Multiplayer Homicidal Chauffeur Reach-Avoid Games via Guaranteed Winning Strategies

Rui Yan, Ruiliang Deng, Haowen Lai, Weixian Zhang, Zongying Shi, Member, IEEE, and Yisheng Zhong

Abstract—This paper studies a planar multiplayer Homicidal Chauffeur reach-avoid differential game, where each pursuer is a Dubins car and each evader has simple motion. The pursuers aim to protect a goal region cooperatively from the evaders. Due to the high-dimensional strategy space among pursuers, we decompose the whole game into multiple one-pursuer-one-evader subgames, each of which is solved in an analytical approach instead of solving Hamilton-Jacobi-Isaacs equations. For each subgame, an evasion region (ER) is introduced, based on which a pursuit strategy guaranteeing the winning of a simple-motion pursuer under specific conditions is proposed. Motivated by the simple-motion pursuer, a strategy for a Dubins-car pursuer is proposed when the pursuer-evader configuration satisfies separation condition (SC) and interception orientation (IO). The necessary and sufficient condition on capture radius, minimum turning radius and speed ratio to guarantee the pursuit winning is derived. When the IO is not satisfied (Non-IO), a heading adjustment pursuit strategy is proposed, and the condition to achieve IO within a finite time, is given. Then, a two-step pursuit strategy is proposed for the SC and Non-IO case. A non-convex optimization problem is introduced to give a condition guaranteeing the winning of the pursuer. A polynomial equation gives a lower bound of the non-convex problem, providing a sufficient and efficient pursuit winning condition. Finally, these pairwise outcomes are collected for the pursuer-evader matching. Simulations are provided to illustrate the theoretical results.

Index Terms—Differential games, Homicidal Chauffeur, reach-avoid games, winning strategies, multi-agent systems.

I. INTRODUCTION

Problem description and motivation: Differential game theory provides a proper framework for analyzing the strategic interactions among multiple dynamical agents. Reach-avoid differential games, which consider two parties with conflicting objectives, have received significant attention in the past few years. However, due to the hardness of solving the Hamilton-Jacobi-Isaacs (HJI) equation, most of works focus on either complex dynamical models with numerical methods, or simple dynamical models with analytical methods. Motivated by the classical Homicidal Chauffeur game which involves nonlinear dynamics and has limited analytical results, this paper studies a planar multiplayer Homicidal Chauffeur reach-avoid differential game via guaranteed winning strategies in a pairwise and analytical way. In this game, a group of pursuers is used to protect a region cooperatively from a group of evaders, in which each pursuer is a Dubins car and each evader has simple motion.

Literature review: The first instances of reach-avoid differential games were developed in [18], [20], [34], where one player aims to reach a predefined goal region, while avoiding adversarial circumstance induced by an opposing player. Building on these pioneers, a variety of variations have been proposed, such as multiple players [6], [13], [31], time-varying targets and constraints [10], analytical approach [29], non-convex target sets [26] and perimeter defense [25]. Such games encompass a huge number of adversarial scenarios in robotics and control [17], [32], [33], such as safe motion-planning, collision avoidance, oil pipelines protection, and border protection.

The current research into reach-avoid differential games has largely focused on the computation of the barrier, or called the boundary of the reach-avoid set, and optimal strategies. For complex dynamical models such as Dubins car [5], differential drive robot [24] and double integrator dynamics, the analytical expressions of the barrier and optimal strategies are intractable due to the hardness of the associated HJI equation, for which a number of numerical tools based on grids have been proposed [4], [5], [10]. Unfortunately, these approaches suffer from the tradeoffs between execution time and accuracy, because the computational burden explodes as the grid scale increases. For simple dynamical models such as simple-motion model [15], analytical barriers and optimal strategies have been computed for many different variants, including bounded environments [12], [29], [31], three- or high-dimensional game spaces [11], [27], [30], and time constraints [28]. However, the simple-motion model is a little restrictive, because the player is allowed to change its direction instantaneously, which is often infeasible in many control applications such as safe planning for autonomous vehicles and border guarding by robots with minimum turning radius. As discussed in [22], [31], the analytical methods for reach-avoid differential games with complex dynamical models are urgently needed.

This paper considers a variant of the classical Homicidal Chauffeur game, called Homicidal Chauffeur reach-avoid differential games, in which the chauffeurs or pursuers (Dubins-car models) aim to protect a region by capturing the pedestrians or evaders (simple-motion models [15]). The Homicidal Chauffeur game was initially invented by Isaacs in [15] and then a systematic description of the solution structure was presented in [19] by Breakwell and Merz. The steps to obtain the full solution for the parameter range in the heart of the speed ratio and capture radius parameter space, are quite complex and also fantastic. We refer the interested readers...
to the references [22] and [23] for a thorough understanding of history and modern studies on Homicidal Chauffeur game. Compared with the classical Homicidal Chauffeur game where the capture is the unique goal, Homicidal Chauffeur reach-avoid games are more complicated and have more practical significance, because the pedestrians not only aim to avoid the capture but also strive to reach a goal region. Two terminal conditions, the capture of evader or arrival in the goal region, make it difficult to extend the analytical method in [15] and [19] for the variant we are considering in this paper, as this method requires backward integration from terminal manifold and different backward trajectories may produce complicated singular surfaces, for which there exist no systematic analysis methods [16].

There are several attempts to analytically study adversarial games with Dubins cars. For example, Bopardikar et al. [3] proposed a multi-phase strategy to confine an evader into a bounded region formed by the pursuers for a cooperative Homicidal Chauffeur game. In [21], the authors studied the dominance regions for the Homicidal Chauffeur game. The work [9] introduced a reversed Homicidal Chauffeur game, called Suicidal Pedestrian differential game, and derived the winning regions and optimal strategies. In [7], the optimal control of a Dubins car was discussed for the Homicidal Chauffeur game. In [21], the authors studied the proposed a multi-phase strategy to confine an evader into winning regions and optimal strategies. In [7], the optimal control of a Dubins car was discussed for the Homicidal Chauffeur game with a stationary evader. However, to our best knowledge, there is no existing literature to analytically study the Homicidal Chauffeur reach-avoid differential games with Dubins cars, especially Homicidal Chauffeur reach-avoid differential games.

Contributions: In this paper, we study the analytical cooperative strategies for multiple Dubins-car pursuers to protect a region in the plane from multiple simple-motion evaders. Compared with [3]–[6], [10]–[13], [26]–[31], we combine the advantages of analytical methods in accuracy and computational efficiency, and Dubins-car models in broader applications. The main contributions are as follows:

(i) For each subgame with one pursuer and one evader, when the minimum turning radius is zero, i.e., a simple-motion pursuer is considered, a pursuit strategy based on the evasion region (ER), is proposed such that the pursuer can protect the goal region from the evader under specific initial configurations.

(ii) Building on the above, when the minimum turning radius is positive, i.e., a Dubins-car pursuer is considered, a pursuit strategy is proposed when the pursuer-evader configuration satisfies separation condition (SC) and interception orientation (IO). Then, the necessary and sufficient condition on capture radius, minimum turning radius and speed ratio to guarantee the pursuit winning, is derived.

(iii) If the configuration does not satisfy IO (i.e., Non-IO), a heading adjustment pursuit strategy is proposed. Under this strategy, a sufficient condition on capture radius, minimum turning radius and speed ratio for steering the configuration into IO after a finite time, is presented. Furthermore, an upper bound for the heading adjustment time is given.

(iv) For the SC and Non-IO case, a two-step pursuit strategy is proposed by merging the heading adjustment strategy and the strategy in the case of SC and IO. A sufficient condition on capture radius, minimum turning radius and speed ratio, as well as the optimal value of a non-convex optimization problem, for the guaranteed pursuit winning, is given. A lower bound of the non-convex optimization problem is computed by solving a sextic equation, thus providing a sufficient and efficient pursuit winning condition. Finally, all pairwise outcomes are collected for the maximum pursuer-evader matching and thus a receding horizon pursuit strategy is proposed.

Paper organization: We introduce the Homicidal Chauffeur reach-avoid differential games in Section II, including problem description, information structure and assumptions. In Section III, the case where one simple-motion pursuer plays against one evader, is discussed. Based on it, Section IV presents the main results of one Dubins-car pursuer against one simple-motion evader, including pursuit winning strategy and heading adjustment strategy. In Section V, a receding horizon pursuit strategy based on pairwise outcomes and maximum matching is proposed. Numerical results are presented in Section VI, and we conclude the paper in Section VII.

Notation: Let $R_0$ and $R$ be the set of reals, positive reals and nonnegative reals, respectively. Let $(R^n)$, be the set of $n$-dimensional real column vectors and $\|\cdot\|$ be the Euclidean norm. All vectors in this paper are column vectors. Let $0$ denote the zero vector whose dimension will be clear from the context. Denote the unit disk in $R^n$ by $S^{n-1}$, i.e., $S^{n-1} = \{u \in R^n | \|u\|_2 \leq 1\}$. For any set $S \subset R^n$, let $int(S)$, $\partial S$ and $S$ be the interior, boundary and closure of $S$, respectively. Let $\text{sgn}(\cdot)$ be the sign function.

