Minkowski dimension of the boundaries of the lakes of Wada

Zhangchi Chen

July 13, 2021

Abstract
The lakes of Wada are three disjoint simply connected domains in $S^2$ with the counterintuitive property that they all have the same boundary. The common boundary is a indecomposable continuum. In this article we calculated the Minkowski dimension of such boundaries. The lakes constructed in the standard Cantor way has $\ln(6)/\ln(3) \approx 1.6309$-dimensional boundary, while in general, for any number in $[1, 2]$ we can construct lakes with such dimensional boundaries.

Keywords: Minkowski dimension, Lakes of Wada.

1 Introduction

A famous counterintuitive example in planar topology, called the lakes of Wada, is that there exists three disjoint simply connected domains $U_1, U_2, U_3$ in $S^2$ such that $\partial U_1 = \partial U_2 = \partial U_3$. The classical constructions in [4, P60] and in [2] explain the infinite procedure, while [3, Sect. 8] presents it with an interesting scenario of the perils of philanthropy.

To simplify computations later, we introduce the lakes of Wada on the unit square constructed in the standard Cantor way:

Day 1: we dig a simply connected blue lake $B_1$ by digging $[0, \frac{2}{3}] \times [\frac{1}{3}, \frac{2}{3}]$ on the island so that every point on the island is at most $\sqrt{2}/3$ far away from the blue lake.

Day 2: we dig a simply connected red lake $R_2$ on the island with width $\frac{1}{9}$ so that every point on the island is at most $\sqrt{2}/9$ far away from the red lake.

Day 3: we dig a simply connected green lake $G_3$ on the island with width $\frac{1}{27}$ so that every point on the island is at most $\sqrt{2}/27$ far away from the green lake.
Day 4: we extend our blue lake as $B_4$ by digging a continuous canal of width $\frac{1}{81}$ on the island so that every point on the island is at most $\frac{\sqrt{2}}{81}$ far away from the blue lake. The canal starts from the peak point of $B_1$: $\left(\frac{2}{3}, \frac{1}{2}\right)$, separate into two directions: up and down, and terminates at two peak points in violet colour in the lower left corner of the figure.

Day 5: we extend our red lake as $R_5$ by digging a continuous canal of width $\frac{1}{243}$ on the island so that every point on the island is at most $\frac{\sqrt{2}}{243}$ far away from the red lake. The canal starts from the peak point of $R_2$, in dark red colour in the upper left corner of the figure, separate into two directions: up and down, and terminates at two peak points, in violet colour near $\left(\frac{2}{3}, \frac{1}{2}\right)$.

On the following days, we extend the lake with colour green, red, blue in turns, by digging a continuous canal of width $1/3$ of the day before and make sure that every point on the island is closer to our lakes. The canal starts from one of the peak points (at most two), separate into two directions and terminates at two peak points.
Thus we get

\[ B_1 \subset B_4 \subset B_7 \subset \ldots \]
\[ R_2 \subset R_5 \subset R_8 \subset \ldots \]
\[ G_3 \subset G_6 \subset G_9 \subset \ldots \]

three increasing series of domains. The union

\[ U_B := \bigcup_{k=0}^{\infty} B_{3k+1}, \quad U_R := \bigcup_{k=0}^{\infty} R_{3k+2}, \quad U_G := \bigcup_{k=0}^{\infty} G_{3k+3} \]

are simply connected domains. Moreover their boundaries in the unit square \((0,1)^2\) are the same, noted by \(W_{\text{cantor}} := (0,1)^2 \cap \partial U_B = (0,1)^2 \cap \partial U_R = (0,1)^2 \cap \partial U_G\).

To obtain simply connected domaines on \(S^2\) with the same boundary, one can paste the unit square with its reflection, and deform the two squares into two half-balls covering \(S^2\). The common edge \(V_A V_B\) and \(V'_A V'_B\) cover one meridian, while other edges \(V_A V_D V_C\) and \(V'_A V'_D V'_C\) cover the opposite meridian.

