We analyze the collision of three identical spin-polarized fermions at zero collision energy, assuming arbitrary finite-range potentials, and define the corresponding three-body scattering hypervolume $D_F$. The scattering hypervolume $D$ was first defined for identical bosons in 2008 by one of us. It is the three-body analog of the two-body scattering length. We solve the three-body Schrödinger equation asymptotically when the three fermions are far apart or one pair and the third fermion are far apart, deriving two asymptotic expansions of the wave function. Unlike the case of bosons for which $D$ has the dimension of length to the fourth power, here the $D_F$ we define has the dimension of length to the eighth power. We then analyze the interaction energy of three such fermions with momenta $\hbar k_1$, $\hbar k_2$ and $\hbar k_3$ in a large periodic cubic box. The energy shift due to $D_F$ is proportional to $D_F/\Omega^2$, where $\Omega$ is the volume of the box. We also calculate the shifts of energy and pressure of spin-polarized Fermi gases due to a nonzero $D_F$ and the three-body recombination rate of spin-polarized ultracold atomic Fermi gases at finite temperatures.

I. INTRODUCTION

When electrically neutral particles collide with small energies, such that the de Broglie wave lengths are large compared to the range of interaction, their effective interactions can be characterized by a small number of parameters such as the two-body $s$-wave scattering length. For identical spin-polarized fermions, however, the $s$-wave collision is forbidden due to the Pauli exclusion principle, and the low-energy effective interaction is dominated by the $p$-wave scattering volume $a_p$. All the two-body effective parameters for the interaction can be extracted from the wave functions for the two-body collision at energies equal to or close to zero, outside of the physical range of the interaction potential [1]. The $p$-wave scattering volume $a_p$, for example, can be extracted from the wave function of the two fermions colliding at zero incoming kinetic energy [2]:

$$\phi^{(1,m)}(s) = \left(\frac{s}{3} - \frac{a_p}{s^2}\right) \sqrt{\frac{4\pi}{3}} Y_1^m(s), \quad s > r_e, \tag{1}$$

where $s$ is the spatial vector extending from one fermion to the other, $r_e$ is the range of the interaction potential, $Y_1^m(s)$ is the spherical harmonic ($m = -l, -l+1, \ldots, l$ is the magnetic quantum number).

The effective three-body interaction at small collision energies can also be described by some effective parameters, such as the scattering hypervolume $D$ which was first defined for three identical bosons by one of us [1]. It is the three-body analog of the two-body $s$-wave scattering length $a$, and is a fundamental parameter determining the effective strength of three-body interactions at small collision energies. $D$ affects the energies of dilute Bose-Einstein condensates [1]. The three-body recombination [3,4] rate is proportional to the imaginary part of $D$ [10,11]. $D$ determines the effective three-body coupling constant in the effective-field theoretical description of low energy particles [1,10,12]. The value of $D$ has been numerically computed for identical bosons interacting with hard-sphere [1], Gaussian [10], square-well [13] and Lennard-Jones [14] potentials. Recently, the definition of scattering hypervolume is generalized to three particles with unequal masses [2], two identical bosons and a particle with a different mass [15], and three identical spin-1 bosons [16]. In these three-body systems, the dimensions of the corresponding scattering hypervolumes are all [length]$^4$.

Can we also define a scattering hypervolume for three identical fermions in the same spin state? In this paper, we study the zero energy collision of three spin-polarized fermions with total orbital angular momentum $L = 1$, assuming arbitrary finite-range potentials. We solve the three-body Schrödinger equation asymptotically and get two expansions for the wave function $\Psi$, one of which is applicable when all the three fermions are far away from each other and is named 111 expansion, the other of which is applicable when two fermions are held at a fixed distance and the third fermion is far away from the two and is named 21 expansion. The new scattering hypervolume $D_F$ is the dominant three-body parameter in these expansions. The dimension of $D_F$ is [length]$^8$. The parameter $D_F$ is applicable only if the thermal de Broglie wavelengths of the fermions are much larger than $r_e$, namely if the temperature $T \ll T_e$, where

$$T_e = \frac{\hbar^2}{2MF^2r_e^2k_B}. \tag{2}$$

Here $\hbar$ is Planck’s constant over $2\pi$, $M_F$ is the mass of each fermion, and $k_B$ is the Boltzmann constant.

In Section 11 of this paper, we derive the 111 expansion and the 21 expansion for the collision of three identical spin-polarized fermions. We assume that the fermions are electrically neutral, and the interaction potentials are finite-ranged, vanishing beyond a certain range $r_e$. In this paper we will expand $\Psi$ to the order $B^{-6}$ in the

* shinatan@pku.edu.cn
111 expansion and to the order $R^{-7}$ in the 21 expansion, which are the orders at which the three-body scattering hypervolume $D_F$ first appears.

In Section III we calculate the shift of the energy of three fermions in a large periodic cubic box due to a nonzero $D_F$. We then further calculate the shifts of energy and pressure caused by $D_F$ for a homogeneous spin-polarized Fermi gas at finite temperatures.