II. PROBLEM STATEMENT

A. Homicidal Chauffeur Reach-Avoid Differential Games

Consider a reach-avoid differential game in the plane $R^2$ with $N_p + N_e$ players, where there are $N_p$ pursuers $P = \{P_1, \ldots, P_{N_p}\}$ and $N_e$ evaders $E = \{E_1, \ldots, E_{N_e}\}$. The players are assumed to be mass points and their dynamics are described by Homicidal Chauffeur models [15]. Each pursuer $P_i \in P$ is modeled as a Dubins car:

$$
\begin{align*}
\dot{x}_{P_i} &= v_{P_i} \cos \theta_{P_i}, \quad x_{P_i}(0) = x_{P_i,0}, \\
\dot{y}_{P_i} &= v_{P_i} \sin \theta_{P_i}, \quad y_{P_i}(0) = y_{P_i,0}, \\
\dot{\theta}_{P_i} &= v_{P_i} u_{P_i}/\kappa_i, \quad \theta_{P_i}(0) = \theta_{P_i,0},
\end{align*}
$$

where $x_{P_i} = [x_{P_i}, y_{P_i}]^T \in R^2$, $\theta_{P_i} \in [0, 2\pi)$ and $u_{P_i} \in S^0$ are pursuer $P_i$’s position, heading and control input respectively, and $v_{P_i} \in R_{>0}$ and $\kappa_i \in R_{>0}$ are the constant speed and minimum turning radius of $P_i$ respectively. The initial position and heading of $P_i$ are $x_{P_i,0} = [x_{P_i,0}, y_{P_i,0}]^T \in R^2$ and $\theta_{P_i,0} \in [0, 2\pi)$, respectively. Each evader $E_j \in E$ has simple motion:

$$
\begin{align*}
\dot{x}_{E_j} &= v_{E_j} u_{E_j}, \quad x_{E_j}(0) = x_{E_j,0}, \\
\dot{y}_{E_j} &= v_{E_j} u_{E_j}, \quad y_{E_j}(0) = y_{E_j,0},
\end{align*}
$$

where $x_{E_j} = [x_{E_j}, y_{E_j}]^T \in R^2$ and $u_{E_j} = [u_{E_j}^x, u_{E_j}^y]^T \in S^1$ are evader $E_j$’s position and control input respectively, and $v_{E_j} \in R_{>0}$ is the constant speed of $E_j$. The initial position of $E_j$ is $x_{E_j,0} = [x_{E_j,0}, y_{E_j,0}]^T \in R^2$. The goal region $\Omega_{goal} \subset R^2$. The
is assumed to be a half-plane, and its boundary is denoted by $\mathcal{T} \subset \mathbb{R}^2$, as shown in Fig. 1. The complementary set of $\Omega_{\text{goal}}$ in $\mathbb{R}^2$ is called play region $\Omega_{\text{play}}$. We take

$$
\Omega_{\text{goal}} = \{x \in \mathbb{R}^2 | g(x) \leq 0\},
$$

$$
\mathcal{T} = \{x \in \mathbb{R}^2 | g(x) = 0\},
$$

$$
\Omega_{\text{play}} = \{x \in \mathbb{R}^2 | g(x) > 0\},
$$

where $g(x) := [0,1]x$.

Suppose that the pursuer $P_i$ has capture radius $r_i > 0$. The evader is captured as soon as its distance to at least one pursuer becomes equal to or less than the corresponding capture radius. Assume that the number of pursuers remains constant, and the pursuers chase the evaders until no evaders in $\Omega_{\text{play}}$, that is, the game ends in this situation.

The evaders $\mathcal{E}$ (evasion team) strive to send as many evaders as possible into the goal region $\Omega_{\text{goal}}$ before being captured, while the pursuers $\mathcal{P}$ (pursuit team) try to protect $\Omega_{\text{goal}}$ by capturing as many evaders as possible in the play region $\Omega_{\text{play}}$. This paper aims at designing a receding horizon pursuit strategy for the pursuit team which can give a lower bound of the number of guaranteed captured evaders.

### B. Information Structure and Assumptions

In the differential games, the information available to each player plays an important role in determining game outcomes. This paper considers a nonanticipative information structure (see for example [8], [20]). Under this information structure, the pursuit team makes decisions about its current input with the information of all players’ current states, plus the evasion team’s current control input. While the evasion team is at a slight disadvantage under this information structure, at a minimum it has access to the information of all players’ current states, because the pursuit team must declare its strategy before the evasion team chooses a specific input and thus the evasion team can determine the response of the pursuit team to any input signal. Thus, the game formulated here is an instantiation of the Stackelberg game [1].

Assume that the initial positions of all players satisfy the following conditions, which can focus our attention on the main situations and remove some technical problems (e.g., two pursuers or evaders initially lie at the same position).

**Assumption 1** (Initial deployment). The initial positions of all players satisfy the following four conditions:

1) $\|x_{P_i0} - x_{P_j0}\|_2 > 0$ for all $P_i, P_j \in \mathcal{P}, P_i \neq P_j$;
2) $\|x_{E_i0} - x_{E_j0}\|_2 > 0$ for all $E_i, E_j \in \mathcal{E}, E_i \neq E_j$;
3) $\|x_{P_i0} - x_{P_j0}\|_2 > r_i$ for all $P_i \in \mathcal{P}, E_j \in \mathcal{E}$;
4) $x_{P_i0} \in \mathbb{R}^2$ for all $P_i \in \mathcal{P}$ and $x_{E_i0} \in \Omega_{\text{play}}$ for all $E_j \in \mathcal{E}$.

In the Homicidal Chauffeur game, the chauffeur is faster. Similarly, we focus on the faster pursuer case.

**Assumption 2** (Speed ratio). Suppose that the speed ratio $\alpha_{ij} = v_{P_i}/v_{E_j} > 1$ for all $P_i \in \mathcal{P}$ and $E_j \in \mathcal{E}$.

### III. ONE VS. ONE GAMES: SIMPLE-MOTION PURSUER

It is intractable to analyze the whole game directly due to the high-dimensional strategy space and complex cooperation. We here overcome this intractability by decomposing the game into multiple one-pursuer-one-evader subgames. Then, we look into these subgames and collect the pairwise outcomes for the pursuer-evader matching. Next, these subgames will be discussed.

It is known that the strategies in the Homicidal Chauffeur games are quite complex [19]. The strategies in the Homicidal Chauffeur reach-avoid games become more complicated, because the evader not only tries to escape but also strives to enter a goal region. We will start with the simple-motion pursuer, and propose a pursuit strategy under which a guaranteed pursuit winning condition is derived. Then, these insights will be used for the Dubins-car pursuer in the next section.

Suppose that $\kappa_i$ is small enough. Each pursuer $P_i \in \mathcal{P}$ in (1) becomes simple motion:

$$
\begin{align*}
\dot{x}_{P_i} &= v_{P_i}u_{P_i}, \\
\dot{y}_{P_i} &= v_{P_i}u_{P_i}, \\
\dot{y}_{P_i}(0) &= y_{P_i0},
\end{align*}
$$

where $u_{P_i} = [u_{P_i}^x, u_{P_i}^y]^\top \in S^1$ is the control input of $P_i$. In this section, we focus on (3) for the pursuer.

### A. Evasion Region

First, we revisit a class of potential functions introduced in [27] with a little revision, that is, we drop off the capture radius.

**Definition 1** (Potential function). Given any $x_{P_i}$ and $x_{E_j}$ at time $t \geq 0$, define the potential function $f_{ij} : \mathbb{R}^2 \times \mathbb{R}_{\geq 0} \to \mathbb{R}$ associated with $P_i$ and $E_j$ as follows

$$
f_{ij}(x,t) = \|x - x_{P_i}\|^2 - \alpha_{ij} \|x - x_{E_j}\|^2, \quad (4)
$$

whose gradient with respect to $x$ is denoted by $\nabla_x f_{ij}(x,t) \in \mathbb{R}^2$, and given by

$$
\nabla_x f_{ij}(x,t) = \frac{x - x_{P_i}}{\|x - x_{P_i}\|^2} - \alpha_{ij} \frac{x - x_{E_j}}{\|x - x_{E_j}\|^2}, \quad (5)
$$

when $x \neq x_{P_i}$ and $x \neq x_{E_j}$.

We consider the concept introduced in Section 6.7 in Isaacs’ book [15] as follows.
Definition 2 (Evasion region). Given \(x_{P_i} \) and \(x_{E_j} \), the evasion region (ER) \(E_{ij} \), is the set of positions in \(\mathbb{R}^2 \) that \(E_j \) can reach before \(P_i \) for any control input \(u_{P_i} \in S^1 \), i.e., \(E_{ij} = \{ x \in \mathbb{R}^2 \mid f_{ij}(x,t) > 0 \} \).

Unless for clarity, we will suppress the dependence on \(t \). Let \(\partial E_{ij} \) and \(E_{ij} \) denote the boundary and closure of \(E_{ij} \), respectively. Thus, they can be respectively formulated as
\[
\begin{align*}
\partial E_{ij} &= \left\{ x \in \mathbb{R}^2 \mid f_{ij}(x,t) = 0 \right\}, \\
E_{ij} &= \left\{ x \in \mathbb{R}^2 \mid f_{ij}(x,t) \geq 0 \right\}.
\end{align*}
\]

By Definition 2, the ER \(E_{ij} \) is the interior of a circle with center: \( \frac{\alpha_{ij}^2 x_{E_j} - x_{P_i}}{\alpha_{ij}^2 - 1} \), radius: \( \frac{\alpha_{ij} \| x_{P_i} - x_{E_j} \|_2}{\alpha_{ij}^2 - 1} \).

B. Pursuit Winning Strategy

The distance between two points \(x \in \mathbb{R}^2 \) and \(y \in \mathbb{R}^2 \) is defined as \(\rho(x,y) = \| x - y \|_2 \), the distance between a point \(x \in \mathbb{R}^2 \) and a non-empty set \(M \subset \mathbb{R}^2 \) is defined as \(\rho(x,M) = \inf_{y \in M} \| x - y \|_2 \), and the distance between two non-empty sets \(M_1 \) and \(M_2 \) is
\[
\rho(M_1,M_2) = \begin{cases} 
\inf_{x \in M_1,y \in M_2} \| x - y \|_2, & \text{if } \text{int}(M_1) \cap \text{int}(M_2) = 0, \\
-\infty, & \text{otherwise.}
\end{cases}
\]

Let \(\rho_T : \mathbb{R}^2 \rightarrow \mathbb{R} \) be the signed distance function to \(T \):
\[
\rho_T(x) := \begin{cases} 
\rho(x,T), & x \in \Omega_{\text{play}}, \\
-\rho(x,T), & x \in \Omega_{\text{goal}}.
\end{cases}
\]

For any \(x_{P_i} \) and \(x_{E_j} \), according to the radius of \(E_{ij} \), let
\[
\gamma(x_{P_i},x_{E_j}) = \begin{cases} 
0, & \text{if } \text{int}(M_1) = \emptyset, \\
-\sqrt{\alpha_{ij}^2 - 1}, & \text{otherwise.}
\end{cases}
\]

Next, a critical point in \(E_{ij} \) is introduced.

Definition 3 (Interception point). Given any \(x_{P_i} \) and \(x_{E_j} \), let the interception point \(I_{ij} \) given by \(x_{I_{ij}} = [x_{I_{ij}},y_{I_{ij}}]^T \) be the unique point in \(E_{ij} \) that has the minimum signed distance to \(T \), i.e., \(x_{I_{ij}} = \arg \min_{x \in E_{ij}} \rho_T(x) \) and is given by
\[
x_{I_{ij}} = \frac{\alpha_{ij}^2 x_{E_j} - x_{P_i}}{\alpha_{ij}^2 - 1} + \gamma(x_{P_i},x_{E_j}).
\]

For clarity, the indexes \(i\) and \(j\) are omitted hereinafter. Note that if \(x_{P_i} \neq x_{E_j} \), then \(x_{P_i} \neq x_{I_{ij}} \) and \(x_{E_j} \neq x_{I_{ij}} \). The following theorem presents a pursuit winning strategy.

