Near optimal spectral gaps for hyperbolic surfaces

Will Hide and Michael Magee

July 13, 2021

Abstract

We prove that if \( X \) is a finite area non-compact hyperbolic surface, then for any \( \epsilon > 0 \), with probability tending to one as \( n \to \infty \), a uniformly random degree \( n \) Riemannian cover of \( X \) has no eigenvalues of the Laplacian in \( [0, \frac{1}{4} - \epsilon) \) other than those of \( X \), and with the same multiplicities.

As a result, using a compactification procedure due to Buser, Burger, and Dodziuk, we settle in the affirmative the question of whether there exist a sequence of closed hyperbolic surfaces with genera tending to infinity and first non-zero eigenvalue of the Laplacian tending to \( \frac{1}{4} \).

1 Introduction

Let $X$ be a finite-area complete hyperbolic surface, that is, a smooth surface with Riemannian metric of constant curvature $-1$. The Laplacian operator $\Delta_X$ on $L^2(X)$ has spectrum in $[0, \infty)$. The bottom of the spectrum is always a discrete eigenvalue at 0 that is simple if and only if $X$ is connected.

If $X$ is non-compact, which is the first focus of our paper, then the spectrum of $\Delta_X$ in $[0, 1^4)$ consists of finitely many discrete eigenvalues and the spectrum is absolutely continuous in $[1^4, \infty)$ [LP81]. As such, the spectral gap between 0 and the rest of the spectrum has size at most $\frac{1}{4}$.

We are interested in the size of this spectral gap for random surfaces. The random model we use is the random covering model from [MN20, MNP20, MN21]. For any $n \in \mathbb{N}$, the space of degree $n$ Riemannian covering spaces of $X$ is a finite set that we equip with the uniform probability measure. We say that a family of events, depending on $n$, holds asymptotically almost surely (a.a.s.) if they hold with probability tending to one as $n \to \infty$. We also note that any eigenvalue of the Laplacian on $X$ will be an eigenvalue of any cover of $X$, with at least as large multiplicity. Therefore these ‘old eigenvalues’ must always be taken into account.

The first theorem of the paper is the following.

**Theorem 1.1.** Let $X$ be a finite-area non-compact hyperbolic surface. Let $X_n$ denote a uniformly random degree $n$ covering space of $X$. For any $\epsilon > 0$, a.a.s.

$$\text{spec}(\Delta_{X_n}) \cap \left[0, \frac{1}{4} - \epsilon\right] = \text{spec}(\Delta_X) \cap \left[0, \frac{1}{4} - \epsilon\right]$$

and the multiplicities on both sides are the same.

This theorem is the analog, for finite-area non-compact hyperbolic surfaces of Alon’s and Friedman’s conjectures [Alo86, Fri03] about random regular graphs proved by Friedman [Fri08] and Bordenave and Collins [BC19].

If $X$ has Euler characteristic $\chi(X) = -1$, then a result of Otal and Rosas [OR09, Thm. 2] states that $\text{spec}(\Delta_X) \cap \left[0, \frac{1}{4}\right]$ is just the multiplicity one eigenvalue at 0. We therefore obtain the following corollary.

**Corollary 1.2.** There exist connected finite-area non-compact hyperbolic surfaces $X_i$ with $\chi(X_i) \to -\infty$ and

$$\inf (\text{spec}(\Delta_{X_i}) \cap (0, \infty)) \to \frac{1}{4}.$$ 

In fact one can take $\chi(X_i) = -i$.

The corresponding question for compact surfaces $X$ is as follows. If $X$ is compact then the spectrum of $\Delta_X$ consists of eigenvalues

$$0 = \lambda_0(X) \leq \lambda_1(X) \leq \cdots \leq \lambda_i(X) \leq \cdots$$

2
with $\lambda_i(X) \to \infty$ as $i \to \infty$. The question of whether there are closed $X_i$ with genera $g(X_i) \to \infty$ and $\limsup \lambda_1(X_i) \geq \frac{1}{4}$ first appears implicitly in [Bus78], where actually, it was conjectured not to be true. This was corrected in [Bus84] where it was put forward that ‘probably’ the question above has a positive answer. See [WX18, Conj. 5], [Wri20, Problem 10.3] for more recent iterations of this question. Note that by a result of Huber [Hub74], in the situation of this paragraph $\limsup(\lambda_1(X_i)) \leq \frac{1}{4}$ so the question is whether there are compact hyperbolic surfaces of large genus with asymptotically optimal spectral gaps.

We are able to resolve this question here by combining Corollary 1.2 with the ‘handle lemma’ of Buser, Burger, and Dodziuk [BBD88]; see Brooks and Makover [BM01, Lemma 1.1] for the extraction of the lemma. We obtain

**Corollary 1.3.**

There exist closed hyperbolic surfaces $X_i$ with genera $g(X_i) \to \infty$ and $\lambda_1(X_i) \to \frac{1}{4}$. In fact one can take $g(X_i) = i$.

**1.1 Prior work**

The analog of Theorem 1.1 was proved for conformally compact infinite area hyperbolic surfaces by the second named author and Naud in [MN21], following a previous work with an intermediate result [MN20]. The reader should see however [MN21] for details because the spectral theory is more subtle for infinite area surfaces and moreover the results in [MN21] go beyond statements about $L^2$ eigenvalues.

The very first uniform spectral gap for certain combinatorial models of random surfaces (the ‘Brooks-Makover’ models), yielding both finite-area non-compact and closed surfaces, appears in work of Brooks and Makover [BM04]. This spectral gap is non-explicit.

The analog of Theorem 1.1 for closed hyperbolic surfaces is still unknown. The best known result in the random cover model is due to the second named author, Naud, and Puder [MNP20], building on [MP20], that gives an a.a.s. relative spectral gap of size $\frac{3}{10} - \epsilon$ for random covers of a closed hyperbolic surface. The fact that a Weil-Petersson random closed hyperbolic surface enjoys spectral gap of size $\frac{3}{10} - \epsilon$ with probability tending to one as genus $\to \infty$ was proved independently by Wu and Xue [WX21] and Lipnowski and Wright [LW21]. The first uniform spectral gap of size $\approx 0.0024$ for Weil-Petersson random surfaces was proved by Mirzakhani in [Mir13].

The previous best results towards Corollary 1.2, just for the case of $\chi(X_i) \to -\infty$, all came from arithmetic hyperbolic surfaces. The records were held by Selberg [Sel65] (spectral gaps of size $\frac{3}{10} = 0.1875$), Gelbart and Jacquet [GJ78] (existence of spectral gaps larger than $\frac{1}{6}$), Luo, Rudnick, and Sarnak [LRS95] (spectral gaps of size $\frac{1}{72} \approx$ 0.0024 for Weil-Petersson random surfaces was proved by Mirzakhani in [Mir13].

The previous best results towards Corollary 1.2, just for the case of $\chi(X_i) \to -\infty$, all came from arithmetic hyperbolic surfaces. The records were held by Selberg [Sel65] (spectral gaps of size $\frac{3}{10} = 0.1875$), Gelbart and Jacquet [GJ78] (existence of spectral gaps larger than $\frac{1}{6}$), Luo, Rudnick, and Sarnak [LRS95] (spectral gaps of size $\frac{1}{72} \approx$ 0.0024 for Weil-Petersson random surfaces was proved by Mirzakhani in [Mir13].

---

1Here relative refers to disregarding eigenvalues of the base surface.
0.218), Kim and Shahidi [KS02b, KS02a] (spectral gaps of size $\frac{77}{324} \approx 0.23765$), and currently, Kim and Sarnak [Kim03, Appendix 2] (spectral gaps of size $\frac{975}{4096} \approx 0.23804$).

The history of Corollary 1.3 began with McKean’s paper [McK72, McK74] where it was wrongly asserted that the first eigenvalue of any compact hyperbolic surface is at least $\frac{1}{4}$; this was disproved by Randol in [Ran74] who actually showed that there can be arbitrarily many eigenvalues in $(0, \frac{1}{4})$. Buser proved in [Bus84] using Selberg’s $\frac{3}{16}$ theorem and the Jacquet-Langlands machinery [JL70] that there exist closed hyperbolic surfaces $X_i$ with genera $g(X_i) \to \infty$ and $\lambda_1(X_i) \geq \frac{3}{16}$. Buser, Burger, and Dodziuk proved in [BBD88] that one can get the slightly weaker result $\lambda_1(X_i) \to \frac{3}{16}$ but without using Jacquet-Langlands. This turns out to be instrumental in the current work; see Lemma 8.1 below.

Following these works, all progress towards Corollary 1.3 ran parallel to the previously discussed progress to Corollary 1.2. In particular, the previous best known result towards Corollary 1.3 comes from combining the Kim-Sarnak bound with either Jacquet-Langlands or [BBD88] to obtain Corollary 1.3 with $\frac{1}{4}$ replaced by $\frac{975}{4096}$.