In Section IV we derive the formula for the three-body recombination rate in spin-polarized ultracold atomic Fermi gases. We find that in an intermediate temperature regime $T_F \ll T \ll T_c$, where $T_c$ is the Fermi temperature, $d n/d t$ is proportional to $n^3 T^2$, in agreement with Refs. [17–19], while at low temperatures, $T \ll T_F$, $d n/d t$ is proportional to $n^{13/3}$.

II. ASYMPTOTICS OF THE THREE-BODY WAVE FUNCTION

We consider identical spin-polarized fermions with mass $M_F$ each. We assume that the interactions among these fermions are finite-ranged and depend only on the interparticle distances, and thus they are invariant under translation, rotation and Galilean transformations.

If the three fermions collide with zero energy, the three-body wave function $\Psi$ satisfies the Schrödinger equation:

$$\left[-\frac{\hbar^2}{2M_F}(\nabla_i^2 + \nabla_j^2 + \nabla_k^2) + V(s_{1}) + V(s_{2}) + V(s_{3}) + V_{123}(s_{1}, s_{2}, s_{3})\right] \Psi(r_1, r_2, r_3) = 0,$$

where $r_i$ is the position vector of the $i$th fermion, and $s_i \equiv r_j - r_k$.

In the above equation and in the following, $(i,j,k) = (1,2,3), (2,3,1), \text{ or } (3,1,2).$ $V(s_i)$ is the interaction potential between the $j$th fermion and the $k$th fermion, and $V_{123}(s_1, s_2, s_3)$ is the three-body potential. We assume the total momentum of three fermions is zero (which means we study the problem in the center-of-mass frame), and thus $\Psi$ is translationally invariant:

$$\Psi(r_1 + \delta r, r_2 + \delta r, r_3 + \delta r) = \Psi(r_1, r_2, r_3)$$

for any $\delta r$.

Equations (3) and (5) do not uniquely determine the wave function for the zero energy collision. We need to also specify the asymptotic behaviour of $\Psi$ when the three fermions are far apart. The leading-order term in $\Psi$ when $s_1, s_2, s_3$ go to infinity simultaneously, $\Psi_0$, should satisfying the Laplace equation $(\nabla_i^2 + \nabla_j^2 + \nabla_k^2) \Psi_0 = 0$, and scale like $B^p$ at large $B$, where

$$B \equiv \sqrt{(s_1^2 + s_2^2 + s_3^2)}/2$$

is the hyperradius. The most important three-body wave function for zero-energy collisions, for purposes of understanding ultracold collisions, should be the one with the minimum value of $p$. The larger the value of $p$, the less likely it is for the three particles to come to the range of interaction within which they can interact. (For this same reason, in the study of two-body ultracold collisions of identical fermions, the $p$-wave collision is usually the most important one.) One can easily show that the minimum value of $p$ for three identical spin-polarized fermions in three spatial dimensions is 2. There are only three linearly independent three-body wave functions for the zero-energy collision with $p = 2$, and they all have total orbital angular momentum quantum number $L = 1$, and they form an irreducible representation of the rotational group, and can be distinguished using the magnetic quantum number $M = -1, 0, 1$. These three-body wave functions are denoted as $\Psi_{1}^{11}$.

For later use, we define the Jacobi coordinates $[11, 20]$ used in this paper. $s_i$ has been defined in Eq. (1). We define $R_i$ as the vector extending from the center of mass of the $j$th fermion and the $k$th fermion to the $i$th fermion:

$$R_i \equiv r_i - (r_j + r_k)/2.$$  

We also define three hyperangles:

$$\theta_i \equiv \arctan \frac{2R_i}{\sqrt{3}s_i},$$

$s_i, R_i, \theta_i$ and $B$ satisfy the following relations:

$$s_i = \frac{2}{\sqrt{3}} B \cos \theta_i, \quad R_i = B \sin \theta_i.$$  

The $s_i, R_i, B, \theta_i$ defined above are the same as the corresponding variables defined for identical bosons in Ref. [1].

A. Two-body special functions

We define the two-body special functions $\phi^{(l,m)}(s)$, $f^{(l,m)}(s)$, $g^{(l,m)}(s)$, . . . , for the collision of two particles with orbital angular momentum quantum number $l$ and magnetic quantum number $m$ along the $z$ direction [12]

$$\begin{align*}
\tilde{H} \phi^{(l,m)} &= 0, \\
\tilde{H} f^{(l,m)} &= \phi^{(l,m)}, \\
\tilde{H} g^{(l,m)} &= f^{(l,m)},
\end{align*}$$

where $\hbar^2 \tilde{H}/M_F$ is the two-body Hamiltonian for the collision of two fermions in the center-of-mass frame, and

$$\tilde{H} \equiv -\nabla_s^2 + \frac{M_F}{\hbar^2} V(s).$$

For identical spin-polarized fermions, $l$ must be odd due to Pauli principle. We use symbols $p, f, h, \cdots$ to represent $l = 1, 3, 5, \cdots$.

