(Dated: July 13, 2021)

We investigate an asymptotic expansion of the solution of the master equation under the modulation of control parameters. In this case, the dominant part of the solution becomes the dynamical steady state expressed as an infinite series using the pseudo-inverse of the Liouvillian, whose convergence is not granted in general. We demonstrate that for the relaxation time approximation, the Borel summation of the infinite series is compatible with the exact solution. By exploiting the series expansion, we obtain the analytic expression of the heat. In the two-level system coupled to a single bath, we consider that the linear modulation of the energy as a function of time and demonstrate that the infinite series expression is the asymptotic expansion of the exact solution. The equality of a trade-off relation between the speed of the state transformation and the entropy production (Shiraishi, Funo, and Saito, Phys. Rev. Lett. 121, 070601 (2018)) holds in the lowest order of the frequency of the energy modulation in the two-level system. To obtain this result, the heat emission and absorption at edges (the initial and end times) or the differences of the Shannon entropy between the instantaneous steady state and the dynamical steady state at edges are essential: If we ignore these effects, the trade-off relation can be violated.

I. INTRODUCTION

Time-dependent open systems have been studied actively in recent years. These studies relate to quantum pump [1–8], excess entropy production [9–13], efficiency and power of heat engine [14–18], shortcuts to adiabaticity [19, 20], and speed limits [21–23]. In the studies of quantum pumping and excess entropy production for systems governed by the master equation, the time dependence is described using the pseudo-inverse of the Liouvillian [1–3, 5–7, 12, 13, 24]. However, the solution using the pseudo-inverse of the Liouvillian is an asymptotic expansion and does not converge in general: The solution is obtained by iterative applications of the pseudo-inverse and the time derivative, which can make the series expansion divergent similarly to the case for the adiabatic iteration [25]. In this paper, we will give an analytically tractable model, the relaxation time approximation model, whose solution expressed by the pseudo-inverse is an asymptotic expansion of the exact solution and provides a good approximation in the first few terms.

One of the trade-off relations between the speed of the state transformation and the entropy production for the classical stochastic process is given in Ref. 22: If the Liouvillian satisfies the local detailed balance condition

\[ r := \frac{2\sigma A}{L^2} \tau \geq 1 \]

holds. Here, \( L \) is the total variation distance, \( A \) is the average activity and \( \sigma \) is the total entropy production (for the definitions, see §V). The authors of Ref. 22 considered a two-level system and provided a specific protocol, which realizes \( r = (5/2)\ln(3/2) = 1.01366... \) in the limit of slow driving. In the present paper, based on the asymptotic expansion of our relaxation time approximation model, we will demonstrate protocols that achieve the equality of (1).

The structure of the paper is as follows. First, we give an infinite series expression of the dynamical steady state which is the solution of the master equation under the modulation of control parameters (§II). Next, in §III A we introduce the relaxation time approximation and show that the Borel summation of the infinite series expression becomes the exact solution. In §III B for the two-level system (like spinless one-level quantum dot) coupled to a single bath, we consider that linear modulation of the energy as a function of time and show that the infinite series expression is the asymptotic expansion of the exact solution. In §IV we calculate the heat current and heat using the asymptotic expansion of the dynamical steady state for the relaxation time approximation. In §V we show that the equality of a trade-off relation of Shiraishi-Funo-Saito [22] holds in the lowest order of the frequency of the energy modulation in the two-level system. In §VI we summarize this paper. In Appendix A we derive the exact solution of the master equation. In Appendix B we explain a prescription getting the exact solution from the asymptotic expansion in the two-level system. In Appendix C we give an instance of the convergent infinite series expression of the dynamical steady state. In Appendix D we calculate entropy production in the two-level system.

II. GENERAL THEORY

In this section, we give an infinite series expression of the dynamical steady state using the pseudo-inverse of the Liouvillian.

We consider a master equation

\[ \frac{d}{dt} p_i(t) = \sum_{j=0}^{N-1} K_{ij}(\alpha_t) p_j(t). \]  

(2)

Here, \( p_i \) is the probability of state \( i (= 0, 1, \cdots, N - 1) \) at time \( t \) and \( \alpha_t \) is the value of the set of the control parameters at time \( t \). We assume that the master equation has a unique instantaneous steady state \( p^{ss}_i(\alpha) \) which satisfies \( \sum_j K_{ij}(\alpha_t) p^{ss}_j(\alpha) = 0 \) and \( \sum_i p^{ss}_i(\alpha) = 1 \). The pseudo-inverse of the Liouvillian \( K_{ij}(\alpha) \) is defined by

\[ \sum_k R_{ik}(\alpha_t) K_{kj}(\alpha) = \delta_{ij} - p^{ss}_i(\alpha). \]  

(3)

Applying the pseudo-inverse \( R(\alpha_t) \) to the master equation (2), we obtain

\[ \left[ 1 - R(\alpha_t) \frac{d}{dt} \right] \delta p(t) = R(\alpha_t) \frac{dp^{ss}(\alpha_t)}{dt}, \]  

