ENUMERATING MAGIC DISTINCT LABELLINGS OF THE CUBE

GUOCE XIN¹*, YINGRUI ZHANG² AND ZIHAO ZHANG³

Abstract. We find by applying MacMahon’s partition analysis that all magic labellings of the cube are of eight types, each generated by six basis elements. A combinatorial proof of this fact is given. The number of magic labellings of the cube is thus reobtained as a polynomial in the magic sum of degree 5. Then we enumerate magic distinct labellings, the number of which turns out to be a quasi-polynomial of period 720720. We also find the group of symmetry can be used to significantly simplify the computation.

Mathematic subject classification: Primary 05A19; Secondary 11D04; 05C78.

Keywords: magic labelling; group action; linear Diophantine equations; quasi-polynomials.

1. Introduction

Let G be a finite graph. A labelling of G is an assignment of a nonnegative integer (in \( \mathbb{N} \)) to each edge of G. A magic labelling of G with magic sum r is a labelling such that for each vertex v of G the sum of the labels of all edges incident to v is equal to r (loops are counted as incident only once). It is called a magic distinct labellings if all labels are distinct. Graphs with a magic labelling are also called magic graphs. Magic graphs were studied in great detail by Stanley in [5, 6] and Stewart in [7, 8].

In this paper, we study magic distinct labellings of the cube. The main difficulty lies in the “distinct” condition on the labels. The number of magic labellings of the cube has been enumerated to be a polynomial in the magic sum of degree 5 [1], but the distinct case turns out to be a quasi-polynomial of period 720720. Our starting point is a simple structure result for magic labellings, from which we are able to extract information about magic distinct labellings.

The cube is a well-known object with 8 vertices, 12 edges (and 6 faces which is irrelevant here), and each vertex has degree 3. See Figure 1, where we use numbers \{1,...,12\} to mark the 12 edges. Assume the \( i \)-th edge has label \( x_i \) for \( 1 \leq i \leq 12 \). The labelling is magic of magic sum r if and only if \( (\alpha, r) = (x_1, ..., x_{12}, r) \in \mathbb{N}^{13} \) is a solution to the following linear system.

\[
\begin{align*}
    x_1 + x_2 + x_9 &= r \\
    x_2 + x_3 + x_{10} &= r \\
    x_3 + x_4 + x_{11} &= r \\
    x_5 + x_6 + x_9 &= r \\
    x_5 + x_7 + x_{10} &= r \\
    x_6 + x_8 + x_{12} &= r \\
    x_7 + x_8 + x_{11} &= r
\end{align*}
\]

Denote by \( S_\mathbb{R} \) the set of \( \mathbb{R} \) solutions of the linear system (1), and by \( S_\mathbb{Z} = S_\mathbb{R} \cap \mathbb{Z}^{13} \) and similar for \( S_\mathbb{N} \). Then \( S_\mathbb{N} \) is just the set of magic labellings. Since \( r \) is determined by \( \alpha \), we will omit the \( r \) by saying that \( S_\mathbb{R} \subseteq \mathbb{R}^{12} \) when clear from the context.

Date: July 9, 2021.
By linear algebra, it is easy to see that $S_R$ is a subspace of $\mathbb{R}^{12}$ of dimension 6. There would be little problem to describe $S_Z$, since it forms a subgroup of $\mathbb{Z}^{12}$ and is hence a finitely-generated free abelian group. The number of generators of $S_Z$ is equal to 6, and there are well-known algorithm for finding the generators of $S_Z$ explicitly. The structure of $S_N$ is not so clear: it is only a monoid (semi-group with a unit).

**Question 1.** Can we decompose $S_N$ into some shifted free monoids? That is, can we find sets $S_{N1}^1, \ldots, S_{Nt}^t$, each of the form

$$S_i^t = \{ \alpha | \alpha = T_i + k_1\beta_{i1} + \cdots + k_6\beta_{i6}, T_i \in S_N, k_j \geq 0, \beta_{ij} \in S_N \text{ are linearly independent} \},$$

such that $S_N = \bigcup_{i=1}^t S_i^t$, where $\bigcup$ means disjoint union.

As a reward for getting question 1, it is better to use generating functions. Define $G(x) = G(x_1, \ldots, x_{12}) = \sum_{\alpha \in S_N} x^\alpha$, where if $\alpha = (a_1, \ldots, a_{12})$ then $x^\alpha = x_1^{a_1}\cdots x_{12}^{a_{12}}$. And define $G_i(x)$ similarly for $S_{Ni}^i$. Then the decomposition give rise the following.

$$G(x) = \sum_{i=1}^t G_i(x) = \sum_{i=1}^t \frac{x^{T_i}}{\prod_{j=1}^6 (1 - x^{\beta_{ij}})}, \text{ for } 1 \leq i \leq t,$$

where each $G_i(x)$ corresponds to a shifted free monoid.

In order to answer question 1, we use unit vectors $e_i \in \mathbb{N}^{12}(1 \leq i \leq 12)$ that has digit 1 at the $i$-th position and has digit 0 at all the others. For example, $\alpha = (1, 0, 0, 2, 0, 1, 0, 0, 1, 0, 0)$ can be written as $\alpha = e_1 + 2e_4 + e_6 + e_{10}$.

Let

$$\begin{align*}
\alpha_1 &= e_2 + e_3 + e_5 + e_8, & \alpha_2 &= e_1 + e_4 + e_6 + e_7, & \alpha_3 &= e_1 + e_5 + e_{11} + e_{12}, \\
\alpha_4 &= e_2 + e_6 + e_{10} + e_{11}, & \alpha_5 &= e_1 + e_4 + e_5 + e_8, & \alpha_6 &= e_4 + e_8 + e_9 + e_{10}, \\
\alpha_7 &= e_3 + e_7 + e_9 + e_{12}, & \alpha_8 &= e_2 + e_3 + e_6 + e_7, & \alpha_9 &= e_9 + e_{10} + e_{11} + e_{12}, \\
\alpha_{10} &= e_1 + e_{11} + e_{12}, & \alpha_{11} &= e_2 + e_3 + e_5 + e_8, & \alpha_{12} &= e_4 + e_6 + e_7 + e_{10}.
\end{align*}$$

(4) $T = \sum_{i=1}^{12} e_i$. 