Given the two-body special functions $\phi^{(l,m)}$, $f^{(l,m)}$, $g^{(l,m)}$, . . . , we can express the wave function for the
collision of two particles at any small nonzero energy \( E = h^2 k^2 / M_F \) as an infinite series in \( k^2 \) [1 2]:

\[
\phi^{(l,m,k)} = \phi^{(l,m)} + k^2 f^{(l,m)} + k^4 g^{(l,m)} + \ldots .
\]

(12)

To complete the definition of \( \phi^{(l,m)} \), we need to specify its overall amplitude. Since the potential \( V \) vanishes beyond a finite range \( r_c \), \( \phi^{(l,m)} \) takes a simple form at \( s > r_c \):

\[
\phi^{(l,m)} = \left[ \left( \frac{s^l}{2l+1} \right)^{l+1} - \frac{(2l - 1)!! a_l s^l}{2^{l+1}/(2l+1)!!} \right] \sqrt{\frac{4\pi}{2l+1}} Y_l^m(\hat{s}),
\]

(13)

where \( Y_l^m \) is the spherical harmonic, and \( a_l \) is the two-body \( l \)-wave scattering volume (or hypervolume). We have fixed the overall amplitude of \( \phi^{(l,m)} \) by specifying the coefficient of the term \( \propto s^l \).

The solution to the equation \( \tilde{H} f^{(l,m)} = \phi^{(l,m)} \) is not unique, because if \( f^{(l,m)} \) satisfies this equation, then \( f^{(l,m)} \) also satisfies this equation. To complete the definition of \( f^{(l,m)} \), we specify that in the expansion of \( f^{(l,m)}(s) \) at \( s > r_c \) we do not have the term \( \propto s^{-1} \) (if such a term exists, we can add a suitable coefficient times \( \phi^{(l,m)}(s) \) to \( f^{(l,m)}(s) \) to cancel this term). Then at \( s > r_c \) we have the following analytical formula for \( f^{(l,m)}(s) \):

\[
f^{(l,m)}(s) = \left[ - \frac{s^{l+2}}{2(2l+3)!!} - \frac{a_l r_s s^l}{2(2l+1)!!} \right] \sqrt{\frac{4\pi}{2l+1}} Y_l^m(\hat{s}) - \frac{(2l - 3)!! a_l s^{l-1}}{2} \sqrt{\frac{4\pi}{2l+1}} Y_l^m(\hat{s}).
\]

(14)

For brevity we do not show the explicit formula for \( g^{(l,m)} \) as it is not used in this paper.

The two-body special functions will appear in the 21 expansions of the three-body wave functions at zero collision energy. If the magnetic quantum number \( m = 0 \), these two-body special functions we have defined here are the same as the special functions defined in Ref. [2] if one sets \( \hat{n} = \hat{z} \) in Ref. [2].

One can show [1 2] that \( a_l \) which first appears in Eq. (13) is the two-body \( l \)-wave scattering volume, \( r_l \) which first appears in Eq. (14) is the two-body \( l \)-wave effective range, and they are related to the scattering phase shift \( \delta_l(k) \) in the well-known effective range expansion [21 22]:

\[
k^{2l+1} \cot \delta_l(k) = - \frac{1}{a_l} + \frac{1}{2} r_l k^2 + O(k^4).
\]

(15)

B. 111 expansion and 21 expansion

As in previous works [1 2], we derive two asymptotic expansions for the three-body wave function \( \Psi_1^M \). When the three fermions are all far apart from each other, such that the pairwise distances \( s_1, s_2, s_3 \) go to infinity simultaneously for any fixed ratio \( s_1 : s_2 : s_3 \), we expand \( \Psi_1^M \) in powers of \( 1/B \), and this expansion is called the 111 expansion. When one fermion (the \( i \)th fermion) is far away from the other two (the \( j \)th and \( k \)th fermions), but the two fermions \( (j \) and \( k \)) are held at a fixed distance \( s_t \), we expand \( \Psi_1^M \) in powers of \( 1/R_t \), and this is called the 21 expansion. The two expansions are

\[
\Psi_1^M = \sum_{pm=-2}^{\infty} T^{(-p)}(r_1, r_2, r_3),
\]

(16a)

\[
\Psi_1^M = \sum_{q=-1}^{\infty} S^{(-q)}(R, s),
\]

(16b)

where \( T^{(-p)} \) scales as \( B^{-p} \), \( S^{(-q)} \) scales as \( R^{-q} \). Without loss of generality, here we suppose the Jacobi coordinates \( s = s_1 \), and \( R = R_1 \).