![Gluing two squares on \(S^2\)](image)

The common boundary \(W_{\text{cantor}}\) is a nowhere dense closed continuous fractal set of infinite length and of 0 area. The Minkowski-Bouligand (also called ‘box-counting’) dimension and Hausdorff-
Besicovitch dimension describe how ‘rough’ this fractal set is. We abbreviate them as Minkowski dimension and Hausdorff dimension.

**Definition 1.1** (Minkowski dimension). For any bounded set $S \subset \mathbb{R}^n$ and for any $\epsilon > 0$, let $N(\epsilon)$ be the number of boxes (squares) required to cover $S$. We define the Minkowski dimension of $S$

$$
\mathcal{H}^d(S) := \lim_{r \to 0+} \inf \{ \sum_i r_i^d : \text{there is a countable cover of } S \text{ by balls with radius } r_i \in (0, r) \},
$$

and we define the *upper Minkowski dimension of $S$* as

$$
\overline{\dim}_{\text{box}}(S) := \limsup_{\epsilon \to 0+} \frac{\ln (N(\epsilon))}{\ln(1/\epsilon)}
$$

and the *lower Minkowski dimension of $S$* as

$$
\underline{\dim}_{\text{box}}(S) := \liminf_{\epsilon \to 0+} \frac{\ln (N(\epsilon))}{\ln(1/\epsilon)}.
$$

When the two numbers agree, we define the *Minkowski dimension of $S$* as

$$
\dim_{\text{box}}(S) := \lim_{\epsilon \to 0+} \frac{\ln (N(\epsilon))}{\ln(1/\epsilon)}.
$$

**Definition 1.2** (Hausdorff dimension). For any bounded set $S \subset \mathbb{R}^n$ and for any $d > 0$ we define the *$d$-dimensional Hausdorff outer measure of $S$*

$$
\mathcal{H}^d(S) := \lim_{r \to 0+} \inf \{ \sum_i r_i^d : \text{there is a countable cover of } S \text{ by balls with radius } r_i \in (0, r) \},
$$

and we define the *Hausdorff dimension of $S$*

$$
\dim_H(S) := \inf\{d \geq 0 \mid \mathcal{H}^d(S) = 0\}.
$$

The Minkowski dimension is relative easy to calculate, while the Hausdorff dimension deals with countable unions better. There are several basic properties of these dimensions. Assuming $S, S'$ have Minkowski dimensions.

1. If $S$ is a dimension $d \in \mathbb{Z}$ manifold, then $\dim_H(S) = \dim_{\text{box}}(S) = d$;
2. If $S' \subset S$ then $\dim_H(S') \leq \dim_H(S)$ and $\dim_{\text{box}}(S') \leq \dim_{\text{box}}(S)$;
3. If $S = \bigcup_{i=1}^n S_i$ then $\dim_{\text{box}}(S) = \max \dim_{\text{box}}(S_i)$;
4. If $S = \bigcup_{i=1}^\infty S_i$ then $\dim_H(S) = \sup \dim_H(S_i)$;
5. In general $\dim_H(S) \leq \dim_{\text{box}}(S) \blacktriangle$. The equality holds when $S$ is strictly self-similar.

From the properties we have $1 \leq \dim_H(W_{\text{cantor}}) \leq \dim_{\text{box}}(W_{\text{cantor}}) \leq 2$. In Section 2 we prove
Theorem 1.3. The boundary of the lakes of Wada constructed in the standard Cantor way $W_{\text{cantor}}$ has

$$\dim_{\text{box}}(W_{\text{cantor}}) = \frac{\ln(6)}{\ln(3)} \approx 1.6309.$$ 

By changing parameters we can construct the lakes of Wada in the modified Cantor way. Take a series of real numbers $\mathcal{A} := \{a_i > 2\}_{i=1}^\infty$.

Day 1: we dig a simply connected red lake $B_1$ by digging a continuous canal of width $w_1 := 1 - \frac{2}{a_1}$ from the left on the island so that every point on the island is at most $\sqrt{\frac{2}{a_1}}$ far away from the blue lake.