![Figure 1. A cube with its edges marked.](image-url)
Observe that each $\alpha_i$ corresponds to a perfect matching. These vectors have the following relations.

$$
\begin{align*}
\alpha_1 &= \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7 - \alpha_2 - 2\alpha_9, \\
\alpha_2 &= \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7 - \alpha_1 - 2\alpha_9, \\
\alpha_3 &= \alpha_1 + \alpha_2 + \alpha_4 + \alpha_7 - \alpha_6 - 2\alpha_8, \\
\alpha_4 &= \alpha_1 + \alpha_2 + \alpha_3 + \alpha_6 - 2\alpha_5 - \alpha_7, \\
\alpha_5 &= \alpha_1 + \alpha_2 - \alpha_8 = \alpha_3 + \alpha_6 - \alpha_9 = \frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + \alpha_6 - \alpha_4 - \alpha_7), \\
T &= \alpha_1 + \alpha_2 + \alpha_9 = \alpha_3 + \alpha_6 + \alpha_8 = \alpha_4 + \alpha_5 + \alpha_7 = \frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7).
\end{align*}
$$

Now, we give the structure result as follows.

**Theorem 2.** Every magic labelling of the cube, i.e., $\alpha \in S_8$, can be written uniquely in one of the following eight types.

1. $k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_3 + k_4\alpha_4 + k_5\alpha_5 + k_6\alpha_6,$
2. $\alpha_7 + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_3 + k_4\alpha_4 + k_5\alpha_6 + k_6\alpha_7,$
3. $\alpha_9 + k_1\alpha_2 + k_2\alpha_3 + k_3\alpha_4 + k_4\alpha_6 + k_5\alpha_7 + k_6\alpha_9,$
4. $(\alpha_1 + \alpha_9) + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_4 + k_4\alpha_6 + k_5\alpha_7 + k_6\alpha_9,$
5. $(\alpha_6 + \alpha_8) + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_4 + k_4\alpha_6 + k_5\alpha_7 + k_6\alpha_8,$
6. $(\alpha_8 + \alpha_9) + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_3 + k_4\alpha_4 + k_5\alpha_6 + k_6\alpha_7,$
7. $(\alpha_4 + \alpha_7) + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_3 + k_4\alpha_4 + k_5\alpha_6 + k_6\alpha_7,$
8. $T + k_1\alpha_1 + k_2\alpha_2 + k_3\alpha_3 + k_4\alpha_4 + k_5\alpha_6 + k_6\alpha_7,$

where $k_i \in \mathbb{N}$, $1 \leq i \leq 6$ and $\alpha_1, \ldots, \alpha_9, T$ are as in (2), (3), (4).

**Corollary 3.** The generating function of $S_8$ can be decomposed as

$$G(x, y) = \sum_{\alpha \in S_8} x^{\alpha} y^{r(\alpha)} = \sum_{i=1}^{8} G_i(x, y),$$

where $G(x) = G(x, 1)$ and

- $G_1(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_2(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_3(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_4(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_5(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_6(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_7(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$
- $G_8(x, y) = \frac{1}{x^{2}y} (1-x^{2y})(1-x^{3y})(1-x^{4y})(1-x^{5y})(1-x^{6y})(1-x^{7y})$

The paper is organized as follows. In this introduction, we have introduced the basic concepts and our main result. In Section 2, we give a combinatorial proof of Theorem 2. In Section 3, we enumerate magic distinct labellings of the cube in two ways using MacMahon’s partition analysis. One way is by direct computation and divide and
lemma 5. If conquer; the other way is by using group of symmetry to simplify the computation. Now
the enumeration result can be reproduced in 3 minutes.

2. A Combinatorial Proof for Magic Labellings

In this section, we will give a combinatorial proof of Theorem 2. The $T$ and $\alpha_i$’s are all as in (2), (3), (4). To prove Theorem 2, we need two lemmas for checking if a given
$\alpha \in S_\mathbb{R}$ belongs to $S_\mathbb{N}$ when it is written using the basis $\alpha_1, \ldots, \alpha_6$ as
\[ \alpha = q_1 \alpha_1 + q_2 \alpha_2 + q_3 \alpha_3 + q_4 \alpha_4 + q_5 \alpha_5 + q_6 \alpha_6, \quad q_1, \ldots, q_6 \in \mathbb{R}. \]

Lemma 4. For $\alpha$ satisfying (1), the condition $\alpha \in S_\mathbb{N}$ is equivalent to the following
conditions on the $q_i$’s.

C1: $q_1, q_2, q_3, q_6 \in \mathbb{N}$;
C2: $(q_1 + q_4), (q_2 + q_4), (q_3 + q_4), (q_6 + q_4) \in \mathbb{N}$;
C3: $q_1 + q_3 + q_5, q_1 + q_5 + q_6, q_2 + q_3 + q_5, q_2 + q_5 + q_6 \in \mathbb{N}.