Theorem 1 (Pursuit winning strategy). Consider \(P \in S \) and \(E \in S \) under the model (3) and (2), respectively. Suppose that \(\rho(\bar{E},\Omega_{\text{goal}}) \geq 0 \). If \(P \) adopts the feedback strategy \(u_P = \frac{x_{I_{ij}} - x_{P_i}}{\| x_{I_{ij}} - x_{P_i} \|_2} \), then \(P \) guarantees that \(\bar{E} \) does not approach \(\Omega_{\text{goal}} \), that is,
\[
\frac{d}{dt} \rho(\bar{E},\Omega_{\text{goal}}) \geq 0,
\]
for any \(u_E \in S^1 \). Moreover, the equality holds if and only if \(E \) adopts the feedback strategy \(u_E = \frac{x_{I_{ij}} - x_{E_j}}{\| x_{I_{ij}} - x_{E_j} \|_2} \).
A. Pursuit Winning Strategy for SC and IO

Before presenting the main results, we first define several notations. Let \( X(t) = (x_P(t), \theta_P(t), x_E(t)) \in \mathbb{R}^2 \times [0, 2\pi) \times \mathbb{R}^2 \) denote the state of the game at time \( t \). Define two mappings \( F : \mathbb{R}^2 \times [0, 2\pi) \times \mathbb{R}^2 \to \mathbb{R}^2 \) and \( G : \mathbb{R}^2 \times [0, 2\pi) \times \mathbb{R}^2 \to \mathbb{R}^2 \), where \( F(X) = [F_x(X), F_y(X)]^\top \) and \( F_x(X), F_y(X) \) and \( G(X) \) are given by (10). Let \( h(\alpha) \) be the optimal value of the following problem:

\[
\begin{align*}
\text{maximize} & \quad y + \alpha \frac{x}{2\alpha y + \alpha^2 + 1} + \frac{\alpha x(y + \alpha)}{(2\alpha y + \alpha^2 + 1)^{\frac{3}{2}}} \\
\text{subject to} & \quad x^2 + y^2 = 1.
\end{align*}
\]

Next, we introduce two conditions to classify the states into several classes, and analyze them separately.

**Definition 4** (Separation condition). A state \( X \) satisfies separation condition (SC) if \( \rho(\Xi, \Omega_{\text{goal}}) \geq 0 \) holds.

**Definition 5** (Interception orientation). For any given state \( X = (x_P, \theta_P, x_E) \), the interception angle \( \theta_I \in [0, 2\pi) \) is defined by

\[
\cos \theta_I = \frac{x_I - x_P}{\|x_I - x_P\|_2}, \quad \sin \theta_I = \frac{y_I - y_P}{\|x_I - x_P\|_2}.
\]

Then, the state \( X \) satisfies interception orientation (IO) if \( P \)'s heading is equal to the interception angle, i.e., \( \theta_P = \theta_I \).

We now present the pursuit winning strategy when the state \( X \) satisfies SC and IO.

**Theorem 2** (Pursuit winning strategy for SC and IO). Consider \( P \in \mathcal{P} \) and \( E \in \mathcal{E} \) under the model (1) and (2), respectively. Let a state \( X \) which satisfies SC and IO. If \( P \) adopts the feedback strategy

\[
u_P = F(X)^\top u_E + G(X),
\]

then the SC and IO hold all the time before the capture and \( P \) also guarantees that \( \Xi \) does not approach \( \Omega_{\text{goal}} \), i.e.,

\[
\frac{d}{dt} \rho(\Xi, \Omega_{\text{goal}}) \geq 0,
\]

for any \( u_E \in S^1 \), if and only if the capture radius \( r \), minimum turning radius \( \kappa \) and speed ratio \( \alpha \) satisfy

\[
r - \kappa h(\alpha) \geq 0.
\]

Moreover, the equality in (12) holds if and only if \( E \) adopts the feedback strategy \( u_E = \frac{x_I - x_E}{\|x_I - x_E\|_2} \).

**Proof.** Note that the state \( X \) satisfies SC. Thus, according to Theorem 1, by starting from \( X \), if the positions of \( P \) and \( E \) evolve along the following dynamics

\[
\dot{x}_E = v_E u_E, \quad \dot{x}_P = v_P \frac{x_I - x_P}{\|x_I - x_P\|_2},
\]

then the SC and IO hold all the time and \( P \) can guarantee that \( \Xi \) does not approach \( \Omega_{\text{goal}} \), i.e., (12) holds for any \( u_E \in S^1 \). Therefore, our goal is to design a pursuit strategy such that the dynamics (14) is satisfied unless \( E \) is captured by \( P \).

Note that (14) can be regarded as a nonlinear dynamical system with a unique control input \( u_E \). For any given \( u_E \), the signed curvature [14] of \( P \)'s trajectory under the dynamics (14) can be computed by

\[
\frac{d\theta_P}{ds_P} = \frac{\hat{y}_P \hat{x}_P - \hat{x}_P \hat{y}_P}{(\hat{x}_P^2 + \hat{y}_P^2)^{\frac{3}{2}}} = \frac{\hat{y}_P \hat{x}_P - \hat{x}_P \hat{y}_P}{v_P^2},
\]

where \( s_P \in \mathbb{R}_\geq 0 \) is \( P \)'s moving distance. If \( x_I \neq x_P \), through the time derivation, (14) leads to the following condition

\[
\begin{align*}
\hat{y}_P &= \frac{y_I - y_P}{x_I - x_P} = \frac{\hat{y}_P \hat{x}_P - \hat{x}_P \hat{y}_P}{x_I - x_P} \\
\hat{x}_P &= \frac{y_I - y_P}{x_I - x_P} = (\hat{y}_I - \hat{y}_P)(x_I - x_P) - (\hat{x}_I - \hat{x}_P)(y_I - y_P) \bigg/ (x_I - x_P)^2.
\end{align*}
\]

Combining the above condition with (14), we can eliminate the second-order derivatives in (15) as follows

\[
\begin{align*}
\frac{d\theta_P}{ds_P} &= \frac{\hat{x}_P^2 (\hat{y}_I - \hat{y}_P)(x_I - x_P) - (\hat{x}_I - \hat{x}_P)(y_I - y_P)}{v_P^2} \\
&= \frac{(\hat{y}_I - \hat{y}_P)(x_I - x_P) - (\hat{x}_I - \hat{x}_P)(y_I - y_P)}{v_P^2} \frac{v_P}{\|x_I - x_P\|_2} \\
&= \frac{\hat{y}_I(x_I - x_P) - \hat{x}_I(y_I - y_P)}{v_P^2} \frac{v_P}{\|x_I - x_P\|_2}\|x_I - x_P\|_2.
\end{align*}
\]

If \( y_I \neq y_P \), we still have (16). According to Definition 3, the time derivative of \( x_I \) is

\[
\begin{align*}
\dot{x}_I &= \frac{\alpha^2 \hat{x}_E - \hat{x}_P}{\alpha^2 - 1} \\
\dot{y}_I &= \frac{\alpha^2 \hat{y}_E - \hat{y}_P}{\alpha^2 - 1} - \frac{\alpha(x_P - x_E)^\top (x_P - \hat{x}_E)}{(\alpha^2 - 1)\|x_P - x_E\|_2}.
\end{align*}
\]
Combining the above condition with (14), we can replace the terms \( \dot{x}_I \) and \( \dot{y}_I \) in (16) as follows
\[
\frac{d\theta_p}{ds_p} = \frac{(\alpha^2 y_E - \dot{y}_P)(x_I - x_P) - (\alpha^2 \dot{x}_E - \dot{x}_P)(y_I - y_P)}{v_p(\alpha^2 - 1)\|x_I - x_P\|^2} - \frac{\alpha(x_I - x_P)(x_P - x_E)^T(\dot{x}_P - \dot{x}_E)}{v_p(\alpha^2 - 1)\|x_I - x_P\|^2\|x_P - x_E\|^2} = \frac{F(X)^T u_P + G(X)}{\kappa}.
\]
Furthermore, according to (1), the control input of the pursuer is given by
\[
u_P = \frac{\kappa}{v_p} \frac{d\theta_p}{dt} = \frac{\kappa}{v_p} \frac{ds_p}{dt} \frac{d\theta_p}{ds_p} = \frac{\kappa}{ds_p} \frac{d\theta_p}{ds_p} = \frac{F(X)^T u_P + G(X)}{\kappa}.
\]
From the above, if \( P \) adopts the feedback strategy (17), then the positions of \( P \) and \( E \) will evolve along the dynamics (14), thus leading to (12) for any \( u_E \in \mathbb{S}^1 \). The only constraint for the controller (17) is \( u_P \in \mathbb{S}^0 \), i.e., \( |u_P| \leq 1 \).