Day 2: we dig a simply connected red lake $R_2$ on the island with width $w_2 := \frac{1}{a_1}(1 - \frac{2}{a_2})$ so that every point on the island is at most $\sqrt{\frac{2}{a_1a_2}}$ far away from the red lake.

Day 3: we dig a simply connected green lake $G_3$ on the island with width $w_3 := \frac{1}{a_1a_2}(1 - \frac{2}{a_3})$ so that every point on the island is at most $\sqrt{\frac{2}{a_1a_2a_3}}$ far away from the green lake.

In the future days, write

$$w_n := \prod_{i=1}^{n-1} a_i^{-1}(1 - \frac{2}{a_n}), \quad t_n := \prod_{i=1}^n a_i^{-1}, \quad (n \geq 2)$$

for the width of canals and $\sqrt{\frac{2}{2}} \times$ (the maximal distances between points on the islands and the extended canals on Day $n$).

Then for $k = 1, 2, \ldots$, on day $3k + 1$, we extend our blue lake as $B_{3k+1}$ by digging a continuous canal of width $w_{3k+1}$ on the island so that every point on the island is at most $\sqrt{2} f_{3k+1}$ far away from the blue lake. On day $3k + 2$ we extend the red while keeping it simply connected, while on day $3k + 3$ we work on the green. Finally we get the boundary of the lakes of Wada $W_{\mathcal{A}}$ depends on the series $\mathcal{A}$.

We write $W_c$ for $W_{\mathcal{A}}$ when $\mathcal{A}$ is a constant sequence $c, c, c, \ldots$ with $c > 2$. In particular $W_3 = W_{\text{cantor}}$. In Section 3 we prove

Theorem 1.4. Using the notations above

$$\dim_{\text{box}}(W_c) = \frac{\ln(2c)}{\ln(c)} \to 1, \quad (c \to +\infty)$$

In general

$$\dim_{\text{box}}(W_{\mathcal{A}}) = 1 + \lim_{n \to +\infty} \frac{n \ln(2)}{\sum_{i=1}^n \ln(a_i)}$$

Corollary 1.5. For any real number $d \in [1, 2]$ there exists a series $\mathcal{A} := \{a_i > 2\}_{i=1}^\infty$ such that

$$\dim_{\text{box}}(W_{\mathcal{A}}) = d.$$ 

Higher dimensional lakes of Wada can be obtained by taking products of 2-dimensional lakes of Wada with $\mathbb{R}^{n-2}$. 

5
Corollary 1.6. In $\mathbb{R}^n$ with $n \geq 2$, for any real number $d \in [n-1, n]$ there exists three disjoint domains $U_1, U_2, U_3$ sharing the same boundary

$$W = \partial U_1 = \partial U_2 = \partial U_3$$

and

$$\text{dim}_{\text{box}}(W) = d.$$

The Hausdorff dimension will be calculated in the next version of the paper.

Acknowledgement: The author thanks the organisers of meeting GDR (Groupe de Recherche) GDM (Géométrie Différentielle et Mécanique) at La Rochelle 07-09 July 2021, especially Boris Kolev for introducing the lakes of Wada during a chat in a bar after the meeting.

2 Minkowski dimension of the boundary in the standard Cantor case

From the construction

$$W_{\text{cantor}} = \bigcup_{k=0}^{\infty} \partial B_{3^k+1} = \bigcup_{k=0}^{\infty} \partial R_{3^k+2} = \bigcup_{k=0}^{\infty} \partial G_{3^k+3}.$$

To simplify notations, we write $W_{3^k+1}, W_{3^k+2}$ and $W_{3^k+3}$ for $\partial B_{3^k+1}, \partial R_{3^k+2}$ and $\partial G_{3^k+3}$ respectively. Thus

$$W_{\text{cantor}} = \bigcup_{n=0}^{\infty} W_n.$$

First we calculate its dimension by box-counting.