Proof. We have
\[
\alpha = q_1 \alpha_1 + q_2 \alpha_2 + q_3 \alpha_3 + q_4 \alpha_4 + q_5 \alpha_5 + q_6 \alpha_6
\]
\[
=q_2 + q_3 + q_5 e_1 + (q_1 + q_4) e_2 + q_1 e_3 + (q_2 + q_5 + q_6) e_4 + (q_1 + q_3 + q_5) e_5 + (q_2 + q_4) e_6
\]
\[
+ q_2 e_7 + (q_1 + q_5 + q_6) e_8 + q_6 e_9 + (q_1 + q_6) e_{10} + (q_3 + q_4) e_{11} + q_3 e_{12}.
\]
The lemma clearly follows since $\alpha \in S_\mathbb{N}$ if and only if each coordinate belongs to $\mathbb{N}$.  

Lemma 5. If $\alpha$ can be written as
\[ \alpha = T_0 + k_1 \alpha_1 + k_2 \alpha_2 + \cdots + k_9 \alpha_9, \]
where $T_0$ can be easily checked to be in $S_\mathbb{N}$ and $k_i \in \mathbb{N}, 1 \leq i \leq 9$, then $\alpha \in S_\mathbb{N}$.

The lemma clearly follows since $\alpha_i \in S_\mathbb{N}$ for $1 \leq i \leq 9$. Indeed, the $\alpha_i$’s are the
extreme rays of $S_\mathbb{N}$. See [4] for further concepts.

Now we are ready to outline the idea of the proof of Theorem 2: According to
Lemma 4, $q_1, q_2, q_3, q_6 \in \mathbb{N}$, so it suffices to characterize $q_4$ and $q_5$. It is easy to see
that $q_4, q_5 \in \mathbb{Z}$. Therefore we need to divide this condition into small pieces so that
each piece has a combinatorial interpretation. Indeed, the types are named after our
decompositions.

Proof of Theorem 2. Throughout this proof, $\alpha$ is always written as in formula (1). By
Lemma 4, we can always assume that $q_1, q_2, q_3, q_6 \in \mathbb{N}$, and $q_4, q_5 \in \mathbb{Z}.

We first decompose $S_\mathbb{N}$ into small pieces. By Figure 2 we divide $S_\mathbb{N}$ into three disjoint
parts according to

P1: $q_4, q_5 \in \mathbb{N}$;
P2: $q_4 < 0, q_5 \geq 2q_4$;
P3: $q_5 < 0, q_5 < 2q_4$.

If we denote by $P(S_\mathbb{N}) = \{ \alpha \in S_\mathbb{N} : \alpha \text{ satisfies } P \}$, then $S_\mathbb{N} = P1(S_\mathbb{N}) \cup P2(S_\mathbb{N}) \cup P3(S_\mathbb{N})$.

We further decompose $P3(S_\mathbb{N})$ into small pieces. Now condition P3 holds true. By
condition C2, it is easy to see that $2q_1 + q_5, 2q_2 + q_5, 2q_3 + q_5$ and $2q_6 + q_5 \in \mathbb{Z}$. We use
two rectangular coordinate systems to form a four-dimensional space in Figure 3. The
regions are as follows
A1: $2q_1 + q_5 \geq 0$ and $2q_2 + q_5 \geq 0$;
B1: $2q_1 + q_5 < 0$ or $2q_2 + q_5 < 0$;
A2: $2q_3 + q_5 \geq 0$ and $2q_6 + q_5 \geq 0$;
B2: $2q_3 + q_5 < 0$ and $2q_6 + q_5 < 0$.

Figure 2. Cut the $(q_4, q_5)$-plane into three disjoint regions.

Figure 3. A four-dimensional space: $2q_1 + q_5, 2q_2 + q_5, 2q_3 + q_5, 2q_6 + q_5 \in \mathbb{Z}$.

Now $P_3(S_n)$ is decomposed into four disjoint pieces according to:

1: $A_1$ and $A_2$;
2: $A_1$ and $B_2$;
3: $B_1$ and $A_2$;
4: $B_1$ and $B_2$.

It is easy to check that the last piece is empty by condition C3. For instance, if $2q_1 + q_5 < 0$ and $2q_3 + q_5 < 0$ then $2(q_1 + q_3 + q_5) < 0$, which is impossible by condition C3. The second piece $A_1$ and $B_2$ can be reduced by condition C3 to $A_1^\circ$ and $B_2$ where $A_1^\circ$ means excluding the equal case in $A_1$. Similarly, the third part $B_1$ and $A_2$ can be reduced to $B_1$ and $A_2^\circ$ where $A_2^\circ$ means excluding the equal case in $A_2$. Then, we only need to consider the following three pieces:

1: $A_1$ and $A_2$;
2: $A_1^\circ$ and $B_2$;
3: $B_1$ and $A_2^\circ$. 
By slicing $B1$ and $B2$ at the diagonals, we divide them into five disjoint pieces under the condition $P3$ according to

- **P31**: $2q_1 + q_5 < 0$ and $2q_1 + q_5 \leq 2q_2 + q_5$ written as $q_1 \leq q_2$;
- **P32**: $2q_2 + q_5 < 0$ and $2q_2 + q_5 < 2q_1 + q_5$ written as $q_2 < q_1$;
- **P33**: $2q_3 + q_5 < 0$ and $2q_3 + q_5 < 2q_6 + q_5$ written as $q_3 < q_6$;
- **P34**: $2q_6 + q_5 < 0$ and $2q_6 + q_5 \leq 2q_3 + q_5$ written as $q_6 \leq q_3$;
- **P35**: $q_5 < 0, q_5 < 2q_4, 2q_1 + q_5 \geq 0, 2q_2 + q_5 \geq 0, 2q_3 + q_5 \geq 0$ and $2q_6 + q_5 \geq 0$.

The specific division method is as follows: 1) The first part $A1$ and $A2$ under the condition $P3$ becomes the condition $P35$; 2) Slicing of $B2$ by the diagonal gives $P33$ and $P34$. On the other hand, either $P33$ or $P34$ will be easily seen to imply the conditions $A1^\circ$ and $P3$; 3) Slicing of $B1$ by the diagonal gives $P31$ and $P32$. Similarly, either $P31$ or $P32$ will imply the conditions $A2^\circ$ and $P3$.