Next, we prove the necessary and sufficient condition on the capture radius \( r \), minimum turning radius \( \kappa \) and speed ratio \( \alpha \), such that \( |u_P| \leq 1 \) holds for any \( u_E \in \mathbb{S}^1 \), and for any \( x_P \) and \( x_E \) satisfying \( \|x_P - x_E\|_2 \geq r \). Define
\[
x = \frac{x_P - x_E}{\|x_P - x_E\|_2}, \quad y = \frac{y_P - y_E}{\|x_P - x_E\|_2}.
\]
Note that \( x \) and \( y \) are two variables independent of the value of \( \|x_P - x_E\|_2 \). Then, according to (17), we have
\[
\min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} \min_{u_P} = \min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} F(X)^T u_P + G(X)
\]
\[
= \min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} \left( k\alpha(y + \alpha)u_E^T - \kappa x(y + \alpha)u_E \right)
\]
\[
= \min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} \left( \kappa \alpha x(y + \alpha) - 2\kappa(2\alpha y + \alpha^2 + 1) \right)
\]
\[
= \min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} \left( \kappa \alpha x(y + \alpha) - 2\kappa(2\alpha y + \alpha^2 + 1) \right) \geq -1,
\]
which is equivalent to
\[
h(\alpha) = \max_{(x,y) \in \mathbb{S}^1} \frac{y + \alpha}{2\alpha y + \alpha^2 + 1} + \frac{\alpha x(y + \alpha)}{2\alpha y + \alpha^2 + 1}
\]
\[
\leq \frac{\|x_P - x_E\|_2}{\kappa},
\]
holds for any \( x_P \) and \( x_E \) satisfying \( \|x_P - x_E\|_2 \geq r \). Thus, under the condition \( \|x_P - x_E\|_2 \geq r \), we have
\[
\min_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} u_P \geq -1 \iff r - \kappa h(\alpha) \geq 0.
\]

Similarly, when \( r - \kappa h(\alpha) \geq 0 \), we can obtain
\[
\max_{(x,y) \in \mathbb{S}^1} \max_{u_E \in \mathbb{S}^1} u_P
\]
\[
= \max_{(x,y) \in \mathbb{S}^1} \max_{u_E \in \mathbb{S}^1} \left( \kappa y + \alpha \right) u_E^T - \kappa x(y + \alpha)u_E \|x_P - x_E\|_2 \\left( 2\alpha y + \alpha^2 + 1 \right)
\]
\[
= \max_{(x,y) \in \mathbb{S}^1} \max_{u_E \in \mathbb{S}^1} \left( \kappa \alpha x(y + \alpha) - 2\kappa(2\alpha y + \alpha^2 + 1) \right)
\]
\[
= \max_{(x,y) \in \mathbb{S}^1} \min_{u_E \in \mathbb{S}^1} \left( \kappa \alpha x(y + \alpha) - 2\kappa(2\alpha y + \alpha^2 + 1) \right)
\]
\[
\leq \frac{\kappa h(\alpha)}{r} \leq 1,
\]
which completes the proof.

In Fig. 2, the curve \( r - \kappa h(\alpha) = 0 \) is plotted in red, and the condition (13) corresponds to the region above this curve. Although (13) is a necessary and sufficient condition such that (12) holds under the pursuit strategy (11), solving (9) for \( h(\alpha) \) might be inefficient. Next, we provide an elegant and sufficient condition to make (13) feasible.
\textbf{Lemma 1} (Sufficient condition for parameters). If the parameters \((r, \kappa, \alpha)\) satisfy
\[ r \geq \frac{2\alpha - 1}{(\alpha - 1)^2}, \tag{18} \]
then \(r - \kappa \alpha \geq 0\) in (13) is true.

\textit{Proof.} Let \(\tilde{h}(\alpha)\) be the optimal value of the problem
\[ \max_{y \in \mathbb{R}} h_1(\alpha, y) \quad \text{subject to} \quad |y| \leq 1, \tag{19} \]
where
\[ h_1(\alpha, y) = \frac{y + \alpha}{2\alpha y + \alpha^2 + 1} + \frac{\alpha (y + \alpha)}{(2\alpha y + \alpha^2 + 1)^2}. \]
For any \(x^2 + y^2 = 1\) and for any \(\alpha > 1\),
\[ h_1(\alpha, y) \geq \frac{y + \alpha}{2\alpha y + \alpha^2 + 1} + \frac{\alpha x(y + \alpha)}{(2\alpha y + \alpha^2 + 1)^2}. \]
Thus, the problems (9) and (19) are related by \(h(\alpha) \leq \tilde{h}(\alpha)\).

Then, we observe for \(h_1(\alpha, y)\) that
\[ \frac{\partial h_1(\alpha, y)}{\partial y} = \frac{1 - \alpha^2}{(2\alpha y + \alpha^2 + 1)^2} + \frac{\alpha(1 - 2\alpha^2 - \alpha y)}{(2\alpha y + \alpha^2 + 1)^2} \]
\[ < \frac{\alpha(1 - \alpha^2)}{(2\alpha y + \alpha^2 + 1)^2} < 0. \]
Thus, the optimal value \(\tilde{h}(\alpha)\) of (19) is given by
\[ \tilde{h}(\alpha) = h_1(\alpha, -1) = \frac{2\alpha - 1}{(\alpha - 1)^2}. \]
If (18) holds, then
\[ r - \kappa \alpha \geq r - \kappa \tilde{h}(\alpha) = r - \kappa \frac{2\alpha - 1}{(\alpha - 1)^2} \geq 0, \]
which completes the proof.

In Fig. 2, the curve \(z = \frac{2\alpha - 1}{(\alpha - 1)^2}\) is plotted in green. The region above this curve, which is easy to verify, can guarantee (13) feasible.

\section{B. Heading Adjustment Strategy for Non-IO}

In many cases, the state \(X\) does not satisfy IO, because it is highly likely that \(P\) is moving along a direction different from the interception angle \(\theta_I\) when starting to capture an evader. Next, we will discuss how to design controllers for pursuer \(P\) such that it can steer a given state \(X\) under the model (1) and (2), respectively. Let a Non-IO state \(X\) such that \(\|x_p - x_E\|_2\) is sufficiently large but finite. If \(P\) adopts the feedback strategy
\[ u_p = \begin{cases} \text{sgn}(\sin(\theta_I - \theta_P)), & \text{if } |\theta_I - \theta_P| \neq \pi, \\ -1, & \text{otherwise}, \end{cases} \tag{20} \]
then the IO will hold after a finite time, regardless of \(E\)'s control input \(u_E \in \mathbb{S}^1\), if the parameters \((r, \kappa, \alpha)\) satisfy
\[ \frac{r}{\kappa} > \frac{(\alpha + 1)^2}{\alpha(\alpha - 1)} \tag{21} \]

\textbf{Theorem 3} (Heading adjustment strategy). Consider \(P \in \mathcal{P}\) and \(E \in \mathcal{E}\) under the model (1) and (2), respectively. Let a Non-IO state \(X\) such that \(\|x_p - x_E\|_2\) is sufficiently large but finite. If \(P\) adopts the feedback strategy
\[ u_p = \begin{cases} \text{sgn}(\sin(\theta_I - \theta_P)), & \text{if } |\theta_I - \theta_P| \neq \pi, \\ -1, & \text{otherwise}, \end{cases} \tag{20} \]
then the IO will hold after a finite time, regardless of \(E\)'s control input \(u_E \in \mathbb{S}^1\), if the parameters \((r, \kappa, \alpha)\) satisfy
\[ \frac{r}{\kappa} > \frac{(\alpha + 1)^2}{\alpha(\alpha - 1)}. \tag{21} \]
Then, substituting the above conditions into (23) leads to
\[
\dot{q} = \frac{1}{\|x_I - x_P\|_2} \left\{ \frac{v_P u_P}{K} (x_I - x_P)^\top e_\theta + \frac{\alpha^2 v_E u_E^\top e_\theta}{\alpha^2 - 1} - \frac{\alpha^2 v_P}{\alpha^2 - 1} + \frac{\alpha \sin \theta_P (x_I - x_P)^\top (v_E u_E - v_p e_\theta)}{\|x_I - x_P\|_2^2} \right\}.
\]
where \(\gamma \in [0, 2\pi]\) and \(\delta \in [0, 2\pi]\) are two angles given by
\[
\cos \gamma = \frac{x_P - x_E}{\|x_P - x_E\|_2}, \quad \sin \gamma = \frac{y_P - y_E}{\|x_P - x_E\|_2},
\]
\[
\cos \delta = u_E^\top, \quad \sin \delta = u_E^\top_e,
\]
and the part \(s(\theta_P, \theta_I, \gamma, \delta)\) is as follows
\[
s(\theta_P, \theta_I, \gamma, \delta) = \frac{\alpha v_E \cos (\theta_P - \gamma) - \alpha v_P + v_E \sin \theta_P \cos (\gamma - \delta)}{\|x_P - x_E\|_2} - v_P \sin \theta_P \cos (\theta_I - \gamma) - \alpha v_E \cos \theta_P \cos (\gamma - \delta) + \alpha v_P \sin \theta_P \cos (\theta_I - \theta_P) \cos (\gamma - \delta) + v_P \sin \theta_P \cos (\theta_I - \theta_P) \cos (\gamma - \delta) = v_P \sin (\theta_I - \theta_P) \sin (\theta_I - \gamma) - \alpha \sin (\theta_I - \theta_P) = - \frac{1}{\alpha} \cos \theta_I \cos (\gamma - \delta) + \cos \theta_I \cos (\gamma - \theta_P),
\]
where \(\dot{s}(\theta_P, \theta_I, \gamma, \delta) := \sin (\theta_I - \delta) - \alpha \sin (\theta_I - \theta_P) - \frac{1}{\alpha} \cos \theta_I \cos (\gamma - \delta) + \cos \theta_I \cos (\gamma - \theta_P).\) From the above equation, \(\dot{s}(\theta_P, \theta_I, \gamma, \delta)\) has the following bound
\[
\left\| \dot{s}(\theta_P, \theta_I, \gamma, \delta) \right\| = \left\| \sin (\theta_I - \delta) - \alpha \sin (\theta_I - \theta_P) - \frac{1}{\alpha} \cos \theta_I \cos (\gamma - \delta) + \cos \theta_I \cos (\gamma - \theta_P) \right\| 
\leq (1 + \alpha + \frac{1}{\alpha} + 1) \frac{(\alpha + 1)^2}{\alpha}. \tag{25}
\]
There are two cases depending on if \(\sin(\theta_I - \theta_P) = 0\) holds.

**Case 1:** Consider that \(\sin(\theta_I - \theta_P)\) is nonzero. If \(P\) adopts the feedback strategy (20), it follows from (24) and (25) that
\[
\dot{q} \geq \frac{v_P |\sin (\theta_I - \theta_P)|}{\|x_I - x_P\|_2} \left( \left\| x_I - x_P \right\|_2 \frac{\alpha}{\alpha^2 - 1} \right) - \frac{\alpha}{\alpha^2 - 1} \left| \dot{s}(\theta_P, \theta_I, \gamma, \delta) \right| \tag{26}
\]
Furthermore, for any \(x_P\) and \(x_E\) satisfying \(\|x_P - x_E\|_2 > r\), by (6), \(\|x_I - x_P\|_2^2\) has the following bound
\[
\|x_I - x_P\|_2^2 \geq \frac{\alpha^4 + \alpha^2}{(a - 1)^2} \left\| x_P - x_E \right\|_2^2 - \frac{2\alpha^3 (y_P - y_E)}{(a - 1)^2} \left\| x_P - x_E \right\|_2 + \frac{2\alpha^3}{(a - 1)^2} \left( x_E - x_E \right) \left\| x_P - x_E \right\|_2^2 > \frac{\alpha^2}{(a + 1)^2} \|x_P - x_E\|_2^2 \cdot c_{\text{min}}^2 (\|x_I - x_P\|_2) \geq 0,
\]
holds for all \(q \in [0, 2\pi]\), as long as \(\sin(\theta_I - \theta_P)\) is nonzero and \(\|x_P - x_E\|_2 > r\), where \(c_{\text{min}} > 0\).