1.2 Overview of proof

The proof of Theorem 1.1 follows the following strategy. We view

$$X = \Gamma \backslash \mathbb{H}$$

where $\Gamma$ is a discrete torsion free subgroup of $\text{PSL}_2(\mathbb{R})$ and $\mathbb{H}$ is the hyperbolic upper half plane. We explain in §2 that the random degree $n$ covers of $X$ are parameterized by

$$\phi \in \text{Hom}(\Gamma, S_n) \mapsto X_\phi$$

where $\phi$ is a uniformly random homomorphism of the free group $\Gamma$ into the symmetric group $S_n$. Because we disregard eigenvalues and eigenfunctions lifted from $X$, we restrict our attention to the space $L^2_{\text{new}}(X_\phi)$ of functions that are orthogonal to all lifts of $L^2$ functions from $X$. The strategy is then, for any $s_0 > \frac{1}{2}$, to asymptotically almost surely produce a bounded resolvent operator

$$R_{X_\phi}(s) : L^2_{\text{new}}(X_\phi) \to L^2_{\text{new}}(X_\phi)$$

such that

$$(\Delta_{X_\phi} - s(1-s))^{-1} R_{X_\phi}(s) = \text{Id}_{L^2_{\text{new}}(X_\phi)},$$

for any $s \in [s_0, 1]$; this will forbid new eigenvalues in $[0, s_0(1-s_0)]$.

The way we build our resolvent is by a parametrix construction. The fundamental
structure of parametrix construction is to produce a bounded operator

\[ M_\phi(s) : L^2_{\text{new}}(X_\phi) \to L^2_{\text{new}}(X_\phi) \]

such that

\[ (\Delta_{X_\phi} - s(1-s))^{-1} M_\phi(s) = \text{Id}_{L^2_{\text{new}}(X_\phi)} + \mathbb{L}_\phi(s) \]

where we aim to prove \( \mathbb{L}_\phi(s) \) has norm less than one so that we can obtain our bounded

\[ R_{X_\phi}(s) = M_\phi(s) \left( \text{Id}_{L^2_{\text{new}}(X_\phi)} + \mathbb{L}_\phi(s) \right)^{-1} \]

Often in a parametrix construction one also wants the \( L \) term to be compact: this will also be the case here and turns out to be essential for the application of random operator results.

The way we build \( M_\phi(s) \) is by patching together a 'cuspidal parametrix' \( M_\phi^{\text{cusp}}(s) \) based on a model resolvent in the cusp and an interior parametrix \( M_\phi^{\text{int}}(s) \) that only depends on the localization of its argument to a compact part of \( X_\phi \). We then let

\[ M_\phi(s) = M_\phi^{\text{int}}(s) + M_\phi^{\text{cusp}}(s) \]

and we get a resulting splitting

\[ \mathbb{L}_\phi(s) = \mathbb{L}_\phi^{\text{int}}(s) + \mathbb{L}_\phi^{\text{cusp}}(s). \]

In Section 4 we show that for any \( \phi \), the term \( M_\phi^{\text{cusp}}(s) \) can be designed so that \( \| \mathbb{L}_\phi^{\text{cusp}}(s) \| \leq \frac{1}{5} \) (or any small number), so that it will not essentially interfere with our plans of obtaining \( \| \mathbb{L}_\phi(s) \| < 1 \). The ability to do this is a particular feature of the geometry of hyperbolic cusps.

The term \( M_\phi^{\text{int}}(s) \) is based on averaging the resolvent kernel of the hyperbolic plane over the fundamental group of \( \Gamma \) (suitably twisting by \( \phi \)) to obtain an integral operator on \( L^2_{\text{new}}(X_\phi) \). The problem with this is that the averaging will not obviously converge, so we have to multiply the hyperbolic resolvent kernel by a radial cutoff that localizes to radii \( \leq T + 1 \) to get a priori convergence for all \( s \in (\frac{1}{2}, 1] \). This gives us that \( M_\phi^{\text{int}}(s) \) is bounded (Lemma 5.4).

The effect of this cutoff is that the error term \( \mathbb{L}_\phi^{\text{int}}(s) \) is an integral operator with smooth kernel. We prove that we can unitarily conjugate \( \mathbb{L}_\phi^{\text{int}}(s) \) to

\[ \sum_{\gamma \in \Gamma} a_\gamma(s) \otimes \phi(\gamma) \]

acting on \( L^2(F) \otimes V^0_n \), where \( F \) is a Dirichlet fundamental domain for \( \Gamma \) and \( V^0_n \) is the standard \( n - 1 \) dimensional irreducible representation of \( S_n \). The \( a_\gamma(s) \) are compact
operators on $L^2(F)$ and there are only finitely many $\gamma \in \Gamma$ for which $a_\gamma(s)$ is non-zero. If instead, the $a_\gamma(s)$ were elements of $\text{End}(C^r)$ for some fixed finite $r$, because $\Gamma$ was free we would now be exactly in the situation to apply the breakthrough results of Bordenave and Collins from [BC19]. These random operator results, combined with a linearization trick of Pisier [Pis18], would tell us that for any $\epsilon > 0$, a.a.s

$$\|L^\text{int}_\phi(s)\| \leq \left\| \sum_{\gamma \in \Gamma} a_\gamma(s) \otimes \rho_\infty(\gamma) \right\| + \epsilon \quad (1.1)$$

where $\rho_\infty : \Gamma \to \text{End}(\ell^2(\Gamma))$ is the right regular representation. Because we only need to know say $L^\text{int}_\phi(s) \leq \frac{1}{3}$ we do not need to be very precise here and so can accept a loss by approximating our compact coefficients by finite rank ones on both sides of this argument.

The key point (which is a sticking point in other approaches to this problem using e.g. transfer operators) is that we understand the operator in the right hand side of (1.1) well: it can be unitarily conjugated to an operator on $L^2(\mathbb{H})$ that is the composition of multiplication with a cutoff (with norm $\leq 1$) and an integral operator with real-valued radial kernel that localizes to radii in $[T, T+1]$.

The key is that as this latter operator is self-adjoint we can use the theory of the Selberg transform to estimate its norm in Lemma 5.2. By choosing $T$ sufficiently large in the beginning, we can force the norm in the right hand side of (1.1) to be as small as we like, given any $s_0 > \frac{1}{2}$, for all $s \geq s_0$.

Assembling these arguments, for any $s \geq s_0 > \frac{1}{2}$, a.a.s. $1 + L_\phi(s)$ can be inverted which rules out $X_\phi$ having a new eigenvalue at $s(1 - s)$. To be able to get this result for all $s \geq s_0$ with probability tending to one, we make sure that $\|L_\phi(s)\| \leq \frac{2}{3}$ at a fine enough net of $s \in [s_0, 1]$ and then use a deviations estimate (Lemma 6.1) to show (deterministically) that $\|L_\phi(s)\|$ fluctuates at most by $\frac{1}{3}$ from point to point.

Acknowledgments

We thank A. Gamburd, C. Bordenave, B. Collins, F. Naud, D. Puder, and P. Sarnak for conversations about this work. This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No 949143).

2 Random covers

Let $X$ be a finite area non-compact connected hyperbolic surface. We view $X$ as

$$X = \Gamma \backslash \mathbb{H}$$
where
\[ H = \{ x + iy : x, y \in \mathbb{R}, y > 0 \} \]
with metric
\[ \frac{dx^2 + dy^2}{y^2} \]
where \( \Gamma \) is a discrete torsion-free subgroup of \( \text{PSL}_2(\mathbb{R}) \) that acts, via Möbius transformations, by orientation preserving isometries on \( H \).

For \( n \in \mathbb{N} \) let \( [n] \overset{\text{def}}{=} \{1, \ldots, n\} \) and \( S_n \) denote the group of permutations of \( [n] \). For any homomorphism \( \phi \in \text{Hom}(\Gamma, S_n) \) we construct a hyperbolic surface as follows. Let \( \Gamma \) act on \( H \times [n] \) by
\[ \gamma(z, x) \overset{\text{def}}{=} (\gamma z, \phi(\gamma)[x]) \]
and let
\[ X_\phi \overset{\text{def}}{=} \Gamma \backslash \phi(H \times [n]). \]
If we choose \( \phi \) uniformly at random in \( \text{Hom}(\Gamma, S_n) \), the resulting \( X_\phi \) is a uniformly random degree \( n \) covering space of \( X \). Note that \( \Gamma \) is a free group freely generated by some
\[ \gamma_1, \ldots, \gamma_d \in \Gamma \]
and choosing \( \phi \) is the same as choosing
\[ \sigma_i \overset{\text{def}}{=} \phi(\gamma_i), \quad i = 1, \ldots, d \]
independently and uniformly at random in \( S_n \).

Let \( V_n \overset{\text{def}}{=} \ell^2([n]) \) and \( V_n^0 \subset V_n \) the subspace of functions on \( [n] \) with zero mean. The representation of \( S_n \) on \( \ell^2([n]) \) is its standard representation by 0-1 matrices and the subspace \( V_n^0 \) is an irreducible subspace of dimension \( (n - 1) \): we write
\[ \rho_n^0 : \Gamma \to \text{End}(V_n^0) \]
for the random representation of \( \Gamma \) induced by the random \( \phi \). We define
\[ L^2_{\text{new}}(X_\phi) \]
to be the space of functions that are orthogonal to all pullbacks of \( L^2 \) functions from \( X \). This space is preserved by the Laplacian and we have
\[ L^2(X_\phi) \cong L^2_{\text{new}}(X_\phi) \oplus L^2(X). \]
This induces a multiplicity respecting inclusion \( \text{spec}(\Delta_X) \subset \text{spec}(\Delta_{X_\phi}) \). All other spectra of \( \Delta_{X_\phi} \) (with multiplicities) arise from eigenfunctions in the subspace \( L^2_{\text{new}}(X_\phi) \).
3 Background random matrix theory

In this section we give an account of the breakthrough result of Bordenave and Collins [BC19] and its amplification through a linearization trick that appears in Pisier [Pis18, Cor. 14] (see also, historically, [Pis96, HT05], and [BC19, §6]).