Day 1: we cover the blue boundary $\partial B_1$ by exactly 1 square of length 1. So $N(1) = 1$. This square also covers $W_{\text{cantor}}$.

Day 2: we cover the red boundary $\partial R_2$ by 7 squares of length $3^{-1}$. So $N(3^{-1}) = 7$. These squares also covers $W_{\text{cantor}}$.

Day 3: we cover the green boundary $\partial G_3$ by 43 squares of length $3^{-2}$. So $N(3^{-2}) = 43$. These squares also covers $W_{\text{cantor}}$. 
On day $n$, all the $N(3^{1-n})$ squares covering $W_n$ hence covering $W_{\text{cantor}}$, up to a rotation, are classified into 4 cases:

- **Case 1 (Terminal):** The new canal ends in this square, like the square 1 on Day 2.
- **Case 2 (Straight):** The new canal passes this square straightly, like squares 2, 4, 6, 7 on Day 2.
- **Case 3 (Turning):** The new canal passes this square with a left or right turn, like squares 3, 5 on Day 2.
- **Case 4 (Separation):** The new canal enters this square from the left and separates into two branches up and down. It appears exactly once everyday from Day 4.
In the first three days, there is exactly one Terminal and no Separation. From Day 4, there will be exactly two Terminals and one Separation.

On day $n + 1$, all the $N(3^{-n})$ squares required to cover $W_{n+1}$ are sub-squares of the Terminal, the Straights and the Turnings used one day before. In fact

- each Terminal is covered by and requires 7 sub-squares;
- each Straight and each Turning is covered by and requires 6 sub-squares.
- each Separation is covered by and requires 5 sub-squares.

thus

$$\begin{cases} 
N(1) = 1, \\
N(3^{-n}) = 6N(3^{1-n}) + 1, & n = 1, 2, 3, \ldots 
\end{cases}$$

We conclude that $N(3^{-n}) = O(6^n)$ so

$$\lim_{n \to +\infty} \frac{\ln \left( N(3^{-n}) \right)}{\ln(3^n)} = \frac{\ln(6)}{\ln(3)}.$$ 

For any $\epsilon \in [3^{-n-1}, 3^{-n}]$ clearly we have

$$N(3^{-n}) \leq N(\epsilon) \leq N(3^{-n-1}).$$
Thus
\[
\frac{\ln(N(3^{-n}))}{\ln(3^{n+1})} \leq \frac{\ln(N(\epsilon))}{\ln(1/\epsilon)} \leq \frac{\ln(N(3^{n-1}))}{\ln(3^n)}
\]
\[
\frac{\ln(N(3^{-n}))/\ln(3^n)}{1 + \ln(3)/\ln(3^n)} \leq \frac{\ln(N(\epsilon))}{\ln(1/\epsilon)} \leq \frac{\ln(N(3^{n-1}))/\ln(3^{n+1})}{1 - \ln(3)/\ln(3^{n+1})}
\]

We conclude that the Minkowski dimension exists and
\[
\dim_{\text{box}}(W_{\text{cantor}}) = \frac{\ln(6)}{\ln(3)} \approx 1.6309.
\]

3 Minkowski dimension of the boundary in the modified Cantor case

First we treat the case \( A := \{a_i \in \mathbb{Z}_{\geq 3}\}_{i=1}^{\infty} \) of integer series.

Recall the notations
\[
w_n = \prod_{i=1}^{n-1} a_i^{-1} (1 - \frac{2}{a_i}), \quad t_n = \prod_{i=1}^{n} a_i^{-1}, \quad (n \geq 2)
\]

Figure 10: \( W_4 \), the lakes of Wada constructed by a constant sequence 4, 4, 4, \ldots
for the width of canals and $\sqrt{2}/2 \times$ (the maximal distances between points on the islands and the extended canals on Day $n$).

On Day $n$ we use $N(t_n)$ squares of length $t_n = \prod_{i=1}^{n} a_i^{-1}$. They are also classified into one Terminal (two Terminals and one Separation from Day 4) and finitely many Straights and Turnings.