(4)

where \( \delta p(t) := p(t) - p^{ss}(\alpha_t) \). Here, \( R \) denotes the matrix \( (R_{ij}) \) and \( p \) is the vector \( (p_0, p_1, \cdots, p_{N-1})^t \). The formal solution of (4) is given by

\[ \delta p^{(ss)}(t) := \sum_{n=1}^{\infty} \left[ R(\alpha_t) \frac{d}{dt} \right]^n p^{ss}(\alpha_t) =: \sum_{n=1}^{\infty} p^{(n)}(t). \]  

(5)

The general solution of (4) is

\[ \delta p(t) = \delta p^{(ss)}(t) + \tilde{\delta} p(t). \]  

(6)

Here, \( \tilde{\delta} p(t) \) is the solution of

\[ \left[ 1 - R(\alpha_t) \frac{d}{dt} \right] \tilde{\delta} p(t) = 0 \]  

(7)

under \( \tilde{\delta} p(0) = \delta p(0) - \delta p^{ss}(0) \). \( \tilde{\delta} p(t) \) also satisfies \( \frac{d}{dt} \tilde{\delta} p(t) = K(\alpha_t) \tilde{\delta} p(t) \) and damps exponentially as a function of time [13]. Then, the general solution of the master equation is given by

\[ p(t) = p^{(ss)}(t) + \tilde{\delta} p(t), \]

(8)

where

\[ p^{(ss)}(t) := p^{ss}(\alpha_t) + \delta p^{(ss)}(t) = p^{ss}(\alpha_t) + \sum_{n=1}^{\infty} p^{(n)}(t). \]  

(9)

We call \( p^{(ss)}(t) \) dynamical steady state. The general solution consists of the exponentially damping term \( \tilde{\delta} p(t) \) and the dynamical steady state, which is composed of the instantaneous steady state and the correction \( \delta p^{(ss)}(t) \).

In general, the infinite series \( p^{(ss)}(t) \) does not converge. In the next section, we compare \( p^{(ss)}(t) \) and an exact solution of the master equation.

III. EXACT SOLUTION AND BOREL SUMMATION

In this section, first, we study the relaxation time approximation for an \( N \)-level system and show that the Borel summation of the infinite series \( p^{(ss)}(t) \) is the exact solution of the master equation. Next, we study the two-level system and demonstrate that \( p^{(ss)}(t) \) is identical with the asymptotic expansion of the exact solution.
A. $N$-level system

We introduce a Liouvillian

$$K_{ij}(\alpha) = \gamma(p_i^{ss}(\alpha) - \delta_{ij}) \quad (i, j = 0, 1, \cdots, N - 1)$$

with $\gamma > 0$. This Liouvillian satisfies the detailed balance condition $K_{ij}(\alpha)p_j^{ss}(\alpha) = K_{ji}(\alpha)p_i^{ss}(\alpha)$ \[26\]. As a special case, this Liouvillian includes

$$K(\alpha) = \gamma \left(-f \frac{1 - f}{-f} - (1 - f)\right), \quad f = \sum_b \frac{\gamma_b}{\gamma} e^{\beta_b \Delta} + 1$$

with $\sum_b \gamma_b = \gamma$. Here, $\gamma_b$ is the coupling strength and $\beta_b$ is the inverse temperature of bath $b$. For instance, a spinless one-level quantum dot coupled to leads has this Liouvillian. The master equation of (10) is given by

$$\frac{d}{dt} p_i(t) = -\gamma(p_i(t) - \gamma)(p_i^{ss}(\alpha_t)).$$

This is the relaxation time approximation of which relaxation time is $1/\gamma$. A pseudo-inverse of (10) is given by

$$R_{ij}(\alpha) = \frac{1}{\gamma}(p_i^{ss}(\alpha) - \delta_{ij}).$$

For simplify, we assume $\gamma$ is a constant in the following of this paper. Substituting (9) and (13) to (10), we obtain

$$\tilde{F}_i(t) := p_i^{(ss)}(t) = \sum_{n=0}^{\infty} \left(-\frac{1}{\gamma}\right)^n \frac{d^n}{d\alpha^n} p_i^{ss}(\alpha_t).$$

In \[11-13\] we show that $\tilde{F}_i(t)$ diverges in the two-level system.

We calculate the Borel summation of $\tilde{F}_i(t)$. For a series $\tilde{S}(t) := \sum_{n=0}^{\infty} a_n(t)$, if (i) the Borel function $B[\tilde{S}(t)](s) := \sum_{n=0}^{\infty} \frac{a_n(t)}{n!} s^n$ converges to an analytic function for $0 \leq s < \rho$ ($\rho > 0$) and can be analytically continued along the positive real axis and (ii) $S(t) := \int_0^{\infty} ds e^{-s} B[\tilde{S}(t)](s)$ is well defined, $S(t)$ is called as the Borel summation of $\tilde{S}(t)$ \[27\]. The Borel function of $\tilde{F}_i(t)$ is given by

$$B[\tilde{F}_i(t)](s) = \sum_{n=0}^{\infty} \frac{1}{n!} s^n \left(-\frac{1}{\gamma}\right)^n \frac{d^n}{d\alpha^n} p_i^{ss}(t),$$

where $p_i^{ss}(t)$ denotes $p_i^{ss}(\alpha_t)$. This series converges to an analytic function $p_i^{ss}(t - \frac{s}{\gamma})$ for small $s$. Then, the Borel summation of $\tilde{F}_i(t)$ is given by

$$\int_0^{\infty} ds e^{-s} B[\tilde{F}_i(t)](s) = \int_0^{\infty} ds e^{-s} p_i^{ss}(t - \frac{s}{\gamma}) =: F_i(t).$$