Now we have

$$S_N = P1(S_N) \bigcup P2(S_N) \bigcup P31(S_N) \bigcup P32(S_N) \bigcup P33(S_N) \bigcup P34(S_N) \bigcup P35(S_N).$$

Next we show that each piece corresponds to one type in Theorem 2. Observe that the uniqueness for each type follows by the linear independency of the $\alpha_i$’s. For instance, in the type $t2$ case, the linear independency of $\alpha_1, \alpha_2, \alpha_3, \alpha_5, \alpha_6, \alpha_7$ can be straightforwardly checked.

- **P1**: When condition $P1$ holds, simply let $k_i = q_i$ for all $1 \leq i \leq 6$. Then $k_i \in \mathbb{N}$ and this is exactly the type $t1$ case.
- **P2**: When condition $P2$ holds, we have $q_5 - 2q_4 \in \mathbb{N}$ and $-(q_4 + 1) \in \mathbb{N}$. Substituting $\alpha_4 = \alpha_1 + \alpha_2 + \alpha_3 + \alpha_6 - 2\alpha_5 - \alpha_7$ in formula (1) gives

$$\alpha = \alpha_7 + (q_1 + q_4)\alpha_1 + (q_2 + q_4)\alpha_2 + (q_3 + q_4)\alpha_3 + (q_5 - 2q_4)\alpha_5 + (q_6 + q_4)\alpha_6 - (q_4 + 1)\alpha_7$$

Comparing with the type $t2$ case, we shall have

$$k_1 = (q_1 + q_4), \quad k_2 = (q_2 + q_4), \quad k_3 = (q_3 + q_4),$$
$$k_4 = (q_5 - 2q_4), \quad k_5 = (q_6 + q_4), \quad k_6 = -(q_4 + 1).$$

The condition $k_i \in \mathbb{N}$ can be easily checked.

Conversely, if $\alpha$ is as in the type $t2$ case, then by Lemma 5 $\alpha \in S_N$ so that all conditions in Lemma 4 holds. Then it is easy to check that $P2$ holds so that $\alpha \in P2(S_N)$. The converse part for the other pieces are similar so we will omit that part of the proof.

- **P31**: When condition $P31$ holds, we have $-(2q_1 + q_5 + 1) \in \mathbb{N}$ and $q_2 - q_1 \in \mathbb{N}$. Substituting $\alpha_1 = \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7 - \alpha_2 - 2\alpha_9, \alpha_5 = \alpha_3 + \alpha_6 - \alpha_9$ in formula (1) gives

$$\alpha = \alpha_9 + (q_2 - q_1)\alpha_2 + (q_1 + q_3 + q_5)\alpha_3 + (q_1 + q_4)\alpha_4 + q_1\alpha_7 + (q_1 + q_5 + q_6)\alpha_6 - (2q_1 + q_5 + 1)\alpha_9.$$  

By comparing with the type $t31$ case, we shall have

$$k_1 = q_2 - q_1, \quad k_2 = q_1 + q_3 + q_5, \quad k_3 = q_1 + q_4,$$
$$k_4 = q_1, \quad k_5 = q_1 + q_5 + q_6, \quad k_6 = -(2q_1 + q_5 + 1).$$

Then $k_i \in \mathbb{N}$ by conditions $C1$, $C2$ and $C3$.  

P32: When condition P32 holds, we have \(-(2q_2 + q_5 + 1) \in \mathbb{N}\) and \(q_1 - q_2 - 1 \in \mathbb{N}\). Substituting \(\alpha_2 = \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7 - \alpha_1 - 2\alpha_9, \alpha_5 = \alpha_3 + \alpha_6 - \alpha_9\) in formula (1) gives
\[
\alpha = (\alpha_1 + \alpha_9) + (q_1 - q_2 - 1)\alpha_1 + (q_2 + q_3 + q_5)\alpha_3 + (q_2 + q_4)\alpha_4 + q_2\alpha_7 + (q_2 + q_5 + q_6)\alpha_6 - (2q_2 + q_5 + 1)\alpha_9
\]
By comparing with the type t32 case, we shall have
\[
k_1 = q_1 - q_2 - 1, \quad k_2 = q_2 + q_3 + q_5, \quad k_3 = q_2 + q_4, \\
k_4 = q_2, \quad k_5 = q_2 + q_5 + q_6, \quad k_6 = -(2q_2 + q_5 + 1)
\]
Then \(k_i \in \mathbb{N}\) by conditions C1, C2 and C3.

P33: When \(2q_3 + q_5 < 0\) and \(q_3 < q_6\), we have \(-(2q_3 + q_5 + 1) \in \mathbb{N}\) and \(q_6 - q_3 - 1 \in \mathbb{N}\). Substituting \(\alpha_3 = \alpha_1 + \alpha_2 + \alpha_4 + \alpha_7 - \alpha_6 - 2\alpha_8\) and \(\alpha_5 = \alpha_1 + \alpha_2 - \alpha_8\) in formula (1) gives
\[
\alpha = (\alpha_6 + \alpha_8) + (q_1 + q_3 + q_5)\alpha_1 + (q_2 + q_3 + q_5)\alpha_2 + (q_3 + q_4)\alpha_4 + (q_6 - q_3 - 1)\alpha_6 + q_3\alpha_7 - (2q_3 + q_5 + 1)\alpha_8
\]
By comparing with the type t33 case, we shall have
\[
k_1 = q_1 + q_3 + q_5, \quad k_2 = q_2 + q_3 + q_5, \quad k_3 = q_3 + q_4, \\
k_4 = q_3, \quad k_5 = q_6 - q_3 - 1, \quad k_6 = -(2q_3 + q_5 + 1).
\]
Then \(k_i \in \mathbb{N}\) by conditions C1, C2 and C3.