Note that as \(\theta_I - \theta_P \to 0\), then \(1 - q \to 0\) and \(\dot{q} \to 0\) hold. Define \(x_I = \theta_I - \theta_P\) and \(V(x) = 1 - q = 1 - \cos(x)\). Then, for any \(x \in (-\pi, 2\pi/\alpha)\), we have
\[
V(x) = \dot{q} \leq -c_{\text{min}} |\sin(x)| \leq -\frac{2c_{\text{min}}}{\pi} |x| \leq -\frac{2c_{\text{min}}}{\pi} \sqrt{V(x)}.
\]
It follows from [2, Theorem 4.2] that \(x = 0\) is a finite-time-stable equilibrium. Therefore, \(q = 1\) can be reached within a finite time.

**Case 2:** If \(\sin(\theta_I - \theta_P) = 0\), then \(\theta_I - \theta_P\) is valid. Note that (24) implies that \(q = 0\). Furthermore, we take u_p = -1 as in (20). According to (24) and the bound (25), the second-order term derivative of \(q\) at this point is
\[
\dot{q} |_{\theta_I - \theta_P = \pi} = -\frac{1}{\|x_I - x_P\|_2^2} \left( \frac{v_P u_P}{K} \|x_I - x_P\|_2 + \frac{\alpha v_P}{\alpha^2 - 1} \dot{s}(\theta_P, \theta_I, \gamma, \delta) \right) \geq \frac{v_P |\sin (\theta_I - \theta_P)|}{\|x_I - x_P\|_2} \left( \frac{\alpha}{\alpha + 1} \right) \left( \frac{\alpha}{\alpha + 1} \right) \geq 0.
\]
Therefore, \(X\) will deviate from \(\theta_I - \theta_P = \pi\) as time goes by, combing back to Case 1. Thus, we complete the proof. 

Theorem 3 shows that if \(P\) and \(E\) are far from each other initially, then the heading adjustment strategy (20) can steer a Non-IO state \(X\) to achieve IO within a finite time, no matter what strategy the evader adopts. Thus, the Non-IO case becomes the IO case for which we have proposed a pursuit winning strategy. In Fig. 2, the curve \(r = \frac{(\alpha + 1)^2}{\alpha (\alpha - 1)}\) is plotted in blue, and the region above this curve can sufficiently guarantee the transfer from the Non-IO to the IO via strategy (20) within a finite time.
C. Pursuit Winning Strategy for SC and Non-IO

Now, we will present the pursuit winning strategy when the state $X$ satisfies SC but does not satisfy IO, by merging the strategies proposed in Sections IV-A and IV-B.

Suppose that the pursuer $P$ adopts the strategy (20) aiming to reach IO, while the evader $E$ strives to put the interception point when $q = 1$ (i.e., the IO holds), at a position having a minimum signed distance to $T$, because once the IO is achieved, the distance between the interception point and $T$ decides the game winner (i.e., whether the SC holds), as Theorem 2 shows. Formally, the terminal set $Ψ$ and payoff function $J$ respectively are

$$Ψ = Ψ_1 \cup Ψ_2, \quad J = ρ_T(x_f(t_f)),$$

(27)

where $Ψ_1 = \{X \mid θ_P = θ_1\}$, $Ψ_2 = \{X \mid ∥x_P - x_E∥_2 \leq r\}$, and the terminal time $t_f \in \mathbb{R}_{\geq 0}$ is defined as the time instant when the state $X$ enters $Ψ$. Suppose that (21) holds. Then, $t_f$ is finite, because Theorem 3, if $P$ and $E$ are close to each other, $E$ will be captured before achieving IO.

**Lemma 2 (Optimal evasion control).** Consider the optimal control problem (1), (2), and (27). The optimal control of the evader $E$ is constant and the optimal evasion trajectory is a straight line.

**Proof.** The Hamiltonian associated with this problem is

$$\mathcal{H} = λ_1 v_P \cos θ_P + λ_2 v_P \sin θ_P + λ_3 v_P u_P / κ + λ_4 v_E w_E + λ_5 v_E u_E^p,$$

where $λ_i \in \mathbb{R}$ $(i = 1, 2, \ldots, 5)$ is the Lagrange multiplier, and $u_P = 1$ or $−1$. The optimal control $u_E^∗ = [u_E^∗, u_E^p]^T$ satisfies

$$u_E^∗ = \arg \min_{u_E \in S^1} \mathcal{H} = \left[ \frac{−λ_4}{\sqrt{λ_2^2 + λ_5}}, \frac{−λ_5}{\sqrt{λ_3^2 + λ_5}} \right]^T.$$

The costate equations with respect to $λ_4$ and $λ_5$ are

$$−λ_4 = \frac{∂N}{∂x_E}, \quad −λ_5 = \frac{∂N}{∂y_E} = 0.$$

Thus, $u_E^∗$ is constant, as $λ_4$ and $λ_5$ are both constant. Furthermore, the optimal trajectory of $E$ is a straight line, which completes the proof.

Since the optimal control of the evader $E$ is constant, the optimal control problem (1), (2), and (27) can be reformulated as the following optimization problem.

**Problem 1 (Minimal signed distance to $T$).** For any state $X(t) = (x_P, θ_P, x_E)$, define $ρ_T(X)$ be the optimal value of the problem

$$\begin{align*}
\text{minimize} & \quad \rho_T(x_T(θ_E)) \\ \text{variables} & \quad θ_E \in [0, 2π),\ t \in [t, +∞) \\ \text{subject to} & \quad X_T(θ_E) \in Ψ, \\ & \quad \ X_s(θ_E) \notin Ψ, \quad ∀ t \leq s < τ,
\end{align*}$$

(28a-28d)

where for every $s \in [t, τ],$

$$\begin{align*}
x_P^+ &= x_P + v_P(s - t)[\cos θ_E, \sin θ_E]^T, \\
x_E^+ &= x_E + v_E(s - t)[\cos θ_E, \sin θ_E]^T, \\
θ_P^+ &= θ_P + \frac{v_P(s - t)\sin(θ_1 - θ_P)}{κ}, \\
θ_E^+ &= θ_E + \frac{v_E(s - t)\sin(θ_1 - θ_P)}{κ}, \\
κ &= \sin(θ_1 - θ_P), \\
κ &= \cos(θ_1 - θ_P), \\
γ^+ &= \left[0, -\frac{α(∥x_P^+ - x_E∥_2)}{α^2 - 1}\right]^T,
\end{align*}$$

(28e-28h)

If the problem is infeasible, we define $ρ_T(X) = +∞.$

Since $P$ adopts the strategy (20), then it moves along (29b) and (29c), where $(x_P^+, θ_P^+)$ is the state of $P$ at time $s$ starting from $(x_P, θ_P)$ at time $t$. Suppose that $E$ follows the strategy corresponding to the solution to the optimal control problem (1), (2), and (27). According to Lemma 2, the optimal control is constant. Thus, $E$ moves along (29a) if $θ_E$ is the optimal heading angle, where $x_E^+$ is the state of $E$ at time $s$ starting from $x_E$ at time $t.$ Note that (29d)-(29f) are the computations of $x_s(θ_E)$ and $X_s(θ_E)$ by $x_P^+, θ_P^+$ and $x_E^+.$ If the system state hits $Ψ_1$ before $Ψ_2,$ then $τ^*$ is $P$’s heading adjustment time.

Next, we relate the optimal value to Problem 1 with the outcomes when $P$ adopts the heading adjustment strategy.

**Lemma 3 (Function of the optimal value).** For any state $X$, let $(θ_E^∗, τ^∗)$ be an optimal solution to Problem 1 when $ρ_T(X) < +∞.$ If (21) holds and $P$ adopts the strategy (20), then

(i) if $ρ_T(X) < 0,$ then by strategy $u_E = [\cos θ_E^∗, \sin θ_E^∗]^T,$ there exists a time instant $s \in [t, τ^∗]$ at which the SC fails before achieving IO or the capture;

(ii) if $0 \leq ρ_T(X) < +∞,$ then there exists a finite time instant $s \in [t, +∞)$ at which the SC holds, and furthermore IO holds or $E$ is captured, regardless of $E$’s strategy;

(iii) if $ρ_T(X) = +∞,$ then $X \in Ψ,$ that is, at time $t$, the IO holds or $E$ is captured by $P.$

**Proof.** The constraints (28c) and (28d) are feasible if and only if $X \notin Ψ,$ i.e., $X_t(θ_E) \notin Ψ,$ because the strategy (20) can always steer $X_T(θ_E)$ into $Ψ_1$ within a finite time, even if $X_T(θ_E)$ does not enter $Ψ_2.$ Thus, if $ρ_T(X) = +∞,$ we have $X \notin Ψ,$ implying that (iii) is straightforward.

Regarding (i), $ρ_T(X) < 0$ implies that if $E$ adopts the strategy $u_E = [\cos θ_E^∗, \sin θ_E^∗]^T,$ then it can steer $x_s(θ_E)$ into $Ω_{goal}$ before $X_s(θ_E)$ getting into $Ψ.$ Thus, the conclusion is obtained.

Regarding (ii), $ρ_T(X) < +∞$ implies that no matter what strategy $E$ adopts, $P$ can steer $X_s(θ_E)$ into $Ψ$ at a time instant $s \in [t, τ^∗]$, i.e., either $E$ is captured or the IO is satisfied. Additionally, $ρ_T(X) \geq 0$ means that the SC still holds at the time instant $s.$

Although the optimal value to Problem 1 is attractive, it is hard to compute it directly due to the infinite constraints and the non-convexity. We next present an approximation solution to Problem 1, thus providing a sufficient condition for the
pursuer’s winning. We first give a nontrivial upper bound of the heading adjustment time.