Let \( \text{std}_n : S_n \to \text{End}(V_n^0) \) denote the linear action of \( S_n \) on \( V_n^0 \). We let \( \rho_\infty : \Gamma \to \text{End}(\ell^2(\Gamma)) \) denote the right regular representation of \( \Gamma \). We are going to use the following direct consequence of [BC19, Thm. 2].

**Theorem 3.1 (Bordenave-Collins).** Suppose that \( r \in \mathbb{N} \) and \( a_0, a_1, \ldots, a_d \in \text{Mat}_{r \times r}(\mathbb{C}) \). Suppose \( a_0^* = a_0 \). Then for any \( \epsilon > 0 \), with probability tending to one as \( n \to \infty \), we have

\[
\left\| a_0 \otimes \text{Id}_{V_n^0} + \sum_{i=1}^d a_i \otimes \text{std}_n(\sigma_i) + a_i^* \otimes \text{std}_n(\sigma_i^{-1}) \right\|_{\mathbb{C}^r \otimes V_n^0} \\
\leq \left\| a_0 \otimes \text{Id}_{\ell^2(\Gamma)} + \sum_{i=1}^d a_i \otimes \rho_\infty(\gamma_i) + a_i^* \otimes \rho_\infty(\gamma_i^{-1}) \right\|_{\mathbb{C}^r \otimes \ell^2(\Gamma)} + \epsilon.
\]

The norm on the top is the operator norm on \( \mathbb{C}^r \otimes V_n^0 \). The norm on the bottom is the operator norm on \( \mathbb{C}^r \otimes \ell^2(\Gamma) \).

**Remark 3.2.** Note in the above that \( \text{std}_n(\sigma_i) = \rho_0^n(\gamma_i) \).

This will be combined with the following result of Pisier [Pis18, Cor. 14 and following remark].

**Proposition 3.3 (Pisier).** The result of Theorem 3.1 implies that for any \( R, k \in \mathbb{N} \), any non-commutative polynomials

\[
P_1, P_2, \ldots, P_k
\]

in the variables \( \sigma_1, \ldots, \sigma_d, \sigma_1^{-1}, \ldots, \sigma_d^{-1} \) with complex coefficients, and any \( a_1, \ldots, a_k \in \text{Mat}_{R \times R}(\mathbb{C}) \) we have the following. For any \( \epsilon > 0 \), with probability tending to one as \( n \to \infty \), we have

\[
\left\| \sum_{i=1}^k a_i \otimes \text{std}_n(P_i(\sigma_1, \ldots, \sigma_d, \sigma_1^{-1}, \ldots, \sigma_d^{-1})) \right\|_{\mathbb{C}^R \otimes V_n^0} \\
\leq \left\| \sum_{i=1}^k a_i \otimes \rho_\infty(P_i(\gamma_1, \ldots, \gamma_d, \gamma_1^{-1}, \ldots, \gamma_d^{-1})) \right\|_{\mathbb{C}^R \otimes \ell^2(\Gamma)} + \epsilon.
\]

This type of ‘linearization’ is obviously extremely powerful and has played a role in many of the major breakthroughs in random operators in recent years [HT05, CM14,
Notice that one way to obtain an operator as in (3.1) is as
\[
\sum_{\gamma \in \Gamma} a_{\gamma} \otimes \rho^0_n(\gamma)
\]
where all \(a_{\gamma} \in \text{Mat}_{R \times R}(C)\) and there are only finitely many non-zero \(a_{\gamma}\). Therefore we obtain combining Theorem 3.1 and Proposition 3.3 the following:

**Corollary 3.4.** For any \(r \in \mathbb{N}\) and any finitely supported map \(\gamma \in \Gamma \mapsto a_{\gamma} \in \text{Mat}_{r \times r}(C)\), for any \(\epsilon > 0\), with probability tending to one as \(n \to \infty\) we have
\[
\left\| \sum_{\gamma \in \Gamma} a_{\gamma} \otimes \rho^0_n(\gamma) \right\|_{C^r \otimes V^0_n} \leq \left\| \sum_{\gamma \in \Gamma} a_{\gamma} \otimes \rho^\infty(\gamma) \right\|_{C^r \otimes \ell^2(\Gamma)} + \epsilon.
\]

No originality is claimed here: Corollary 3.4 is essentially already contained in [BC19] and in fact, [BC19, Thm. 3] is the version of this corollary when all \(a_i\) are scalar.

### 4 Cusp parametrix

To simplify notation, we assume there is just one cusp of the finite-area non compact hyperbolic surface \(X\). This does not affect the arguments. This single cusp can be identified with
\[ C \overset{\text{def}}{=} (1, \infty) \times S^1 \]
with the metric
\[
\frac{dr^2 + dx^2}{r^2};
\]
here the \(x\) coordinate is in \(S^1 \overset{\text{def}}{=} \mathbb{R}/\mathbb{Z}\) and the \(r\) coordinate is in \([1, \infty)\). In the following, \(\chi^+_C, \chi^-_C : (1, \infty) \to [0, 1]\) will be functions that are identically zero in a neighborhood of \(\{r = 1\}\), identically equal to 1 in some region \(r \geq r_0 > 1\), and such that
\[
\chi^+_C \chi^-_C = \chi^-_C. \tag{4.2}
\]
We view these as functions on \(C\) via the \(r\)-coordinate. We will extend both these functions by zero to functions on \(X\), and define
\[
\chi^\pm_C,\phi \overset{\text{def}}{=} \chi^\pm_C \circ \pi_\phi
\]
where \(\pi_\phi : X_\phi \to X\) is the covering map. Indeed, the cusp of \(X\) splits in \(X_\phi\) into several regions of the form
\[
[1, \infty) \times (\mathbb{R}/n\mathbb{Z}), \tag{4.3}
\]
with \( n \in \mathbb{N} \), and with the same metric (4.1). In these coordinates the covering isometry sends
\[
\pi_\phi : (y, x + n\mathbb{Z}) \mapsto (y, x + \mathbb{Z}).
\]
In particular, it preserves the \( y \) coordinate.

**Lemma 4.1.** For any \( \epsilon > 0 \), it is possible to choose \( \chi_C^+ \) as above so that for any \( \phi \)
\[
\| \nabla \chi_{C,\phi}^+ \|_{\infty}, \| \Delta \chi_{C,\phi}^+ \|_{\infty} \leq \epsilon.
\]

**Proof.** Given \( \epsilon > 0 \), let \( \chi_C^+ : [0, \infty) \to [0, 1] \) be a function such that \( \chi_C^+(\tau) \equiv 0 \) for \( \tau \) in \([0, 1]\), \( \chi_C^+(\tau) \equiv 1 \) for \( \tau \geq \tau_0 \), for some \( \tau_0 > 0 \), and such that we have the following bounds for the derivatives of \( \chi_C^+ \)
\[
\sup_{[0, \infty)} |(\chi_C^+)'|, \sup_{[0, \infty)} |(\chi_C^+)''| \leq \frac{\epsilon}{2}
\]
(this can be achieved by scaling some fixed cutoff).

Let \( C' \) be any cusp region of \( X_\phi \) as in (4.3). Using the change of coordinates \( r = e^\tau \) we view \( C' \) as
\[
(0, \infty)_\tau \times \mathbb{R}/n\mathbb{Z}
\]
with the metric \((d\tau)^2 + e^{-2\tau}(dx)^2\); \( x \) being the coordinate in \( \mathbb{R}/n\mathbb{Z} \). In these coordinates,
\[
\| \nabla \chi_{C,\phi}^+ \|((\tau, x + n\mathbb{Z})) = |[\chi_C^+]'(\tau)| \leq \epsilon
\]
and
\[
|\Delta \chi_{C,\phi}^+|((\tau, x + n\mathbb{Z})) = |[\chi_C^+]''(\tau) - [\chi_C^+]'(\tau)| \leq \epsilon
\]
as required. Finally, one can easily choose \( \chi_C^- \) to be a function with \( \chi_C^-(\tau) \equiv 0 \) for \( \tau \leq \tau_0 \) and \( \chi_C^-(\tau) \equiv 1 \) for \( \tau \geq 2\tau_0 \). This will fulfill (4.2). \( \Box \)

Let \( C_\phi \) denote the subset of \( X_\phi \) that covers \( C \). Let \( H^2(C_\phi) \) denote the completion of \( C^\infty(C_\phi) \) with respect to the given norm
\[
\|f\|_{H^2}^2 \overset{\text{def}}{=} \|f\|_{L^2}^2 + \|\Delta f\|_{L^2}^2.
\]
Notice that here \( C_\phi \) is assumed open so \( C^\infty(C_\phi) \) consists of functions zero in a neighborhood of the horocycles that bound the cusps. The Laplacian \( \Delta = \Delta_{C_\phi} \) extends to a self-adjoint unbounded operator on \( L^2(C_\phi) \) with domain \( H^2(C_\phi) \).