Next, we show that the exact solution of the master equation is identical with the Borel summation of $\tilde{F}_i(t)$. Using the general theory of first-order linear ordinary differential equation, the exact solution under the initial condition $p_i(t = 0) = p_i(0)$ is given by

$$p_i(t) = e^{-\gamma t} \left[p_i(0) + \gamma \int_0^t du p_i^{ss}(u)e^{\gamma u}\right].$$

This equation can be rewritten as (Appendix \[A\])

$$p_i(t) = e^{-\gamma t}[p_i(0) - F_i(0)] + F_i(t),$$

where $F_i(t)$ was introduced in (14). The first term of (18) corresponds to $\delta p(t)$ because this term damps exponentially. The second term of (18) corresponds to the dynamical steady state. We note that the exact solution of the master equation is identical with the Borel summation of $p_i^{(ss)}(t)$ even if $\gamma$ is time dependent.
B. Demonstration in two-level system

In this subsection, we consider the two-level system [11] and show that $\tilde{F}_i(t)$ ($i = 0, 1$) diverges and is identical with the asymptotic expansion of the exact solution $F_i(t)$.

In the following of this paper, we assume that the instantaneous steady state $p^s(\alpha) = e^{-\beta E_i}/Z$ where $E_i$ is the energy of the state $i$, $\beta$ is the inverse temperature and $Z := \sum_i e^{-\beta E_i}$ is the partition function. We focus on the energy modulation

$$E_i = \alpha(t)E_i^{(0)}$$

with fixed $E_i^{(0)}$ and $\beta$ and study the linear modulation $\alpha(t) = h_1 + \omega t$ in particular. In this case, the control parameter is $\alpha(t)$.

We consider [11] with $\Delta(t) = (h_1 + \omega t)\Delta$ and fixed $\gamma$ and $\beta$ in the following of this section. In this case, $\tilde{F}(t) := \tilde{F}_1(t)$ is given by

$$\tilde{F}(t) = \sum_{n=0}^{\infty} \left( -\frac{1}{\gamma} \right)^n \frac{d^n}{dt^n} f(W + V t)$$

with $f(x) := 1/(e^x + 1)$. Here, $W := \beta h_1$, $V := \beta \omega > 0$. Figure [1] shows that $f(W + V t)$, $F(t) := F_1(t)$) and $\tilde{F}(N) := \sum_{n=0}^{N} \left( -\frac{1}{\gamma} \right)^n \frac{d^n}{dt^n} f(W + V t)$ for $N = 5, 24, 25, \text{ and } 26$ at $V/\gamma = 0.3$. $\tilde{F}(t)$ dose not converge. For $N = 5$, the asymptotic expansion $\tilde{F}(t)$ well agrees with the exact solution $F(t)$. However, for large $N = 24, 25 \text{ and } 26$, the deviations increase and the asymptotic expansions oscillate. $f(W + V t)$ can be written as

$$f(W + V t) = \frac{1}{2} - \frac{1}{V} \sum_{k=0}^{\infty} \left[ t - \frac{1}{2} \right]^{(k+1)} + \frac{1}{V} \left[ t - \frac{1}{2} \right]^{(k+1)}.$$ \hspace{1cm} (21)

The dominant contribution of $\frac{d^n}{dt^n} f(W + V t)$ (for large $n$) comes from two poles ($k = 0$) most nearly above and below $t$. In general, $n$-th derivative of $g(t) = \sum_{k} A_k/(t - a_k)$ ($a_k$ are complex numbers) is given by

$$g^{(n)}(t) = (-1)^n n! \sum_{k} \frac{A_k}{(t - a_k)^{n+1}}.$$ \hspace{1cm} (22)

The factorial increase with $n$ of the coefficients underlies the divergence commonly encountered in asymptotic series, and, together with the increasingly fast oscillations, reflects the instability of differentiation [28]. In the studies of the full-counting statistics, the oscillations coming from the higher derivative by the counting field have been observed [2, 29, 31].

The dynamical steady state $F(t) := F_1(t)$ is given by

$$F(t) = \int_{0}^{\infty} ds \ e^{-s f(W + V t)} = 2F_1(1, c; c + 1; -e^{W+Vt}) = f(W + V t)2F_1(1, 1; c + 1; 1 - f(W + V t))$$ \hspace{1cm} (23)

with $c := \gamma/V$. $2F_1(a, b; c; z)$ is the hypergeometric function. The third equality of (23), we used the Kummer’s relation $2F_1(a, b; c; z) = \frac{1}{(1-z)^a} 2F_1(a, c - b; c; 1)$.