\( T^{(-p)} \) satisfies the free Schrödinger equation outside of the interaction range:

\[
- \frac{h^2}{2M_F} \left( \nabla_s^2 + V(s) - \frac{3M^2}{4M_F} \nabla_R^2 \right) \Psi_1^M = 0.
\]

(17)

If one fermion is far away from the other two, Eq. (3) becomes

\[
- \frac{h^2}{2M_F} \nabla_s^2 + V(s) - \frac{3M^2}{4M_F} \nabla_R^2 \Psi_1^M = 0.
\]

(18)

Therefore, \( S^{(-q)} \) satisfies the following equations,

\[
\tilde{H} S^{(2)} = 0, \quad \tilde{H} S^{(1)} = 0,
\]

\[
\tilde{H} S^{(-q)} = \frac{3}{4} \nabla_R^2 S^{(-q+2)} \quad (q \geq 0).
\]

(19)

If \( s \ll R \), we can further expand \( T^{(-p)} \) as

\[
T^{(-p)} = \sum_i t^{(i, -p - i)},
\]

(20)

where \( t^{(i,j)} \) scales like \( R^i s^j \). If \( s \gg r_c \), we can further expand \( S^{(-q)} \) as

\[
S^{(-q)} = \sum_j t^{(-q,j)}.
\]

(21)

Because the three-body wave function \( \Psi_1^M \) may be expanded as \( \sum_p T^{(-p)} \) at \( B \to \infty \), and may also be expanded as \( \sum_q S^{(-q)} \) at \( R \to \infty \), the \( t^{(i,j)} \) in the above two expansions should be the same. In fact the wave function has a double expansion \( \Psi_1^M = \sum_{i,j} t^{(i,j)} \) in the region \( r_c \ll s \ll R \).

We show the points at which \( t^{(i,j)} \neq 0 \) on the \( (i, j) \) plane in Fig. 1. \( T^{(-p)} \) corresponds to the straight line with slope equal to \(-1\) and intercept equal to \(-p\). \( S^{(-q)} \) corresponds to the vertical line \( i = -q \). Therefore, all the points \( t^{(i,j)} \) satisfying \( i + j = -p \) are on the line corresponding to \( T^{(-p)} \), and all the points \( t^{(-q,j)} \) are on the line of \( S^{(-q)} \).
leading-order term in the 111 expansion (which fixes the overall amplitude of \( \Psi_1^M \)):

\[
\mathcal{T}^{(2)} = Q_1^M (s \times \mathbf{R}), \quad M = -1, 0, 1,
\]

where \( Q_L^M(\mathbf{u}) \) is the harmonic polynomial,

\[
Q_L^M(\mathbf{u}) = \sqrt{\frac{4\pi}{2L+1}} u^L Y_L^M(\mathbf{u}).
\]

More explicitly, for \( M = 0 \),

\[
\mathcal{T}^{(2)} = A_z,
\]

and for \( M = \pm 1 \),

\[
\mathcal{T}^{(2)} = -\frac{M}{\sqrt{2}} (A_x + iMA_y),
\]

where

\[
\mathbf{A} = s \times \mathbf{R} = -(\mathbf{r}_1 \times \mathbf{r}_2 + \mathbf{r}_2 \times \mathbf{r}_3 + \mathbf{r}_3 \times \mathbf{r}_1)
\]

is a vector perpendicular to the plane of the triangle formed by the three fermions, and \( \mathbf{A} \) is equal to twice the area of such triangle. One can check the leading-order term \( \mathcal{T}^{(2)} \) satisfies the free Schrödinger equation. It is also translationally invariant, and is antisymmetric under the exchange of the fermions. \( \mathcal{T}^{(2)} = t^{(1,1)} \) is denoted by the point with coordinates \((1,1)\) in Fig. 1.

We then first derive \( S^{(1)} \), and then derive \( \mathcal{T}^{(1)} \), and then derive \( S^{(0)} \), and then derive \( \mathcal{T}^{(0)} \), and so on, all the way until \( S^{(−7)} \). At every step, we require the 111 expansion and the 21 expansion to be consistent in the region \( r_c \ll s \ll R \).

Our resultant 111 expansion is

\[
\Psi_1^M = Q_1^M (s \times \mathbf{R}) \cdot \left[ 1 - 3a_p \sum_{i=1}^{3} \frac{1}{s_i^3} + \frac{36a_p^2}{\pi} \sum_{i=1}^{3} \left( \frac{\theta_i - \frac{1}{2}\sin 4\theta_i}{R_i^3 s_i^3} \right) - \frac{9\sqrt{3}D_F}{4\pi^3 B^8} \right] + O(B^{-7}),
\]

where \( D_F \) is the three-body scattering hypervolume of identical spin-polarized fermions, and it appears at the order of \( B^{-6} \). We have chosen the coefficient \(-9\sqrt{3}/4\pi^3 \) in front of \( D_F \) to simplify the formula for the energy shift of three identical fermions in a large periodic volume due to the three-body parameter; see Sec. IIIA for details.