For any \( f \in H^2(C_\phi) \) we have
\[
\langle \Delta f, f \rangle \geq \frac{1}{4} \|f\|^2.
\]
(4.4)
This follows from [Mag15, Lemma 3.2]. It follows that
\[ R_{\phi}(s) \stackrel{\text{def}}{=} (\Delta - s(1-s))^{-1} : L^2(C_\phi) \to H^2(C_\phi) \]
is a holomorphic family of bounded operators in Re(s) > 1/2, each a bijection to their image. This gives an a priori bound for the resolvent: using
\[ (\Delta - s(1-s)) R_{\phi}(s)f = f \]
and (4.4) we obtain that for \( f \in L^2(C_\phi) \) and \( s \in (\frac{1}{2}, 1] \)
\[ \| R_{\phi}(s)f \|_{L^2} \leq \left( \frac{1}{4} - s(1-s) \right)^{-1} \| f \|_{L^2} \]  
(4.5)
and as
\[ \Delta R_{\phi}(s)f = f + s(1-s)R_{\phi}(s)f \]
we obtain for \( s \in (\frac{1}{2}, \infty) \)
\[ \| \Delta R_{\phi}(s)f \|_{L^2} \leq \| f \|_{L^2} + s(1-s)\| R_{\phi}(s)f \|_{L^2} \]
\[ \leq \left( 1 + \frac{s(1-s)}{\frac{1}{2} - s(1-s)} \right) \| f \|_{L^2} \]
\[ = \frac{1}{1 - 4s(1-s)} \| f \|_{L^2}. \]  
(4.6)
We now define the cusp parametrix as
\[ M^\phi_{\text{cusp}}(s) \stackrel{\text{def}}{=} \chi^+_{C,\phi} R_{\phi}(s) \chi^-_{C,\phi}. \]  
(4.7)
Since (multiplication by) \( \chi^+_{C,\phi} \) is bounded from \( L^2(X_\phi) \) to \( L^2(C_\phi) \), \( R_{\phi}(s) \) is bounded from \( L^2(C_\phi) \) to \( L^2(C_\phi) \), and \( \chi^-_{C,\phi} \) is bounded on \( L^2(X_\phi) \), \( M^\phi_{\text{cusp}}(s) \) is a bounded operator from \( L^2(X_\phi) \) to itself.

Because \( \chi^+_{C,\phi} \chi^-_{C,\phi} = \chi^-_{C,\phi} \),
\[ (\Delta - s(1-s)) M^\phi_{\text{cusp}}(s) = \chi^-_{C,\phi} + [\Delta, \chi^+_{C,\phi}] R_{\phi}(s) \chi^-_{C,\phi} = \chi^-_{C,\phi} + \mathbb{L}^\phi_{\text{cusp}}(s) \]  
(4.8)
where
\[ \mathbb{L}^\phi_{\text{cusp}}(s) \stackrel{\text{def}}{=} [\Delta, \chi^+_{C,\phi}] R_{\phi}(s) \chi^-_{C,\phi}. \]
This is an operator on \( L^2(X_\phi) \).

**Lemma 4.2.** Given \( s_0 > \frac{1}{2} \), there exists \( C(s_0) > 0 \) such that for \( s \in [s_0, 1] \), the operator
\( L_{\phi}^{\text{cusp}}(s) \) is a self-adjoint, bounded operator on \( L^2(X_\phi) \) with norm bounded by

\[
\| L_{\phi}^{\text{cusp}}(s) \|_{L^2} \leq \left( \|(\Delta \chi_{C,\phi}^+)\|_\infty + 2\|\nabla \chi_{C,\phi}^+\|_\infty \right) C(s_0).
\]

**Proof.** As an operator on \( H^2(C_{\phi}) \)

\[
[\Delta, \chi_{C,\phi}^+] = (\Delta \chi_{C,\phi}^+) - 2(\nabla \chi_{C,\phi}^+) \cdot \nabla.
\]

The first summand is a multiplication operator; for \( f \in H^2(C_{\phi}) \) we have

\[
\|(\Delta \chi_{C,\phi}^+) f\|_{L^2} \leq \|(\Delta \chi_{C,\phi}^+)\|_\infty \|f\|_{L^2}
\]

and by Schwarz inequality if \( \|f\|_{H^2} \leq 1 \) then

\[
\|(\nabla \chi_{C,\phi}^+) \cdot \nabla f\|_{L^2} \leq \|\nabla \chi_{C,\phi}^+\|_\infty \|\nabla f\|_{L^2}
\]

\[
= \|\nabla \chi_{C,\phi}^+\|_\infty \|\Delta f\|_2^{\frac{1}{2}} \leq \|\nabla \chi_{C,\phi}^+\|_\infty \|\Delta f\|_2 \|f\|_2^{\frac{1}{2}}
\]

\[
\leq \|\nabla \chi_{C,\phi}^+\|_\infty.
\]

The two estimates (4.9), (4.10) hence show that \( [\Delta, \chi_{C,\phi}^+] \) has norm bounded by \( \|(\Delta \chi_{C,\phi}^+)\|_\infty + 2\|\nabla \chi_{C,\phi}^+\|_\infty \) as a map \( H^2(C_{\phi}) \to L^2(C_{\phi}) \). Since multiplication by \( \chi_{C,\phi}^- \) has norm \( \leq 1 \) from \( L^2 \) to \( L^2 \), and \( R_{C,\phi}(s) \) has norm \( \leq C(s_0) \) from \( L^2(C_{\phi}) \) to \( H^2(C_{\phi}) \) by (4.5) and (4.6), we obtain the stated result.

We can now obtain the following proposition by combining Lemmas 4.1 and 4.2.

**Proposition 4.3.** Given any \( s_0 > \frac{1}{2} \), we can choose \( \chi_{C}^+ \) and \( \chi_{C}^- \) (depending on \( s_0 \)) such that for any \( n \in \mathbb{N} \) and \( \phi \in \text{Hom}(\Gamma, S_n) \) and any \( s \in [s_0, 1] \), we have

\[
\| L_{\phi}^{\text{cusp}}(s) \|_{L^2} \leq \frac{1}{5}.
\]

We assume that \( \chi_{C}^- \) and \( \chi_{C}^+ \) have been fixed to satisfy Proposition 4.3 in the rest of the paper.
5 Interior parametrix

5.1 Background on spectral theory of hyperbolic plane

Resolvent

Let

\[ R_{\mathbb{H}}(s) : L^2(\mathbb{H}) \to L^2(\mathbb{H}), \]

\[ R_{\mathbb{H}}(s) \overset{\text{def}}{=} (\Delta_{\mathbb{H}} - s(1 - s))^{-1}. \]

Since \( \text{spec}(\Delta_{\mathbb{H}}) \subset \left[ \frac{1}{4}, \infty \right) \) [Bor16, Thm. 4.3], this is well defined as a bounded operator for \( \text{Re}(s) > \frac{1}{2} \).

Given \( x, y \in \mathbb{H} \), we write \( r = d_{\mathbb{H}}(x, y) \) where \( d_{\mathbb{H}} \) is hyperbolic distance and \( \sigma \overset{\text{def}}{=} \cosh^2 \left( \frac{r}{2} \right) \).

The operator \( R_{\mathbb{H}}(s) \) is an integral operator with kernel [Bor16, Prop. 4.2]

\[ R_{\mathbb{H}}(s; x, y) = \frac{1}{4\pi} \int_0^1 \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s}} dt. \]  

(5.1)

For \( \sigma > 1 \) we have

\[ \frac{\partial}{\partial r} \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s}} = -s \sinh \left( \frac{r}{2} \right) \cosh \left( \frac{r}{2} \right) \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s+1}}, \]

\[ \frac{\partial}{\partial s} \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s}} = \log \left( \frac{t(1-t)}{(\sigma-t)} \right) \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s}}, \]

\[ \frac{\partial^2}{\partial s \partial r} \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s}} = -\sinh \left( \frac{r}{2} \right) \cosh \left( \frac{r}{2} \right) \frac{t^{s-1}(1-t)^{s-1}}{(\sigma-t)^{s+1}} \left[ 1 + s \log \left( \frac{t(1-t)}{(\sigma-t)} \right) \right]. \]

Each of these are smooth in \( (s, r, t) \in \left[ \frac{1}{2}, 1 \right] \times [1, \infty) \times (0, 1) \). Because for \( s, r \) in a fixed compact set of \( \left[ \frac{1}{2}, 1 \right] \times [1, \infty) \), these all have absolute values majorized by integrable functions of \( t \in (0, 1) \), we can interchange derivatives and integrals to get corresponding bounds for \( R_{\mathbb{H}} \) as follows. We define

\[ R_{\mathbb{H}}(s; r) \overset{\text{def}}{=} R_{\mathbb{H}}(s; x, y). \]

Firstly, there is a constant \( C > 0 \) such that for \( r \geq 1 \) and \( s \in \left[ \frac{1}{2}, 1 \right] \) we have

\[ |R_{\mathbb{H}}(s; r_0)|, \left| \frac{\partial R_{\mathbb{H}}(s; r_0)}{\partial r} \right| \leq Ce^{-sr_0}. \]  

(5.2)

Secondly, for any \( T > 1 \) and \( r_0 \) in the compact region \( [1, T+1] \) we obtain for constant
Integral operators