We show that $\tilde{F}(t)$ is an asymptotic expansion of $F(t)$. A divergent series $\sum_{k=0}^{\infty} a_k/c^k$ is the asymptotic expansion of a function $G(c)$ if $R_n(c) := c^n [G(c) - \sum_{k=0}^{n} a_k/c^k]$ satisfies $|R_n(c)| \rightarrow 0 \ (c \rightarrow \infty)$. In the third line of (23), $2F_1(1, 1; c + 1; z)$ can be expanded in $z$ as

$$2F_1(1, 1; c + 1; z) = 1 + \sum_{k=1}^{\infty} \frac{k!}{(c+1)(c+2)\cdots(c+k)} z^k$$

$$= 1 + \sum_{k=1}^{\infty} \frac{k!}{(c+1)(c+2)\cdots(c+k)} z^k + \delta_n(c, z).$$ \hspace{1cm} (24)

The second term can be expanded in $1/c$ as

$$\sum_{k=1}^{n} \frac{k!}{(c+1)(c+2)\cdots(c+k)} z^k = \sum_{k=1}^{n} \frac{a_k(z)}{c^k} + r_n(c, z)$$ \hspace{1cm} (25)
FIG. 1. \(f(W + V t), F(t) := F_1(t)\) and \(\tilde{F}_{(N)}(t)\) for \(N = 5, 24, 25,\) and \(26\) at \(V/\gamma = 0.3\). \(F(t)\) (red) and \(\tilde{F}_{(5)}(t)\) (gray) are overlapping. For specific parameters, the asymptotic expansion above 24th order deviates significantly from the exact solution.

with \(r_n(c, z) = O(1/c^{n+1})\). Here, \(a_1(z) = z, a_2(z) = -z + 2z^2, a_3(z) = z - 6z^2 + 6z^3, a_4(z) = -z + 14z^2 - 36z^3 + 24z^4\) and \(a_5(z) = z - 30z^2 + 150z^3 - 240z^4 + 120z^5\). Then, \(2F_1(1, 1; c + 1; z)\) is given by

\[
2F_1(1, 1; c + 1; z) = 1 + \sum_{k=1}^{n} \frac{a_k(z)}{c^k} + \frac{R_n(c, z)}{c^n}
\]  

with \(R_n(c, z) := c^n [r_n(c, z) + \delta_n(c, z)]\). The first and second terms of the right hand side provide \(\tilde{F}_{(n)}(t)\). If \(c\) is large enough, \(2F_1(1, 1; c + 1; z)\) \((0 \leq z \leq 1)\) is well approximated by first few terms. The truncation error \(\delta_n(c, z)\) satisfies

\[
|\delta_n(c, z)| \leq \delta_n(c, 1) = \frac{(n + 1)!}{(c - 1)(c + 1)(c + 2) \cdots (c + n)}
\]

where \(\Gamma(z)\) is the gamma function. The above inequality leads \(|R_n(c, z)| \to 0\) \((c \to \infty)\). Then, \(\tilde{F}(t)\) is the asymptotic expansion of \(F(t)\). We obtain \(\tilde{F}(t)\) from \(F(t)\) if we expand \(2F_1(1, 1; c + 1; z)\) regarding \(c\) is larger than any natural number \(n\).

In Appendix B we explain a prescription getting \(F(t)\) from \(\tilde{F}(t)\). We note that any infinite series expansion is not necessarily divergent. For example, the protocol discussed in Ref. [22] leads a convergent series expansion. In Appendix C we give an instance of the convergent infinite series expression of the dynamical steady state.

IV. HEAT CURRENT AND HEAT

In this section, we evaluate the heat current

\[
q(t) := -\sum_i E_i \frac{d}{dt} p_i
\]
using the asymptotic expansion \((19)\). We denote the heat current contributed from \(p^{\alpha}(\alpha_t)\) and \(p^{(n)}(t)\) by \(q_0(t)\) and \(q_n(t)\) respectively. We obtain

\[
q_0(t) = - \sum_i E_i \frac{dp_i^{\alpha}}{dt},
\]

\[
q_1(t) = - \sum_{i, k} E_i \left[ R_{ik} \frac{dp_i^{\alpha}}{dt} - \left( R_{ik} \frac{dK}{dt} R_{ik} \right) \frac{dp_k^{\alpha}}{dt} \right].
\]