Our resultant 21 expansion is
\[ \Psi_1^M = 6i \sqrt{\frac{2\pi}{3}} \left[ R - \frac{6\alpha_p}{R^2} + \frac{12\alpha_p^2}{R^5} \left( 8 - \frac{9\sqrt{3}}{\pi} \right) - \frac{\xi}{R^6} \right] \sum_m C_{1,M-m;1,m}^1 \phi^{(1,m)}(s) + i \left[ -\frac{630\sqrt{\pi}a_p}{R^4} + \frac{4032\sqrt{\pi}a_p^2}{R^7} \left( 16 - \frac{27\sqrt{3}}{\pi} \right) \right] \sum_m C_{1,M-m;3,m}^3 \phi^{(3,m)}(s) - \frac{31185}{4R^6} \sum_m C_{1,5;5,m}^{1,M} V_5^{M-m}(R) \phi^{(5,m)}(s) + i \frac{324\sqrt{6}\alpha_p^2}{R^7} \left( 8 - \frac{9\sqrt{3}}{\pi} \right) \sum_m C_{1,M-m;1,m}^1 V_1^{M-m}(R) \phi^{(1,m)}(s) + O(R^{-8}), \]

where

\[ C_{t_1,m_1;t_2,m_2}^{J,M} = \langle l_1, m_1; l_2, m_2 | J, M \rangle \] (29)
is the Clebsch-Gordan coefficient, and \( \xi \) is a parameter related to \( D_F \).

\[ \xi = \frac{9\sqrt{3}D_F}{4\pi^3} - 81\alpha_p^3 r_p \left( 8 - \frac{9\sqrt{3}}{\pi} \right). \] (30)

### III. Energy Shifts and Thermodynamic Properties

In this section, we study the energy shifts of \( N \) identical spin-polarized fermions caused by the scattering hypervolume \( D_F \) in a periodic box. Using this result we derive the thermodynamic properties, including the energy and the pressure, of the spin-polarized Fermi gas due to a nonzero \( D_F \).

#### A. Three fermions in a cubic box

In this subsection, for the sake of simplicity we assume that the fermions have vanishing or negligible two-body interactions but have a nonzero three-body scattering hypervolume \( D_F \), and the 111 expansion for the zero-energy three-body wave function in Eq. [27] is simplified as

\[ \Psi_1^M = Q_1^M (s \times R) \left( 1 - \frac{9\sqrt{3}D_F}{4\pi^3 B^3} \right) + O(B^{-7}). \] (31)

For purposes of calculating the energy shifts due to a nonzero \( D_F \), we can replace the true interaction potential \( V(s_1) + V(s_2) + V(s_3) + V_{123}(s_1, s_2, s_3) \), which in general has a complicated dependence on the interparticle distances, by a three-body pseudopotential \( V_{ps} \). We use the following pseudopotential:

\[ V_{ps} = \frac{\hbar^2 D_F}{6M_F} \left\{ \left[ \nabla^2 \nabla \cdot \frac{1}{\epsilon} - \left( \nabla \cdot \nabla \right)^2 \right] \delta(s) \delta(R) \right\} \Lambda, \] (32)

where \( \Lambda \) is a projection operator which, when acting on the \( O(B^{-6}) \) term in the three-body wave function, yields zero. The operator \( \Lambda \) is an analog of the operator \( \frac{\partial}{\partial r} \) in the two-body pseudopotential for \( s \)-wave two-body collisions in Refs. [23, 24]. One can check the pseudopotential in Eq. (32) is symmetric under the interchange of the three fermions. The coefficient on the right hand side of Eq. (32) has been chosen such that

\[ \left[ -\frac{\hbar^2}{2M_F} (\nabla_2^2 + \nabla_3^2 + \nabla_1^2) + V_{ps} \right] \Psi_1^M = 0. \] (33)

We now consider three fermions in a large periodic cubic box with volume \( \Omega \). Their momenta are \( \hbar k_1 \), \( \hbar k_2 \) and \( \hbar k_3 \) in the absence of interactions. When we introduce interactions that give rise to a nonzero \( D_F \), the energy eigenvalue of the three-body state is shifted by the following amount at first order in the perturbation:

\[ \mathcal{E}_{k_1,k_2,k_3} = \int d^3r_1 d^3r_2 d^3r_3 |\Psi_{k_1,k_2,k_3}^0|^2 V_{ps}, \] (34)

where \( \Psi_{k_1,k_2,k_3} \) is the normalized unperturbed wave function and it can be written as a Slater determinant:

\[ \Psi_{k_1,k_2,k_3} = \frac{1}{\sqrt{6\Omega^{3/2}}} \left[ e^{ik_1} e^{ik_2} e^{ik_3} \right]. \] (35)

We get

\[ \mathcal{E}_{k_1,k_2,k_3} = \frac{\hbar^2 D_F}{3M_F \Omega} (k_1 \times k_2 + k_2 \times k_3 + k_3 \times k_1)^2. \] (36)

Note that \( |k_1 \times k_2 + k_2 \times k_3 + k_3 \times k_1| \) is twice the area of the \( k \)-space triangle whose vertices are \( k_1, k_2, k_3 \).