P34: When condition P34 holds, we have \(-(2q_6 + q_5 + 1) \in \mathbb{N}\) and \(q_3 - q_6 \in \mathbb{N}\). Substituting \(\alpha_6 = \alpha_1 + \alpha_2 + \alpha_4 + \alpha_7 - \alpha_3 - 2\alpha_8\) and \(\alpha_5 = \alpha_1 + \alpha_2 - \alpha_8\) in formula (1) gives
\[
\alpha = \alpha_8 + (q_1 + q_5 + q_6)\alpha_1 + (q_2 + q_3 + q_6)\alpha_2 + (q_3 - q_6)\alpha_3 + (q_4 + q_6)\alpha_4 + q_6\alpha_7 - (2q_6 + q_5 + 1)\alpha_8
\]
By comparing with the type t34 case, we shall have
\[
k_1 = q_1 + q_5 + q_6, \quad k_2 = q_2 + q_5 + q_6, \quad k_3 = q_3 - q_6, \\
k_4 = q_4 + q_6, \quad k_5 = q_6, \quad k_6 = -(2q_6 + q_5 + 1).
\]
Then \(k_i \in \mathbb{N}\) by conditions C1, C2 and C3.

P35: When condition P35 holds, we can substitute \(\alpha_5 = \frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + \alpha_6 - \alpha_4 - \alpha_7)\) in formula (1) and get
\[
\frac{1}{2}q_5
\]
\[
\alpha = (q_1 + \frac{1}{2}q_5)\alpha_1 + (q_2 + \frac{1}{2}q_5)\alpha_2 + (q_3 + \frac{1}{2}q_5)\alpha_3 + (q_4 - \frac{1}{2}q_5)\alpha_4 - \frac{1}{2}q_5\alpha_7 + (q_6 + \frac{1}{2}q_5)\alpha_6.
\]
According to the parity of \(q_5\), we divide it into two cases:

Case 351: When \(q_5\) is even, we rewrite \(\alpha\) as
\[
\alpha = (\alpha_7 + \alpha_4) + (q_1 + \frac{1}{2}q_5)\alpha_1 + (q_2 + \frac{1}{2}q_5)\alpha_2 + (q_3 + \frac{1}{2}q_5)\alpha_3 + (q_4 - \frac{1}{2}q_5 - 1)\alpha_4 - \frac{1}{2}q_5 + 1)\alpha_7 + (q_6 + \frac{1}{2}q_5)\alpha_6.
\]
By comparing with the type t351 case, we shall have
\[
\begin{align*}
k_1 &= q_1 + \frac{1}{2}q_5, \\
k_2 &= q_2 + \frac{1}{2}q_5, \\
k_3 &= q_3 + \frac{1}{2}q_5, \\
k_4 &= q_4 - \frac{1}{2}q_5 - 1, \\
k_5 &= -(\frac{1}{2}q_5 + 1), \\
k_6 &= q_6 + \frac{1}{2}q_5.
\end{align*}
\]

By condition P35 and the assumption \(q_5\) is even, we see that \(k_i \in \mathbb{N}\) for all \(i\).

Case 352: When \(q_5\) is odd, we rewrite \(\alpha\) as
\[
\alpha = \frac{1}{2} (\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7) + \left( q_1 + \frac{1}{2}q_5 - \frac{1}{2} \right) \alpha_1 \\
+ \left( q_2 + \frac{1}{2}q_5 - \frac{1}{2} \right) \alpha_2 + \left( q_3 + \frac{1}{2}q_5 - \frac{1}{2} \right) \alpha_3 + \left( q_4 - \frac{1}{2}q_5 - \frac{1}{2} \right) \alpha_4 \\
- \left( \frac{1}{2}q_5 + \frac{1}{2} \right) \alpha_7 + \left( q_6 + \frac{1}{2}q_5 - \frac{1}{2} \right) \alpha_6.
\]

By comparing with the type t352 case, we shall have
\[
\begin{align*}
T &= \frac{1}{2} (\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 + \alpha_6 + \alpha_7), \\
k_1 &= q_1 + \frac{1}{2}q_5 - \frac{1}{2}, \\
k_2 &= q_2 + \frac{1}{2}q_5 - \frac{1}{2}, \\
k_3 &= q_3 + \frac{1}{2}q_5 - \frac{1}{2}, \\
k_4 &= q_4 - \frac{1}{2}q_5 - \frac{1}{2}, \\
k_5 &= -(\frac{1}{2}q_5 + \frac{1}{2}), \\
k_6 &= q_6 + \frac{1}{2}q_5 - \frac{1}{2}.
\end{align*}
\]

By condition P35 and the assumption \(q_5\) is odd, we see that \(k_i \in \mathbb{N}\) for all \(i\).

3. Enumeration for Magic distinct Labellings of the Cube

Let \(S_N^*\) be the set of magic labellings of the cube. Then \(S_N^*\) is obtained from \(S_N\) by slicing out \(\binom{12}{2}\) hyper planes. We are interested in the generating function
\[
G^*(x, y) = \sum_{\alpha \in S_N^*} x^\alpha y^{r(\alpha)}.
\]

It turns out to be so complicated that we only report the enumeration result. That is, we will give the generating function for the number \(h_r\) of magic distinct labellings of the cube with magic sum \(r\):
\[
G^*(y) = G^*(1, \ldots, 1, y) = \sum_{r \geq 0} h_r y^r.
\]

3.1. Preliminaries. MacMahon’s Omega operators on formal series are defined by
\[
\Omega = \sum_{k=0}^{\infty} c_i \lambda^i = c_0, \\
\sum_{k=0}^{\infty} c_i \lambda^i = \sum_{k=0}^{\infty} c_i.
\]

They are basic ingredients of MacMahon’s partition analysis, which has been restudied by Andrews and his coauthors in a series of papers starting with [2].