If $k_0 : [0, \infty) \to \mathbb{R}$ is smooth and compactly supported, which will suffice here, then one can construct a kernel

$$k(x, y) \overset{\text{def}}{=} k_0(d_H(x, y))$$

with corresponding integral operator $C^\infty(\mathbb{H}) \to C^\infty(\mathbb{H})$

$$K[f](x) \overset{\text{def}}{=} \int_{y \in \mathbb{H}} k(x, y)f(y)dH(y)$$

where $dH$ is the hyperbolic area form on $\mathbb{H}$. Such an operator commutes with the Laplacian on $\mathbb{H}$ and hence preserves its generalized eigenspaces. If $f \in C^\infty(\mathbb{H})$ is an generalized eigenfunction of $\Delta$ with eigenvalue $\frac{1}{4} + \xi^2, \xi \geq 0$, then by [Ber16, Thm. 3.7, Lemma 3.9] (cf. also Selberg’s original article [Sel56])

$$K[f] = h(\xi)f$$

where

$$h(\xi) = \sqrt{2} \int_{-\infty}^{\infty} e^{i\xi u} \int_{|u|}^{\infty} \frac{k_0(\rho) \sinh(\rho)}{\cosh(\rho) - \cosh(u)} d\rho du.$$  

By our assumptions on $k_0$ the integral above is convergent. It will be estimated more precisely for particular choice of $k_0$ later. For now note that if $k_0$ is real valued then $h$ is the Fourier transform of a real valued even function and hence real-valued. Since $L^2(\mathbb{H})$ has a generalized eigenbasis of $C^\infty$ eigenfunctions of the Laplacian, by Borel functional calculus $K$ extends from e.g. $C^\infty_c(\mathbb{H})$ to a (possibly unbounded) self-adjoint operator on $L^2(\mathbb{H})$ with operator norm

$$\|K\|_{L^2(\mathbb{H})} = \sup_{\xi \geq 0} |h(\xi)|.$$  

5.2 Function spaces

Let $F$ denote a Dirichlet fundamental domain for $X$, that is, for some fixed $o \in \mathbb{H}$,

$$F \overset{\text{def}}{=} \bigcap_{\gamma \in \Gamma \setminus \{\text{id}\}} \{z \in \mathbb{H} : d(o, z) < d(z, \gamma o)\}.$$
Let $C^\infty(\mathbb{H}; V_n^0)$ denote the smooth $V_n^0$-valued functions on $\mathbb{H}$. Recalling the definition of $L^2_{\text{new}}(X_\phi)$ from §2, there is an isometric linear isomorphism between

$$C^\infty(X_\phi) \cap L^2_{\text{new}}(X_\phi)$$

and the space of smooth $V_n^0$-valued functions on $\mathbb{H}$ satisfying

$$f(\gamma z) = \rho_n^0(\gamma)f(z) \quad (5.5)$$

for all $\gamma \in \Gamma$, with the norm

$$\|f\|_{L^2(F)}^2 \overset{\text{def}}{=} \int_F \|f(z)\|^2_{V_n^0}d\mathbb{H}.$$ 

We will denote $C^\infty(\mathbb{H}; V_n^0) \subset C^\infty(\mathbb{H}; V_n^0)$ for these functions. Under this isomorphism, the Laplacian on $C^\infty(X_\phi) \cap L^2_{\text{new}}(X_\phi)$ is intertwined with the Laplacian that acts on $C^\infty(\mathbb{H}; V_n^0)$ in the obvious way (this can be defined by choosing any basis of $V_n^0$ and letting the Laplacian act coordinatewise on $V_n^0$-valued functions).

The completion of $C^\infty(\mathbb{H}; V_n^0)$ with respect to $\| \cdot \|_{L^2(F)}$ is denoted by $L^2_{\phi}(\mathbb{H}; V_n^0)$; the isomorphism above extends to one between $L^2_{\text{new}}(X_\phi)$ and $L^2_{\phi}(\mathbb{H}; V_n^0)$.

### 5.3 Interior parametrix on hyperbolic plane

Let $\chi_0 : \mathbb{R} \to [0, 1]$ denote a smooth function with $\chi_0|_{(-\infty, 0]} \equiv 1$ and $\chi_0|_{[1, \infty)} = 0$. Then let

$$\chi_T(t) \overset{\text{def}}{=} \chi_0(t - T)$$

so $\chi_T$ is supported on $(-\infty, T + 1]$; note for later that all derivatives of $\chi_T$ are supported in $[T, T + 1]$ and have uniform bounds independent of $T$.

We define

$$R_{\mathbb{H}}^{(T)}(s; r) \overset{\text{def}}{=} \chi_T(r)R_{\mathbb{H}}(s; r).$$

Let $R_{\mathbb{H}}^{(T)}(s)$ denote the corresponding integral operator. In radial coordinates the Laplacian on $\mathbb{H}$ is given by [Ber16, (3.2)]

$$-\frac{\partial^2}{\partial r^2} - \frac{1}{\tanh r} \frac{\partial}{\partial r} - \frac{1}{(2 \sinh r)^2} \frac{\partial^2}{\partial \theta^2}.$$ 

We now perform the following calculation, writing $\Delta_x$ for the Laplacian acting on coordinate $x$:

$$[\Delta_x - s(1 - s)] R_{\mathbb{H}}^{(T)}(s; r) = [\Delta_x - s(1 - s)] \chi_T(r)R_{\mathbb{H}}(s; r)$$

$$= \left[ -\frac{\partial^2}{\partial r^2} - \frac{1}{\tanh r} \frac{\partial}{\partial r}, \chi_T \right] R_{\mathbb{H}}(s; r) + \delta_{r=0} \quad (5.6)$$
which is understood in a distributional sense. We further calculate
\[
\left[ -\frac{\partial^2}{\partial r^2} - \frac{1}{\tanh r} \frac{\partial}{\partial r}, \chi_T \right] = -\frac{\partial^2}{\partial r^2} [\chi_T] - 2 \frac{\partial}{\partial r} [\chi_T] \frac{\partial}{\partial r} - \frac{1}{\tanh r} \frac{\partial}{\partial r} [\chi_T]. \tag{5.7}
\]
Combining (5.6) and (5.7) we obtain as an identity of operators
\[
[\Delta - s(1 - s)] R^{(T)}_{H} (s) = 1 + L^{(T)}_{H} (s) \tag{5.8}
\]
where \( L^{(T)}_{H} (s) \) is the integral operator with real-valued radial kernel
\[
L^{(T)}_{H} (s; r_0) \overset{\text{def}}{=} \left( -\frac{\partial^2}{\partial r^2} [\chi_T] - \frac{1}{\tanh r} \frac{\partial}{\partial r} [\chi_T] \right) R_{H} (s; r_0) - 2 \frac{\partial}{\partial r} [\chi_T] \frac{\partial R_{H}}{\partial r} (s; r_0).
\]
We note the following properties of this kernel that are straightforward consequences of the way \( \chi_T \) was chosen and (5.2), (5.3).

**Lemma 5.1.** We have

1. For \( s \in \left[ \frac{1}{2}, 1 \right] \), \( L^{(T)}_{H} (s; \bullet) \) is smooth and supported in \( [T, T + 1] \).
2. There is a constant \( C > 0 \) such that for any \( T > 0 \) and \( s \in \left[ \frac{1}{2}, 1 \right] \) we have

\[
\| L^{(T)}_{H} (s; r_0) \| \leq C e^{-sr_0}
\]

3. For any \( T > 0 \) there is a constant \( c(T) > 0 \) such that for any \( r_0 \in [T, T + 1] \)

\[
\left| \frac{\partial L^{(T)}_{H}}{\partial s} (s_0; r_0) \right| \leq c(T).
\]

We can now show the following.

**Lemma 5.2.** There is a constant \( C > 0 \) such that for any \( T > 0 \) and \( s \in \left[ \frac{1}{2}, 1 \right] \) the operator \( L^{(T)}_{H} (s) \) extends to a bounded operator on \( L^2 (\mathbb{H}) \) with

\[
\| L^{(T)}_{H} (s) \|_{L^2} \leq C T e^{(\frac{1}{2} - s) T}.
\]
Proof. We do this using (5.4) which tells us

\[
\|L_H^{(T)}(s)\|_{L^2} \leq \sup_{\xi \geq 0} \left| \sqrt{2} \int_{-\infty}^{\infty} e^{\xi u} \int_{|u|}^{\infty} \frac{k_0(\rho) \sinh(\rho)}{\cosh(\rho) - \cosh(u)} d\rho du \right|
\]

\[
\leq \sqrt{2} \int_{-\infty}^{\infty} \int_{|u|}^{\infty} \frac{|L_H^{(T)}(s; \rho)| \sinh(\rho)}{\cosh(\rho) - \cosh(u)} d\rho du
\]

\[
\leq 2\sqrt{2} C \int_{0}^{T+1} \int_{\max(|u|, T)}^{T+1} \frac{e^{-s\rho} \sinh(\rho)}{\cosh(\rho) - \cosh(u)} d\rho du
\]

\[
\leq C' e^{-sT} \int_{0}^{T+1} \int_{\cosh(T+1)}^{\cosh\max(|u|, T)} \frac{\sinh(\rho)}{\sqrt{\cosh(\rho) - \cosh(u)}} \frac{dy}{dy} d\rho du
\]

\[
= C'' e^{-sT} \int_{0}^{T+1} \left[ \sqrt{\cosh(T+1) - \cosh u} - \sqrt{\cosh\max(|u|, T) - \cosh |u|} \right] du
\]

\[
\leq C''' e^{\left(1 - \frac{s}{2}\right)T}
\]

where the third inequality used Lemma 5.1.

The implication of this is that for any \( s_0 > \frac{1}{2} \) we can choose \( T = T(s_0) \) such that for all \( s \in [s_0, 1] \) we have

\[
\|L_H^{(T)}(s)\|_{L^2} \leq \frac{1}{5}.
\]

We will do this later.