Lemma 4 (Heading adjustment time, upper bound). Let a state \(X = (x_P, \theta_P, x_E)\) satisfying the following conditions:

(i) \(\|x_P - x_E\|_2 > r\);
(ii) \(\theta_P \neq \theta_I\);
(iii) \(\|x_C - x_E\|_2 > \nu_P \Delta(X)/\sqrt{\alpha^2 - 1}\). The variables satisfy \(x_C = [x_C, y_C]^T = x_P + \kappa \kappa [\cos(\theta_C, \sin(\theta_C)]^T, \theta_C = \theta_2 + \frac{\pi}{2} \theta_2 \sin(\theta_I - \theta_P), \text{and}

\[
\Delta(X) = \frac{[\theta_{E} - \theta_C - \pi] \sin(\theta_I - \theta_P) + 2 \pi n \|\|}{v_P},
\]

where \(\theta_2 \in [0, 2\pi)\) is given by \(\cos(\theta_2, \sin(\theta_2)) = \frac{x_2 - x_2}{\|x_2 - x_2\|_2}\) and \(n\) is the unique non-negative integer such that \(\Delta(X) \in (0, 2\pi \nu_P/v_P)\) holds.

If (21) holds, for any optimal solution \((\theta^*_E, \tau^*)\) to Problem 1, we have \(t \leq \tau^* \leq t + \Delta(X)\).

Proof. Note that \(X\) satisfies conditions (i) and (ii), so the value of \(\theta(\theta_I - \theta_P)\) can be determined. Without loss of generality, let \(\sin(\theta_2, \theta_2) = -1\), i.e., \(P\) turns in the clockwise direction as Fig. 4 shows. Thus, \(P\) moves along a circular orbit \(C_1 = \{x \in \mathbb{R}^2 | \|x - x_C\|_2 = \kappa \}\) where \(x_C = x_P + \kappa \kappa [\cos(\theta_2 - \frac{\pi}{2})] + \sin(\theta_2 - \frac{\pi}{2})\). According to the condition (iii) in Lemma 3, Problem 1 is feasible, because \(X \notin \Psi\) under the conditions (i) and (ii). Let \((\theta^*_E, \tau^*) \in [0, 2\pi) \times [t, +\infty)\) be any optimal solution to Problem 1.

Let \(x_A\) be the projection of \(x_E\) on the orbit \(C_1\) in Fig. 4. For \(P\), the time of moving from \(x_P\) to \(x_A\) along \(C_1\) is

\[
\Delta(X) = \frac{[\theta_{E} - \theta_C - \pi] \sin(\theta_I - \theta_P) + 2 \pi n \|\|}{v_P} > 0,
\]

where \(\theta_2 \in [0, 2\pi)\) is the angle of \(x_2 - x_2\) and \(n\) is the unique non-negative integer such that \(\Delta \in (0, 2\pi \nu_P/v_P)\) holds. Additionally, \(\Delta > 0\) is because \(X \notin \Psi\) and \(P\) turns in the clockwise direction. When \(P\) reaches \(x_A\), \(E\)'s extreme position could be any point on the circle \(C_2 = \{x \in \mathbb{R}^2 | \|x - x_E\|_2 = \nu_P \Delta\}\), depending on the value of \(\theta_2\). Let \(x_P^+ = [x_P^+, y_P^+] \in C_2\) and \(x_P^+ = x_A\) be \(E\)'s and \(P\)'s positions at time \(t + \Delta\), respectively. Thus, the closure of the ER at time \(t + \Delta\) is

\[
\mathbb{E}(t + \Delta) = \{x \in \mathbb{R}^2 | \|x - x_E^+\|_2 = \kappa + y_P^+\}
\]

Note that the condition (iii) implies that \(\|x_C - x_E\|_2 > \kappa\), i.e., \(x_E\) lies out of \(C_1\). For simplicity of description, we build a local Cartesian coordinate system with \(x_A\) as the origin, the tangent line of \(C_1\) at \(x_A\) as the \(x\)-axis, and \(x_E - x_A\) as the \(y\)-axis. In the local coordinate system, we have \(x_P^+ = 0\) and \(y_E = [0, y_E]^T\) with \(y_E > 0\). Thus, for any given \(x_E^+ \in C_2\), the minimal \(y\)-coordinate of points on \(\mathbb{E}(t + \Delta)\) is

\[
\min_{x \in \mathbb{E}(t + \Delta)} y = \frac{\alpha^2 y_E^2 - y_P^2}{\alpha^2 - 1} = \frac{\alpha^2 - 1}{\alpha^2 - 1} \frac{\|x_P^+ - x_E^+\|_2}{\alpha^2 - 1} = \frac{\alpha^2 - 1}{\alpha^2 - 1} \frac{\|x_P^+ - x_E^+\|_2}{\alpha^2 - 1}
\]

(31)

We consider a function \(h_2(y_E^+) = \alpha^2(y_E^2)^2 - 2\nu_E y_E^+ + y_E^2 - \nu_E^2 \Delta^2\) in \(y_E^+\). Then, we have

\[
\min_{x \in \mathbb{E}(t + \Delta)} y > 0 \iff y_E^+ \geq 0, h_2(y_E^+) > 0.
\]

(32)

Next we analyze the minimal value of \(h_2(y_E^+)\). Since \(x_E^+ \in C_2\), then \(y_E^+ \in [y_E - \nu_E \Delta, y_E + \nu_E \Delta]\). Thus, if \(\alpha^2 - 1)(y_E - \nu_E \Delta) \geq \nu_E \Delta^2\), then

\[
\min_{x \in \mathbb{E}(t + \Delta)} h_2(y_E^+) = h_2(y_E - \nu_E \Delta) = \frac{\alpha^2 - 1)(y_E - \nu_E \Delta)^2}{\alpha^2 - 1} - \nu_E \Delta^2.
\]

(33)

If \(\alpha^2 - 1)(y_E - \nu_E \Delta) \geq \nu_E \Delta^2\), then

\[
\min_{x \in \mathbb{E}(t + \Delta)} y > 0 \iff y_E \geq \frac{\alpha v_E \Delta}{\sqrt{\alpha^2 - 1}}.
\]

(35)

Since \(y_E^+ \in [y_E - \nu_E \Delta, y_E + \nu_E \Delta]\), we have

\[
\min_{x \in \mathbb{E}(t + \Delta)} y > 0 \iff y_E \geq \nu_E \Delta.
\]

(36)

Thus, by (31), (32), (35) and (36), the minimal \(y\)-coordinate of points on \(\mathbb{E}(t + \Delta)\) for all \(x_E^+ \in C_2\), is positive, i.e.,

\[
\min_{x \in \mathbb{E}(t + \Delta)} y > 0,
\]

(37)

if and only if

\[
\|x_C - x_E\|_2 = \kappa + y_E > \kappa + \frac{\alpha v_E \Delta}{\sqrt{\alpha^2 - 1}}
\]

that is, the condition (iii) holds.

Let \(\theta_2^+ \in [0, 2\pi)\) and \(\theta_2^+ \in [0, 2\pi)\) be \(P\)'s heading and interception angle at time \(t + \Delta\), respectively. Note that (37) implies that for any \(\theta_2 \in [0, 2\pi)\), the interception point \(x_I\) at time \(t + \Delta\) lies at the left side of \(\theta_2^+\). Thus, \(\sin(\theta_2^+ - \theta_2^+) = 1\), that is, \(P\) needs to turn in the counterclockwise direction. According to the continuity of \(\theta_2 - \theta_2\) in time \(t\), there exists a time \(s \in [t, t + \Delta]\) such that \(\theta_2 = \theta_2\) at time \(s\). Thus, for any optimal solution \((\theta_2, \tau^*) \in [0, 2\pi) \times [t, +\infty)\), we have \(t \leq \tau^* \leq t + \Delta\), which completes the proof.

According to Lemma 4, if the pursuer \(P\) swerves with the minimum turning radius and toward the direction given by the heading adjustment strategy (20), then at time \(t\), the pursuer will achieve an upper bound of the heading adjustment time.
constant. Thus, the conclusion is obtained. Objective functions between Problems 1 and 2 is a positive positions for the constraint in Problem 2 allows two larger sets of reachable Proof. Regarding (i), Lemma 4 has proved that the IO will be satisfied before the heading adjustment strategy (20). It is proved that under certain conditions, the IO will be satisfied before P reaches x_A, where x_A is the point on C_1 closest to x_E. The circle C_2 is the set of E’s possible positions under maximal constant evasion controls when P reaches x_A. capture E before coming back to its starting position. In other words, P needs at most one period to achieve IO or capture E. Based on this characteristic, we next introduce a simpler optimization problem, which is a relaxation of Problem 1. **Problem 2** (Minimal signed distance to T, lower bound). For any state X = (x_p, \theta_p, x_E), define \hat{\rho}_T(X) be the optimal value of the problem

\begin{align*}
\text{minimize} & \quad (\alpha^2 - 1)\rho_T(x^+_i) \\
\text{variables} & \quad x^+_p \in \mathbb{R}^2, x^+_E \in \mathbb{R}^2 \\
\text{subject to} & \quad \|x^+_E - x^+_E\|_2 \leq \frac{2\pi \kappa}{\alpha}, \\
& \quad \|x^+_p - x^+_C\|_2 \leq \kappa, \\
& \quad \forall \alpha \in [0, \infty), \\
& \quad x^+_p = \frac{\alpha^2 x^+_E - x^+_C + \Upsilon^+}{\alpha^2 - 1}, \\
& \quad x^+_E = \frac{\alpha^2 x^+_E - x^+_C + \Upsilon^+}{\alpha^2 - 1},
\end{align*}

where \( \lambda \in \mathbb{R}_{>0} \) is the solution of the sextic equation

\begin{align*}
k_0 \alpha^6 + k_5 \alpha^5 + k_4 \alpha^4 + k_3 \alpha^3 + k_2 \alpha^2 + k_1 \alpha + k_0 &= 0, \quad (39)
\end{align*}

which is parameterized by

\begin{align*}
k_0 &= \|x_C - x_E\|^2, \\
k_5 &= \kappa(4\pi + 2)(y_C - y_E), \\
k_4 &= (2\pi + 1)^2 \kappa^2 - 2(1 + \alpha^2) \|x_C - x_E\|^2, \\
k_3 &= \kappa(8\pi + 4)(1 + \alpha^2)(y_E - y_C), \\
k_2 &= (1 + \alpha^2)^2(x_E - x_C)^2 + (1 - \alpha^2)(y_E - y_C)^2 - 2\kappa(2\pi + 1)^2(1 + \alpha^2), \\
k_1 &= \kappa(4\pi + 2)(1 - \alpha^2)^2(y_E - y_C), \\
k_0 &= k^2(2\pi + 1)^2(1 - \alpha^2)^2.
\end{align*}

Proof. The Lagrangian function for Problem 2 is

\begin{align*}
\mathcal{L}(x^+_p, x^+_E, \lambda_1, \lambda_2) &= \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_C\|_2 \\
&\quad + \lambda_1(\|x^+_E - x^+_C\|_2 - \frac{2\pi \kappa}{\alpha}) + \lambda_2(\|x^+_E - x^+_C\|_2 - \kappa),
\end{align*}

where \( \lambda_i \in \mathbb{R} \) \((i = 1, 2)\) is the Lagrange multiplier. Let \((x^+_p, x^+_E)\) be an optimal solution to Problem 2, leading to the optimal value \( \hat{\rho}_T(X) = \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_C\|_2 \). In view

Regarding (ii), note that (38c) and (38d) are independent and both convex. Thus, the constraint set is convex. The objective function (38a) can be rewritten as

\begin{align*}
(\alpha^2 - 1)\rho_T(x^+_i) &= \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_C\|_2,
\end{align*}

which is concave on the interval \((x^+_p, x^+_E) \in \mathbb{R}^2 \times \mathbb{R}^2\). Thus, Problem 2 is a non-convex.