If there are two-body interactions, the shift of the energy of the three particles will also contain terms due to the two-body parameters including \( a_p, r_p, a_f \) etc.; nevertheless, the shift due to \( D_F \) in Eq. (36) is still valid. If \( a_p \neq 0 \), the leading-order shift of the three-body energy due to \( a_p \) is

\[ \mathcal{E}^{2\text{-body}}_{k_1,k_2,k_3} = \frac{6\pi\hbar^2 a_p}{M_F \Omega} \left[ (k_1^2 - k_2^2)^2 + (k_2^2 - k_3^2)^2 + (k_3^2 - k_1^2)^2 \right]. \] (37)
B. Energy shift of many fermions and thermodynamic consequences

We generalize the energy shift in Eq. (36) to \( N \) fermions in the periodic volume \( \Omega \). The number density of the fermions is \( n = N/\Omega \). We define the Fermi wave number \( k_F = (6\pi^2 n)^{1/3} \), the Fermi energy \( \epsilon_F = h^2 k_F^2/2M_F \), and the Fermi temperature \( T_F = \epsilon_F / k_B \). We assume that the density is low such that the average interparticle distance \( n^{-1/3} \gg r_e \).

1. Adiabatic shifts of energy and pressure in the thermodynamic limit

Starting from a many-body state at a finite temperature \( T \), if we introduce a nonzero \( D_F \) adiabatically, the energy shift at first order in \( D_F \) is equal to the sum of the contributions from all the triples of fermions, namely

\[
\Delta E = \frac{1}{6} \sum_{k_1 k_2 k_3} \mathcal{E}_{k_1 k_2 k_3} n_{k_1} n_{k_2} n_{k_3}, \tag{38}
\]

where \( n_k = \left( 1 + e^{\beta(\epsilon_k - \mu)} \right)^{-1} \) is the Fermi-Dirac distribution function, \( \beta = 1/k_B T \), \( \epsilon_k = h^2 k^2/2M_F \) is the kinetic energy of a fermion with linear momentum \( h k \), and \( \mu \) is the chemical potential. The summation over \( k \) can be replaced by a continuous integral \( \sum_k = \Omega \int d^3k/(2\pi)^3 \) in the thermodynamic limit. Carrying out the integral, we get

\[
\Delta E(T) = \frac{N\hbar^2 D_F}{36\pi^4 M_F} k_F^{10} \left[ \frac{9\pi}{64} \right] T^5 \left[ f_{3/2}(e^{\beta \mu}) \right]^2, \tag{39}
\]

where \( T = T/T_F \), and the function \( f_{\nu}(z) \) is defined as

\[
f_{\nu}(z) \equiv -Li_{\nu}(-z) = z - \frac{z^2}{2\nu} + \frac{z^3}{3\nu} - \frac{z^4}{4\nu} + \cdots. \tag{40}
\]

The chemical potential \( \mu \) is determined by the number of fermions,

\[
N = \Omega \int \frac{d^3k}{(2\pi)^3} \frac{1}{e^{\beta(\epsilon_k - \mu)} + 1}, \tag{41}
\]

which is equivalent to

\[
1 = \frac{3\sqrt{\pi}}{4} \frac{\pi^{3/2}}{T^{3/2}} f_{3/2}(e^{\mu/T}), \tag{42}
\]

where \( \tilde{\mu} = \mu/\epsilon_F \).

In the low temperature limit, \( T \ll T_F \),

\[
\Delta E(T) = \frac{N\hbar^2 D_F}{36\pi^4 M_F} k_F^{10} \left[ \frac{1}{25} \frac{\pi^2}{30} T^2 + O(T^4) \right]. \tag{43}
\]

In particular, at absolute zero temperature,

\[
\Delta E(0) = \frac{N\hbar^2 D_F}{900\pi^4 M_F} k_F^{10}. \tag{44}
\]

and the ground state energy of the Fermi gas is

\[
E = \frac{3}{5} \epsilon_F N \left( 1 + \frac{D_F \hbar^2 k_F^6}{270\pi^4} + \cdots \right). \tag{45}
\]

If there are two-body interactions, the total ground state energy should contain terms that depend on the two-body parameters such as \( a_{rr}, r_p, a_f \), but the term due to \( D_F \) remains the same as in the above formula to leading order in \( D_F \).

In an intermediate temperature regime, \( T_F \ll T \ll T_e \),

\[
\Delta E(T) = \frac{N\hbar^2 D_F}{36\pi^4 M_F} k_F^{10} \left[ \frac{1}{4} \frac{\pi^2}{T^2} + O(T^{-1}) \right]. \tag{46}
\]

If \( T \) is comparable to or higher than \( T_e \), the de Broglie wave lengths of the fermions will be comparable to or shorter than the range \( r_e \) of interparticle interaction potentials, and we can no longer use the effective parameter \( D_F \) to describe the system. See Fig. 2 for \( \Delta E \) as a function of the initial temperature.