MacMahon’s idea is to use new variables to replace linear constraints so that many problems can be converted into the constant term of a special kind of rational functions.
It is standard to express \( G(x, y) \) by the following constant term in \( \lambda_1, \ldots, \lambda_8 \).

\[
G(x, y) = \frac{1}{(1 - \lambda_1 \lambda_2 x_1)(1 - \lambda_3 \lambda_4 x_4)(1 - \lambda_2 \lambda_3 x_3)(1 - \lambda_1 \lambda_4 x_2)} \times \frac{1}{(1 - \lambda_5 \lambda_6 x_5)(1 - \lambda_7 \lambda_8 x_8)(1 - \lambda_6 \lambda_7 x_7)(1 - \lambda_5 \lambda_8 x_6)} \times \frac{1}{(1 - \lambda_1 \lambda_5 x_9)(1 - \lambda_2 \lambda_6 x_{10})(1 - \lambda_3 \lambda_7 x_{11})(1 - \lambda_4 \lambda_8 x_{12})(1 - \frac{y}{x_1 \lambda_2 \lambda_3 \lambda_4 \lambda_5 \lambda_6 \lambda_7 \lambda_8})}.
\]

The \( \lambda \) variables are usually clear from the context and the whole theory relies on unique series expansion of rational functions. There are algorithm for evaluating this type of constant terms. Such as the Mathematica package Omega in [3]. We use the first named author’s Maple packages Ell, CTEuclid in [10] and (often better) CTEuclid in [11]. See [10] for a rigorous description about how the above works in general situation, i.e., in a field of iterated Laurent series.

Let us describe briefly how we discovered the formula (5) in Corollary 3. By using CTEuclid, we can obtain an expression of \( G(x, y) \) as a sum of rational functions quickly. The normal form of \( G(x, y) \) is given by

\[
G(x, y) = \frac{N(x, y)}{(1 - x^a y)(1 - x^b y) \cdots (1 - x^c y)}, \quad \text{where} \quad N(x, y) = 1 - y^2 x_2 x_3 x_6 x_7 y x_{10} x_{11} x_{12} - y^2 x_1 x_4 x_5 x_8 x_9 x_{10} x_{11} x_{12} - y^2 x_1 x_2 x_3 x_4 x_5 x_6 y x_8 + y^4 x_1 x_2 x_3 x_4 x_5 x_6 x_7 x_8 y^2 x_9 x_{10} x_{11} x_{12}^2 + y^4 x_1 x_2 x_3 x_4 x_5 x_6 x_7 x_8 y^2 x_9 x_{10} x_{11} x_{12} + y^4 x_1 x_2 x_3 x_4 x_5 x_6 x_7 x_8 y^2 x_9 x_{10} x_{11} x_{12}^2 - y^6 x_1 x_2 x_3 x_4 x_5 x_6 x_7 x_8 y^2 x_9 x_{10} x_{11} x_{12}^2.
\]

Such a formula is usually too complex to use. Formula (5) is desirable and is easy to be verified, but it is unclear how to obtain such a decomposition. We guessed such a formula by using certain criteria.

By setting \( x_i = 1 \) for all \( i \), we obtain \( G(y) = G(1, y) = \frac{y^3 + 3 y^2 + 3 y + 1}{(1 - y)^6} \). This agree with [1, p. 73].

When dealing with magic distinct labelings, we also use the following two operators:

\[
\text{diag} \sum_{i,j \geq 0} a_{i,j} x^i y^j = \sum_{i \geq 0} a_{i} x^i y^i, \quad \text{diag} \sum_{i,j \geq 0} a_{i,j} x^i y^j = \sum_{i,j \geq 0} a_{i,j} x^i y^j.
\]

They can be realized by the Omega operators. See [12] for details. Clearly, they can be naturally extended to \( \text{diag}_{x_1 > x_2 > \cdots > x_k} \), which is treated as the identity operator \( 1 \) when \( k \leq 1 \).

Let \( A \) and \( B \) be two disjoint sets. For permutations \( \pi \in S_A \) and \( \sigma \in S_B \), a permutation \( \tau \in S_{A \cup B} \) is said to be a shuffle of \( \pi \) and \( \sigma \) if \( \tau \mid A = \pi \) and \( \tau \mid B = \sigma \), where \( \tau \mid C \), called the restriction of \( \tau \) in \( C \), is obtained from \( \tau \) by omitting elements not in \( C \). Denote by \( Sh(\pi, \sigma) \) the set of shuffle permutations of \( (\pi, \sigma) \). For instance, if \( \pi = 253 \) and \( \sigma = 41 \), then \( Sh(\pi, \sigma) = \{ 25341, 25431, 25431, 24531, 24531, 24153, 42531, 42531, 42513, 42153, 42153 \} \).

For \( \pi = \pi_1 \pi_2 \cdots \pi_a \in S_A \) and \( \sigma = \sigma_1 \sigma_2 \cdots \sigma_b \in S_B \), define the linear operator

\[
\Pi_{\pi, \sigma} F(x, y) = \text{diag}_{x_{\pi_1} > x_{\pi_2} > \cdots > x_{\pi_a}} \cdot \text{diag}_{x_{\sigma_1} > x_{\sigma_2} > \cdots > x_{\sigma_b}} F(x, y)
\]

acting on a formal power series \( F(x, y) \). We allow \( \sigma \) to be empty.
3.2. Direct computation by divide and conquer. Now we describe how to extract $G^*(y)$ from $G(x, y)$. Because it is important to keep the number of factors in the denominator of $F$ small when extracting constant term of $F$, we prefer using $G_i$, $i = 1, \ldots, 8$ rather than $G$.

