq e^{-a}\} \cap Y(z,r)) \leq CN|Y(z,r)|^{q^*}e^{-\nu a/2CN}. \quad (4.2)$$

Now we can prove the lemma. Let $E \subset Y(z,r)$ with $H^{2n-2+\nu}(E) \geq \gamma|Y(z,r)|^{q^*}$. Pick $a$ so that the $CN e^{-\nu a/2CN} = \gamma/2 < \gamma$ ($\gamma$ must be small in order that $a$ be large enough to apply (4.2). This determines $c)$. Since $a$ is large, (4.2) forces $E \setminus F$ to be non-empty and thus

$$\sup_E |f| \geq e^{-a} = \left(\frac{\gamma}{2CN}\right)^{2CN\nu^{-1}}$$

which proves (4.1) when $p = \infty$. \hfill \square

**Corollary 4.3.** There exists $C, \tilde{\gamma}, \varepsilon > 0$ such that (4.1) holds for $\nu = 0$ in the form

$$\|f\|_{L^p(Y(z,r))} \leq C\|f\|_{L^p(E,H^{2n-2})}$$

for all $z \in \Omega_\varepsilon$, $f \in \text{Hol}(Y(z,R))$ with $N_p(z,f,r,R) \leq N^*$, and $E \subset Y(z,r)$ satisfying

$$\frac{|Y(z,r)|^{-\nu/2n} H^{2n-2}(E)}{|Y(z,r)|^{(2n-2)/2n}} \geq \tilde{\gamma}.$$