On Day $n+1$ those squares splits into sub-squares of length $t_{n+1} = \prod_{i=1}^{n+1} a_i^{-1}$, while

- each Terminal is covered by and requires $3a_{n+1} - 2$ sub-squares;
- each Straight and each Turning is covered by and requires $2a_{n+1}$ sub-squares;
- each Separation is covered by and requires $a_{n+1} + 2$ sub-squares.

Thus we get recurrence formulas

$$
\begin{align*}
N(t_0) &= N(1) = 1, \\
N(t_{n+1}) &= 2a_{n+1}N(t_n) + a_{n+1} - 2, \quad n = 1, 2, 3, \ldots
\end{align*}
$$

We conclude that $N(t_{n+1}) = O(\prod_{i=1}^{n} 2a_i)$.

If the sequence $\mathcal{A}$ satisfies

$$
\lim_{n \to +\infty} \frac{\ln(a_{n+1})}{n} = 0
$$

for example, if $\mathcal{A}$ is bounded or $a_n = O(n^k)$ for some $k \in \mathbb{Z}$, then by the same argument as before, we conclude that

$$
\dim_{\text{box}}(W_{\mathcal{A}}) = \lim_{n \to +\infty} \frac{\ln(N(t_n))}{\ln(t_n)} = \lim_{n \to +\infty} \frac{\ln(\prod_{i=1}^{n} 2a_i)}{\ln(\prod_{i=1}^{n} a_i)} = 1 + \lim_{n \to +\infty} \frac{n \ln(2)}{\sum_{i=1}^{n} a_i}.
$$

But if $\mathcal{A}$ does not satisfy the condition (1), for example if $a_n = 2^n$, then we need to analyse more delicately.

For any $\epsilon \in (0, 1)$ there is a unique $n$ such that $t_{n+1} \leq \epsilon < t_n$, i.e.

$$
\prod_{i=1}^{n} a_i < 1/\epsilon \leq a_{n+1} \prod_{i=1}^{n} a_i.
$$

Recall that $a_{n+1} \in \mathbb{Z}_{\geq 3}$. Thus there is a unique integer $p \in \{1, 2, \ldots, a_{n+1} - 1\}$ such that

$$
p \prod_{i=1}^{n} a_i < 1/\epsilon \leq (p+1) \prod_{i=1}^{n} a_i.
$$

On Day $n+1$, for any $q \in \{1, 2, \ldots, a_{n+1}\}$, if we use sub-squares of length $q^{-1}t_n$ instead of $a_{n+1}^{-1}t_n$, then
• each Terminal is covered by and requires $3q-2$ sub-squares;
• each Straight and each Turning is covered by and requires $2q$ sub-squares;
• each Separation is covered by and requires $q+2$ sub-squares.

Thus

$$N(q^{-1} t_{n+1}) = 2qN(t_n) + q - 2, \quad q = 1, 2, \ldots, a_{n+1}.$$ 

In particular

$$N(p^{-1} t_n) \leq N(\epsilon) \leq N((p + 1)^{-1} t_n)$$

$$2pN(t_n) \leq N(\epsilon) \leq 2(p + 1)N(t_n) + p - 2 (2p + 3)N(t_n)$$

$$\frac{\ln(2p) + \ln(N(t_n))}{\ln(p + 1) + \ln\left(\prod_{i=1}^{n} a_i\right)} \leq \frac{\ln(N(\epsilon))}{\ln(\epsilon)} \leq \frac{\ln(2p + 3) + \ln(N(t_n))}{\ln(p) + \ln\left(\prod_{i=1}^{n} a_i\right)}$$

Both sides converges to $1 + \lim_{n \to +\infty} \frac{n \ln(2)}{\ln\left(\prod_{i=1}^{n} a_i\right)}$. The Minkowski dimension is then

$$\dim_{\text{box}}(W_A) = 1 + \lim_{n \to +\infty} \frac{n \ln(2)}{\ln\left(\prod_{i=1}^{n} a_i\right)}$$

In particular, when $A$ is a constant sequence $c, c, c, \ldots$ we get

$$\dim_{\text{box}}(W_c) = 1 + \frac{\ln(2)}{\ln(c)}$$

which tends to 1 when $c \to +\infty$.