### 5.4 Automorphic kernels

At two points in the rest of the paper we use the following geometric lemma. Recall \( F \) is a Dirichlet fundamental domain for \( \Gamma \) in \( \mathbb{H} \).

**Lemma 5.3.** For any compact set \( K \subset \bar{F} \), and \( T > 0 \), there is another compact set \( K' = K'(K, T) \subset \bar{F} \) and a finite set \( S = S(K, T) \subset \Gamma \) such that for all \( x, y \in \mathbb{H} \) with

\[
x \in \bar{F}, \; y \in \bigcup_{\gamma \in \Gamma} \gamma(K), \quad d(x, y) \leq T,
\]

we have

\[
x \in K', \quad y \in \bigcup_{\gamma \in S} \gamma(K).
\]

**Proof.** Suppose that \( y = \gamma y' \) with \( y' \in K \), \( x \in \bar{F} \), \( \gamma \in \Gamma \) and \( d(x, y) \leq T \). Then \( d(\gamma y', x) = d(y', \gamma^{-1} x) \leq T + 1 \) implies \( \gamma^{-1} F \) intersects the compact set

\[
\{ z : d(z, K) \leq T + 1 \}.
\]
Since we took $F$ to be a Dirichlet fundamental domain, by [Bea83, Thm. 9.4.2] there are only a finite number of $\gamma$ for which this is possible. Let $S$ be this finite subset of $\Gamma$. Then furthermore, if we let $o$ denote a fixed point in $\bar{K}$ we have
\[
d(x, o) \leq d(x, \gamma y') + d(\gamma y', \gamma o) + d(\gamma o, o).
\]
\[
\leq T + d(y', o) + d(\gamma o, o) \leq C'(K, T).
\]
This implies that $x$ must be in some compact set $K' = K'(K, T) \subset \bar{F}$.

Define
\[
R_{\mathbb{H}, n}^{(T)}(s; x, y) \overset{\text{def}}{=} R_{\mathbb{H}}^{(T)}(s; x, y)\text{Id}_{V_n}^o,
\]
\[
\mathbb{F}_{\mathbb{H}, n}^{(T)}(s; x, y) \overset{\text{def}}{=} \mathbb{F}_{\mathbb{H}}^{(T)}(s; x, y)\text{Id}_{V_n}^o,
\]
and $R_{\mathbb{H}, n}^{(T)}(s), \mathbb{F}_{\mathbb{H}, n}^{(T)}(s)$ the corresponding integral operators on $C^\infty(\mathbb{H}; V_n^0)$. The identity (5.8) extends easily to
\[
[\Delta - s(1-s)] R_{\mathbb{H}, n}^{(T)}(s) = 1 + \mathbb{F}_{\mathbb{H}, n}^{(T)}(s)
\]
as operators on $C^\infty(\mathbb{H}; V_n^0)$. All operators involved here preserve $C^\infty(\mathbb{H}; V_n^0)$. In the following we regard the function $\chi_{\mathcal{C}}$ defined in §4 as a $\Gamma$-invariant $C^\infty$ function on $\mathbb{H}$. The action of multiplication by $\chi_{\mathcal{C}, \phi}$ on new functions in $C^\infty(\mathcal{X}_\phi)$ corresponds to multiplication by the scalar-valued invariant function $\chi_{\mathcal{C}}$ on $C^\infty(\mathbb{H}; V_n^0)$.

**Lemma 5.4.** For all $s \in [\frac{1}{2}, 1]$, the integral operator $R_{\mathbb{H}, n}^{(T)}(s)(1 - \chi_{\mathcal{C}})$ is a well-defined and bounded operator on $L_2^o(\mathbb{H}; V_n^0)$.

**Proof.** Suppose first that $f \in C^\infty(\mathbb{H}; V_n^0)$. We have for $x \in F$
\[
R_{\mathbb{H}, n}^{(T)}(s)(1 - \chi_{\mathcal{C}, \phi})[f](x) \overset{\text{def}}{=} \int_{y \in \mathbb{H}} R_{\mathbb{H}}^{(T)}(s; x, y)(1 - \chi_{\mathcal{C}}(y))f(y)d\mathbb{H}(y).
\]

The integrand here is non-zero unless $d(x, y) \leq T + 1$ and $y$ is in the the support of $1 - \chi_{\mathcal{C}}$, which is a union of the $\Gamma$-translates of a compact set $K$ of of $\bar{F}$. Applying Lemma 5.3 tells us then that there is compact $K_1 = K_1(T, \chi_{\mathcal{C}}) \subset \bar{F}$ such that the integrand in (5.11) is supported on the compact set $K_2 \overset{\text{def}}{=} \cup_{\gamma \in S} \gamma^{-1}K$ and the whole integral is zero unless $x \in K_1$ (given $x \in \bar{F}$ to begin with). This means that for $x \in \bar{F}$
\[
\int_{y \in \mathbb{H}} R_{\mathbb{H}}^{(T)}(s; x, y)(1 - \chi_{\mathcal{C}}(y))f(y)d\mathbb{H}(y) = \mathbf{1}\{x \in K_1\} \int_{y \in K_2} R_{\mathbb{H}}^{(T)}(s; x, y)(1 - \chi_{\mathcal{C}}(y))f(y)d\mathbb{H}(y),
\]
where $\mathbf{1}\{x \in \mathcal{S}\}$ is the function that is 1 if $x \in \mathcal{S}$ and 0 else (the indicator function of
allows us to define our interior parametrix

\[ \| R_{\text{int}}^{(T)}(s)(1 - \chi_{C,\phi}^{-})[f]\|_{L^2(F)}^2 \leq \int_{x \in K_1} \left( \int_{y \in K_2} R_{\text{int}}^{(T)}(s; x, y)(1 - \chi_{C}^{-}(y))f(y)d\mathbb{H}(y) \right)^2 d\mathbb{H}(x) \leq \int_{x \in K_1} \left( \int_{y \in K_2} \left( R_{\text{int}}^{(T)}(s; x, y)(1 - \chi_{C}^{-}(y)) \right)^2 d\mathbb{H}(y) \right) \left( \int_{y \in K_2} |f(y)|^2 d\mathbb{H}(y) \right) d\mathbb{H}(x). \]

But as above, since \( K_2 \) is covered by \( |S| \) disjoint translates of \( F \), and the contribution to \( \int_{y \in K_2} |f(y)|^2 d\mathbb{H}(y) \) from each of these is at most \( \|f\|_{L^2(F)}^2 \) by the automorphy equation (5.5), we obtain

\[ \| R_{\text{int}}^{(T)}(s)(1 - \chi_{C,\phi}^{-})[f]\|_{L^2(F)}^2 \leq |S| \|f\|_{L^2(F)}^2 \int_{x \in K_1} \left( \int_{y \in K_2} \left( R_{\text{int}}^{(T)}(s; x, y) \right)^2 d\mathbb{H}(y) \right) d\mathbb{H}(x). \]  

(5.12)

Recall that we write \( r = d_\mathbb{H}(x, y) \), hence the inner integral can be written in polar coordinates as

\[ \int_{y \in K_2} \left( R_{\text{int}}^{(T)}(s; x, y) \right)^2 d\mathbb{H}(y) = \int_0^{2\pi} \int_0^\infty \left( R_{\text{int}}^{(T)}(s; r) \right)^2 \sinh r \, dr \, d\theta \leq 2\pi \int_0^{M} \left( R_{\text{int}}^{(T)}(s; r) \right)^2 \sinh r \, dr \]  

(5.13)

for some \( M = M(K_1, K_2) \) independent of \( x \) and \( y \). Because \( \chi_T \equiv 1 \) near 0, the type of singularity that \( R_{\text{int}}^{(T)}(s; r) \) has at \( r = 0 \) is exactly the same as the type of singularity of \( R_{\mathbb{H}}(s; r) \) near \( r = 0 \); namely by [Bor16, (4.2)]

\[ R_{\text{int}}^{(T)}(s; r) = -\frac{1}{4\pi} \log \left( \frac{r}{2} \right) + O(1) \]  

(5.14)

as \( r \to 0 \). The function \( R_{\text{int}}^{(T)}(s; r) \) is smooth away from 0. Hence, since \( \left( \log \left( \frac{r}{2} \right) \right)^2 \sinh r \to 0 \) as \( r \to 0 \), \( R_{\text{int}}^{(T)}(s; r) \) is in particular square integrable on \([0, M]\). Combining this with (5.12) and (5.13) gives the result.

Lemma 5.4 allows us to define our interior parametrix

\[ \mathcal{M}_{\phi}^{\text{int}}(s) : L^2_{\text{new}}(X_\phi) \to L^2_{\text{new}}(X_\phi) \]

to be the operator corresponding under \( L^2_{\text{new}}(X_\phi) \cong L^2_{\phi}(\mathbb{H}; V_0^0) \) to the integral operator \( R_{\text{int}}^{(T)}(s)(1 - \chi_{-}) \). The equation (5.10) becomes for \( s > \frac{1}{2} \)

\[ (\Delta_{X_\phi} - s(1 - s))\mathcal{M}_{\phi}^{\text{int}}(s) = (1 - \chi_{C,\phi}^{-}) + \mathbb{L}_{\phi}^{\text{int}}(s) \]  

(5.15)

19
where
\[ L_{\phi}^{\text{int}}(s) : L^{2}_{\text{new}}(X_{\phi}) \to L^{2}_{\text{new}}(X_{\phi}) \]
is the operator corresponding under \( L^{2}_{\text{new}}(X_{\phi}) \cong L^{2}(\mathbb{H}; V_{n}^{0}) \) to the integral operator
\[ L^{(T)}_{2, n}(s)(1 - \chi_{C}^{-}) \] (the dependence on \( T \) is suppressed here but remembered).