We can compute $G^*(x, y)$ by the formula

$$G^*(x, y) = \sum_{\pi \in S_{12}} \Pi_{\pi} G(x, y) = \sum_{i=1}^{8} \sum_{\pi \in S_{12}} \Pi_{\pi} G_i(x, y).$$

But then we need to compute $8 \times 12! \approx 3.83 \times 10^9$ cases, which is out of question.

Thus we device to compute $G^*(y)$ by divide and conquer.

Firstly we partition the index set $\{1, 2, \ldots, 12\}$ of the edges into disjoint union of $A = \{1, 4, 6, 7, 9, 10, 11, 12\}$ and $B = \{2, 3, 5, 8\}$. Note that edges with labels in $B$ form an extreme ray, and edges with labels in $A$ form a Hamiltonian cycle. Other choices of $A$ and $B$ might work, but that take time to test and we find a better way by using symmetry.

Next we compute $\Pi_{\pi, \sigma} G_i(x, y)$ for each pair $(\pi, \sigma) \in S_A \times S_B$ and keep only those non-vanishing cases. It turns out that for $i = 1, 2, 5, 6$, $\Pi_{\pi, \sigma} G_i(x, y) \neq 0$, only for 160 out of $8! \times 4! = 967680$ pairs $(\pi, \sigma)$. The other cases are also reasonable.

Finally for each non-vanishing case, we compute $\Pi_{\tau} \Pi_{\pi, \sigma} G_i(x, y)$ for all $\binom{12}{4} = 495$ permutations $\tau \in Sh(\pi, \sigma)$, setting $x_j = 1$ for all $j$, and take their sum. The final result is $G^*(y)$. In this way we can compute $G^*(y)$ in 240 minutes.

The decomposition on the permutations is:

$$S_{12} = \bigsqcup_{(\pi, \sigma) \in S_A \times S_B} Sh(\pi, \sigma).$$

This leads to the following formula:

$$G^*(x, y) = \sum_{\pi \in S_A} \sum_{\sigma \in S_B} \sum_{\tau \in Sh(\pi, \sigma)} \Pi_{\tau} G(x, y).$$

Now for each $(\pi, \sigma)$, we can write, for all $\tau \in Sh(\pi, \sigma)$,

$$\Pi_{\tau} G(x, y) = \Pi_{\tau} (\Pi_{\pi, \sigma} G(x, y)) = \sum_{i=1}^{8} \Pi_{\tau} (\Pi_{\pi, \sigma} G_i(x, y)).$$

Then for each $i$, we can discard those $(\pi, \sigma)$ with $\Pi_{\pi, \sigma} G_i(x, y) = 0$.

We remark that in practice, we check the nullity of $\Pi_{\pi, \sigma} G_i(x, y)_{x_j = 1}$ instead. The reason is that $G_i(x, y)$ has only nonnegative coefficients, and so does $\Pi_{\pi, \sigma} G_i(x, y)$. This is crucial because it is not easy to check if a multivariate rational function (written as a sum) is 0.

3.3. Simplification using group action. Denote by $U$ the automorphism group of the cube. It is well-known that $U$ has cardinality $3! \times 2^3 = 48$. (The symmetry group of the geometric cube (in $\mathbb{R}^3$) has cardinality 24.) The group $U$ induces an action on the edges, say $x_1, \ldots, x_{12}$. 
For any magic labelling of the cube $\alpha = (x_1, x_2, \ldots, x_{12}) \in S_N$, we may assume $x_1$ to be the smallest under the action of $U$. Since the all 1 labelling is in $S_N$, we may further assume $x_1 = 0$ by subtracting $(x_1, x_1, \ldots, x_1)$.

Let $U_1$ be the subgroup of $U$ that fixes $x_1$. Then $U_1$ consists of 4 elements generated by: i) $(2,3)(9,10)(6,7)(11,12)$, corresponding to flipping along the center of edges $x_1$ and $x_8$ in $\mathbb{R}^3$; ii) $(3,10)(4,5)(7,11)(6,12)(2,9)$, which cannot be realized in $\mathbb{R}^3$. When $U_1$ acting on the edges, we get 5 orbits: $\{x_1\}$, $\{x_8\}$, $\{x_4, x_5\}$, $\{x_2, x_3, x_9, x_{10}\}$, $\{x_6, x_7, x_{11}, x_{12}\}$. The next lemma says that the second smallest label can only appear in two of the orbits.

**Lemma 6.** Suppose $\alpha = (x_1, \ldots, x_{12}) \in S_N$ with $x_1 < x_i$ and $x_i = \min\{x_2, \ldots, x_{12}\}$. Then $i \notin \{2, 3, 9, 10\}$ and $i \neq 8$.

**Proof.** Under the action of $U_1$, we only need to check the case $i = 2$ and $i = 8$.

If $x_2$ is the second smallest, then combing $x_1 + x_2 + x_9 = r$ and $x_5 + x_6 + x_9 = r$ gives $x_2 + x_1 = x_5 + x_6$. This is a contradiction.

If $x_8$ is the second smallest, by using

$$x_5 + x_6 + x_9 = r, x_6 + x_8 + x_{12} = r \quad \text{and} \quad x_1 + x_2 + x_9 = r, x_2 + x_4 + x_{12} = r,$$

we obtain respectively: $x_5 + x_9 = x_8 + x_{12}$ and $x_1 + x_9 = x_4 + x_{12}$. Combining them gives $x_8 + x_1 = x_4 + x_5$. This is again a contradiction. 

The next result tells how to choose the representative for $\alpha \in S_N^*$ under the action of $U$.