The pressure of the spin-polarized Fermi gas changes by the following amount due to the adiabatic introduction of \( D_F \):

\[
\Delta p(T) = -\frac{\partial \Delta E}{\partial \Omega} = \frac{10\Delta E}{3\Omega} = \frac{5n\hbar^2 D_F}{54\pi^4 M_F} k_F^{10} \left[ \frac{9\pi}{64} \frac{\pi^5}{T^5} [f_{3/2}(e^{\beta \mu})]^2 \right]. \tag{47}
\]

The subscripts \( S, N \) in Eq. (47) mean that we keep the entropy \( S \) and the particle number \( N \) fixed when taking the partial derivative. See Fig. 3 for \( \Delta p \) as a function of the initial temperature. In particular, at zero temperature,

\[
\Delta p(0) = \frac{n\hbar^2 D_F}{270\pi^4 M_F} k_F^{10}. \tag{48}
\]

2. Isothermal shifts of energy and pressure in the thermodynamic limit

If the interaction is introduced adiabatically, the temperature will increase (if \( D_F > 0 \)) or decrease (if \( D_F < 0 \)). The change of temperature is

\[
\Delta T = \left( \frac{\partial \Delta E}{\partial S} \right)_{N,\Omega}. \tag{49}
\]

Therefore, if we introduce \( D_F \) isothermally, the energy shift \( \Delta E' \) should be approximately

\[
\Delta E' = \Delta E - C \Delta T = \left( 1 - T \frac{\partial}{\partial T} \right) \Delta E, \tag{50}
\]

where \( C \) is the heat capacity of the noninteracting Fermi gas at constant volume. In the low temperature limit, \( T \ll T_F \),

\[
\Delta E'(T) = \frac{N\hbar^2 D_F}{36\pi^4 M_F} k_F^{10} \left[ \frac{1}{25} \frac{\pi^2}{30} T^2 + O(T^4) \right], \tag{51}
\]
In an intermediate temperature regime, \( T_F \ll T \ll T_c \),
\[
\Delta E'(T) = \frac{N\hbar^2 D_F}{36\pi^4 M_F} k_F^4 \left[ \frac{1}{4} T^2 + \frac{\sqrt{T}}{12\sqrt{2\pi}} + O(T^{-1}) \right].
\]

According to Eqs. (51) and (52), \( \Delta E' \) changes sign as we increase the temperature. Therefore, there is a critical temperature \( T_c \) at which \( \Delta E' = 0 \). We find
\[
T_c \simeq 0.377 T_F.
\]

The pressure of the spin-polarized Fermi gas changes by the following amount due to the isothermal introduction of \( D_F \):
\[
\Delta p' = \Delta p - \frac{2C\Delta T}{3\Omega} \left( 1 - \frac{1}{5} \frac{T}{\partial T} \right) \Delta p.
\]

In the low temperature limit, \( T \ll T_F \),
\[
\Delta p' = \frac{5n\hbar^2 D_F}{54\pi^4 M_F} k_F^4 \left[ \frac{1}{25} \frac{T}{\partial T} + \frac{\pi^2}{50} T^2 + O(T^4) \right].
\]

In an intermediate temperature regime, \( T_F \ll T \ll T_c \),
\[
\Delta p' = \frac{5n\hbar^2 D_F}{54\pi^4 M_F} k_F^4 \left[ \frac{3}{20} \frac{T}{\partial T} + \frac{3\sqrt{T}}{20\sqrt{2\pi}} + O(T^{-1}) \right].
\]

The energy shift and the pressure change as functions of temperature are shown in Fig. 2 and Fig. 3 respectively.

**IV. THE THREE-BODY RECOMBINATION RATE**

If the collision of the three particles is purely elastic, \( D_F \) is a real number. But if the two-body interactions support bound states, then the three-body collisions are usually not purely elastic, three-body recombination \( \text{[3, [9]} \) will occur, and \( D_F \) will acquire some negative imaginary part. The three-body recombination rate constant is proportional to the imaginary part of \( D_F \) \( \text{[10, [11]} \).

Within a short time \( \Delta t \), the probability that no recombination occurs is \( \exp(-2|\text{Im}E|\Delta t/\hbar) \simeq 1 - 2|\text{Im}E|\Delta t/\hbar \). Then the probability that one recombination event occurs is \( 2|\text{Im}E|\Delta t/\hbar \). Since each recombination event causes the loss of three low-energy atoms, the change of the number of remaining low-energy atoms in the short time \( dt \) is
\[
dN = -\frac{1}{6} \sum_{k_1 k_2 k_3} 3 \cdot \frac{24t}{\hbar} |\text{Im}E_{k_1 k_2 k_3}| n_{k_1} n_{k_2} n_{k_3}.
\]

This leads to
\[
\frac{dn}{dt} = -L_3 n^3,
\]
and the three-body recombination rate constant \( L_3 \) is
\[
L_3 = 6(6\pi^2)^{4/3} \left( \frac{9\pi}{64} \right)^{2/3} \frac{f_{3/2}(e^{\beta\mu})^2 \hbar |\text{Im}D_F|}{M_F} n^{1/3}.
\]

\( L_3 \) now in general depends on the density \( n \) and the temperature \( T \).