Therefore if we define
\[ M_{\phi}(s) \overset{\text{def}}{=} M_{\phi}^{\text{int}}(s) + M_{\phi}^{\text{cusp}}(s), \]
and combining (4.8) and (5.15) we obtain
\[ (\Delta_{X_{\phi}} - s(1 - s)) M_{\phi}(s) = (1 - \chi_{C, \phi}) + L_{\phi}^{\text{int}}(s) + \chi_{C, \phi} + L_{\phi}^{\text{cusp}}(s) \]
\[ = 1 + L_{\phi}^{\text{int}}(s) + L_{\phi}^{\text{cusp}}(s). \quad (5.16) \]

The aim is to show, with high probability, we can invert the right hand side of (5.16) to define a bounded resolvent in \( s \geq s_{0} > \frac{1}{2} \). Since we have already suitably bounded \( L_{\phi}^{\text{cusp}}(s) \) in Proposition 4.3, it remains to bound the operator \( L_{\phi}^{\text{int}}(s) \); this random operator will be studied in detail in the next section.

6 Random operators

6.1 Set up

Suppose that \( f \in C_{c}^{\infty}(\mathbb{H}; V_{n}^{0}) \) with \( \|f\|_{L^{2}(F)} < \infty \). We have
\[ L^{(T)}_{2, n}(s)(1 - \chi_{C}^{-})[f](x) = \int_{y \in \mathbb{H}} L^{(T)}_{2, n}(s; x, y)(1 - \chi_{C}^{-})(y) f(y) \]
\[ = \sum_{\gamma \in \Gamma} \int_{y \in F} L^{(T)}_{2, n}(s; \gamma x, y) \rho_{n}^{0}(\gamma^{-1})(1 - \chi_{C}^{-})(y) f(y). \quad (6.1) \]

Using that \( L^{(T)}_{2, n}(s; x, y) \) localizes to \( d(x, y) \leq T + 1 \), Lemma 5.3 implies that there is a compact set \( K = K(T, \chi_{C}^{-}) \subset F \) and a finite set \( S = S(T, \chi_{C}^{-}) \subset \Gamma \) such that for \( x, y \in F \) and \( \gamma \in \Gamma \)
\[ L^{(T)}_{2, n}(s; \gamma x, y) \rho_{n}^{0}(\gamma^{-1})(1 - \chi_{C}^{-})(y) = 0 \]
unless \( x, y \in K \) and \( \gamma \in \Gamma \).

The point of view we take in the rest of this section is that there is an isomorphism of Hilbert spaces
\[ L^{2}_{\phi}(\mathbb{H}; V_{n}^{0}) \cong L^{2}(F) \otimes V_{n}^{0}; \]
\[ f \mapsto \sum_{e_{i}} \langle f | F, e_{i} \rangle \otimes e_{i} \]
where $e_i$ is an orthonormal basis of $V^0_n$ (the choice of this basis does not matter). When conjugated by this isomorphism, (6.1) shows that

$$
L^{(T)}_{H,n}(s)(1 - \chi_C^{-}) \cong \sum_{\gamma \in S} \alpha_\gamma(s) \otimes \rho_n^0(\gamma^{-1})
$$

where

$$
\alpha_\gamma(s) : L^2(F) \to L^2(F)
$$

$$
\alpha_\gamma(s)[f](x) \overset{\text{def}}{=} \int_{y \in F} L^{(T)}_{H}(s; \gamma x, y)(1 - \chi_C^{-}(y)) f(y) d\mathbb{H}(y).
$$

Again, this sum is supported on a finite set $S = S(T) \subset \Gamma$ depending only on $T$ and $\chi_C$. Since $L^{(T)}_{H}(s; \gamma x, y)$ is bounded depending on $T$ and smooth we have

$$
\int_{x,y \in F} |L^{(T)}_{H}(s; \gamma x, y)|^2 (1 - \chi_C^{-}(y))^2 d\mathbb{H}(x) d\mathbb{H}(y) =
$$

$$
\int_{x,y \in K} |L^{(T)}_{H}(s; \gamma x, y)|^2 (1 - \chi_C^{-}(y))^2 d\mathbb{H}(x) d\mathbb{H}(y) < \infty
$$

shows that each integral operator $\alpha_\gamma(s)$ is bounded, and in fact Hilbert-Schmidt, so compact. We also produce the following deviations estimate for the $\alpha_\gamma(s)$.

**Lemma 6.1.** For fixed $T > 0$, there is a constant $c_1 = c_1(T) > 0$ such that for $s_1, s_2 \in [\frac{1}{2}, 1]$ and $\gamma \in S(T)$ we have

$$
||\alpha_\gamma(s_1) - \alpha_\gamma(s_2)||_{L^2(F)} \leq c_1 |s_1 - s_2|.
$$

**Proof.** Suppose $s_1, s_2 \in [\frac{1}{2}, 1]$, and $\gamma$ is fixed. The operator $\alpha_\gamma(s_1) - \alpha_\gamma(s_2)$ is a Hilbert-Schmidt operator on $L^2(F)$ with kernel

$$
[L^{(T)}_{H}(s_1; \gamma x, y) - L^{(T)}_{H}(s_2; \gamma x, y)](1 - \chi_C^{-}(y));
$$

once again this is zero unless $x, y$ are in compact set $K(T)$.

We have by Lemma 5.1 Part 3 that for all $x, y \in K$

$$
|L^{(T)}_{H}(s_1; \gamma x, y) - L^{(T)}_{H}(s_2; \gamma x, y)| \leq c(T)|s_1 - s_2|.
$$

It follows that there is a constant $c_1 = c_1(T)$ such that, writing $\| \cdot \|_{\text{H.S.}}$ for Hilbert-Schmidt norm of a Hilbert-Schmidt operator on $L^2(F)$, we have

$$
||\alpha_\gamma(s_1) - \alpha_\gamma(s_2)||_{L^2(F)} \leq ||L^{(T)}_{H}(s_1) - L^{(T)}_{H}(s_2)||_{1 - \chi_C^{-}} \|_{\text{H.S.}}
$$

$$
\leq c_1(T)|s_1 - s_2|.
$$

Finally, because $\gamma$ is in the finite set $S(T)$, the estimate can be taken uniformly over all
\( \gamma \in S(T) \) by taking the maximal value of \( c_1 \).

### 6.2 The operator on the free group

We are momentarily going to apply Corollary 3.4 to the random operator

\[
\mathcal{L}_{s,\phi}^{(T)}(T) \overset{\text{def}}{=} \sum_{\gamma \in S} a_{\gamma}(s) \otimes \rho_n^0(\gamma^{-1})
\]

Up to an intermediate step, where we approximate the coefficients \( a_{\gamma}(s) \) by finite rank operators, we expect to learn that the operator norm of \( \mathcal{L}_{s,\phi}^{(T)} \) is close to the operator norm of

\[
\mathcal{L}_{s,\infty}^{(T)}(T) \overset{\text{def}}{=} \sum_{\gamma \in S} a_{\gamma}(s) \otimes \rho_\infty(\gamma^{-1})
\]

on \( L^2(F) \otimes \ell^2(\Gamma) \), where

\[
\rho_\infty : \Gamma \to \text{End}(\ell^2(\Gamma))
\]

is the right regular representation of \( \Gamma \). So we must understand the operator \( \mathcal{L}_{s,\infty}^{(T)} \).

Under the isomorphism

\[
L^2(F) \otimes \ell^2(\Gamma) \cong L^2(\mathbb{H}),
\]

\[
f \otimes \delta_\gamma \mapsto f \circ \gamma^{-1}
\]

(with \( f \circ \gamma^{-1} \) extended by zero from a function on \( \gamma F \)) the operator \( \mathcal{L}_{s,\infty}^{(T)} \) is conjugated to none other than

\[
\mathbb{I}_{\mathbb{H}}^{(T)}(s)(1 - \chi_{\overline{C}}) : L^2(\mathbb{H}) \to L^2(\mathbb{H})
\]

from §§5.3. Since \( (1 - \chi_{\overline{C}}) \) is valued in \([0,1]\), multiplication by it has operator norm \( \leq 1 \) on \( L^2(\mathbb{H}) \). Hence we obtain the following corollary of Lemma 5.2.

**Corollary 6.2.** For any \( s_0 > \frac{1}{2} \) there is \( T = T(s_0) > 0 \) such that for any \( s \in [s_0,1] \) we have

\[
\| \mathcal{L}_{s,\infty}^{(T)} \|_{L^2(F) \otimes \ell^2(\Gamma)} \leq \frac{1}{5}.
\]

### 6.3 Probabilistic bounds for operator norms

The aim of this section is to prove the following result as a consequence of Corollary 3.4.