Substituting \((19)\) to \((29)\), we obtain

\[
q_0(t) = \alpha'(t) \alpha(t) \beta \left[ \langle (E^{(0)})^2 \rangle - \langle E^{(0)} \rangle^2 \right],
\]

where \(\langle (E^{(0)})^n \rangle := \sum_i \langle E^{(0)}(t) \rangle p_i^{\alpha}(\alpha_t)\) is the \(n\)-th moment of energy. \(q_0(t)\) is proportional to the variance of the energy and does not depend on the Liouvillian. It is also expressed by using the Fisher information \([21, 34, 32]\). For our energy modulation \((19)\), we can also interpret that the inverse temperature is time dependent \(\beta_t := \alpha(t) \beta\). Then, we obtain

\[
q_1(t) = \beta \alpha(t) \left[ - \{ \alpha''(t) + 2 \langle E^{(0)} \rangle \alpha'(t) \} \mu_1(\beta_t) + \beta \langle \alpha'(t) \rangle \mu_2(\beta_t) \right],
\]

where \(\mu_1(\beta_t) := - \sum_{i, k} E_i^{(0)} R_{ik}^{(0)} E_k^{(0)} p_k^{\alpha}(\alpha_t)\) and \(\mu_2(\beta_t) := - \sum_{i, k} E_i^{(0)} R_{ik}^{(0)} E_k^{(0)} p_k^{\alpha}(\alpha_t) - \sum_{i, k} E_i^{(0)} (R_{ik}^{(0)} \frac{dK}{dt} R_{ik}^{(0)})_{ik} E_k^{(0)} p_k^{\alpha}(\alpha_t)\).

Here, \(R_{ik}^{(0)}\) defined by \((33)\) and \(\sum_k R_{ik}^{(0)}(\alpha)p_k^{\alpha}(\alpha) = 0\) is called the Drazin inverse \([32]\).

In the following of this section, we consider the Liouvillian \((10)\) with fixed \(\gamma\) and \(\beta\). In this case, using the Fa`a di Bruno’s formula \([32]\), we obtain

\[
q_{n-1}(t) = \frac{(-1)^n}{\gamma^{n-1}} \alpha(t) \sum m_1! m_2! \cdots m_n! (\alpha(t) \beta)^m C_k(\beta_t) \prod_j \left( \frac{\alpha(t)}{\beta_t} \right)^{m_j} (k := \sum m_j),
\]

where the sum is over all \(n\)-tuples of nonnegative integers \((m_1, \cdots, m_n)\) satisfying the constraint \(\sum_{j=1}^n j m_j = n\).

Here, \(C_n(\beta_t)\) is \(n\)-th order cumulant of \(E_i^{(0)}\):

\[
C_n(\beta_t) = (-1)^n \frac{\partial^n \ln Z(\beta_t)}{\partial \beta_t^n}
\]

and \(Z(\beta_t) := \sum_e e^{-\beta_t E_i^{(0)}}\). In particular, if \(\alpha(t) = h_i + \omega t\) while \(0 < t < \tau\), \(q_{n-1}(t)\) is given by

\[
q_{n-1}(t) = \frac{1}{\gamma^{n-1}} \alpha(t) \omega^n \beta^n C_{n+1}(\beta_t).
\]

The heat is given by

\[
Q_n := \int_0^\tau dt \ q_n(t) = \left( \frac{\omega \beta}{\gamma} \right)^n \left[ \beta_t C_{n+1}(\beta_t) + C_n(\beta_t) - \beta_t C_{n+1}(\beta_t) - C_n(\beta_t) \right].
\]

Here, \(\beta_t := h_t \beta, \ \beta_{\tau} := h_{\tau} \beta, \ \text{and} \ h_{\tau} := h_1 + \omega \tau\).

V. TRADE-OFF RELATION

In this section, we show that the equality of a trade-off relation of Shiraishi-Funo-Saito \([22]\) holds in the lowest order of the frequency of the energy modulation in the two-level system.

If the Liouvillian satisfies the local detailed balance condition, a trade-off relation between the speed of the state transformation and the total entropy production

\[
\frac{L^2}{2\tau A} \leq \tau
\]

holds \([22]\). Here, \(L := \sum_i |p_i(\tau) - p_i(0)|\) is the \(l_1\) norm \([34]\). The average activity

\[
A := \frac{1}{\tau} \int_0^\tau dt \ A(t)
\]

(38)
In the following, we show that the zeroth order of the state of the system at $t = \delta/2$ is given by
\[ r(t) = h_i + \omega t \] for $-\delta/2 < t < \tau + \delta/2$, where $\delta$ is a small value:
\[
\alpha(t) = \begin{cases} 
  h_i - \omega t/2 & (t \leq -\delta) \\
  h_i + \omega t & (-\delta \leq t \leq \tau + \delta) \\
  h_i + \omega(\tau + \delta/2) & (\tau + \delta/2 \leq t)
\end{cases}
\] (41)

In the first protocol (protocol A), we consider $-\delta \leq t < \tau + \delta$. The heat contributed from the term $(\alpha''(t))$ including the delta function in (39) is given by
\[
\delta Q_1 = \omega \left[ \beta_i \mu_1(\beta_i) - \beta_i \mu_1(\beta_i) \right].
\] (42)

In the second protocol (protocol B), we consider $0 \leq t \leq \tau$ and suppose that the state of the system at $t = 0$ is the dynamical steady state $p^{ss}$. In the third protocol (protocol C), we consider $-\delta \leq t \leq \tau$ and suppose that the state of the system at $t = -\delta$ is the instantaneous steady state. The ratio $r$ defined by (42) can be expanded as
\[
r = r_0 + r_1 \omega + r_2 \omega^2 + \cdots.
\] (43)

In the following, we show that $r_0 = 1$ for protocol A, B, and C in the two-level system (44). To calculate $r_0$, we estimate $\sigma$ up to first order of $\omega$ (we denote this by $\sigma^{(1)}$) and the average activity $A$ and $L$ up to zeroth order. In the zeroth order of $\omega$, $A$ is given by $A^0 := \frac{1}{\beta} \int_0^\tau dt A^\omega(\alpha_i)$ with $A^\omega(\alpha_i) := \sum_{i \neq j} K_{ij}(\alpha_i) p_i^\omega(\alpha_i)$, and $L$ is given by $L^0 := \sum_i |p_i^\omega(\alpha_i) - p_i^\omega(\alpha_0)|$.