In the general case when $a_n > 2$ may not be integers, we may not be able to decompose squares of length $t_n = \prod_{i=1}^{n} a_i^{-1}$ into squares of length $t_{n+1} = \prod_{i=1}^{n+1} a_i^{-1}$. Instead, we can keep square Terminal and Turnings, and rectangular Straights, like the part 1, 2, 3 in the following figures.

Figure 11: $W_A$ with $A = 3.8, 4, 4 \ldots$

Figure 12: $W_A$ with $A = 16/7, 7/3, 12/5 \ldots$

The number of rectangles are bounded by the sum of the number of Turnings, of Terminals and of Separations, since there are at most one rectangle between two Turnings, between one Turning and one Terminal, etc.
Lemma 3.1. Let $T(n)$ be the number of Turnings after the $n$-th digging. Then

$$T(n) = \frac{9}{8} \cdot 2^n - 4, \quad n \geq 5$$

Proof. We calculate $T(n)$ by recurrence. Start with $T(1) = 0, T(2) = 2, T(3) = 6, T(4) = 14$. From Day 4,

- each Straight produces no Turnings;
- each Turning produces two Turnings;
- one Terminal where we start our canal, produces one Separation and two Turnings;
- the other Terminal produces two Turnings;
- the Separation produces two Terminals and no Turnings.

Thus we get the recurrence formula

$$T(n + 1) = 2T(n) + 4, \quad n \geq 4$$

which implies that

$$\frac{T(n + 1)}{2^{n+1}} = \frac{T(n)}{2^n} + 2^{1-n}$$

$$= \frac{T(4)}{2^4} + (2^{1-n} + 2^{2-n} + \cdots + 2^{1-4})$$

$$= \frac{14}{2^4} + 2^{-2} - 2^{1-n}, \quad n \geq 4$$

$$T(n + 1) = \frac{9}{8} \cdot 2^{n+1} - 4, \quad n \geq 4$$

$$T(n) = \frac{9}{8} \cdot 2^n - 4, \quad n \geq 5$$

Thus there are at most $T(n) + 3 = \frac{9}{8} \cdot 2^n - 1$ rectangles on Day $n$ with $n \geq 5$. We can cover each rectangle by sub-squares with at most two overlaps.

![Diagram of rectangles]
So at each rectangle, the area that we covered twice are bounded by two sub-squares of length \( t_n \). In total, we over-covered at most \( 2(T(n) + 3) t_n^2 \) area. Write \( A(n) \) as the area of the island after \( n \)-th digging. Then

\[
A(n) \leq N(t_n) t_n^2 \leq A(n) + 2(T(n) + 3)t_n^2 = A(n) + \left( \frac{9}{4} \cdot 2^n - \frac{9}{4} \right) t_n^2
\]

(2)

**Lemma 3.2.** The area of the island after \( n \)-th digging satisfies

\[
2^n t_n < A(n) < 2^{n+1} t_n, \quad n \geq 1
\]

**Proof.** We calculate \( A(n) \) by recurrence. Start with \( A(0) = 1 \). After \( n \)-th digging,

- the area of each Straight, no matter a square or a rectangle, is shrunk by \( 2/a_n \);
- the area of each of the \( T(n) \) Turnings is changed from \( t_{n-1}^2 \) to \( t_{n-1}^2 \cdot \frac{2}{a_n} \), i.e. shrunk by \( 2/a_n \);
- the area of each of the two Terminals is changed from \( t_{n-1}^2 \) to \( t_{n-1}^2 \cdot \frac{1}{a_n^2} \cdot (3a_n - 2) \);
- the area of the Separation is changed from \( t_{n-1}^2 \) to \( t_{n-1}^2 \cdot \frac{1}{a_n^2} \cdot (a_n + 2) \);