In the low temperature limit, \( T \ll T_F \),
\[
L_3 \simeq 55.396 \left( 1 + \frac{5\pi^2}{6} T^2 \right)^2 \frac{\hbar |\text{Im}D_F|}{M_F} n^{1/3}.
\]

In this limit, \( dn/dt \) is proportional to \( n^\alpha \) where \( \alpha = 13/3 = 4.333 \cdots \). In particular, at absolute zero temperature,
\[
\frac{dn}{dt} = -55.396 \frac{\hbar |\text{Im}D_F|}{M_F} n^{13/3}.
\]
In an intermediate temperature regime, $T_F \ll T \ll T_e$, we find that
\[ L_3 = \frac{M_F}{R^3} |\text{Im} D_F| (k_B T)^2, \] (62)
and $L_3$ is approximately independent of $n$, and is proportional to $T^2$. It was predicted that $L_3 \propto T^2$ according to the Wigner threshold law [17]. Our Eq. (62) is consistent with this prediction. In Refs. [18, 19] the quadratic dependence of $L_3$ on the temperature was experimentally confirmed for ultracold $^6$Li atoms in the $|F = 1/2, m_F = 1/2 \rangle$ state.

In Ref. [19] it was reported that $L_3 = (3.55 \pm 0.22) \times 10^{-23} \times T^2 \text{cm}^3/\text{s} \ (T \text{ in units of Kelvin})$ at $T \sim 100 - 300 \mu \text{K}$ for $^6$Li atoms in a magnetic field of 1G (far away from the $p$-wave Feshbach resonance located at 159G). Using this result in Ref. [19] we find that the order of magnitude of $|\text{Im} D_F|$ for these fermionic atoms in such magnetic field is about $-(125a_0)^8$, where $a_0$ is the Bohr radius.

V. SUMMARY AND DISCUSSION

We have defined the three-body scattering hypervolume $D_F$ for identical spin-polarized fermions by considering the collision of three such fermions at zero energy. We solved the three-body Schrödinger equation asymptotically at large interparticle distances and expanded the three-body wave function in powers of $1/R$ when the pairwise distances go to infinity simultaneously (here $B$ is the three-body hyperradius), and expanded the same wave function in powers of $1/R$ when two fermions are held at a fixed distance and the third fermion is far away from the two (here $R$ is the distance between this third fermion and the center of mass of the other two fermions). In the expansion in powers of $1/B$, the parameter $D_F$ first appears at the order $1/B^6$. In the expansion in powers of $1/R$, the parameter $D_F$ first appears at the order $1/R^7$. For any given microscopic interaction potentials, one can solve the three-body Schrödinger equation numerically and match the solution to these expansions to compute $D_F$.

The three-body scattering hypervolume we have defined in this paper plays a fundamental role in three-body, four-body, ..., and many-body physics for ultracold Fermi gases. Although usually the two-body $p$-wave scattering volume is the dominant parameter for the effective interactions in spin-polarized ultracold Fermi gases, and $D_F$ serves as a small correction, $D_F$ may become the dominant parameter if $a_F$ happens to be zero or tiny or is tuned to zero, or if the system is near a three-body resonance close to zero energy. If the system is near a three-body resonance close to zero energy, $D_F$ may be anomalously large.

In the second part of this paper we computed the energy shift of three fermions in a large periodic volume due to $D_F$. From this result we computed the energy shift of many fermions in the thermodynamic limit due to $D_F$. We also computed the shift of pressure due to $D_F$. The energy shift and the pressure shift are related. We computed the two shifts in two scenarios as functions of temperature: either introducing the three-body parameter adiabatically or introducing it isothermally. For isothermal introduction of $D_F$, we found that the shift of energy changes sign at temperature $T \sim 0.37T_F$, where $T_F$ is the Fermi temperature. The energy and pressure shifts could be experimentally detected in trapped ultracold atomic Fermi gases. In particular, $D_F$ will cause a small change of the atomic cloud size and small changes of the collective mode frequencies.

If the two-body interactions are sufficiently attractive such that there are two-body bound states, $D_F$ will acquire some negative imaginary part related to the three-body recombination processes. We computed the three-body recombination rate constant $L_3$ in terms of $\text{Im} D_F$ as functions of temperature. In particular, we found that at low temperatures ($T \ll T_F$) $L_3 \propto n^{4/3}$. These results could be verified in future experiments concerning ultracold atomic Fermi gases.