In this paragraph, we calculate $\sigma^{(1)}$ in the general system. The zeroth order of the heat $Q_0 = \int_0^\tau dt q_0(t)$ is given by
\[
Q_0 = \frac{1}{\beta} \left[ \beta \langle E^0(0) \rangle(\beta_i) + \ln Z(\beta_i) - \beta \langle E^0(0) \rangle(\beta_i) - \ln Z(\beta_i) \right].
\] (44)

The Shannon entropy is given by $S_{\text{Sh}}(p) = S_{\text{Sh}}(\beta_i) + \delta S_{\text{Sh}}$ with $S_{\text{Sh}}(\beta_i) := \beta_i \langle E^0(0) \rangle(\beta_i) + \ln Z(\beta_i)$. Therefore, $\beta Q_0 + S_{\text{Sh}}(\beta_i) - S_{\text{Sh}}(\beta_i) = 0$ and
\[
\sigma^{(1)} = \beta(Q_1 + \delta Q_1) \quad \text{(protocol A)},
\]
\[
\sigma^{(1)} = \beta Q_1 + \delta S_{\text{Sh}} \bigg|_{t=\tau} - \delta S_{\text{Sh}} \bigg|_{t=0} \quad \text{(protocol B)},
\]
\[
\sigma^{(1)} = \beta(Q_1 + \delta' Q_1) - \delta S_{\text{Sh}} \bigg|_{t=0}, \quad \delta' Q_1 = \omega \left[ \beta_i \mu_1(\beta_i) \right] \quad \text{(protocol C)}
\] (47)
FIG. 3. (a) $(r−1)$ for protocol C, (b) $(r−1)$ for protocol B, (c) $(r_A−1)/(r_C−1)$ and (d) $(r_A−1)/(r_C−1)$ for $(h_i, h_f) = (0, 10)$ (blue), $(h_i, h_f) = (1, 10)$ (black) and $(h_i, h_f) = (0, 3)$ (red). Here, $r_A$ and $r_C$ denote $r$ for protocol A and C respectively. In these figures, we set $\beta_\Delta = 1$.

We estimate $A^{ss}$ and $\delta S_{Sh}$ in the the relaxation time approximation (10). In this case, we obtain

$$A^{ss}(\alpha t) = \gamma \left[1 - \sum_i (p_{i}^{ss})^2\right].$$  

(48)

The right hand side is related to the purity [30]. Using $p_{i}^{(1)} = \frac{\omega}{\gamma} \beta [E_i^{(0)} - \langle E(0) \rangle (\beta_i)] p_{i}^{ss}$, we have $\delta S_{Sh} = -\frac{1}{\gamma} \beta \sum_i E_i^{(0)} p_{i}^{ss} \ln p_{i}^{ss} - \frac{\omega}{\gamma} \beta \langle E(0) \rangle (\beta_i) S_{Sh}(\beta_i)$. In the two-level system [11] with $\Delta(t) = \alpha(t) \Delta$, $A^{ss}$ becomes

$$A^{ss} = \frac{2\gamma}{\Delta(\beta_i - \beta_f)} \left[f(\beta_i \Delta) - f(\beta_f \Delta)\right].$$  

(49)

We show that $r_0 = 1$ for protocol A, B, and C in the two-level system. $\sigma^{(1)}$ is given by

$$\sigma^{(1)} = \frac{\omega}{\gamma} \beta \Delta [f(\beta_i \Delta) - f(\beta_f \Delta)]$$  

(50)

for protocol A, B, and C (Appendix [11]). From (49), (50) and

$$L^{ss} = 2[f(\beta_i \Delta) - f(\beta_f \Delta)],$$  

(51)

we obtain

$$r_0 = \frac{2\sigma^{(1)} A^{ss}}{(L^{ss})^2} \tau = 1$$  

(52)

for protocol A, B, and C.

To obtain [22], the heat emission and absorption at edges $(t = -\delta/2, \tau + \delta/2)$ or the correction of the Shannon entropy $\delta S_{Sh}$ at edges $(t = 0, \tau)$ are essential. If we ignore these corrections, $r_0$ can be less than 1.