Regarding (iii), it directly follows from (i) and the conclusion (ii) in Lemma 3.

Next, the non-convex Problem 2 is addressed by a sextic equation which can be solved more efficiently.

**Theorem 4** (Solution to Problem 2). Let a state \( X = (x_p, \theta_p, x_E) \) such that the conditions (i)-(iii) in Lemma 4 are true. Let \( \sigma = \text{sgn}(x_C - x_E) \). Then

(i) if \( (x^+_p, x^+_E) \) is an optimal solution to Problem 2, then \( \text{sgn}(x^+_p - x_C) = \text{sgn}(x^+_E - x_C) = \text{sgn}(x^+_p - x_E) = \sigma \); (ii) the optimal value to Problem 2 is

\begin{align*}
\hat{\rho}_T(X) &= \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_C\|_2,
\end{align*}

and the optimal solution \((x^+_p, x^+_E)\) is

\begin{align*}
x^+_p &= x_C + \frac{\sigma \kappa}{2\lambda} \sqrt{2(1 + \alpha^2)\lambda^2 - \lambda^4 - (1 - \alpha^2)^2}, \\
y^+_p &= y_C + \frac{1 - \alpha^2 + \lambda^2}{2\lambda} \kappa, \\
x^+_E &= x_E - \frac{\sigma \pi \kappa}{\alpha^2 \lambda} \sqrt{2(1 + \alpha^2)\lambda^2 - \lambda^4 - (1 - \alpha^2)^2}, \\
y^+_E &= y_E + \frac{1 - \alpha^2 - \lambda^2}{\alpha^2 \lambda} \kappa,
\end{align*}

where \( \lambda \in \mathbb{R}_{>0} \) is the solution of the sextic equation

\begin{align*}
k_0 \lambda^6 + k_5 \lambda^5 + k_4 \lambda^4 + k_3 \lambda^3 + k_2 \lambda^2 + k_1 \lambda + k_0 &= 0, \quad (39)
\end{align*}

Proof. The Lagrangian function for Problem 2 is

\begin{align*}
\mathcal{L}(x^+_p, x^+_E, \lambda_1, \lambda_2) &= \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_C\|_2 \\
&\quad + \lambda_1(\|x^+_E - x^+_C\|_2 - \frac{2\pi \kappa}{\alpha}) + \lambda_2(\|x^+_E - x^+_C\|_2 - \kappa),
\end{align*}

where \( \lambda_i \in \mathbb{R} \) \((i = 1, 2)\) is the Lagrange multiplier. Let \((x^+_p, x^+_E)\) be an optimal solution to Problem 2, leading to the optimal value \( \hat{\rho}_T(X) = \alpha^2 y^+_E - y^+_p - \alpha \|x^+_p - x^+_E\|_2 \). In view

Fig. 4: An upper bound of the heading adjustment time such that the IO is satisfied, when the initial state \((x_p, \theta_p, x_E)\) is Non-IO. The pursuer \( P \) at \( x_p \) swerves along the circle \( C_1 \) with the minimum turning radius \( \kappa \) and center \( x_C \), toward the direction given by the heading adjustment strategy (20). It is proved that under certain conditions, the IO will be satisfied before \( P \) reaches \( x_A \), where \( x_A \) is the point on \( C_1 \) closest to \( x_E \). The circle \( C_2 \) is the set of \( E \)’s possible positions under maximal constant evasion controls when \( P \) reaches \( x_A \).
of the condition (ii) in Lemma 5, \((x^*_p, x^*_e)\) lies at the boundary of the constraint set. The KKT condition for Problem 2 is
\[
0 = \frac{\partial L}{\partial x^*_E} = \alpha \frac{x^*_p - x^*_E}{\|x^*_p - x^*_E\|^2} + \lambda_1 \frac{x^*_E - x_E}{\|x^*_E - x_E\|^2}, \tag{40a}
\]
\[
0 = \frac{\partial L}{\partial y^*_E} = \alpha \frac{\tilde{y}_p - y^*_E}{\|\tilde{y}_p - y^*_E\|^2} + \lambda_2 \frac{y^*_E - y_E}{\|y^*_E - y_E\|^2}, \tag{40b}
\]
\[
0 = \frac{\partial L}{\partial x^*_p} = \alpha \frac{x^*_p - x_p}{\|x^*_p - x_p\|^2} + \lambda_3 \frac{y^*_E - y_E}{\|y^*_E - y_E\|^2}, \tag{40c}
\]
\[
0 = \frac{\partial L}{\partial y^*_p} = \alpha \frac{y^*_p - y_p}{\|y^*_p - y_p\|^2} + \lambda_4 \frac{y_p - y_E}{\|y_p - y_E\|^2} - 1, \tag{40d}
\]
and
\[
\|x^*_E - x_E\|^2 = \frac{2\pi \kappa}{\alpha}, \quad \|x^*_p - x_p\|^2 = \frac{2\pi \kappa}{\alpha}, \tag{41}
\]
The reason for \(\lambda_1 \neq 0\) and \(\lambda_2 \neq 0\) is as follows. By \(40b\), we have \(\lambda_1 \neq 0\). If \(\lambda_2 = 0\), then \(40c\) and \(40d\) lead to the contraction that \(\text{sgn}(y^*_E - y_p)\alpha = 1\).

Regarding (i), consider the case \(\sigma = \text{sgn}(x_C - x_E) = 1\), i.e., \(x_C > x_E\) first. If \(x^*_p = x_C\), then it follows from \(40a\) and \(40c\) that \(x_C = x_E\). Thus, we have \(x^*_p \neq x_C\).

Assume that \(x^*_p < x_C\). Let \(\tilde{x}_p = [\tilde{x}_p, \tilde{y}_E]^{\top} = [2x_C - x^*_p, y^*_E]^{\top}\) and \(\tilde{x}_E = [\tilde{x}_E, \tilde{y}_E]^{\top} = [x_E - x_E - x^*_E, y^*_E]^{\top}\). Then, we have
\[
\|\tilde{x}_p - x_C\|^2 < \kappa, \quad \|\tilde{x}_E - x_E\|^2 < \kappa,
\]
and
\[
\tilde{x}_p - \tilde{x}_E = 2x_C - x^*_p - x_E + x_E - x^*_p
\]
\[
= |x_C - x_E| + |x_C - x^*_p| + |x_E - x^*_E|
\]
\[
\geq |x_C - x_E - x_C + x^*_E + x_E - x^*_E| = |x^*_p - x^*_E|
\]
\[
\Rightarrow \|\tilde{x}_p - \tilde{x}_E\|^2 > \|x^*_p - x^*_E\|^2.
\]
Thus, \((\tilde{x}_p, \tilde{x}_E)\) is a distinct feasible solution to Problem 2 and its induced value \(\tilde{\rho}\) satisfies
\[
\tilde{\rho} = \alpha^2 \tilde{y}_E - \tilde{y}_p - \alpha \|\tilde{x}_p - \tilde{x}_E\|^2
\]
\[
= \rho_T(X) + \alpha \|x^*_p - x^*_E\|^2 - \alpha \|\tilde{x}_p - \tilde{x}_E\|^2 < \rho_T(X),
\]
which contradicts with the fact that \(\rho_T(X)\) is the optimal value. Therefore, \(x^*_p > x_C\) holds, i.e., \(\text{sgn}(x^*_p - x_C) = \sigma\).

As for the case \(\sigma = \text{sgn}(x_C - x_E) = -1\), the conclusion can be verified similarly.

Next, consider the case \(\sigma = \text{sgn}(x_C - x_E) = 0\), i.e., \(x_C = x_E\). Suppose that \(x^*_p \neq x_C\). Without loss of generality, let \(x^*_p > x_C\). Then, according to \(40a\) and \(40c\), we obtain that \(x^*_p > x_C > x^*_E\). Let a unit vector \(e = [e_1, e_2]^{\top}\) such that \((x^*_p - x^*_E)^{\top} e = 0\). Thus, we have \(e_2 = 0\). Furthermore, we select \(e_1\) such that starting from \(x_p\), \(e\) points into or is tangent with the constraint set of \(x_p\) such that \(x^*_p\) is feasible for \(x^*_p\) to move along the direction \(e\). By fixing \(x^*_E = x_E\), the directional derivative of the objective function \((38a)\) along the vector \(e\) at \(x^*_p\) is
\[
(\alpha^2 - 1)\nabla \rho_T(x^*_p)^{\top} e = \alpha (x^*_E - x^*_p)^{\top} e \|x^*_p - x^*_E\|^2 - e_2 = -e_2 \neq 0,
\]
which conflicts with the optimality of \((x^*_p, x^*_E)\). Therefore, we have \(x^*_p = x_C\), i.e., \(\text{sgn}(x^*_p - x_C) = \sigma\).

By following the same arguments, we also have \(\text{sgn}(x_E - x^*_E) = \sigma\). It follows from \(\text{sgn}(x^*_E - x^*_C) = \text{sgn}(x_E - x^*_E) = \text{sgn}(x_C - x_E) = \sigma\) that \(\text{sgn}(x^*_E - x^*_E) = \sigma\) holds.