**Proposition 7.** For any magic distinct labelling of the cube $\alpha \in S_N^*$, there is a unique $u \in U$ such that $\alpha$ is transformed by $u$ into $(x_1, \ldots, x_{12})$ belongs to one of the following 2 types.

i) $x_1$ is the smallest, $x_6$ is the second smallest.

ii) $x_1$ is the smallest, $x_4$ is the second smallest, and $x_6 < x_7$.

**Proof.** We have assumed that $x_1$ is the smallest. Now by fixing $x_1$ we act by the group $U_1$. By Lemma 6, the second smallest label can only belongs to two orbits, thus we can transform by element in $U_1$ so that either $x_6$ or $x_4$ is the second smallest.

Case 1: $x_6$ is the second smallest. Since the orbit of $x_6$ is of size 4, the subgroup $U_{1,6}$ of $U_1$ fixes $x_6$ only contains the identity element.

Case 2: $x_4$ is the second smallest. Since of orbit of $x_4$ is 2, the subgroup $U_{1,4}$ of $U_1$ fixes $x_4$ contains two element: the identity element and $(2, 3)(9, 10)(6, 7)(11, 12)$. In this case, add the condition $x_6 < x_7$ to make the transformation unique.

Thus we can compute $G^*(x, y)$ according to the above two cases. For the first case, we let

$$F_1(x, y) = \left( \begin{array}{cccc} \text{diag} & \text{diag} & \cdots & \text{diag} \\ x_6 > x_1 & x_2 > x_6 & x_5 > x_6 & x_7 > x_6 \end{array} \right) G(x, y) \right|_{x_1 = 0}.$$
By using CTEuclid, we get

\[ F_1(x, y) = \frac{1}{(1 - yx_4x_8x_9x_{10})(1 - yx_5x_7x_9x_{12})} \times \frac{y^8x_{10}^3x_{11}^3x_{12}^2x_6x_7x_8^4x_9^3x_2^4x_4^3x_2^4x_4^2}{(1 - yx_9x_{10}x_{11}x_{12})(1 - yx_2x_3x_5x_8)(1 - y^4x_2^2x_3^2x_4x_5x_6x_7x_8x_9^2x_{10}^2x_{11}x_{12})}. \]

The computation of the second case is similar. By using CTEuclid, we get

\[ F_2(x, y) = \frac{1}{(1 - yx_6x_2x_7x_3)(1 - yx_3x_7x_9x_{12})} \times \frac{y^8x_{12}^3x_{11}^3x_{10}^4x_5x_3^2x_2^3x_4^5}{(1 - yx_9x_{10}x_{11}x_{12})(1 - yx_2x_3x_5x_8)(1 - y^4x_2^2x_3^2x_4x_5x_6x_7x_8x_9^2x_{10}^2x_{11}x_{12})}. \]

Use the method of the previous subsection for \( F_1(x, y) \) and \( F_2(x, y) \) respectively, we can easily obtain \( F_1^*(y) \) and \( F_2^*(y) \). Finally, by using the fact \( G^*(y) = \frac{F_1^*(y) + F_2^*(y)}{1 - y^2} \), we obtain

\[ G^*(y) = \frac{y^{17}(1 - y)^4(1 - y^2)^2N}{(1 - y^2)(1 - y^2)^{16}} \prod_{i=5}^{14}(1 - y^i) \]

where

\[ N = \frac{6 + 37y + 158y^2 + 514y^3 + 1451y^4 + 3621y^5 + 8284y^6 + 17569y^7 + 35070y^8 + 66312y^9 + 119823y^{10} + 207728y^{11}}{1 + 347391y^{12} + 561997y^{13} + 882742y^{14} + 1348938y^{15} + 2010779y^{16} + 2928154y^{17} + 4173803y^{18} + 5830039y^{19}} + \]

\[ + \frac{7992068y^{20} + 10761439y^{21} + 14249943y^{22} + 18568515y^{23} + 23832260y^{24} + 30144300y^{25} + 37602930y^{26}}{1 + 46279969y^{27} + 56232269y^{28} + 67474300y^{29} + 79996493y^{30} + 93732893y^{31} + 108588539y^{32} + 124402462y^{33}} + \]

\[ + \frac{14098732y^{34} + 158087400y^{35} + 175431907y^{36} + 192688207y^{37} + 209528800y^{38} + 225578607y^{39} + 240495470y^{40}}{1 + 253908861y^{41} + 26551859y^{42} + 274990182y^{43} + 282121684y^{44} + 286693656y^{45} + 288607900y^{46} + 287784490y^{47}} + \]

\[ + \frac{284268896y^{48} + 278123786y^{49} + 269535199y^{50} + 258694438y^{51} + 245902795y^{52} + 231445735y^{53} + 215696263y^{54}}{1 + 19887144y^{55} + 18171391y^{56} + 164197341y^{57} + 146808026y^{58} + 129822649y^{59} + 113534001y^{60} + 98140965y^{61}} + \]

\[ + \frac{83842462y^{62} + 70743178y^{63} + 58943269y^{64} + 48456737y^{65} + 39295487y^{66} + 31400920y^{67} + 24718505y^{68}}{1 + 19141614y^{69} + 14576321y^{70} + 10894761y^{71} + 7988749y^{72} + 5731894y^{73} + 4021600y^{74} + 2748644y^{75} + 1828595y^{76}} + \]

\[ + \frac{1177014y^{77} + 732167y^{78} + 435841y^{79} + 247875y^{80} + 132180y^{81} + 65960y^{82}}{1 + 29549y^{83} + 11862y^{84} + 3740y^{85} + 897y^{86}}. \]

By using the above basic ideas, we can reproduce \( G^*(y) \) in 3 minutes.

4. Summary

In this paper, we give a complete construction of all magic labellings of the cube. They are classified by eight types. We used them to enumerate magic distinct labellings of the cube. The computation is significantly simplified when the group of the symmetry encountered. The method will apply to much larger graphs with good group of symmetry.