Figure 3 shows the numerical results of $(r−1)$ for the three protocols calculated from (28) and (38) by exploiting the exact solution for the two-level system [23]. For all protocols, during the duration $0 \leq t \leq \tau$, the system is driven
as \( \alpha(t) = h_1 + \omega t \). The initial states for the protocols A, B and C are the instantaneous steady state \( p_1(t=0) = f(W) \), the dynamical steady state \( p_1(t=0) = F(0) \) and the instantaneous steady state \( p_1(t=0) = f(W) \), respectively. In addition, only for the protocol A, after we turn off the driving at time \( \tau \), we fix \( \alpha(t) = h_1 + \omega \tau \) \((\tau \leq t \leq \tau + 30/\gamma)\) and wait until the system relaxes to the instantaneous steady state. In this duration the heat is emitted from the system.

In Fig. 3 we plot \((r_C - 1), (r_B - 1)\) and \((r_A - 1)/(r_C - 1)\) for various \( h_1\) and \( h_f\): \((h_1, h_f) = (0, 10)\) (blue), \((h_1, h_f) = (1, 10)\) (black) and \((h_1, h_f) = (0, 3)\) (red) at \( \beta \Delta = 1 \). Here, \( r_A \) and \( r_C \) denote \( r \) for protocol A and C respectively. Figure 3 shows that \( r_0 = 1, r_1 > 0 \) for protocol A and C and \( r_0 = 1, r_1 = 0, r_2 > 0 \) for protocol B. Namely, for small \( \omega \), the correction \((r - 1)\) is a linear function for protocol A and C and a quadratic function for protocol B.

In systems described by the master equation having the Liouvillian \((10)\) or more general Liouvillians, in general, \( r_0 > 1 \) if \( N \geq 3 \). For instance, in the relaxation time approximation, \( r_0 \) of protocol A of a \( N \)-level \((N \geq 2)\) system of which energies are \( E_{0}^{(0)} = 0 \) and \( E_{i}^{(0)} = \Delta \) \((i = 1, 2, \cdots, N - 1)\) is given by

\[
{r_0} = \frac{N}{2(N - 1)} + \frac{N - 2}{2(N - 1)^2} \ln \frac{1 + (N - 1)e^{-\beta \Delta}}{1 + (N - 1)e^{-\beta \Delta}} \geq 1. \tag{53}
\]

VI. SUMMARY

In summary, for the relaxation time approximation, we calculated the infinite series expansion of the solution of driven master equation using the pseudo-inverse of the Liouvillian. We demonstrated that the Borel summation of the series becomes the exact solution. For the two-level system coupled to a single bath, we considered that the linear modulation of the energy and showed that the series expression is the asymptotic expansion of the exact solution. Based on the asymptotic expansion for the relaxation time approximation, we demonstrated that the equality of the trade-off relation of Shiraishi-Funo-Saito \([22]\) holds in the lowest order of the frequency of the energy modulation in the two-level system. To our knowledge, this is the first instance where the equality sign holds in the trade-off relation of Ref. \([22]\). If we ignore the heat emission and absorption at edges (the initial and end times) or the differences of the Shannon entropy between the instantaneous steady state and the dynamical steady state at edges, the trade-off relation can be broken.

Appendix A: Derivation of (18)

We derive \([18]\). By variable transformation \( s = \gamma(t - u) \), \((17)\) becomes

\[
p_\tau(t) = e^{-\gamma t} p_\tau(0) + \int_0^{\gamma t} ds \, p_\tau^\infty \left( 1 - \frac{s}{\gamma} \right) e^{-s} \\
= e^{-\gamma t} p_\tau(0) + \int_0^\infty ds \, p_\tau^\infty \left( 1 - \frac{s}{\gamma} \right) e^{-s} - \int_{\gamma t}^\infty ds \, p_\tau^\infty \left( 1 - \frac{s}{\gamma} \right) e^{-s}. \tag{A1}
\]

Using variable transformation \( -\frac{s'}{\gamma} = t - \frac{s}{\gamma} \) in the last term, we obtain \((18)\).

Appendix B: A prescription getting \( F(t) \) from \( \tilde{F}(t) \)

We can obtain \( F(t) \) from \( \tilde{F}(t) \) by following prescription. Because of the analytic continuation, it is enough to consider \(|e^{W+Vt}| < 1\) case. Then, \( F(t) \) is given by

\[
F(t) = 2F_1(1,c+1; -e^{W+Vt}) = \sum_{n=0}^{\infty} \frac{1}{1+n/c} (-e^{W+Vt})^n. \tag{B1}
\]
On the other hand, \( \tilde{F}(t) \) is expressed as

\[
\tilde{F}(t) = \sum_{m=0}^{\infty} \left( -\frac{1}{\gamma} \right)^m \frac{d^m}{dt^m} \sum_{n=0}^{\infty} (-e^{W+Vt})^n 
\]

\[
= \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} \left( -\frac{1}{\gamma} \right)^m (nV)^m (-e^{W+Vt})^n 
\]

\[
= \sum_{n=0}^{\infty} \left[ \sum_{m=0}^{\infty} \left( -\frac{n}{c} \right)^m \right] (-e^{W+Vt})^n 
\]

\[
= \sum_{n=0}^{\infty} \frac{1}{1 + n/c} (-e^{W+Vt})^n. \tag{B2}
\]

In the second line, we changed the order of the sum, and in the fourth line, we suppose that \( c > n \) for all \( n \). Then, \( \tilde{F}(t) \) becomes \( F(t) \).