![Figure 13: The change of the area from \( A(n-1) \) to \( A(n) \)](image)
Thus

\[
A(n) = \begin{cases} 
\frac{(A(n-1) - t_{n-1}^2)}{a_n} + \frac{t_{n-1}^2}{a_n} \cdot \frac{1}{a_n^2} \cdot (3a_n - 2), & n = 1, 2, 3, \\
\frac{(A(n-1) - 3t_{n-1}^2)}{a_n} + \frac{2t_{n-1}^2}{a_n} \cdot \frac{1}{a_n^2} \cdot (3a_n - 2) + t_{n-1}^2 \cdot \frac{1}{a_n^2} \cdot (a_n + 2), & n \geq 4
\end{cases}
\]

\[
= \frac{2}{a_n} A(n-1) + \frac{t_{n-1}^2}{a_n^2} (a_n - 2), \quad n \geq 1
\]

\[
= \frac{2}{a_n} A(n-1) + t_n^2 (a_n - 2), \quad n \geq 1
\]

\[
\frac{A(n)}{2^n t_n} = \frac{A(n-1)}{2^{n-1} t_{n-1}} + \frac{t_n (a_n - 2)}{2^n}, \quad n \geq 1
\]

The last term is bounded by

\[
0 < \frac{t_n (a_n - 2)}{2^n} < \frac{t_n a_n}{2^n} = \frac{t_{n-1}}{2^n}
\]

Recall that \( t_n = \prod_{i=1}^{n} a_i^{-1} < \prod_{i=1}^{n} 2^{-1} = 2^{-n} \), so

\[
0 < \frac{t_n (a_n - 2)}{2^n} < 2^{1-2n}.
\]

Thus for \( n \geq 1 \)

\[
\frac{A(n-1)}{2^{n-1} t_{n-1}} < \frac{A(n)}{2^n t_n} < \frac{A(n-1)}{2^{n-1} t_{n-1}} + 2^{1-2n},
\]

\[
A(0) < \frac{A(n)}{2^n t_n} < A(0) + 2^{-1} + 2^{-3} + \ldots
\]

\[
1 < \frac{A(n)}{2^n t_n} < 1 + 1 = 2,
\]

\[
2^n t_n < A(n) < 2^{n+1} t_n.
\]

**Definition 3.3.** Let \( F(n), G(n) \) be two positive functions of \( n \in \mathbb{Z}_{\geq 1} \). We write

\[
F(n) \simeq G(n),
\]

if there exist some constant \( c > 1 \) such that

\[
c^{-1} G(n) < F(n) < c G(n).
\]

So we can write \( A(n) \simeq 2^n t_n \). In the equation (2)

\[
A(n) \leq N(t_n) t_n^2 \leq A(n) + \left( \frac{9}{4} \cdot 2^n - \frac{9}{4} \right) t_n^2
\]

\[
< 2^{n+1} t_n + \frac{9}{4} 2^n t_n^2
\]

\[
< 2^{n+1} t_n + \frac{9}{4} 2^n t_n, \quad (t_{n+1} < 1)
\]

\[
< (2 + 9/4) A(n).
\]
Thus $N(t_n)t_n^2 \simeq A(n) \simeq 2^n t_n$, implies $N(t_n) \simeq \frac{2^n}{t_n}$ and

$$\dim_{\text{box}}(W_A) = \lim_{n \to +\infty} \frac{\ln(N(t_n))}{\ln(1/t_n)} = \lim_{n \to +\infty} \frac{\ln(2^n/t_n)}{\ln(1/t_n)} = \lim_{n \to +\infty} \frac{n \ln(2) - \ln(t_n)}{- \ln(t_n)}$$

$$= 1 + \lim_{n \to +\infty} \frac{n \ln(2)}{n - \ln(t_n)} = 1 + \lim_{n \to +\infty} \frac{n \ln(2)}{\sum_{i=1}^{n} \ln(a_i)}.$$