Regarding (ii), we solve the solution \((x^*_p, x^*_E, \lambda_1, \lambda_2)\) to \((40)\) and \((41)\). Combining \((40a), (40b)\) and \((41)\) leads to
\[
(40a)^2 + (40b)^2 = y^*_E = y_E + \frac{(\alpha^2 - \alpha^2 - \lambda^2_1)\pi \kappa}{\alpha^3 \lambda_1}, \tag{42}
\]
and combining \((40c), (40d)\) and \((41)\) leads to
\[
(40c)^2 + (40d)^2 = y^*_p = y_C + \frac{(1 - \alpha^2 + \lambda^2_2)\kappa}{2 \lambda_2}. \tag{43}
\]
Furthermore, it follows from \((40b), (40d)\) and \((41)\) that
\[
\lambda_1(40a) + (40c) \Rightarrow x^*_E = x_E - \frac{2\pi \lambda_2 (x^*_p - x_C)}{\lambda_1} \tag{45}
\]
\[
= x_E - \frac{\sigma \pi \kappa}{\alpha^2 \lambda_2} \lambda_1.
\]
Then, by \((40c), (41)\) and \((44)\), we obtain
\[
\frac{\lambda^2_2 (x^*_p - x_C)^2}{\|x^*_p - x^*_E\|^2} = \frac{\phi^2}{4} \Rightarrow (x^*_p - x^*_E)^2 (4 \alpha^2 - \phi^2) = (y^*_E - y^*_p)^2 \phi^2.
\]
Note that
\[
4 \alpha^2 - \phi^2 = 4 \alpha^2 - 2(1 + \alpha^2) \lambda^2_2 + \lambda^2_1 + (1 - \alpha^2)^2
\]
\[
= (1 + \alpha^2 - \lambda^2_2)^2.
\]
Thus, \((46)\) becomes
\[
\|x^*_p - x_E\|^2 = \|y^*_E - y^*_p\| \phi. \tag{47}
\]
Note that by \((43), (44)\) implies that
\[
\text{sgn}(y^*_E - y^*_p) = \text{sgn}(1 + \alpha^2 - \lambda^2_2).
\]
From the condition (i), we have \(\text{sgn}(x^*_p - x^*_E) = \sigma\). Thus, \((47)\) can be simplified as follows
\[
\sigma(x^*_p - x_E)(1 + \alpha^2 - \lambda^2_2) = (y^*_E - y^*_p) \phi
\]
\[
\Rightarrow \left(\left(\pi \kappa \lambda_2 - 2(\pi^2 + 1) \kappa\right) \phi = \sigma(x^*_p - x_C)(\lambda^2_1 - (1 + \alpha^2) \lambda_2),
\]
where \((42), (43), (44), (45)\) and \(\lambda_1 = \alpha \lambda_2\) are used. Substituting the expression of \(\phi\) into the above equation, we obtain that \(\lambda_2\) is a positive solution of the sextic equation \((39)\). Thus,
according to (42), (43), (44) and (45), the conclusion can be obtained.

Now we present the main result in this section, providing a pursuit winning strategy for SC and Non-IO, for which a sufficient and efficient capture condition is given.

**Theorem 5** (Pursuit winning strategy for SC and Non-IO). Consider \( P \in \mathcal{P} \) and \( E \in \mathcal{E} \) under the model (1) and (2), respectively. Let a state \( X = (x_P, \theta_P, x_E) \) such that

(i) \( X \) satisfies SC;

(ii) the conditions (i)-(iii) in Lemma 4 are true.

Then, if the parameters \((r, \kappa, \alpha)\) satisfy

\[
\frac{r}{\kappa} > \max \left\{ h(\alpha), \frac{(\alpha + 1)^2}{\alpha(\alpha - 1)} \right\},
\]

and the optimal value \( \hat{\rho}(X) \geq 0 \), then \( P \) can adopt the feedback strategy (20) such that the IO holds after a finite time, and afterwards \( P \) can adopt the feedback strategy (11) to guarantee \( \rho(\mathcal{F}, \Omega_{goal}) \geq 0 \) and (12), regardless of \( u_E \in S^1 \).

**Proof.** Note that \( X \) satisfies SC but does not satisfy IO. We propose a two-step strategy for the pursuer and give a sufficient condition to guarantee the winning under this strategy. The first step is to adjust its heading by the heading adjustment strategy (20) such that the IO holds after a finite time, as Fig. 3 shows. Then, the second step is to adopt the strategy (11) which has been proved to have the winning guarantee under some conditions when the SC and IO both hold. The key point in this two-step strategy is to determine whether the pursuer and the evader satisfy the pursuer’s winning conditions for the second step once the pursuer completes the first step. This question can be resolved by the solution of Problem 1, which is quite complex. We are able to find a lower bound of the optimal value of Problem 1 by solving a simpler Problem 2 for which we have proposed an efficient solution in Theorem 4.

Under this two-step strategy, the winning capture condition is straightforward by combining Theorems 2, 3 and the conclusion (iii) in Lemma 4.

**Remark 1.** Since Lemma 1 has provided an upper bound of \( h(\alpha) \), we can first check the following condition before (48):

\[
\frac{r}{\kappa} > \max \left\{ \frac{2\alpha - 1}{(\alpha - 1)^2}, \frac{(\alpha + 1)^2}{\alpha(\alpha - 1)} \right\},
\]

which is easy to verify. Furthermore, if \( \alpha \geq \alpha_0 \), the second part is the maximum; otherwise, the first part is the maximum, where \( \alpha_0 \in \mathbb{R}_{>0} \) is the unique positive solution of \( \alpha^3 - \alpha^2 - 1 = 0 \). If \( \alpha < \alpha_0 \) and the above condition fails, then we have to turn to the condition (48).

**V. Multiplayer Games**

We piece together the pairwise outcomes of all pursuers and evaders using maximum matching for the task assignment of pursuers as in [6], [27]. Then, a receding horizon pursuit strategy is proposed, allowing to capture more evaders as the game runs. This strategy is indeed useful because the cooperation among pursuers in the strategy level is not considered and thus a better matching may occur as the game evolves.

Let \( G = (\mathcal{P} \cup \mathcal{E}, \mathcal{E}) \) be an undirected bipartite graph consisting of two node sets \( \mathcal{P} \) and \( \mathcal{E} \), where \( \mathcal{E} \) is a set of edges. Denote by \( e_{ij} \) the edge connecting node \( P_i \in \mathcal{P} \) and node \( E_j \in \mathcal{E} \). An edge \( e_{ij} \in \mathcal{E} \) if and only if \( P_i \) can win against \( E_j \) by Theorems 2 or 5, depending on whether the IO is satisfied.

The receding horizon pursuit strategy is as follows. At time \( t \), the current states of all one-pursuer-one-evader subgames are used to construct the graph \( G \). Then, a maximum matching \( M \) of \( G \) is computed. Each pursuer in \( M \) is assigned to the matched evader, and adopts the guaranteed winning strategy (11) or the combination of (20) and (11), depending on whether the IO holds. The pursuers which are not matched in \( M \) will pursue one of unmatched evaders. Each player updates its position (and heading) after a small constant time step. The new states are then used to construct a new graph, and the process iterates until no evaders in \( \Omega_{goal} \).

**VI. Simulation Results**

To illustrate the proposed guaranteed winning strategies for pursuers in multiplayer reach-avoid games, a simulation of the game with five pursuers and five evaders is shown in Fig. 5. In the game, pursuers are modeled as Dubins cars (1) and evaders have simple-motion (2). We assume that all pursuers have the same minimum turning radius, capture radius and speed, and all evaders have the same speed. The strategies still apply to heterogeneous players. We consider the parameters \( r = 0.1, \kappa = 0.0625, v_P = 0.3 \) and \( \alpha = 0.3 \) which satisfy the parameter relations (13) and (48) for the case of SC and IO and the case of SC and Non-IO, respectively. The trajectories of the matched pursuer and evader are in the same color, with arrows indicating their moving directions. The dashed circles are the boundaries of the capture regions when the evaders are captured. The dash dot line is the minimum turning radius for \( P_1 \).

![Fig. 5: Simulation for a multiplayer game with five pursuers](image-url)
are the boundaries of the capture regions. The dash dot line is the minimum turning radius for \( P_1 \).

Three different cases are included in this example: (a) SC and IO; (b) SC and Non-IO; (c) no guaranteed pursuit winning initially but later have one. The pursuer-evader pairs \((P_3, E_3)\) and \((P_4, E_2)\) satisfy SC and IO in Theorem 2 initially, and each pursuer adopts the feedback strategy (11). The pairs \((P_1, E_4)\) and \((P_3, E_3)\) satisfy SC and Non-IO, as well as the conditions in Theorem 5 initially. Each pursuer adopts the two-step strategy in Theorem 5. Therefore, \( P_3, P_4, P_1 \) and \( P_3 \) can guarantee to win against the matched evaders. For the pair \((P_2, E_5)\), the conditions in Theorems 2 and 5 do not hold, so we cannot tell a guaranteed pursuit winning at this time. Thus, after the task assignment, \( P_2 \) and \( E_5 \) are unmatched. However, as \( P_2 \) adopts strategy (20) and the game evolves, the SC and IO with respect to \( E_5 \) are achieved at the place marked by black crosses. Afterwards, \( P_2 \) turns to the strategy (11) and finally captures \( E_5 \). The strategies of all evaders are selected randomly conditioned that each evader moves along a straight line and gets closer to the goal region \( \Omega_{\text{goal}} \).

VII. CONCLUSION

We presented an analytical approach to multiplayer Homicidal Chauffeur reach-avoid differential games in which pursuers protect a goal region from evaders. We considered Dubins-car pursuers and simple-motion evaders, which is a more accurate model and has broad applications. For the subgame with simple-motion pursuer, the proposed pursuit feedback strategy can guarantee the ER not close to the goal region if they are separate initially (i.e., the SC holds), thus leading to a pursuit winning. Based on it, if the SC holds, we proposed two feedback strategies for the Dubins-car pursuer in the IO and Non-IO cases respectively, and presented the respective conditions on player configurations and parameters to guarantee the pursuer’s winning. To ease the computation burden, an efficient sufficient condition on parameters for the pursuer’s winning in the IO case was given, and a relaxation problem which can be solved efficiently, was proposed to determine the pursuer’s winning sufficiently in the Non-IO case. A strategy for the pursuit team was proposed by piecing together the subgame outcomes with maximum matching and adopting the receding horizon method. Future work will involve reversed Homicidal Chauffeur reach-avoid games and distributed reach-avoid games.