**Appendix C: Instance of the convergent infinite series expression of the dynamical steady state**

In Ref. [22], a two-level system of which Liouvillian is \( K_{10} = 1 \) and \( K_{01} = t \) has been studied. In this case, the instantaneous steady state is given by \( p^{ss}(\alpha) = \left( \frac{2r+1+\alpha}{4r+1}, \frac{2r-\alpha}{4r+1} \right) \). The pseudo-inverse is given by

\[
R(\alpha) = \left( \begin{array}{cc} 0 & \frac{2r-\alpha}{4r+1} \\ \frac{2r+1+\alpha}{4r+1} & 0 \end{array} \right). \tag{C1}
\]

Then, \( p^{(n+1)}(t) \) becomes

\[
p^{(n+1)}(t) = R(\alpha_t) \left[ \frac{dR(\alpha_t)}{dt} \right]^n \frac{dp^{ss}(\alpha_t)}{dt} \quad (n = 0, 1, \ldots). \tag{C2}
\]

The infinite series expression of the dynamical steady state [4] converges to \( p^{ss}(t) = \frac{1}{2} - \frac{t}{2} \) and is identical with the exact solution.

Reference [22] set the energies as \( E_0 = 0 \) and \( K_{01} = e^{\beta E_1} \). For \( \alpha_t = t \) for \( 0 \leq t \leq \tau \) under the initial distribution \( p_0(0) = 1/2 \), \( r \) defined by [11] converges to \( (5/2) \ln(3/2) = 1.01366 \) for large \( \tau \).

**Appendix D: Calculation of entropy production**

We estimate \( \sigma^{(1)} \) in the two-level system. \( \delta S_{Sh} \) and \( Q_1 \) are given by

\[
\delta S_{Sh} = -\frac{\omega}{\gamma} \beta \Delta \left[ p_1^{ss} \ln p_1^{ss} + f(\beta_{h}\Delta)S_{Sh}(\beta_{t}) \right], \tag{D1}
\]

and

\[
\beta Q_1 = \frac{\omega}{\gamma} \beta \Delta \left[ d(\beta_t \Delta) - d(\beta_t \Delta) \right], \tag{D2}
\]

where \( d(x) := e(x) + f(x) \) and \( e(x) := \frac{x}{(e+1)^2} \). Using the above two equations and

\[
\delta Q_1 = \frac{\omega}{\gamma} \beta \Delta \left[ e(\beta_t \Delta) - e(\beta_t \Delta) \right], \tag{D3}
\]

we obtain

\[
\sigma^{(1)} = \frac{\omega}{\gamma} \beta \Delta \left[ f(\beta_t \Delta) - f(\beta_t \Delta) \right] \tag{D4}
\]

for protocol A. For protocol B, \( \sigma^{(1)} \) is given by

\[
\sigma^{(1)} = \frac{\omega}{\gamma} \beta \Delta \left[ d(\beta_t \Delta) - d(\beta_t \Delta) \right] f(\beta_t \Delta) - f(\beta_t \Delta)S_{Sh}(\beta_t) + f(\beta_t \Delta) \ln f(\beta_t \Delta) + f(\beta_{0}\Delta)S_{Sh}(\beta_{t}) \tag{D5}
\]
Here,
\[
d(\beta_t \Delta) + f(\beta_t \Delta) \ln f(\beta_t \Delta) + f(\beta_t \Delta) S_{\text{Sh}}(\beta_t) = f(\beta_t \Delta) \left[ 1 + \beta_t \Delta f(-\beta_t \Delta) + \ln f(\beta_t \Delta) + S_{\text{Sh}}(\beta_t) \right]
\]
(D6)
holds. Using \( S_{\text{Sh}}(\beta_t) = \frac{x}{e^{x+1}} + \ln(1 + e^{-x}) \) and \( \beta_t \Delta f(-\beta_t \Delta) + \ln f(\beta_t \Delta) = -\frac{x}{e^{x+1}} - \ln(1 + e^{-x}) \), where \( x = \beta_t \Delta \), we obtain \( d(\beta_t \Delta) + f(\beta_t \Delta) \ln f(\beta_t \Delta) + f(\beta_t \Delta) S_{\text{Sh}}(\beta_t) = f(\beta_t \Delta) \). Then, [D3] holds for protocol B. Similarly, [D3] also holds for protocol C.

[26] [D1] does not need to satisfy the local detailed balance condition.

[35] The Fisher information is given by $J_{nm} := \sum_i \partial^m (\alpha_n \partial^{n} \ln \rho_{ii}(\alpha)) + \partial^{n} \ln \rho_{ii}(\alpha)$ where $\partial_n = \frac{\partial}{\partial \alpha_n}$ and $\alpha_n$ is the n-th component of the parameters. For $\alpha^n = \beta_t = \alpha(t)\beta$, $J_{nn} = \langle (E^{(0)}-\langle E^{(0)} \rangle)^2 \rangle$.