**Proposition 6.3.** For any \( s_0 > \frac{1}{2} \) there is \( T = T(s_0) > 0 \) such that for any \( s \in [s_0,1] \), with probability tending to one as \( n \to \infty \),

\[
\| \mathcal{L}_{s,\phi}^{(T)} \|_{L^2(F) \otimes V_n} \leq \frac{2}{5}.
\]
Proof. Let $T$ be the one provided by Corollary 6.2 for the given $s_0$, so that
\[
\|L_s^{(T)}\|_{L^2(F)\otimes \ell^2(\Gamma)} \leq \frac{1}{5}. \tag{6.2}
\]
Fix $s \in [s_0, 1]$. Recall that the coefficients $a_\gamma(s)$ are supported on a finite set $S = S(T) \subset \Gamma$. Because the $a_\gamma(s)$ are Hilbert-Schmidt, and hence compact, we can find a finite-dimensional subspace $W \subset L^2(F)$ and operators $b_\gamma^{(T)}(s) : W \to W$ such that
\[
\|b_\gamma^{(T)}(s) - a_\gamma^{(T)}(s)\| \leq \frac{1}{20}|S(T)|
\]
for all $\gamma \in S(T)$. Therefore, since each $\rho_n^0(\gamma)$ is unitary on $V_n^0$ we get
\[
\|L_s^{(T)} - \sum_{\gamma \in S} b_\gamma^{(T)}(s) \otimes \rho_n^0(\gamma^{-1})\| \leq \frac{1}{20}. \tag{6.3}
\]
We now apply Corollary 3.4 to the operator $\sum_{\gamma \in S} b_\gamma^{(T)}(s) \otimes \rho_n^0(\gamma^{-1})$ to obtain that with probability $\to 1$ as $n \to \infty$,
\[
\|\sum_{\gamma \in S} b_\gamma^{(T)}(s) \otimes \rho_n^0(\gamma^{-1})\|_{W \otimes V_n^0} \leq \|\sum_{\gamma \in S} b_\gamma^{(T)}(s) \otimes \rho_\infty(\gamma^{-1})\|_{W \otimes \ell^2(\Gamma)} + \frac{1}{20}. \tag{6.4}
\]
(Above, $\frac{1}{20}$ could be replaced by any $\epsilon > 0$ but this is not needed here.)
On the other hand, we also have by the same argument as led to (6.3)
\[
\|L_s^{(T)} - \sum_{\gamma \in S} b_\gamma^{(T)}(s) \otimes \rho_\infty(\gamma^{-1})\|_{L(F)\otimes \ell^2(\Gamma)} \leq \frac{1}{20}. \tag{6.5}
\]
Then combining (6.2), (6.3), (6.4), and (6.5) gives the result. \qed

7 Proof of Theorem 1.1

Given $\epsilon > 0$ let $s_0 = \frac{1}{2} + \sqrt{\epsilon}$ so that $s_0(1 - s_0) = \frac{1}{4} - \epsilon$. We assume $\lambda_\pm$ were chosen as in Proposition 4.3 for this $s_0$ so that
\[
\|L_\phi^{\text{cusp}}(s)\|_{L^2} \leq \frac{1}{5}. \tag{7.1}
\]
for all $s \in (s_0, 1]$.

Let $T = T(s_0)$ be the value provided by Proposition 6.3 for this $s_0$. To control all
values of \( s \in [s_0, 1] \) we use a finite net. For \( s_1, s_2 \in [s_0, 1] \) we have

\[
\mathcal{L}_{s_1, \phi}^{(T)} - \mathcal{L}_{s_2, \phi}^{(T)} = \sum_{\gamma \in S} [a^{(T)}_\gamma(s_1) - a^{(T)}_\gamma(s_2)] \otimes \rho_0^\phi(\gamma^{-1}) \tag{7.2}
\]

where \( S \subset \Gamma \) is a finite set depending on \( T \). Lemma 6.1 tells us that for \( c_1 = c_1(T) > 0 \) we have

\[
\|a_\gamma(s_1) - a_\gamma(s_2)\|_{L^2(F)} \leq c_1 |s_1 - s_2|
\]

for all \( \gamma \in S \) and \( s_1, s_2 \in [s_0, 1] \); hence we obtain from \( \text{(7.2)} \) and as each \( \rho_0^\phi(\gamma^{-1}) \) is unitary that

\[
\|\mathcal{L}_{s_1, \phi}^{(T)} - \mathcal{L}_{s_2, \phi}^{(T)}\| \leq |S| c_1 |s_1 - s_2|. \tag{7.3}
\]

We choose a finite set \( Y \), depending on \( s_0 \), of points in \([s_0, 1]\) such that every point of \([s_0, 1]\) is within

\[
\frac{1}{5|S||c_1}
\]

of some element of \( Y \). Now, applying Proposition 6.3 to each point of \( Y \) we obtain that with probability tending to one as \( n \to \infty \) we have

\[
\|\mathcal{L}_{s, \phi}^{(T)}\|_{L^2(F) \otimes V_0^\phi} \leq \frac{2}{5}
\]

for all \( s \in Y \). Hence also using \( \text{(7.3)} \) we obtain that with probability tending to one as \( n \to \infty \) we have

\[
\|\mathcal{L}_{s, \phi}^{(T)}\|_{L^2(F) \otimes V_0^\phi} \leq \frac{3}{5}
\]

for all \( s \in [s_0, 1] \).

Recall that we defined

\[
\mathcal{M}_\phi(s) \overset{\text{def}}{=} \mathcal{M}_{\phi}^{\text{int}}(s) + \mathcal{M}_{\phi}^{\text{cusp}}(s)
\]

and understood as an operator on \( L^2_{\text{new}}(X_\phi) \cong L^2_{\phi}(\mathbb{H}; V_0^\phi) \), \( \mathcal{M}_{\phi}^{\text{int}}(s) \) is a bounded operator by Lemma 5.4 and we noted \( \mathcal{M}_{\phi}^{\text{cusp}}(s) \) is bounded for \( s > \frac{1}{2} \) after \( \text{(4.7)} \).

We also proved in \( \text{(5.16)} \)

\[
(\Delta X_\phi - s(1 - s)) \mathcal{M}_\phi(s) = 1 + \mathbb{L}_\phi^{\text{int}}(s) + \mathbb{L}_\phi^{\text{cusp}}(s)
\]

on \( L^2_{\text{new}}(X_\phi) \). The operator \( \mathbb{L}_\phi^{\text{int}}(s) \) is unitarily conjugate to \( \mathcal{L}_{s, \phi}^{(T)} \) as in \( \S \S 6.1 \) and hence a.a.s has operator norm at most \( \frac{3}{5} \). Hence also using the deterministic bound \( \text{(7.1)} \) we obtain that

\[
\|\mathbb{L}_\phi^{\text{int}}(s) + \mathbb{L}_\phi^{\text{cusp}}(s)\|_{L^2_{\text{new}}(X_\phi)} \leq \frac{4}{5}
\]

and hence a.a.s

\[
\left(1 + \mathbb{L}_\phi^{\text{int}}(s) + \mathbb{L}_\phi^{\text{cusp}}(s)\right)^{-1}
\]
exists as a bounded operator from $L_{\text{new}}^2(X_\phi)$ to itself. We now get

$$(\Delta_{X_\phi} - s(1 - s)) M_\phi(s) \left( 1 + L_{\text{int}}^\phi(s) + L_{\text{cusp}}^\phi(s) \right)^{-1} = 1$$

which shows there is a bounded right inverse to $\left( \Delta_{X_\phi} - s(1 - s) \right)$; this shows that $\left( \Delta_{X_\phi} - s(1 - s) \right)$ has dense image and since it is self-adjoint for $s \in [\frac{1}{2}, 1]$, cannot have any kernel. This shows a.a.s. that $\Delta_{X_\phi}$ has no new eigenvalues $\lambda$ with $\lambda \leq s_0(1 - s_0) = \frac{1}{4} - \epsilon$. This concludes the proof of Theorem 1.1.

8 Proof of Corollary 1.3

Take $X$ to be a once-punctured torus or thrice-punctured sphere and apply Corollary 1.2 to obtain a sequence of connected orientable finite area non-compact hyperbolic surfaces $X_i$ with $\chi(X_i) = -i$ and

$$\inf (\text{spec}(\Delta_{X_i}) \cap (0, \infty)) \to \frac{1}{4}. $$

Suppose $X_i$ has genus $g_i$ and $n_i$ cusps. We have

$$-i = \chi(X_i) = 2 - 2g_i - n_i$$

which shows

$$i \equiv \chi(X_i) \equiv n_i \mod 2.$$

In particular, for even $i$, we have an even number of cusps in $X_i$. We use the following result of Buser, Burger, and Dodziuk [BBD88]. See Brooks and Makover [BM01, Lemma 1.1] for the extraction of this lemma from [BBD88].

Lemma 8.1 (Handle Lemma). Let $X$ be a finite area hyperbolic surface with an even number of cusps $\{C_i\}$. It is possible to deform the surface $X$ in a certain way to a finite area hyperbolic surface with boundary, where each cusp becomes a bounding geodesic of length $t$, and then glue the geodesic corresponding to $C_{2i-1}$ to the one corresponding to $C_{2i}$ to form a family of closed hyperbolic surfaces $X^{(t)}$ such that

$$\limsup_{t \to 0} \lambda_1(X^{(t)}) \geq \inf (\text{spec}(\Delta_X) \cap (0, \infty)).$$

In particular, since each $X_{2k}$ has an even number of cusps, we can construct a closed hyperbolic surface $\tilde{X}_{2k}$ of Euler characteristic $-2k$ and

$$\lambda_1(\tilde{X}_{2k}) \geq \inf (\text{spec}(\Delta_{X_{2k}}) \cap (0, \infty)) - \frac{1}{k}.$$

On the other hand, the upper bound of Huber [Hub74] now implies $\lambda_1(\tilde{X}_{2k}) \to \frac{1}{4}$ as
required. □
